Deep neural networks (DNNs) with long-range dependence (LRD) have attracted more and more attention recently. However, LRD of DNNs is proposed from the view on gradient disappearance in training, which lacks theory analysis. In order to prove LRD of foggy images, the Hurst parameters of over 1,000 foggy images in SOTS are computed and discussed. Then, the Residual Dense Block Group (RDBG), which has additional long skips among two Residual Dense Blocks to fit LRD of foggy images, is proposed. The Residual Dense Block Group can significantly improve the details of dehazing image in dense fog and reduce the artifacts of dehazing image.

Keywords: long-range dependence, residual dense block, residual dense block group, deep neural network, image dehazing, Hurst parameter (H)

INTRODUCTION

The single image dehazing based on deep neural networks (DNNs) refers to restoring an image from a foggy image using DNNs. Although some efforts on dehazing have been proposed recently [1–6], foggy image modeling is still an unsolved problem.

The early image model is Gaussian or Mixture Gaussian [7], but it cannot properly fit with foggy images. In fact, the foggy images seem to show long-range dependence. That is, the gray levels seemed to influence pixels in nearby regions. In our framework, each foggy image with m rows and n columns in SOTS is reshaped as an m×n column vector by arranging the elements of the image column by column. Thus, we can fit the images by fractional Gaussian noise (fGn) [8–12] and discuss dependence of an image by its Hurst parameter. The main conclusion of the Hurst parameter of a fGn is as follows.

The auto-correlation function (ACF) of fGn is as follows:

\[ C_{fGn}(\tau) = \frac{V_H}{2} \left[ (|\tau| + 1)2^H + (|\tau| - 1)2^H - 2|\tau|2^H \right] \]  \hspace{1cm} (1)

where

\[ V_H = \Gamma(1 - 2H) \cos \frac{\pi H}{\pi H} \]  \hspace{1cm} (2)

is the strength of fGn and 0 < H < 1 is the Hurst parameter [8–10]. If 0.5 < H < 1, one has the following:

\[ \int_0^\infty C_{fGn}(\tau) d\tau = \infty \]  \hspace{1cm} (3)
Thus, the fGn is of long-range dependency (LRD) when $0.5 < H < 1$.

When $0 < H < 0.5$, one has the following:

$$\int_0^\infty C_{fGn}(\tau)d\tau < \infty \quad (4)$$

The above fGn is of short-range dependence (SRD) [8–12].

Recently, some deep neural networks (DNN) with LRD are proposed [4–6, 13], whose motivation is mainly from avoiding gradient disappearance in training. However, the LRD of these DNNs has never been discussed and proven in theory. In this study, the Hurst parameters of test images in SOTS datasets [14] are computed and LRD of foggy images is proven. Motivated by LRD of foggy images, we proposed a new network module, the Residual Dense Block Group (RDBG) composed of two bundled Residual Dense Block Groups (DRBs) proposed in reference [13]. The RDBG has additional long skips between two DRBs to fit LRD of foggy images and can be used to form a new dehazing network. This structure can significantly improve the quality of dehazing images in heavy fog.

The remainder of this article is as follows: the second section introduces the preliminaries of fGn; the third section gives the case study; then a framework based on LRD of foggy images is presented; finally, there are the conclusions and acknowledgments.

PRELIMINARIES

Fractional Brownian Motion

The fBm of Weyl type is defined by [8].

$$B_H(t) - B_H(0) = \frac{1}{\Gamma(H + 0.5)} \left\{ \int_0^t (t - u)^{H-0.5} \right. - \left. (-u)^{H-0.5} dB(u) + \int_0^t (t - u)^{H-0.5} dB(u) \right\}$$

where $0 < H < 1$, and $B(t)$ is Gaussian.

If m has stationary increment: $B_H(t + \tau) - B_H(t)$

$$= B_H(\tau) - B_H(0) \quad (6)$$

and self-affinity property: $B_H(at) = a^H B_H(t), a > 0 \quad (7)$

Fractional Gaussian Noise

Let $x(t)$ be the gray level of the $i$th pixel of an image and be a fGn [8–12].

$$x(t) = B_H(t) - B_H(0) \quad (8)$$

Its ACF follows Eqs 1, 2.

An approximation of $C_{fGn}(\tau)$ is as follows:

$$C_{fGn}(\tau) \propto \left| \tau \right|^{2H-2} \quad (9)$$

CASE STUDY

Data Set

Synthetic data set RESIDE: Li et al. [16] created a large-scale benchmark data set RESIDE composed of composite foggy images and real foggy images.

Synthetic data set: the SOTS test data set is used as the test set. The SOTS test set includes 500 indoor foggy images and 500 outdoor foggy images.

Real data set: it includes 100 real foggy images in the SOTS data set in the RESIDE and the real foggy data collected on the Internet.

Calculate Hurst Parameter

Rescaled range analysis (RRA) [15] for foggy images is closely associated with the Hurst exponent, $H$, also known as the “index of dependence” or the “index of long-range dependence.” The steps to obtain the Hurst parameter are as follows:

1. Preprocessing: An image with $m$ row and $n$ column is concatenated column by column to form an $m \times n$ column vector. For better understanding, a simple example is presented: the size of the foggy image in Figure 4A is 348×248, and then it is concatenated column by column to form an 86304-column vector.

2. Rescale vector: The original vector can be divided equally into several ranges for further RRA, as follows. The first range at the first layer is defined as $RS_{11}$, representing the original $m \times n$ vector, and then it can be divided into two parts, $RS_{21}$ and $RS_{22}$, at the second layer, whose dimension equals to $(m \times n)/2$. Thus, the dimensions of ranges of the foggy image are as follows:

   Layer 1. $RS_{11}$: original $m \times n$ vector.
   Layer 2. $RS_{21}$: $(m \times n)/2$, $RS_{22}$: $(m \times n)/2$.
   Layer 3. $RS_{31}$: $(m \times n)/4$, $RS_{32}$: $(m \times n)/4$, $RS_{33}$: $(m \times n)/4$, $RS_{34}$: $(m \times n)/4$.

   Thus, the dimensions of ranges of the foggy image are as follows:

   Layer 1. $RS_{11}$: 86304.
   Layer 2. $RS_{21}$: 43152, $RS_{22}$: 43152.
   Layer 3. $RS_{31}$: 21576, $RS_{32}$: 21576, $RS_{33}$: 21576, $RS_{34}$: 21576.

3. Calculate the mean for each range.

   $$m_{ij} = \frac{1}{n_{ij}} \sum_{k_{ij}} x_{k_{ij}} \quad (10)$$

   where $n_{ij}$ represents the number of the elements in the $j$th range of the $i$th layer; $X_{k_{ij}}$ represents the value of the $k_{ij}$th element in the $j$th range of the $i$th layer; $m_{ij}$ represents the mean value of the elements in the $j$th range of the $i$th layer.

4. Calculate the deviations of each element in every range. The deviation can be calculated as follows:
where $Y_{kij}$ represents the deviation of the $kij$th element in the jth range of the ith layer.

5. Obtain the accumulated deviations for each element in the corresponding range.

$$y_{ij,N} = \sum_{k=1}^{N} Y_{kij}, \quad N = 1, \ldots, n_{ij}$$

where $y_{ij,N}$ represents the accumulated deviation for $N$ elements in the jth range of the ith layer.

6. Calculate the widest difference of the deviations in each range.

$$R_{ij} = \max\{y_{ij,1}, y_{ij,2}, \ldots, y_{ij,N}\} - \min\{y_{ij,1}, y_{ij,2}, \ldots, y_{ij,N}\}$$

where $R_{ij}$ represents the widest difference for the jth range of the ith layer.

7. Calculate the rescaled range for each range.

$$\text{Rescaled range} = \left(\frac{R}{S}\right)_{ij} = \frac{R_{ij}}{\sigma_{ij}}$$

where $R/S$ represents the rescaled range for the jth range of the ith layer, while $\sigma_{ij}$ represents the standard deviation of the accumulated deviations for the jth range of the ith layer.

8. Obtain the averaged rescaled range values for each layer.

$$\left(\frac{R}{S}\right)_{i} = \frac{1}{2^{l-1}} \sum_{j=1}^{[\log_{2} l]} \left(\frac{R}{S}\right)_{ij}$$

where $l$ is the layer of the ranges with the identity size. The $R/S$ is calculated using Eq. 15 and the $R/S$ of the example image is shown in Table 1.

9. Obtain the Hurst exponent. Plot the logarithm of the size (x axis) of each range in the ith layer versus the logarithm of the average rescaled range of the corresponding layer using Eq. 15 (y axis) (Figure 1), and the slope of the fitted line is regarded as the value of the Hurst exponent, that is, the Hurst parameter.

### Hurst Parameters $H$ of Foggy Images

The plots of four image sets in SOTS, 500 indoor images, 500 outdoor, 1,000 outdoor and indoor images, and 100 real foggy images, are shown in Figure 2. The x axis represents the serial numbers of the test images while the y axis is the Hurst parameters of the images. That is, the ith point in Figure 2 represents the Hurst parameter of the ith image. Thus, we can know the Hurst parameters of over 1,000 foggy images by observing y values of the points in Figure 2.

From Figure 2, we can observe that the least y values of subfigures in Figure 2 are 0.6 or 0.65, which means that the Hurst parameters of four image data sets are all above 0.6. Thus the foggy images are of LRD, which can help us design some novel dehazing methods.

Moreover, although the Hurst parameter for each image is a constant, the different images have different Hurst parameters because of their different contents. For example, the Hurst parameter of a complex image with more colors and objects (Figures 5A,B) is bigger than a simple image (Figure 5C).

Based on the LRD of the foggy images, the Residual Dense Block Group (RDBG) based on RDB is proposed. The RDBG,
which has additional long skips between two RDBs to fit LRD of foggy images, can significantly improve the details of dehazing image in dense fog and reduce the artifacts of dehazing image.

**DEHAZING BASED ON RESIDUAL DENSE BLOCK GROUP**

### Dependence in Neural Network

The neural network can be considered as a hierarchical graph model whose nodes are connected by weighted edges. The weights of edges are trained according to some predefined cost functions. Generally, the value of the $i$th node in the $k$th layer is decided by the nodes in the $(k-1)$th layer connected to the $i$th node [18–24]. That is,

$$x^{(k)}(i) = f(W^{(k-1)}(i)x^{(k-1)}(i))$$  \hspace{1cm} (16)

where $x^{(k)}(i)$ is the value of the $i$th node in the $k$th layer, $f$ is an activation function, $W^{(k-1)}(i)$ is a vector of weights of edges to connect nodes in the $(k-1)$th layers and the $i$th node, and $x^{(k-1)}(i)$ are values of nodes in the $(k-1)$th layers connected to the $i$th node.

Thus, the value of the $i$th node is only influenced by its directly connected nodes. This assumption may be correct in some cases, but it is not true in images since we have proved the LRD of foggy images. Thus, we should design a new module of the neural network to fit the LRD of the foggy images.

### Residual Dense Block Group

Just as discussed in the above subsection, the most straight method to design a structure fitting LRD of images is to connect a node to nodes with longer distance to it directly. Thus, the information of faraway nodes is introduced to help us to recover the real gray level from foggy observations.
Following this intuitive explanation, the length of a skip (connection edge between two nodes) which is defined as the number of crossing nodes can be used to measure the dependence of a time series approximately.

In this context, motivated by the LRD of foggy images, a new residual module RDBG is proposed by two bundled resident dense blocks (RDBs). As shown in Figure 3A, the RDB is a module with dense connections only in the block. In Figure 3, the features which are values of nodes in different layers of the RDB form a time series. Thus, an RDB only with dense connections in blocks cannot fit the LRD well, especially in dense fog, while the proposed RDBG which adds an additional long skip from the beginning of the first block to the end of the second block can fit the LRD better than the RDB. In heavy fog, since the RBDG fits LRD of images to utilize more information of images, it can obtain a better dehazing image.

As shown in Figure 3C, Yang Aiping [16] et al. and X Liu [17] et al. used consecutive RDBs in a cascade manner. Since connections are also in blocks, in essence, it cannot fit LRD of images well.

**Experimental Results and Discussions**

The method proposed in this article will be compared with four state-of-the-art dehazing methods: DehazeNet, AOD-Net, DCP, and GFN.

Three metrics: PSNR, SSIM, and reference-less FADE are used to evaluate the quality of dehazing images. Our proposed method gets the best PSNR and SSIM among all methods (Table 2), which means that our method has the largest similarities between the original images and the dehazing images in both image gray levels and image structures. It also has satisfied results in FADE (Table 2; Figure 4), which means that our method is robust and stable in dehazing.

The dehazing examples are given in Figures 5, 6, and their Hurst parameters are given under the foggy images.
**FIGURE 5** | Some dehazing images and their image quality metrics of synthetic foggy data in SOATS.
Assuming the foggy images are of fGn and calculating their Hurst parameters, the LRD of over 1,000 foggy images are proven by the fact that their Hurst parameters are all more than 0.6. Motivated by the LRD of foggy images, the Residual Dense Block Group (RDBG) with additional long skips between two RDBs is proposed. The
RDBG utilizes information of LRD foggy images well and can obtain satisfied dehazing images.
