\section*{ABSTRACT}

\textbf{INTRODUCTION AND IMPORTANCE:} Preoperative localization of non-palpable lung nodules plays an important role in video assisted thoracic surgery (VATS). Although percutaneous computed tomography (CT)-guided hook wire marking has become widely accepted, it is accompanied by rare but fatal complications such as air embolisms. We herein report a case of a submillimeter pulmonary nodule successfully localized by a mobile CT scan with a navigation system.

\textbf{CASE PRESENTATION:} A 40-year-old man presented with the two right pulmonary nodules 4 years after a radical left nephrectomy for a renal clear cell carcinoma. One of the nodules was too small to palpate and preoperative marking was applied using a mobile CT scan with a navigation system. We successfully performed VATS wedge resection for both nodules and confirmed a pathological diagnosis of a metastasis from the renal cell carcinoma. The maximum pathological size of the smaller nodule was 500 μm.

\textbf{CLINICAL DISCUSSION:} Preoperative marking of the lower lobe lesion in the present case was essential for VATS. Our novel technique was helpful for the precise marking without any morbidity.

\textbf{CONCLUSION:} Preoperative marking using a mobile CT scan with a navigation system is safe and easily applicable. It might be a useful option for VATS of non-palpable lung nodules.

1. Background

Detection of small lung nodules has increased with the development of diagnostic technologies such as high-resolution computed tomography (CT) and preoperative localization of non-palpable lesions is essential for video assisted thoracic surgery (VATS). Although percutaneous CT-guided hook wire marking has become widely accepted [1–5], it requires percutaneous pleural puncture and is accompanied by rare but fatal complications such as air embolisms [6,7]. We herein report a case of a nonpalpable pulmonary nodule successfully resected using a novel mobile CT scan with a navigation system for preoperative marking. This work has been reported in line with the SCARE criteria [8].

2. Case presentation

A 40-year-old man presented with right pulmonary nodules 4 years after a radical left nephrectomy for a renal clear cell carcinoma (pT2,N0,M0, stage IIA, Fuhrman grade 2) without any drug use nor allergic history. He had no significant familial history. Chest CT revealed two circumscribed nodules in the right upper and lower lobes respectively, suggesting metastatic lung tumors (Fig. 1). Without any metastatic lesion, he was planned to undergo a surgical resection of both nodules. The lower lobe nodule was deemed non-palpable and we applied intraoperative marking using a mobile CT scan with a navigation system.

The details of the procedure have been described elsewhere [9]. Briefly, the patient was placed in the left decubitus position with a navigation reference fixed on the anterior superior iliac spine under general anesthesia. A mobile CT: O-arm\textsuperscript{TM} (Medtronic Japan Co. Ltd Tokyo, Japan) was then brought over the patient to obtain three-dimensional (3D) images. After the initial scanning, a navigation system: Stealth Station\textsuperscript{TM}57 (Medtronic Japan Co. Ltd Tokyo, Japan) synchronized those images with the hand probe through the navigation reference on the patient. A skin marking was placed at the closest point over the target lesion by using the hand probe as vir-

3. Discussion

The lungs are one of the most frequent metastatic sites from a renal cell carcinoma and a pulmonary metastasectomy is a feasible option in selected patients [11]. Two favorable prognostic factors proposed in the literature were met for the present case, the achievement of a complete resection [12–15] and a small diameter of the lesion [14–17]. Our case had only two metastases with a maximum diameter of 8 mm. The lower lobe lesion was too small to palpate and therefore preoperative marking was essential for a VATS resection.

Various methods have been proposed for the localization of non-palpable small pulmonary nodules. A CT-guided hook wire marking is one of the most common procedures and is often accompanied by procedure-related complications such as pneumothorax and pulmonary hemorrhage [1–4]. Air embolisms rarely occur, but could be fatal [6]. These morbidities are all derived from a percutaneous pleural puncture itself and inevitable as long as the hook wire marking is applied. To avoid those morbidities, we introduced a mobile CT with a navigation system, which had been widely used in spinal and orthopedic surgeries [18,19].

The O-arm™ is a mobile preoperative CT imaging system. The obtained images are transferred to the Stealth Station™ S7 navigation system and allow virtual fluoroscopy to identify the preferred skin marking site [20]. The second CT scanning after the lung marking contributes to the verification of the positional relationship between the needle and target lesion without the necessity for digital palpation. A redo marking is also available for marking failure.

cases with this method [9]. In the present case, we could localize the submillimeter nodule without any procedural related morbidity. Because both the marking procedure and surgery were completed under general anesthesia in the operating room as a single stage procedure, it would be beneficial to reduce the patients’ stress as compared to the traditional marking method. These results suggest that this method would be a feasible option for image-guided VATS for preoperative marking of non-palpable lung nodules especially in the peripheral region [9].

4. Conclusion

We herein report a case of a submillimeter metastatic lung tumor successfully resected using a mobile CT with a navigation system for the preoperative marking. This method is safe and easily applicable and might be a useful option for VATS of non-palpable lung nodules even in submillimeter cases.
