Abstract. The Casimir energy for the transverse oscillations of a piecewise uniform closed string is calculated. The great adaptability of this string model with respect to various regularization methods is pointed out. We survey several regularization methods: the cutoff method, the complex contour integration method, and the zeta-function method. The most powerful method in the present case is the contour integration method. The Casimir energy turns out to be negative, and more so the larger is the number of pieces in the string. The thermodynamic free energy and the critical Hagedorn temperature is calculated for a two-piece string. Mass and decay spectra are calculated for quantum massive excitations and the physical meaning of the critical temperatures characterising the radiation in the decay of a massive microstate is discussed.

Date: August, 2001.

1. Introduction

In the standard theory of closed strings - whatever the string is taken
to be in Minkowski space or in superspace - one usually assumes that
the string is homogeneous, i.e. that the tension $T$ is the same every-
where. The composite string model, in which the string is assumed to
consist of two or more separately uniform pieces, is a variant of the
conventional theory. The system is relativistic, in the sense that the
velocity $v_s$ of transverse sound is in each of the pieces assumed to be
equal to the velocity of light: $v_s = \sqrt{T/\rho} = c$ (in the following we
choose $c = \hbar = 1$). Here $T$ and $\rho$ (the density) refer to the piece
under consideration. At each junction between pieces of different ma-
terial there are two boundary conditions: the transverse displacement
$\psi = \psi(\sigma, \tau)$ itself, as well as the transverse force $T\partial \psi/\partial \sigma$,
must be continuous. Using the wave equation $\left(\frac{\partial^2}{\partial \sigma^2} - \frac{\partial^2}{\partial \tau^2}\right) \psi = 0$, one can calculate
the eigenvalue spectrum and the Casimir energy of the string.

The composite string model was introduced in 1990 [1]; the string
was there assumed to consist of two pieces $L_I$ and $L_{II}$. The dispersion
equation was derived, and the Casimir energy calculated for various
integer values of the length ratio $s = L_{II}/L_I$. Later on, the composite
string model has been generalized and studied from various points of
view [2-10]; we may mention, for instance, that the recent paper of Lu
and Huang [9] discusses the Casimir energy for a composite Green -
Schwarz superstring.

Some reasons why the composite strings turns out to be an attractive
theory to study are the following. First, if one performs Casimir energy
calculations, one finds that the system is remarkably easy to regularize:
one has access to the cutoff method [1], the complex contour integration
method [3-5, 7], or the Hurwitz zeta-function method [2, 4, 5, 7] ( [8]
contains a review of the various regularization methods). As a physical
result of the Casimir energy calculations it is also worth noticing that
the energy is in general nonpositive, and is more negative the larger
the number of uniform pieces in the string is.

The composite strings may moreover serve as a useful two-dimensional
field theory in general. Usually, a two-dimensional field theory de-
scribes a particular classical solution of string theory by constructing a
matter system. The vanishing total central charge of a system ensures
the existence of a BRST operator, playing a crucial role in world-sheet
and space-time gauge invariance. Such an operator can be interpreted
as a generator of linearized gauge transformations, mixing ghosts and
matter. It is very important that two-dimensional topological field the-
ories (like ordinary string models) can sometimes be given space-time
interpretations for which the usual decoupling of ghosts and matter does not hold. For example, three-dimensional Chern-Simons gauge theory can arise as a string theory [11]. Relations between gauge fields and strings present fascinating and unanswered questions. The full answer to these questions is of great importance for theoretical physics. It will provide the true gauge degrees of freedom of the fundamental string theories, and therefore also of gravity [12].

As a peculiar application, perhaps can this particular string model even play a role in the theories of the early universe. The notable point is here that the string can in principle adjust its zero point energy: the energy always becomes diminished if the string divides itself into a larger number of pieces.

It is also to be noted that there are strong formal similarities between this kind of theory and the phenomenological electromagnetic theory in material media satisfying the condition $\varepsilon \mu = 1$, $\varepsilon$ denoting the permittivity and $\mu$ the permeability of the medium [13]. Obviously, the basic reason why the two theories become so similar is that the relativistic invariance is satisfied in both cases.

In Sect. 2 we discuss briefly two-piece uniform string and methods of regularization its Casimir energy. The Casimir energy related to $2N–$ piece string is calculated in Sect. 3. In Sect. 4 we discuss the theory of the classical planar string in the Minkowski space: the general dispersion equation, and the junction conditions as well as the eigenvalue spectrum. In Sect. 5 we develop the classical theory of the composite string in flat $D–$ dimensional spacetime. The string coordinates $X^\mu$ are expanded into oscillator coordinates, and formulas are derived for the Hamiltonian and the string mass. The quantum theory, focusing attention on the free energy and the critical Hagedorn temperature, is derived in Sects. 6 and 7. Mass and decay spectra for two-piece composite string we calculate in Sect. 8. Finally we end with some conclusions in Sect. 9.

2. TWO-PIECE STRING

2.1. Dispersion relation. Let the two junction points, lying at $\sigma = 0$ and $\sigma = L_I$, separate the type I and type II pieces from each other. The total length of the closed string is $L = L_I + L_{II}$. We define $x$ to be the tension ratio and define also the function $F(x)$:

$$x = \frac{T_I}{T_{II}}, \quad F(x) = \frac{4x}{(1 - x)^2}. \quad (2.1)$$

The dispersion equation becomes
The Casimir energy $E$ of the system is defined as the zero-point energy $E_{I+II}$ of the two parts, minus the zero-point energy of the uniform string:

$$E = E_{I+II} - E_{\text{uniform}} = \frac{1}{2} \sum \omega_n - E_{\text{uniform}}. \quad (2.3)$$

Here the sum goes over all eigenstates, with account of their degeneracy. It is irrelevant whether $E_{\text{uniform}}$ is calculated for type I material or type II material in the string, the reason for this being the relativistic invariance. We will consider three different methods for regularizing the Casimir energy.

2.2. **Cutoff regularization.** The simplest way to proceed [1] is to introduce a function $f = \exp(-\alpha \omega_n)$, with $\alpha$ a small positive parameter, and to multiply the nonregularized expression for $E$ by $f$ before summing over the modes.

We consider first the case of a uniform string, corresponding to $x = 1$. The dispersion equation (2.2) yields the eigenvalue spectrum $\omega L = 1$, which means

$$\omega_n = 2\pi n / L, \quad n = 1, 2, 3, ... \quad (2.4)$$

Taking into account that these modes are degenerate, we find for the zero-point energy

$$E_{\text{uniform}} = \frac{L}{2\pi \alpha^2} - \frac{\pi}{6L} + O(\alpha^2). \quad (2.5)$$

Let us next consider the limiting case $x \to 0$ (we let $T_I \to 0$ while keeping $T_{II}$ finite). The dispersion relation allows two sequences of modes,

$$\omega_n = \pi n / L_I, \quad \omega_n = \pi n / L_{II}, \quad n = 1, 2, 3, ... \quad (2.6)$$

If $s$ denotes the length ratio, $s = L_{II} / L_I$, we then get the simple formula for the Casimir energy

$$E = -\frac{\pi}{24L}(s + \frac{1}{s} - 2). \quad (2.7)$$

Now let $s$ be an odd integer. The dispersion equation yields one degenerate branch, determined by

$$\sin \omega L_I = 0, \quad \omega L_I = \pi n, \quad (2.8)$$
I. BREVIK, A.A. BYTSENKO, AND B.M. PIMENTEL

and there are in addition \( \frac{1}{2} (s-1) \) nondegenerate double branches, determined by solving an algebraic equation of degree \( \frac{1}{2} (s-1) \) in \( \sin^2 \omega L_I \). The frequency spectrum can be expressed as

\[
\omega L_I = \begin{cases} 
\pi(n + \beta), \\
\pi(n + 1 - \beta), 
\end{cases}
\]

where \( n = 0, 1, 2, \ldots \), and where \( \beta \) is a number in the interval \( 0 < \beta \leq \frac{1}{2} \).

Each double branch yields the four solutions \( \pi \beta, \pi(1 - \beta), \pi(1 + \beta), \) and \( \pi(2 - \beta) \) for \( \omega L_I \) in the region between 0 and \( 2\pi \).

Introducing for convenience the abbreviation \( t = \pi \alpha (s + 1)/L \), we obtain

\[
E(\text{degenerate branch}) = \frac{1}{\alpha t} - \frac{t}{12\alpha} + O(t^2),
\]

\[
E(\text{double branch}) = \frac{1}{\alpha t} + \frac{t}{6\alpha} - \frac{t}{4\alpha} \left[ \beta^2 + (1 - \beta)^2 \right] + O(t^2).
\]

We replace \( \beta \) by \( \beta_i \), sum (2.11) over all \( \frac{1}{2} (s-1) \) double branches, and add (2.10) to obtain \( E_{I+I} \). Subtracting off the uniform string result (2.5), and letting \( t \to 0 \), we get the Casimir energy for odd \( s \),

\[
E = \frac{\pi s(s-1)}{12L} - \frac{\pi(s+1)}{4L} \sum_{i=1}^{(s-1)/2} \left[ \beta_i^2 + (1 - \beta_i)^2 \right].
\]

The cutoff terms drop out.

If \( s \) is an even integer, we obtain by an analogous argument

\[
E = \frac{\pi s(2s+1)}{6L} - \frac{\pi(s+1)}{8L} \sum_{i=1}^{s} \left[ \beta_i^2 + (2 - \beta_i)^2 \right],
\]

where now each \( \beta_i \) lies in the interval \( 0 < \beta_i \leq 1 \).

2.3. Contour integration method. This is a very powerful method. In the context of Casimir calculations it dates back to van Kampen et al. [14]. The method was first applied to the composite string system in Ref. [3]. The starting point is the so-called argument principle, which states that any meromorphic function \( g(\omega) \) satisfies the relation

\[
\frac{1}{2\pi i} \oint \omega \frac{d}{d\omega} \log g(\omega) = \sum \omega_0 - \sum \omega_\infty,
\]

where \( \omega_0 \) are the zeros and \( \omega_\infty \) are the poles of \( g(\omega) \) inside the integration contour. The contour is chosen to be a semicircle of large radius \( R \) in the right half complex \( \omega \) plane, closed by a straight line from \( \omega = iR \) to \( \omega = -iR \). The great advantage of the method - in contradistinction
to the previous cutoff method - is that the \textit{multiplicity} of the zeros (there are no poles in the present case) are automatically taken care of.

We make the following ansatz for \( g(\omega) \):

\[
g(\omega) = \frac{F(x) \sin^2[(s + 1)\omega L_I/2] + \sin(\omega L_I) \sin(s\omega L_I)}{F(x) + 1}.
\]  

This means that \( g(\omega) \) is chosen to be the expression to the left in (2.2), multiplied by \([F(x) + 1]^{-1}\). This choice is convenient, since it allows us to perform partial integrations in the energy integral without encountering any divergences in the boundary terms when \( R \to \infty \).

The final result becomes \((\omega = i\xi)\)

\[
E = \frac{1}{2\pi} \int_0^\infty \log \left| \frac{F(x) + \frac{\sinh(\xi L_I) \sinh(s\xi L_I)}{\sinh^2[(s+1)\xi L_I/2]}}{F(x) + 1} \right| d\xi.
\]  

This zero-temperature result is very general; it holds for any value of \( s \), not only for integers \( s \) as considered in the previous subsection. Since (2.16) is invariant under the interchange \( s \to 1/s \), it follows that \( s \) can be restricted to the interval \( s \geq 1 \) without any loss of generality. If \( x \to 0 \), we recover the simple formula (2.7).

Another advantage of the contour integration method is that the zero-temperature result can easily be generalized to the case of finite temperatures. The integration over continuous imaginary frequencies \( \xi \) then has to be replaced by a sum over discrete Matsubara frequencies \( \xi_n = 2\pi nk_B T, \ n = 0, 1, 2, ... \) We get

\[
E(T) = k_B T \sum_{n=0}^\infty \log \left| \frac{F(x) + \frac{\sinh(\xi_n L_I) \sinh(s\xi_n L_I)}{\sinh^2[(s+1)\xi_n L_I/2]}}{F(x) + 1} \right|,
\]  

valid for any temperature \( T \). The prime on the summation sign means that the \( n = 0 \) term is taken with half weight.

2.4. \textbf{Zeta-function method.} This elegant regularization method has proved to be most useful in many cases. General treatises on it can be found in Refs. \[15, 16\]. The first application to the composite string was made by Li et al. \[2\]. The appropriate zeta function to be used in this case is not the Riemann function \( \zeta(s) \), but instead the Hurwitz function \( \zeta_H(s, a) \), the latter being originally defined as
\[ \zeta_H(s,a) = \sum_{n=0}^{\infty} (n+a)^{-s} \quad (0 < a < 1, \ \Re s > 1). \] (2.18)

For practical purposes on needs only the property

\[ \zeta_H(-1,a) = -\frac{1}{2} \left( a^2 - a + \frac{1}{6} \right) \] (2.19)

of the analytically continued Hurwitz function.

[The Hurwitz function in the form (2.18) is defined only for \( \Re s > 1 \). It is a meromorphic function, with a simple pole in \( s = 1 \). If \( \Re s \) is different from unity, the Hurwitz function can be analytically continued to the whole complex plane. We can also use the functional equation (which is known) in order to calculate the function for \( \Re s < 1 \). Actually, Eq. (2.19) gives the finite value of the Hurwitz function at \( s = -1 \).]

The zeta-function method has one important property in common with the cutoff method: the eigenvalue spectrum must be determined explicitly. Consider the uniform string first: in this case the Riemann function \( \zeta_R(s) \) is adequate, giving the zero-point energy

\[ E_{\text{uniform}} = \frac{2\pi}{L} \zeta_R(-1) = -\frac{\pi}{6L}, \] (2.20)

in agreement with the finite part of (2.5). Consider next the composite string, assuming \( s \) to be an odd integer: by inserting the degenerate branch eigenvalue spectrum (2.8) we have

\[ E(\text{degenerate branch}) = -\frac{\pi}{12L_I}. \] (2.21)

Using the generic form (2.9) for the double branches we obtain analogously

\[ E(\text{double branch}) = \frac{\pi}{2L_I} [\zeta_H(-1, \beta) + \zeta_H(-1, 1 - \beta)] \]

\[ = \frac{\pi}{6L_I} - \frac{\pi}{4L_I} [\beta^2 + (1 - \beta)^2]. \] (2.22)

Summing (2.22) over the \( \frac{1}{2}(s-1) \) double branches, and adding (2.21), we obtain the composite string’s zero-point energy

\[ E_{I+II} = \frac{\pi(s-2)}{12L_I} - \frac{\pi}{4L_I} \sum_{i=1}^{(s-1)/2} [\beta_i^2 + (1 - \beta_i)^2]. \] (2.23)

Now subtracting off (2.20), we obtain the same expression for the Casimir energy \( E \) as in Eq. (2.12).
The case of even integers $s$ is treated analogously. The zeta-function method is somewhat easier to implement than the cutoff method.

3. 2-$N$-PIECE STRING

3.1. **Recursion equation and the Casimir energy.** In the same way one can consider the Casimir theory of a string of length $L$ divided into three pieces, all of the same length. The theory for this case has been given in Refs. [5] and [8]. Here, we shall consider instead a string divided into $2N$ pieces of equal length, of alternating type $I$ (type $II$) material. The string is relativistic, in the same sense as before. The basic formalism for arbitrary integers $N$ was set up in Ref. [4], but the Casimir energy was there calculated in full only for the case of $N = 2$. A full calculation was worked out in Ref. [7]; cf. also Ref. [8]. A key point in [7] was the derivation of a new recursion formula, which is applicable for general integers $N$.

We introduce two new symbols, $p_N$ and $\alpha$:

$$p_N = \omega L/N, \quad \alpha = (1 - x)/(1 + x). \quad (3.1)$$

The eigenfrequencies are determined from

$$\text{Det}[M_{2N}(x, p_N) - 1] = 0. \quad (3.2)$$

Here it is convenient to scale the resultant matrix $M_{2N}$ as

$$M_{2N}(x, p_N) = \left(\frac{(1 + x)^2}{4x}\right)^N m_{2N}(\alpha, p_N), \quad (3.3)$$

and to write $m_{2N}$ as a product of component matrices:

$$m_{2N}(\alpha, p_N) = \prod_{j=1}^{2N} m^{(j)}(\alpha, p_N), \quad (3.4)$$

with

$$m^{(j)}(\alpha, p_N) = \left(\begin{array}{ccc}
1, & \mp \alpha e^{-ip_jN}, & \mp \alpha e^{-ip_jN} \\
\mp \alpha e^{ip_jN}, & 1
\end{array}\right) \quad (3.5)$$

for $j = 1, 2, ..., (2N - 1)$. The sign convention is to use $+$ (or $-$) for even (or odd) $j$. At the last junction, for $j = 2N$, the component matrix has a particular form (given an extra prime for clarity):

$$m'_{2N}(\alpha, p_N) = \left(\begin{array}{ccc}
e^{-iNp_N}, & \alpha e^{-iNp_N} \\
\alpha e^{iNp_N}, & e^{iNp_N}
\end{array}\right). \quad (3.6)$$

Now the recursion formula alluded to above can be stated:
\[ m_{2N}(\alpha, p_N) = \Lambda^N(\alpha, p_N), \] (3.7)

where \( \Lambda \) is the matrix

\[ \Lambda(\alpha, p) = \begin{pmatrix} a & b \\ b^* & a^* \end{pmatrix}, \] (3.8)

with

\[ a = e^{-ip} - \alpha^2, \quad b = \alpha(e^{-ip} - 1). \] (3.9)

The obvious way to proceed is now to calculate the eigenvalues of \( \Lambda \), and express the elements of \( M_{2N} \) as powers of these. More details can be found in [7].

Consider next the Casimir energy. Using the contour regularization method we obtain, for arbitrary \( x \) and arbitrary integers \( N \), at zero temperature,

\[ E_N(x) = \frac{N}{2\pi L} \int_0^\infty \log \left| \frac{2(1 - \alpha^2)^N - \lambda^N_+(iq) + \lambda^N_-(iq)}{4 \sinh^2(Nq/2)} \right| dq. \] (3.10)

Here \( \lambda_{\pm} \) are eigenvalues of \( \Lambda \), for imaginary arguments \( iq \), of the dispersion equation. Explicitly,

\[ \lambda_{\pm}(iq) = \cosh q - \alpha^2 \pm \left( (\cosh q - \alpha^2)^2 - (1 - \alpha^2)^2 \right)^{\frac{1}{2}}. \] (3.11)

Evaluation of the integral shows that \( E_N(x) \) is negative, and the more so the larger is \( N \). A string can thus in principle always diminish its zero-point energy by dividing itself into a larger number of pieces of alternating type I (or II) material.

In the limiting case of \( x \to 0 \) the integral can be solved exactly:

\[ E_N(0) = -\frac{\pi}{6L}(N^2 - 1). \] (3.12)

The generalization of (3.10) to the case of finite temperatures is easily achieved following the same method as above.

As an alternative method, one can instead of contour integration make use of the zeta-function method; one then has to determine the spectrum explicitly and thereafter put in the degeneracies by hand. The latter method is therefore most suitable for low \( N \).
3.2. Scaling invariance. A rather unexpected scaling invariance property of the Casimir energy becomes apparent if we examine the behaviour of the function \( f_N(x) \) defined by

\[
f_N(x) = \frac{E_N(x)}{E_N(0)},
\]

This function generally has a value that lies between zero and one. If we calculate \( E_N(x) \) (usually numerically) versus \( x \) for some fixed value of \( N \), we find that the resulting curve for \( f_N(x) \) is practically the same, irrespective of the value of \( N \), as long as \( N \geq 2 \). (The case \( N = 1 \) is exceptional, since \( E_1(x) = 0 \).) Numerical trials show that the simple analytical form

\[
f_N(x) \to f(x) = (1 - \sqrt{x})^{5/2}
\]

is a useful approximation, in particular in the region \( 0 < x < 0.45 \).

4. Planar oscillations

We begin by considering the classical theory of the oscillating two-piece string in the Minkowski space. The total length of the string is \( L \). For later purpose we shall set \( L = \pi \). With \( L_I, L_{II} \) denoting the length of the two pieces, we thus have \( L_I + L_{II} = \pi \). As mentioned the string is relativistic, in the sense that the velocity \( v_s \) of transverse sound is everywhere required to be equal to the velocity of light \( (\hbar = c = 1) \):

\[
v_s = (T_I/\rho_I)^{1/2} = (T_{II}/\rho_{II})^{1/2} = 1.
\]

Here \( T_I, T_{II} \) are the tensions and \( \rho_I, \rho_{II} \) are the mass densities of the two pieces. We let \( s \) denote the length ratio and \( x \) the tension ratio: \( s = L_{II}/L_I, \quad x = T_I/T_{II} \). Assume now that the transverse oscillations of the string, called \( \psi(\sigma, \tau) \), are linear, and take place in the plane of the string. (We employ usual notation, so that \( \sigma \) is the position coordinate and \( \tau \) the time coordinate of the string.) We can thus write in the two regions

\[
\psi_I = \xi_I e^{i\omega(\sigma-\tau)} + \eta_I e^{-i\omega(\sigma+\tau)},
\]

\[
\psi_{II} = \xi_{II} e^{i\omega(\sigma-\tau)} + \eta_{II} e^{-i\omega(\sigma+\tau)},
\]

with the \( \xi \) and \( \eta \) being constants. Taking into account the junction conditions at \( \sigma = 0 \) and \( \sigma = L_I \), meaning that \( \psi \) itself as well as the transverse force \( T \partial \psi / \partial \sigma \) be continuous, we obtain the dispersion equation

\[
\frac{4x}{(1-x)^2} \sin^2 \frac{\omega \pi}{2} + \sin \left( \frac{\omega \pi}{1+s} \right) \sin \left( \frac{\omega s \pi}{1+s} \right) = 0.
\]
From this equation the eigenvalue spectrum can be calculated, for arbitrary values of \( x \) and \( s \). Because of the invariance under the substitution \( x \to 1/x \), one can restrict the ratio \( x \) to lie in the interval \( 0 < x \leq 1 \). Similarly, because of the invariance under the interchange \( L_I \leftrightarrow L_{II} \) one can take \( L_{II} \) to be the larger of the two pieces, so that \( s \geq 1 \). In the following we shall impose two simplifying conditions:

(i) We take the tension ratio limit to approach zero, \( x \to 0 \). Assuming \( T_{II} \) to be a finite quantity, this limit implies that \( T_I \to 0 \). From the junction conditions given in [1] we obtain in this limit the equations

\[
\xi_I + \eta_I = \xi_{II} e^{i\pi \omega} + \eta_{II} e^{-i\pi \omega},
\]

\[
\xi_I e^{2\pi i \omega / (1+s)} + \eta_I = \xi_{II} e^{2\pi i \omega / (1+s)} + \eta_{II},
\]

\[
\xi_{II} e^{2\pi i \omega} = \eta_{II},
\]

\[
\xi_{II} e^{2\pi i \omega / (1+s)} = \eta_{II}.
\]

According to the dispersion equation (4.3) we obtain now two sequences of modes. The eigenfrequencies are seen to be proportional to integers \( n \), and will for clarity be distinguished by separate symbols \( \omega_n(s) \) and \( \omega_n(s^{-1}) \):

\[
\omega_n(s) = (1+s)n,
\]

\[
\omega_n(s^{-1}) = (1+s^{-1})n,
\]

with \( n = \pm 1, \pm 2, \pm 3, \ldots \), corresponding to the first and the second branch.

(ii) Our second condition is that the length ratio \( s \) is an integer, \( s = 1, 2, 3, \ldots \).

5. Classical string in flat spacetime

5.1. Oscillator coordinates. The hamiltonian. We are now able to generalize the theory. We consider henceforth the motion of a two-piece classical string in flat \( D \)-dimensional space-time. Following the notation in [1] we let \( X^\mu(\sigma, \tau) \) \( (\mu = 0, 1, 2, \ldots (D - 1)) \) specify the coordinates on the world sheet. For each of the two branches - corresponding to Eqs. (4.8) and (4.9) respectively - we can write the general expression for \( X^\mu \) in the form

\[
X^\mu = x^\mu + \frac{p^\mu \tau}{\pi T(s)} + \theta(L_I - \sigma)X_I^\mu + \theta(\sigma - L_I)X_{II}^\mu,
\]
where $x^\mu$ is the center of mass position and $p^\mu$ is the total momentum of the string. Besides $\bar{T}(s)$ denotes the mean tension,

$$T(s) = \frac{1}{\pi} (L_I T_I + L_{II} T_{II}) \rightarrow \frac{s}{1+s} T_{II}. \quad (5.2)$$

The second term in (5.1) implies that the string’s translational energy $p^0$ is set equal to $\pi \bar{T}(s)$. This generalizes the relation $p^0 = \pi T$ that is known to hold for a uniform string [17]. The two last terms in (5.1) contain the step function, $\theta(x > 0) = 1$, $\theta(x < 0) = 0$. To show the structure of the decomposition of $X^\mu$ into fundamental model we give here the expressions for $X^\mu_I$ for each of the two branches: for the first branch

$$X^\mu_I = \frac{i}{2} l(s) \sum_{n \neq 0} \frac{1}{n} \left[ \alpha_n^\mu(s) e^{i(1+s)n(\sigma-\tau)} + \tilde{\alpha}_n^\mu(s) e^{-i(1+s)n(\sigma+\tau)} \right], \quad (5.3)$$

where the $\alpha_n, \tilde{\alpha}_n$ are oscillator coordinates of the right- and left-moving waves respectively. The sum over $n$ goes over all positive and negative integers except from zero. The factor $l(s)$ is a constant. For the second branch in region I, analogously

$$X^\mu_I = \frac{i}{2} l(s^{-1}) \sum_{n \neq 0} \frac{1}{n} \left[ \alpha_{n^{-1}}^\mu(s^{-1}) e^{i(1+s^{-1})n(\sigma-\tau)} + \tilde{\alpha}_{n^{-1}}^\mu(s^{-1}) e^{-i(1+s^{-1})n(\sigma+\tau)} \right], \quad (5.4)$$

where $l(s^{-1})$ is another constant, which in principle can be different from $l(s)$. Since $X^\mu$ is real, we must have

$$\alpha_{-n} = (\alpha_n^*)^*, \quad \tilde{\alpha}_{-n} = (\tilde{\alpha}_n^*)^*. \quad (5.5)$$

When writing expressions (5.3) and (5.4), we made use of Eqs. (4.8) and (4.9) for the eigenfrequencies. The condition $x \to 0$ was thus used. The condition that $s$ be an integer has however not so far been used. This condition will be of importance when we construct the expression for $X^\mu_{II}$. Before doing this, let us however consider the constraint equation for the composite string. Conventionally, when the string is uniform the two-dimensional energy-momentum tensor $T_{\alpha\beta}$ ($\alpha, \beta = 0, 1$), obtainable as the variational derivative of the action $S$ with respect to the two-dimensional metric, is equal to zero. In particular, the energy density component is then $T_{00} = 0$ locally. In the present case the situation is more complicated, due to the fact that the presence of the junctions restricts the freedom of the variations $\delta X^\mu$. We cannot put $T_{\alpha\beta} = 0$ locally anymore. What we have at our disposal, is the expression for the action
\begin{align}
S &= -\frac{1}{2} \int d\tau d\sigma T(\sigma) \eta^\alpha \partial_\alpha X^\mu \partial_\beta X_\mu, \\
\text{where } T(\sigma) \text{ is the position-dependent tension} \\
T(\sigma) &= T_I + (T_{II} - T_I) \theta(\sigma - L_I).
\end{align}

The momentum conjugate to $X^\mu$ is $P_\mu(\sigma) = T(\sigma) \dot{X}^\mu$. The Hamiltonian of the two-dimensional sheet becomes accordingly (here $L$ is the Lagrangian)
\begin{align}
H &= \int_0^\pi \left[ P_\mu(\sigma) \dot{X}^\mu - L \right] d\sigma = \frac{1}{2} \int_0^\pi T(\sigma) (\dot{X}^2 + X'^2) d\sigma.
\end{align}

The basic condition that we shall impose, is that $H = 0$ when applied to the physical states. This is weaker condition than the strong condition $T_{\alpha\beta} = 0$ applicable for a uniform string.

5.2. Classical mass formula. The first branch. Assume that $s$ is an arbitrary integer, $s = 1, 2, 3, \ldots$. When $s$ is different from 1, we have to distinguish between the eigenfrequencies $\omega_n(s)$ and $\omega_n(s^{-1})$ for the first and the second branch. Let us consider the first branch. In region I, the representation for the right- and left-moving modes was given above, in Eq. (5.3). For reasons that will become clear from the quantum mechanical discussion later, we will choose $l(s)$ equal to $l(s) = (\pi T_I)^{-1/2}$. Since we have assumed $T_I$ to be small, that expression will tend to infinity.

When writing the analogous mode expansion in region II, we have to observe the junction conditions (4.4) - (4.7), which hold for all $s$. For the first branch $\omega_n(s)$, and for odd values of $s$, it is seen that the junction conditions impose no restriction on the values of $n$. All frequencies, corresponding to $n = \pm 1, \pm 2, \pm 3, \ldots$, permit the waves to propagate from region I to region II. Equations (4.4) - (4.7) reduce in this case to the equations
\begin{align}
\xi_I + \eta_I = 2\xi_{II} = 2\eta_{II},
\end{align}

which show that the right- and left-moving amplitudes $\xi_I$ and $\eta_I$ in region I can be chosen freely and that the amplitudes $\xi_{II}, \eta_{II}$ in region II are thereafter fixed. Transformed into oscillator coordinate language, this means that $\alpha_\mu$ and $\tilde{\alpha}_\mu$ can be chosen freely.

If $s$ is an even integer, then the validity of Eqs. (5.9) requires $n$ in Eq. (4.8) to be even. If $n$ is odd, the junction conditions reduce instead to
\( \xi_I + \eta_I = 0, \quad \xi_{II} = \eta_{II} = 0, \) \hspace{1cm} (5.10)

which show that the waves are now unable to penetrate into region II. The oscillations in region I are in this case standing waves.

The expansion for the first branch in region II can in view of (5.9) be written as

\[
X_{II}^\mu = -\frac{i}{2\sqrt{T_I}} \sum_{n \neq 0} \frac{1}{n!} \gamma_n(s) e^{-i(1+s)n\sigma} \cos[(1 + s)n\sigma], \hspace{1cm} (5.11)
\]

where we have defined \( \gamma_n(s) \) as

\[
\gamma_n(s) = \alpha_n(s) + \tilde{\alpha}_{n}(s), \quad n \neq 0. \hspace{1cm} (5.12)
\]

The oscillations in region II are thus standing waves; this being a direct consequence of the condition \( x \to 0. \)

It is useful to introduce light-cone coordinates, \( \sigma^- = \tau - \sigma \) and \( \sigma^+ = \tau + \sigma. \) The derivatives conjugate to \( \sigma^\pm \) are \( \partial_{\pm} = \frac{1}{2}(\partial_{\tau} \mp \partial_\sigma). \) In region I we find

\[
\partial_- X^\mu = -\frac{1 + s}{2\sqrt{T_I}} \sum_{-\infty}^{\infty} \alpha_n(s) e^{i(1+s)n(\sigma-\tau)}, \hspace{1cm} (5.13)
\]

\[
\partial_+ X^\mu = -\frac{1 + s}{2\sqrt{T_I}} \sum_{-\infty}^{\infty} \tilde{\alpha}_n(s) e^{-i(1+s)n(\sigma+\tau)}, \hspace{1cm} (5.14)
\]

where we have defined

\[
\alpha_0(s) = \tilde{\alpha}_0(s) = \frac{p^\mu}{T_{II}s} \sqrt{\frac{T_I}{\pi}}. \hspace{1cm} (5.15)
\]

Further, in region II we find

\[
\partial_\mp X^\mu = \frac{1 + s}{4\sqrt{T_I}} \sum_{-\infty}^{\infty} \gamma_n(s) e^{\pm i(1+s)n(\sigma \mp \tau)}, \hspace{1cm} (5.16)
\]

with

\[
\gamma_0(s) = \frac{2p^\mu}{T_{II}s} \sqrt{\frac{T_I}{\pi}} = 2\alpha_0(s). \hspace{1cm} (5.17)
\]

Inserting Eqs. (5.13), (5.14) and (5.16) into the Hamiltonian

\[
H = \int_0^\pi T(\sigma)(\partial_- X \cdot \partial_- X + \partial_+ X \cdot \partial_+ X) d\sigma \hspace{1cm} (5.18)
\]

we get, for the full first branch \( H = H_I + H_{II}, \) where
\[ H_I = T_I \int_I (\partial_- X \cdot \partial_- X + \partial_+ X \cdot \partial_+ X) d\sigma \]
\[ = \frac{1 + s}{4} \sum_{-\infty}^{\infty} [\alpha_{-n}(s) \cdot \alpha_n(s) + \tilde{\alpha}_{-n}(s) \cdot \tilde{\alpha}_n(s)], \quad (5.19) \]

\[ H_{II} = T_{II} \int_{II} (\partial_- X \cdot \partial_- X + \partial_+ X \cdot \partial_+ X) d\sigma \]
\[ = \frac{s(1 + s)}{8x} \sum_{-\infty}^{\infty} \gamma_{-n}(s) \cdot \gamma_n(s), \quad (5.20) \]

with \( x = T_I/T_{II} \) as before.

The case \( s = 1 \) is of particular interest. The string is then divided into two pieces of equal length. We have then

\[ H_I(s = 1) = \frac{1}{2} \sum_{-\infty}^{\infty} (\alpha_{-n} \cdot \alpha_n + \tilde{\alpha}_{-n} \cdot \tilde{\alpha}_n), \quad (5.21) \]

\[ H_{II}(s = 1) = \frac{1}{4x} \sum_{-\infty}^{\infty} \gamma_{-n} \cdot \gamma_n. \quad (5.22) \]

It is notable that Eq. (5.21) is formally the same as the standard expression for a closed uniform string, of length \( \pi \). See, for instance, Eq. (2.1.76) in Ref. [17]. The fact that we recover the characteristics of a closed string in region I is understandable, since this part of our composite string permits both right-moving and left-moving waves. Eq. (5.22) is essentially the standard expression for an open uniform string, corresponding to standing waves. The presence of the inverse tension ratio \( x^{-1} \) in front of the expression is caused by the junction conditions, Eqs. (5.9).

The condition \( H = 0 \) enables us to calculate the mass \( M \) of the string. It must be given by \( M^2 = -p_\mu p^\mu \), similarly as in the uniform string case [17]. From Eqs. (5.19) and (5.20) we obtain, taking into account that \( x << 1 \) and that \( \alpha_0(s) \cdot \alpha_0(s) = -M^2x/(\pi T_{II}s^2) \),

\[ M^2 = \pi T_{II}s \sum_{n=1}^{\infty} \left[ \alpha_{-n}(s) \cdot \alpha_n(s) + \tilde{\alpha}_{-n}(s) \cdot \tilde{\alpha}_n(s) + \frac{s}{2x} \gamma_{-n}(s) \cdot \gamma_n(s) \right]. \quad (5.23) \]

This holds for the first branch, for odd (or for even) values of \( s \).
5.3. The second branch. For the second branch whose eigenfrequencies are $\omega(s^{-1})$ the mode expansion in region I becomes

$$X^\mu_I = \frac{i}{2\sqrt{\pi T_I}} \sum_{n \neq 0} \frac{1}{n} \left[ \alpha_n^\mu(s^{-1}) e^{i(1+s^{-1})n(\sigma-\tau)} + \tilde{\alpha}_n^\mu(s^{-1}) e^{-i(1+s^{-1})n(\sigma+\tau)} \right],$$

(5.24)

and $l(s^{-1})$ is given by the same expression as $l(s)$. This equality follows if one compares Eq. (5.4) and Eq. (5.24), but we ought to state it explicitly also. Analogously in region II

$$X^\mu_{II} = \frac{i}{2\sqrt{\pi T_I}} \sum_{n \neq 0} \frac{1}{n} \gamma_n^\mu(s^{-1}) e^{-i(1+s^{-1})n\tau} \cos[(1 + s^{-1})n\sigma],$$

(5.25)

where

$$\gamma_n^\mu(s^{-1}) = \alpha_n^\mu(s^{-1}) + \tilde{\alpha}_n^\mu(s^{-1}), \ n \neq 0.$$  

(5.26)

The expansions (5.24) and (5.25) hold for all integers $s$. This is so because the basic expressions (4.8) and (4.9) for the eigenfrequencies hold for all values of $s$. However it may be noted that if the junction conditions are required to imply nonvanishing oscillations in region II, corresponding to nonvanishing right hand sides in Eq. (5.9), then further restrictions come into play. Namely, if $s$ is odd, the index $n$ in Eqs. (5.24) and (5.25) has to be a multiple of $s$. If $s$ is even, then $n$ has to be an even integer times $s$. We recall that analogous considerations were made in the case of the first branch. When we later shall consider the quantum mechanical free energy, it becomes necessary to include all modes, including those that lead to zero oscillations in region II according to the classical theory.

Let us calculate the light-cone derivatives: in region I they are

$$\partial_- X^\mu_I = \frac{1 + s^{-1}}{2\sqrt{\pi T_I}} \sum_{-\infty}^{\infty} \alpha_n^\mu(s^{-1}) e^{i(1+s^{-1})n(\sigma-\tau)},$$

(5.27)

$$\partial_+ X^\mu_I = \frac{1 + s^{-1}}{2\sqrt{\pi T_I}} \sum_{-\infty}^{\infty} \tilde{\alpha}_n^\mu(s^{-1}) e^{-i(1+s^{-1})n(\sigma+\tau)},$$

(5.28)

and in region II

$$\partial_\mp X^\mu = \frac{1 + s^{-1}}{4\sqrt{\pi T_I}} \sum_{-\infty}^{\infty} \gamma_n^\mu(s^{-1}) e^{\pm i(1+s^{-1})n(\sigma\mp\tau)},$$

(5.29)

where
\[ \alpha_0^\mu(s^{-1}) = \alpha_0^\mu(s^{-1}) = \frac{1}{2} \gamma_0^\mu(s^{-1}) = \frac{p^\mu}{T_{II} \sqrt{\pi}}. \quad (5.30) \]

Thus \( \alpha_0(s^{-1}) \) differs from \( \alpha_0(s) \), Eq. (5.15). Again writing the Hamiltonian as \( H = H_I + H_{II} \), we now find

\[ H_I = \frac{1 + s^{-1}}{4s} \sum_{-\infty}^{\infty} [\alpha_{-n}(s^{-1}) \cdot \alpha_n(s^{-1}) + \tilde{\alpha}_{-n}(s^{-1}) \cdot \tilde{\alpha}_n(s^{-1})], \quad (5.31) \]

\[ H_{II} = \frac{1 + s^{-1}}{8x} \sum_{-\infty}^{\infty} \gamma_{-n}(s^{-1}) \cdot \gamma_n(s^{-1}). \quad (5.32) \]

If \( s = 1 \), we recover the same expressions for \( H_I \) and \( H_{II} \), Eqs. (5.21) and (5.22), as for the first branch.

From the condition \( H = 0 \) we calculate the mass, observing that \( \alpha_0(s^{-1}) \cdot \alpha_0(s^{-1}) = -M^2 x / (\pi T_{II}) \):

\[ M^2 = \frac{\pi T_{II}}{s} \sum_{n=1}^{\infty} [\alpha_{-n}(s^{-1}) \cdot \alpha_n(s^{-1}) + \tilde{\alpha}_{-n}(s^{-1}) \cdot \tilde{\alpha}_n(s^{-1})] \]

\[ + \frac{\pi T_{II}}{2x} \sum_{n=1}^{\infty} \gamma_{-n}(s^{-1}) \cdot \gamma_n(s^{-1}). \quad (5.33) \]

6. Quantum theory

6.1. Quantization. We shall consider the free energy of the quantum fields with masses given by the mass formula corresponding to the piecewise bosonic string. We quantize the system according to conventional methods as found, for instance, in Ref. \[17\], Chapter 2.2. In accordance with the canonical prescription in region I the equal-time commutation rules are required to be

\[ T_I[\dot{X}^\mu(\sigma, \tau), X^\nu(\sigma', \tau)] = -i\delta(\sigma - \sigma') \eta^{\mu\nu}, \quad (6.1) \]

and in region II

\[ T_{II}[\dot{X}^\mu(\sigma, \tau), X^\nu(\sigma', \tau)] = -i\delta(\sigma - \sigma') \eta^{\mu\nu}, \quad (6.2) \]

where \( \eta^{\mu\nu} \) is the \( D \)-dimensional metric. These relations are in conformity with the fact that the momentum conjugate to \( X^\mu \) is in either region equal to \( T(\sigma)\dot{X}^\mu \). The remaining commutation relations vanish:

\[ [X^\mu(\sigma, \tau), X^\nu(\sigma', \tau)] = [\dot{X}^\mu(\sigma, \tau), \dot{X}^\nu(\sigma', \tau)] = 0. \quad (6.3) \]
The quantities to be promoted to Fock state operators are $\alpha_{\mp n}(s)$ and $\tilde{\alpha}_{\mp n}(s)$ (first branch, region I), $\gamma_{\mp n}(s)$ (first branch, region II), $\alpha_{\mp n}(s^{-1})$ and $\tilde{\alpha}_{\mp n}(s^{-1})$ (second branch, region I), and $\gamma_{\mp n}(s^{-1})$ (second branch, region II). These operators satisfy

$$\alpha_{\mp n}^\mu(s) = \alpha_n^\mu(s), \quad \gamma_{\mp n}^\mu(s) = \gamma_n^\mu(s), \quad (6.4)$$
$$\alpha_{\mp n}^\mu(s^{-1}) = \alpha_n^\mu(s^{-1}), \quad \gamma_{\mp n}^\mu(s^{-1}) = \gamma_n^\mu(s^{-1}) \quad (6.5)$$

for all $n$. We insert our previous expansions for $X^\mu$ and $\dot{X}^\mu$ in the commutation relations in regions I and II for the two branches, and make use of the effective relationship

$$\sum_{-\infty}^{\infty} e^{i(1+s)n(\sigma-\sigma')} = 2 \sum_{-\infty}^{\infty} \cos[(1+s)n\sigma]\cos[(1+s)n\sigma'] \to \frac{2\pi}{1+s}\delta(\sigma-\sigma'). \quad (6.6)$$

For the first branch we then get in region I

$$[\alpha_n^\mu(s), \alpha_m^\nu(s)] = n\delta_{n+m,0}\eta^\mu\nu, \quad (6.7)$$
with a similar relation for the $\tilde{\alpha}_n$. In region II

$$[\gamma_n^\mu(s), \gamma_m^\nu(s)] = 4nx\delta_{n+m,0}\eta^\mu\nu. \quad (6.8)$$

For the second branch we get analogously

$$[\alpha_n^\mu(s^{-1}), \alpha_m^\nu(s^{-1})] = n\delta_{n+m,0}\eta^\mu\nu, \quad [\gamma_n^\mu(s^{-1}), \gamma_m^\nu(s^{-1})] = 4nx\delta_{n+m,0}\eta^\mu\nu. \quad (6.9)$$

By introducing annihilation and creation operators for the first branch in the following way:

$$\alpha_n^\mu(s) = \sqrt{n}a_n^\mu(s), \quad \alpha_{-n}^\mu(s) = \sqrt{n}a_n^\mu(s), \quad (6.10)$$
$$\gamma_n^\mu(s) = \sqrt{4nx}c_n^\mu(s), \quad \gamma_{-n}^\mu(s) = \sqrt{4nx}c_n^\mu(s), \quad (6.11)$$

we find for $n \geq 1$ the standard form

$$[a_n^\mu(s), a_m^\nu(s)] = \delta_{nm}\eta^\mu\nu, \quad (6.12)$$
$$[c_n^\mu(s), c_m^\nu(s)] = \delta_{nm}\eta^\mu\nu. \quad (6.13)$$

The commutation relations for the second branch are analogous, only with the replacement $s \to s^{-1}$. 

6.2. **The free energy.** In the following we shall limit ourselves to the first branch only. Using Eqs. (6.10) and (6.11) in Eqs. (5.19) and (5.20) we may write the two parts of the Hamiltonian as

\[
H_I = -\frac{M^2 x}{2st(s)} + \frac{1}{2} \sum_{n=1}^{\infty} \omega_n(s) [a_n^\dagger(s) \cdot a_n(s) + \tilde{a}_n^\dagger(s) \cdot \tilde{a}_n(s)], \tag{6.14}
\]

\[
H_{II} = -\frac{M^2}{2t(s)} + s \sum_{n=1}^{\infty} \omega_n(s) [c_n^\dagger(s) \cdot c_n(s)], \tag{6.15}
\]

where we for convenience have introduced the symbol \(t(s)\) defined by

\[
t(s) = \pi \bar{T}(s). \tag{6.16}
\]

From the condition \(H = H_I + H_{II} = 0\) in the limit \(x \to 0\) we obtain, either from Eqs. (6.14) and (6.15) or directly from Eq. (5.23),

\[
M^2 = t(s) \sum_{i=1}^{24} \sum_{n=1}^{\infty} \omega_n(s) [a_{ni}^\dagger(s)a_{ni}(s) + \tilde{a}_{ni}^\dagger(s)\tilde{a}_{ni}(s) - A_1]
+ 2st(s) \sum_{i=1}^{24} \sum_{n=1}^{\infty} \omega_n(s) [c_{ni}^\dagger(s)c_{ni}(s) - A_2]. \tag{6.17}
\]

The commutation relations for above operators are given by Eqs. (6.12) and (6.13). The mass of state (obtained by acting on the Fock vacuum
\[ |0 \rangle \text{ with creation operators) can be written as follows (mass)}^2 \sim \langle a_{n_1}^\dagger \cdots a_{n_i}^\dagger c_{n_1}^\dagger \cdots c_{n_i}^\dagger |0 \rangle.

Let us start with the discussion of the free energy in field theory at non-zero temperature. It is quite well-known that the one-loop free energy for the bosonic \((b)\) or fermionic \((f)\) degree of freedom in \(d\)-dimensional space is given by

\[ F_{b,f} = \pm \frac{1}{\beta} \int \frac{d^{D-1}k}{(2\pi)^{D-1}} \log \left( 1 \mp e^{-\beta u_k} \right), \quad (6.19) \]

where \( \beta = (k_B T)^{-1} \), \( u_k = \sqrt{k^2 + m^2} \), and \( m \) is the mass for the corresponding degree of freedom. Expanding the logarithm and performing the (elementary) integration one easily gets

\[ F_b = -\sum_{n=1}^{\infty} (\beta n)^{-D/2} \pi^{-D/2} 2^{-D/2} m^{D/2} K_{D/2}(\beta nm), \quad (6.20) \]

\[ F_f = -\sum_{n=1}^{\infty} (-1)^n (\beta n)^{-D/2} \pi^{-D/2} 2^{-D/2} m^{D/2} K_{D/2}(\beta nm), \quad (6.21) \]

where \( K_{\nu/2}(z) \) are the modified Bessel functions. Using the integral representation for the Bessel function

\[ K_{\nu/2}(z) = \frac{1}{2} \left( \frac{z}{2} \right)^{\nu/2} \int_0^\infty ds \, s^{-1-\nu/2} e^{-s-z^2/(4s)}, \quad (6.22) \]

one can obtain the well-known proper time representation for the one-loop free energy:

\[ \tilde{F}_b = -\int_0^\infty ds \, \pi^{-D/2} 2^{-1-D/2} s^{-1-D/2} e^{-m^2 s/2} \left[ \theta_3 \left( 0 \right| \frac{i\beta^2}{2\pi s} \right) - 1 \right], \quad (6.23) \]

\[ \tilde{F}_f = -\int_0^\infty ds \, \pi^{-D/2} 2^{-1-D/2} s^{-1-D/2} e^{-m^2 s/2} \left[ 1 - \theta_4 \left( 0 \right| \frac{i\beta^2}{2\pi s} \right) \right], \quad (6.24) \]

where \( \theta_3(v|x) = \sum_{n=-\infty}^{\infty} \exp(i\pi xn^2 + 2\pi i vn) \) and \( \theta_4(v|x) = \theta_3(v + 1/2|x) \) are the Jacobi theta functions. Expressions \((6.23)\) and \((6.24)\) is usually the starting point for the calculation of the (super) string free energy in the canonical ensemble (then \( m^2 \) is the mass operator and for closed strings the corresponding constraint should be taken into account).

As usual the physical Hilbert space consists of all Fock space states obeying the condition \((6.18)\), which can be implemented by means of
the integral representation for Kronecker deltas. Thus the free energy of the field content in the "proper time" representation becomes

\[
F = -\frac{1}{24} \left( s + \frac{1}{s} - 2 \right)
- 2^{-14} \pi^{13} \int_0^\infty \frac{d\tau_2}{\tau_2^{14}} \left[ \theta_3 \left( 0 \bigg| \frac{i\beta^2}{2\pi \tau_2} \right) - 1 \right] \text{Tr} \exp \left\{ -\frac{\tau_2 M^2}{2} \right\}
\]

\[
\times \int_{-\pi}^{\pi} \frac{d\tau_1}{2\pi} \text{Tr} \exp \left\{ i\tau_1 \sum_{i=1}^{24} \sum_{n=1}^{\infty} \omega_n(s) \left[ a_{ni}^\dagger(s) a_{ni}(s) - \tilde{a}_{ni}^\dagger(s) \tilde{a}_{ni}(s) \right] \right\},
\]

(6.25)

Performing the trace over the entire Fock space (note that \([H_I, H_{II}] = 0\) and \(\text{Tr} y^{a_{ni} a_{ni}} = (1 - y)^{-1}\)) we have

\[
\text{Tr} \exp \left\{ \sum_{i=1}^{24} \sum_{n=1}^{\infty} \omega_n(s) a_{ni}^\dagger(s) a_{ni}(s) \left( -\frac{1}{2} t(s) \tau_2 \pm i\tau_1 \right) \right\}
= \prod_{n=1}^{\infty} \left[ 1 - e^{\omega_n(s)\left( -\frac{1}{2} t(s) \tau_2 \pm i\tau_1 \right)} \right]^{-24},
\]

(6.26)

\[
\text{Tr} \exp \left\{ -st(s) \tau_2 \sum_{i=1}^{24} \sum_{n=1}^{\infty} \omega_n(s) c_{ni}^\dagger(s) c_{ni}(s) \right\}
= \prod_{n=1}^{\infty} \left[ 1 - e^{-st(s) \tau_2 \omega_n(s)} \right]^{-24}.
\]

(6.27)

Working out the sums in Eq. (6.25) for \(A_1 = 2, A_2 = 1,\) and changing variables to \(\tau_1 \to \tau_1 2\pi, \tau_2 \to \tau_2 4\pi/t(s)\) one can finally get

\[
F = -\frac{1}{24} \left( s + \frac{1}{s} - 2 \right)
- 2^{-40} \pi^{-26} t(s)^{-13} \int_0^\infty \frac{d\tau_2}{\tau_2^{14}} \int_{-1/2}^{1/2} d\tau_1
\times \left[ \theta_3 \left( 0 \bigg| \frac{i\beta^2 t(s)}{8\pi^2 \tau_2} \right) - 1 \right] \left| \eta[(1 + s) \tau] \right|^{-48} \left| \eta(s(1 + s)(\tau - \tau_2)) \right|^{-24},
\]

(6.28)

where we integrate over all possible non-diffeomorphic tori which are characterized by a single Teichmüller parameter \(\tau = \tau_1 + i\tau_2.\) In Eq. (6.28) the condition \(\eta(-\tau) = \bar{\eta}(\tau)\) has been used.

Once the free energy has been found, the other thermodynamic quantities can readily be calculated. For instance, the energy \(U\) and the entropy \(S\) of the system are

\[
U = \frac{\partial(\beta F)}{\partial \beta}, \quad S = k_B \beta^2 \frac{\partial F}{\partial \beta}.
\]

(6.29)
6.3. **Point mass limit.** Finally, let us consider the limiting case in which one of the pieces of the string is much shorter than the other. Physically this case is of interest, since it corresponds to a point mass sitting on a string. Since we have assumed that $s \geq 1$, this case corresponds to $s \to \infty$. We let the tension $T_{II}$ be fixed, though arbitrary. It is seen, first of all, that the critical temperature goes to infinity so that free energy $F$ is always ultraviolet finite. In this limit we have \[ 10 \]:

$$
F(\beta \to 0) = -\frac{s}{24} - (8\pi^3 T_{II})^{-13} \int_0^\infty \frac{d\tau_2}{\tau_2^{11/2}} \int_{-1/2}^{1/2} d\tau_1 \times \exp \left( -\frac{\beta^2 T_{II}}{8\pi \tau_2^2} \right) |\eta[(1+s)\tau]|^{-48} \eta[s(1+s)(\tau - \overline{\tau})]^{-24}.
$$

(6.30)

Physically speaking, the linear dependence of the first term in (6.30) reflects that the Casimir energy of a little piece of string embedded in an essentially infinite string has for dimensional reasons to be inversely proportional to the length $L_I = \pi/(1+s) \approx \pi/s$ of the little string. The first term in (6.30) is seen to outweigh the second, integral term, which goes to zero when $s \to \infty$.

7. **The Hagedorn temperature**

What is the Hagedorn temperature, $T_c = 1/(k_B \beta_c)$, of the composite string? This critical temperature, introduced by Hagedorn in the context of strong interactions a long time ago \[ 18 \], is the temperature above which the free energy is ultraviolet divergent. In order to study the statistical properties of strings (the critical temperatures, in particular) it is useful to have information on asymptotics of the density of states. We discuss some preliminary mathematical results, which, in turn, are relevant in number theory, and then we point out the Meinardus theorem \[ 19, 20, 21, 22 \]. The theorem gives the asymptotics of the level degeneracy which leads to the asymptotics of the level state density.

Let

$$
\mathcal{G}(z) = \prod_{n=1}^\infty [1 - e^{-zn}]^{-a_n} = 1 + \sum_{n=1}^\infty \Omega(n) e^{-zn},
$$

(7.1)

be the generating function, where $\Re z > 0$ and $a_n$ are non-negative real numbers. Let us consider the associated Dirichlet series

$$
\mathcal{D}(s) = \sum_{n=1}^\infty a_n n^{-s}, \quad s = \sigma + it,
$$

(7.2)
which converges for $0 < \sigma < p$. We assume that $\mathcal{D}(s)$ can be analytically continued in the region $\sigma \geq -C_0$ ($0 < C_0 < 1$) and here $\mathcal{D}(s)$ is analytic except for a pole of order one at $s = p$ with residue $A$. Besides we assume that $\mathcal{D}(s) = \mathcal{O}(|t|^C)$ uniformly in $\sigma \geq -C_0$ as $|t| \to \infty$, where $C_1$ is a fixed positive real number. The following lemma \[19, 20, 21\] is useful with regard to the asymptotic properties of $\mathcal{G}(z)$ at $z = 0$:

**Lemma.** If $\mathcal{G}(z)$ and $\mathcal{D}(s)$ satisfy the above assumptions and $z = y + 2\pi i x$ then

$$
\mathcal{G}(z) = \exp \left\{ A \Gamma(p) \zeta_R(1 + p) z^{-p} - \mathcal{D}(0) \log z + \frac{d}{ds} \mathcal{D}(s)|_{s=0} + \mathcal{O}(y^{C_0}) \right\}
$$

uniformly in $x$ as $y \to 0$, provided $|\arg z| \leq \pi/2$ and $|x| \leq 1/2$. Moreover there exists a positive number $\varepsilon$ such that

$$
\mathcal{G}(z) = \mathcal{O}(\exp \{ A \Gamma(p) \zeta_R(1 + p) y^{-p} - C y^{-\varepsilon} \} ),
$$

uniformly in $x$ with $y^\alpha \leq |x| \leq 1/2$ as $y \to 0$, $C$ being a fixed real number and $\alpha = 1 + p/2 - p\nu/4$, $0 < \nu < 2/3$.

The main result below follows from Lemma and permits one to calculate the complete asymptotics of $\Omega(n)$.

**Theorem** (Meinardus \[19, 20\]). For $n \to \infty$ one has

$$
\Omega(n) = C_p n^k \exp \left\{ \frac{1 + p}{p} [A \Gamma(1 + p) \zeta_R(1 + p)] \frac{1}{1+p} n^{\frac{p}{1+p}} \right\} \left( 1 + \mathcal{O}(n^{-k_1}) \right) ,
$$

$$
C_p = [A \Gamma(1 + p) \zeta_R(1 + p)] \frac{1-2\mathcal{D}(0)}{[2\pi (1 + p)]^\frac{1}{2} } \exp \left( \frac{d}{ds} \mathcal{D}(s)|_{s=0} \right),
$$

$$
k = \frac{2\mathcal{D}(0) - p - 2}{2(1 + p)} , \quad k_1 = \frac{p}{1 + p} \min \left( \frac{C_0}{p} - \frac{\nu}{4}, \frac{1}{2} - \nu \right) .
$$

Coming back to composite string problem we note that the generation function has the form

$$
Z(\beta) = \text{Tr} \left[ e^{-\beta M^2} \right]_{(A_1=A_2=0)} = Z^{(I)}(\beta) Z^{(II)}(\beta)
$$

$$
\equiv \prod_{n=1}^{\infty} \left[ 1 - e^{-\beta t(s) \omega_n(s)} \right]^{-48} \prod_{n=1}^{\infty} \left[ 1 - e^{-\beta 2s t(s) \omega_n(s)} \right]^{-24} .
$$

Multiplication of power series for $Z^{(I)}(\beta)$ and $Z^{(II)}(\beta)$ gives
\[ Z^{(I)}(\beta)Z^{(II)}(\beta) = \sum_{n=0}^{\infty} \Omega^{(I)}(n)e^{-\beta n} \sum_{n=0}^{\infty} \Omega^{(II)}(n)e^{-\beta n} \]

\[ = \sum_{n=0}^{\infty} \sum_{\ell=0}^{\infty} C^2p^2n^{2k} \exp \left\{ \frac{1 + p}{p} [A\Gamma(1 + p)\zeta_R(1 + p)]^{\frac{1}{1+p}} ((1 + s)\ell(s))^{-\frac{1}{p}} \right\} 
\times \left[ \ell^{\frac{n}{1+p}} + (2s)^{-\frac{1}{p}} (n - \ell)^{\frac{n}{1+p}} \right] e^{-\beta n} (1 + O(n^{-k_1})). \quad (7.9) \]

Some remarks are in order. Taking into account \( a_n = D - 2 = 24 \), we have \( p = 1 \) (in fact Eq. (7.2) gives the Riemann zeta function). Therefore, from the Meinardus theorem, Eqs. (7.5) - (7.7), it follows

\[ \Omega^{(I)}(n) = C_1 n^{\frac{D+1}{2}} \exp \left\{ \pi \sqrt{\frac{4n(D-2)}{3(1+s)t(s)}} \right\} (1 + O(n^{-k_1})), \quad (7.10) \]

\[ \Omega^{(II)}(n) = C_1 n^{\frac{D+1}{2}} \exp \left\{ \pi \sqrt{\frac{n(D-2)}{3s(1+s)t(s)}} \right\} (1 + O(n^{-k_1})), \quad (7.11) \]

where the constant \( C_1 \) is given by \( C_1 = 2^{-1/2} ((D - 2)/24)^{(D-1)/4} \).

Using the mass formula \( M^2 = n \) (for the sake of simplicity we assume a tension parameter, with dimensions of (mass)\(^{p+1}\), equal to 1) we find for the number of bosonic string states of mass \( M \) to \( M + dM \)

\[ \nu(M)dM \simeq 2C_1 M^{\frac{1-D}{2}} \exp(bM)dM, \quad b = \pi \sqrt{\frac{D-2}{3s(1+s)t(s)}}. \quad (7.12) \]

One can show that the constant \( b \) is the inverse of the Hagedorn temperature.

For the closed bosonic string in the region I the constraint \( N = \tilde{N} \) should be taking into account, where \( N \) is a number operator related to \( M^2 \). As a result in Eq. (7.10) the total degeneracy of the level \( n \) is simply the square of \( \Omega^{(I)}(n) \). Therefore the critical temperatures associated with free energy of composite string (6.28) is given by

\[ \beta_{c(I)} = \pi \sqrt{\frac{D-2}{6(1+s)t(s)}} = \frac{4\pi}{\sqrt{2(1+s)t(s)}}, \quad (7.13) \]

\[ \beta_{c(II)} = \pi \sqrt{\frac{D-2}{3s(1+s)t(s)}} = \frac{4\pi}{\sqrt{2s(1+s)t(s)}}, \quad (7.14) \]

We may mention here that the physical meaning of the Hagedorn temperature is still not clear. There are different interpretations possible:
(i) One may argue that $T_c$ is the maximum obtainable temperature in string systems, this meaning, when applied to cosmology, that there is a maximum temperature in the early Universe.

(ii) One may take $T_c$ to indicate some sort of phase transition to a new stringy phase.

We may also comment on the fact that there emerge two different Hagedorn temperatures from the formalism. These critical temperatures reflect physically that there are effectively two independent types of string: a closed string corresponding to right- and left-moving waves in region I, and an open string corresponding to standing waves in region II. The two critical temperatures follow from one and the same formula for the free energy, namely Eq. (6.28). From a quantum mechanical perspective, we have calculated the expression for the one-loop free energy, corresponding to a mixture of two ideal gases of string modes.

8. Mass and decay spectra

In this section we consider the motion of a two-piece classical string in flat $D$-dimensional space-time. The spectrum for the decay of a massive initial state $|\Phi> \equiv (M, 0)$ into state $|\Phi_X> \otimes |k> \equiv (k^2 = 0)$ can be presented by the modulus squared of the amplitude summed over all state $|\Phi_X>$. The initial state $|\Phi>$ in string theory characterized by a partition $\{N_n\}$ of $N = \sum_{n=1}^{\infty} \omega_n N_n$, where $N_n = \sum_j \alpha_{nj}^+ \alpha_{nj}$ is the occupation number of the $n$-th mode. The inclusive photon spectrum for the decay of state $\Phi_{\{N_n\}}$ is given by the sum over all states $\Phi_X$ satisfying the mass condition and has the form [23]

$$d\Gamma_{\Phi_{\{N_n\}}}(k_0) = \sum_{\{\Phi_X\}} |<\Phi_X|V(k)|\Phi_{\{N_n\}}>|^2 \text{Vol}(S^{D-2}) k_0^{D-3} dk_0.$$  (8.1)

Here $\text{Vol}(S^{D-2}) = 2\pi^{(D-1)/2} \Gamma((D-1)/2)^{-1}$, the photon vertex operator $V(k)$ is given by $V(k) = \xi_\mu \partial_\tau X^\mu(0) \exp(ikX(0))$, $\xi_\mu$ is the photon polarization vector and $\xi_\mu k^\mu = 0$. It can be shown that non-planar contribution does not change the above result [23].

Let $m_0$ and $\omega_0$ be the Kaluza-Klein momentum and winding number associated with the state of closed string compactified on a circle of radius $R$. For the piecewise uniform string the calculation of spectrum factorizes into left-right parts of branch I, and a branch II. Following the calculation presented in [23] we obtain the final result:
\[ d\Gamma_{\Phi(1,II)}(k_0) = C \xi^2 M^2 \prod_{\ell=1}^{3} \left[ \frac{e^{-\frac{k_0}{T_\ell}}}{1 - e^{-\frac{k_0}{T_\ell}}} \right] \frac{\text{Vol}(S^{D-2})}{k_0^{D-1}} dk_0, \quad (8.2) \]

where \( C \) is some constant. For the region II the critical temperature is \( T_{c(II)} = (\beta_{c(II)})^{-1} \), while for the region I the temperatures related with right- and left-moving modes are correspondingly given by
\[
T_{1,c}^{(I)} = 2(M^2 - Q_+^2)^{1/2}/(bM), \quad T_{2,c}^{(I)} = 2(M^2 - Q_-^2)^{1/2}/(bM), \quad \text{where} \quad Q_{\pm} = \frac{m_0}{R \pm \omega_0 R} \quad \text{and} \quad b = 2\beta_{c(II)}.
\]

The decay spectrum can be given by analogy with black holes \([24, 25]\):

\[ d\Gamma_{\Phi(1,II)}(k_0) = C \xi^2 M^2 \Sigma(k_0) \frac{e^{-k_0/T}}{1 - e^{-k_0/T}} \text{Vol}(S^{D-2}) k_0^{D-2} dk_0, \quad (8.3) \]

\[ \Sigma(k_0) = k_0 e^{-k_0/T_1} \left( 1 - e^{-k_0/T} \right) \prod_{\ell=1}^{3} \left[ 1 - e^{-k_0/T_\ell} \right]^{-1}, \quad (8.4) \]

the factor \( \Sigma(k_0) \) depends on temperature \( T_c \), where \( T_c^{-1} = (T_{1,c}^{(I)})^{-1} + (T_{2,c}^{(I)})^{-1} \). The radiative spectrum from microscopic string states related with region I and II is exactly thermal. When \( M \approx Q_+ \), \( T_{1,c}^{(I)} \approx T_{2,c}^{(I)} = 2(M^2 - Q_+^2)^{1/2}/(bM) \) radiation vanishes. The same situation occur when \( s \approx 0 \) \((T_{c(II)} \approx 0)\).

9. Conclusions

Our fundamental theory is based upon the following two conditions at the junctions, namely the transverse displacement itself, as well as the transverse force, has to be continuous. Moreover, we make two simplifying assumptions. First, the tension ratio is taken to be small. This assumption implies that the eigenvalue spectrum for the composite string becomes quite simple: there are two branches, the first branch corresponding to \( \omega_n(s) = (1 + s)n \) while the second branch corresponding to \( \omega_n(s^{-1}) = (1 + s^{-1})n \), with \( n \) an integer. Our second assumption is that \( s \) is an integer.

We considered the first branch only. The right- and left-moving amplitudes in region I can be chosen freely, while the amplitudes in region II are thereafter fixed. The oscillations in region I are therefore as for a closed string, whereas the oscillations in region II are standing waves, corresponding to an open string. This is the physical background why there is only one single critical temperature in region II, while there are two critical temperatures in region I. It should be emphasized once
more that our composite string is relativistic, in the sense that the transverse velocity of sound is everywhere in the string equal to velocity of light. How to construct a composite string theory in the absence of this relativistic requirement is not known.

Finally we note that the black hole entropy behaviour can be understood in terms of the degeneracy of some interacting fundamental string excitation mode. Generally speaking the fundamental string and $p$–brane approach can yield a microscopic interpretation of the entropy. It will be interesting to consider phases of the piecewise uniform (super) string and the Bekenstein - Hawking entropies of black holes associated with this string. The entropies can be derived by counting black hole microstates; the laws of black hole dynamics could then be identified with the laws of thermodynamics. We hope that the proposed calculation will be of interest in view of future applications to concrete problems in string theory, quantum gravity and in black hole physics.
