Abstract

A differential calculus on an associative algebra \(\mathcal{A}\) is an algebraic analogue of the calculus of differential forms on a smooth manifold. It supplies \(\mathcal{A}\) with a structure on which dynamics and field theory can be formulated to some extent in very much the same way we are used to from the geometrical arena underlying classical physical theories and models. In previous work, certain differential calculi on a commutative algebra exhibited relations with lattice structures, stochastics, and parametrized quantum theories. This motivated the present systematic investigation of differential calculi on commutative and associative algebras. Various results about their structure are obtained. In particular, it is shown that there is a correspondence between first order differential calculi on such an algebra and commutative and associative products in the space of 1-forms. An example of such a product is provided by the Itô calculus of stochastic differentials. For the case where the algebra \(\mathcal{A}\) is freely generated by ‘coordinates’ \(x^i, i = 1, \ldots, n\), we study calculi for which the differentials \(dx^i\) constitute a basis of the space of 1-forms (as a left \(\mathcal{A}\)-module). These may be regarded as ‘deformations’ of the ordinary differential calculus on \(\mathbb{R}^n\). For \(n \leq 3\) a classification of all (orbits under the general linear group of) such calculi with ‘constant structure functions’ is presented. We analyse whether these calculi are reducible (i.e., a skew tensor product of lower-dimensional calculi) or whether they are the extension (as defined in this article) of a one dimension lower calculus. Furthermore, generalizations to arbitrary \(n\) are obtained for all these calculi.

\(^{\dagger}\)Temporary address.

5 Conclusions 31

A On generalized differential calculi 32
1 Introduction

During the last years there has been a rapid increase of interest in ‘noncommutative geometry’. Basically, this notion stands for an attempt to get away from the classical concept of a (differentiable) manifold as the arena on which physics takes place. In particular, this is strongly motivated by considerations about space-time structure at very small length scales, and quantum gravity. The manifold is replaced by some abstract algebra $\mathcal{A}$ which is usually assumed to be associative, but not necessarily commutative. In order to be able to formulate dynamics and field theories on or with such ‘generalized spaces’, a convenient tool appears to be a ‘differential calculus’ on it which is an algebraic analogue of the calculus of differential forms on a manifold.$^1$

If the algebra $\mathcal{A}$ is commutative, then one can construct a (topological) space on which it can be realized as an algebra of functions. Besides the familiar continua this case also includes finite or, more generally, discrete spaces. Differential calculi on commutative algebras have been considered and explored in several papers (see [2]-[6], for example). If the algebra $\mathcal{A}$ is (freely) generated by ‘coordinates’ $x^k$, $k = 1, \ldots, n$ (together with a unit), a differential calculus on it can be specified via commutation relations with their ‘differentials’,

$$[dx^k, x^\ell] = C^{k\ell m} dx^m \quad (1.1)$$

where $C^{k\ell m} \in \mathcal{A}$ (subject to certain constraints).$^2$ An example of interest for physics is given by

$$[dx^k, x^\ell] = a^k \delta^{k\ell} dx^k \quad \text{(no summation)} \quad (1.2)$$

which may be regarded as the basic structure underlying lattice theories$^3$ ($a^k$ plays the role of the lattice spacing in the $k$th direction). Another example is

$$[dx^k, x^\ell] = \gamma g^{k\ell} dx^{n+1}, \quad [dx^{n+1}, x^k] = 0 \quad (1.3)$$

where $g^{k\ell}$ are the components (with respect to coordinates $x^i$ on a manifold) of a real contravariant tensor field. For $\gamma = i \hbar$ this may be viewed as a basic structure underlying parametrized (proper time) quantum theories$^4$. For real and positive definite $\gamma g^{ij}$ one recovers the Itô calculus of stochastic differentials$^5$. These examples motivate a systematic investigation of the possibilities. In$^6$ all differential calculi subject to (1.1) with $n = 2$ and constant structure functions, i.e., $C^{k\ell m} \in \mathcal{C}$, were classified.$^7$ The procedure used there does not extend to $n > 2$, however. Here, we therefore propose an alternative method and present the classification of 3-dimensional calculi (see also$^9$).

$^1$Such a point of view has been pioneered by Robert Hermann$^1$.

$^2$On the rhs of the last equation and in the following we are using the summation convention if not stated otherwise.

$^3$In$^3$ the case $n = 2$ and $C^{k\ell m}$ linear in $x^\ell$ has been treated. Such differential calculi are also obtained from calculi on the Heisenberg algebra$^3$ in the limit $\hbar \to 0$. 

3
Section 2 recalls some basic definitions and constructions used in the sequel. Section 3 presents general results about differential calculi on a commutative (and associative) algebra \( \mathcal{A} \). In particular, it is shown that every (first order) differential calculus on \( \mathcal{A} \) determines an \( \mathcal{A} \)-bilinear commutative and associative product in the space of 1-forms. This relates the problem of classifying (first order) differential calculi to that of determining all \( \mathcal{A} \)-bimodules over \( \mathcal{A} \) with such product structures. This correspondence generalizes the relation established in [3] between the Itô calculus of stochastic differentials (where one has a product in the space of 1-forms) and a differential calculus of the form (1.3).

In section 4 we consider the case where \( \mathcal{A} \) is freely generated (as a commutative and associative algebra) by elements \( x^i, i = 1, \ldots, n \), together with a unit 1. The class of differential calculi for which the set of differentials \( dx^i \) are a basis of the space of 1-forms (as a left \( \mathcal{A} \)-module) is then explored in some detail. They may be regarded as deformations of the ordinary differential calculus on \( \mathbb{R}^n \) and are therefore of special interest. We then address the classification problem for such calculi with constant structure functions and describe corresponding results. The action of the ‘exterior derivative’ \( d \) determines left- and right-partial derivatives \( D_{\pm i} : \mathcal{A} \to \mathcal{A} \) via

\[
d f = (D_i f) \, dx^i = dx^i D_{-i} f \quad (\forall f \in \mathcal{A}).
\]

They display the most important properties of a differential calculus. Some general results concerning their structure are obtained (see also section 3.3). Examples are provided by the irreducible calculi which arose from our classification of \( n = 3 \) calculi.

Some of our results extend to a certain generalization of the notion of a differential calculus and this is the subject of an appendix. Section 5 contains our conclusions.

## 2 Algebraic differential calculi on associative algebras

In this section some basic algebraic constructions are recalled which are needed in the following sections.

Let \( \mathcal{A} \) be an associative algebra over \( \mathbb{C} \) with unit 1. A differential calculus \( (\Omega(\mathcal{A}), d) \) over \( \mathcal{A} \) is a graded associative algebra

\[
\Omega(\mathcal{A}) = \bigoplus_{r=0}^{\infty} \Omega^r(\mathcal{A})
\]

Most of the following also works over \( \mathbb{R} \) (or other fields), but for the classification results in section 4 the choice \( \mathbb{C} \) is essential.

5In the mathematical literature it is usually called a differential graded algebra.
where $\Omega^r(\mathcal{A})$ are $\mathcal{A}$-bimodules and $\Omega^0(\mathcal{A}) = \mathcal{A}$. It is supplied with a linear operator of degree 1

$$d : \Omega^r(\mathcal{A}) \rightarrow \Omega^{r+1}(\mathcal{A})$$

satisfying $d^2 = 0$, $d1 = 0$ and

$$d(\omega \omega') = (d\omega) \omega' + (-1)^r \omega d\omega'$$

where $\omega \in \Omega^r(\mathcal{A})$. $d$ is called \textit{exterior derivative}. We also demand that, for $r > 0$, $\Omega^r(\mathcal{A})$ is \textit{generated} by $d$ in the sense that $d\Omega^{r-1}(\mathcal{A})$ generates $\Omega^r(\mathcal{A})$ as an $\mathcal{A}$-bimodule. This additional assumption will be relaxed in the appendix. We also assume that $\Omega(\mathcal{A})$ is unital with unit $(1, 0, \ldots)$. The elements of $\Omega^r(\mathcal{A})$ are called \textit{r-forms}.

$$(\Omega^1(\mathcal{A}), d) \text{ (with } d \text{ restricted to } \mathcal{A}) \text{ is a first order differential calculus on } \mathcal{A}. \text{ d is then a derivation } \mathcal{A} \rightarrow \Omega^1(\mathcal{A}).$$

\subsection{2.1 The universal first order differential calculus}

The tensor product $\mathcal{A} \otimes \mathcal{A}$ consists of finite linear combinations (with coefficients in $\mathcal{C}$) of terms $f \otimes h$ where $f, h \in \mathcal{A}$. With the multiplication

$$(f \otimes h)(f' \otimes h') := ff' \otimes hh' \quad \forall f, f', h, h' \in \mathcal{A}$$

it becomes an associative algebra (over $\mathcal{C}$). Via

$$g(f \otimes h) := (g \otimes 1)(f \otimes h) = (gf) \otimes h$$

$$(f \otimes h)g := (f \otimes h)(1 \otimes g) = f \otimes (hg)$$

$\mathcal{A} \otimes \mathcal{A}$ carries an $\mathcal{A}$-bimodule structure. The multiplication in $\mathcal{A}$ yields a map

$$\mu : \mathcal{A} \otimes \mathcal{A} \rightarrow \mathcal{A}, \quad f \otimes h \mapsto fh$$

which is a bimodule homomorphism (but not an algebra homomorphism, in general). Let us define

$$\tilde{\Omega}^1(\mathcal{A}) := \ker \mu = \{ \sum_a f_a \otimes h_a \mid \sum_a f_a h_a = 0 \}.$$  

Then we have a map

$$\tilde{d} : \mathcal{A} \rightarrow \tilde{\Omega}^1(\mathcal{A}), \quad f \mapsto 1 \otimes f - f \otimes 1.$$  

The image of $\mathcal{A}$ under $\tilde{d}$ generates $\tilde{\Omega}^1(\mathcal{A})$ as an $\mathcal{A}$-bimodule. $(\tilde{\Omega}^1(\mathcal{A}), \tilde{d})$ is the \textit{universal first order differential calculus} on $\mathcal{A}$. It has the following universal property.
Theorem 2.1 For each derivation \( d : \mathcal{A} \rightarrow M \) into some \( \mathcal{A} \)-bimodule \( M \) there is one and only one \( \mathcal{A} \)-bimodule homomorphism \( \phi : \tilde{\Omega}^1(\mathcal{A}) \rightarrow M \) such that \( d = \phi \circ \tilde{d} \), i.e., the following diagram commutes,

\[
\begin{array}{ccc}
\mathcal{A} & \xrightarrow{\tilde{d}} & \tilde{\Omega}^1(\mathcal{A}) \\
& \searrow \phi & \\
& M & \\
\end{array}
\]

Proof: see [10], chapter III, §10.10, for example. \( \square \)

As a consequence of this theorem, every first order differential calculus \((\Omega^1(\mathcal{A}), d)\) on \( \mathcal{A} \) (which is generated by \( d \)) is isomorphic to a quotient of \( \tilde{\Omega}^1(\mathcal{A}) \) by some \( \mathcal{A} \)-subbimodule (the kernel of the respective homomorphism \( \phi \)).

2.2 The universal differential calculus

Let \((\tilde{\Omega}^1(\mathcal{A}), \tilde{d})\) be the universal first order differential calculus. Define

\[
\tilde{\Omega}^0(\mathcal{A}) := \mathcal{A}, \quad \tilde{\Omega}^p(\mathcal{A}) := \tilde{\Omega}^1(\mathcal{A}) \otimes_\mathcal{A} \cdots \otimes_\mathcal{A} \tilde{\Omega}^1(\mathcal{A}) \ .
\] (2.9)

Then

\[
\tilde{\Omega}(\mathcal{A}) := \bigoplus_{p=0}^{\infty} \tilde{\Omega}^p(\mathcal{A})
\] (2.10)

with the multiplication \( \otimes_\mathcal{A} \) becomes a graded associative algebra. The extension of \( \tilde{d} \) to an exterior derivative is given by

\[
\tilde{d}(f_0 \otimes f_1 \otimes \cdots \otimes f_p) := \sum_{q=0}^{p+1} (-1)^q f_0 \otimes \cdots \otimes f_{q-1} \otimes 1 \otimes f_q \otimes \cdots \otimes f_p
\] (2.11)

and \( \mathbb{C} \)-linearity. \((\tilde{\Omega}(\mathcal{A}), \tilde{d})\) is the universal differential calculus on \( \mathcal{A} \). It has a universal property generalizing Theorem 2.1 (see [11], for example). Any differential calculus on \( \mathcal{A} \) (for which \( d\Omega^p(\mathcal{A}) \) generates \( \Omega^{p+1}(\mathcal{A}) \) as an \( \mathcal{A} \)-bimodule) can be obtained from \((\tilde{\Omega}(\mathcal{A}), \tilde{d})\) as a quotient with respect to some two-sided differential ideal in \( \tilde{\Omega}(\mathcal{A}) \) (an ideal which is closed under \( \tilde{d} \)).

2.3 Reducibility and skew tensor products of differential calculi

Let \((\Omega(\mathcal{A}), d)\) and \((\Omega(\mathcal{A}'), d')\) be differential calculi over \( \mathcal{A} \) and \( \mathcal{A}' \), respectively. From these one can build the differential calculus \((\Omega(\mathcal{A}) \hat{\otimes} \Omega(\mathcal{A}'), \hat{d})\), called the skew tensor product

\footnote{It is Karoubi’s differential envelope of \( \mathcal{A} \) (see [11]).}
The underlying set is the tensor product $\Omega(\mathcal{A}) \otimes \Omega(\mathcal{A}') =: \hat{\Omega}$. The grading is given by
\[
\hat{\Omega} = \bigoplus_{r=0}^{\infty} \hat{\Omega}^r \quad \text{with} \quad \hat{\Omega}^r = \bigoplus_{p=0}^{r} \Omega^p(\mathcal{A}) \otimes \Omega^{r-p}(\mathcal{A}') .
\] (2.12)

Multiplication is defined by
\[
(\omega \hat{\otimes} \omega')(\rho \hat{\otimes} \rho') := (-1)^{\partial \omega' \cdot \partial \rho} (\omega \rho \hat{\otimes} \omega' \rho')
\] (2.13)
and $C$-linearity. We use $\hat{\otimes}$ to stress the difference to the canonical multiplication. The linear operator $\hat{d}$ on $\Omega(\mathcal{A}) \hat{\otimes} \Omega(\mathcal{A}')$ acts as follows,
\[
\hat{d}(\omega \hat{\otimes} \omega') = (d \omega) \hat{\otimes} \omega' + (-1)^{\partial \omega} \omega \hat{\otimes} d' \omega' 
\] (2.14)
where $\partial \omega$ denotes the grade of the form $\omega$.

Given a differential calculus on an algebra $\mathcal{A}$, the question arises, whether it is reducible in the sense that it is a skew tensor product of differential calculi. Otherwise we should call the differential calculus irreducible.

### 2.4 Inner extensions of derivations

A derivation $d : \mathcal{A} \to M$ is called inner if there is an element $\rho \in M$ such that
\[
d f = [\rho, f] \quad \forall f \in \mathcal{A} .
\] (2.15)
We say that a (first order) differential calculus is inner if its exterior derivative $d$ is inner.

Given a derivation $d : \mathcal{A} \to M$ (which may already be inner), the $\mathcal{A}$-bimodule $M$ can always be extended into a larger $\mathcal{A}$-bimodule $\hat{M}$ such that $d$ becomes inner. This is done by adding an (independent) element $\rho$ as follows. Let $\mathcal{A}\rho$ be the free left $\mathcal{A}$-module generated by $\rho$ and define $\hat{M} := M \oplus \mathcal{A}\rho$ which is then also a left $\mathcal{A}$-module. A right $\mathcal{A}$-module structure can then be introduced on $\hat{M}$ by requiring $M \subset \hat{M}$ to be an $\mathcal{A}$-subbimodule and setting
\[
(h \rho) f := hf \rho + h df \quad \forall f, h \in \mathcal{A} .
\] (2.16)
Then
\[
(h \rho) f = h (f \rho + df) = h (\rho f)
\] (2.17)
and
\[
\rho (hf) = hf \rho + d(hf) = hf \rho + h df + (dh) f = (\rho \rho f) + (dh) f = (h \rho + dh) f = (\rho h) f
\] (2.18)

\footnote{Instead of skew the term anticommutative is used there.}
which extends the $\mathcal{A}$-bimodule structure of $M$ to $\tilde{M}$.

In some cases it is possible to enlarge the algebra $\mathcal{A}$ (by introducing an additional generator) to an algebra $\tilde{\mathcal{A}}$ and to extend $d$ such that it becomes inner with an element $\rho$ of the $\tilde{\mathcal{A}}$-bimodule generated by $d\tilde{\mathcal{A}}$. See section 4.1.

3 Differential calculi on commutative algebras

In this section, $\mathcal{A}$ always denotes an associative and commutative algebra. For any first order differential calculus $(\Omega^1(\mathcal{A}), d)$ we have

$$[df, h] = [dh, f]$$

which shows that this commutator is actually a function of $df$ and $dh$ (and does not depend directly on $f$ and $h$):

$$[df, h] =: C(df, dh) .$$

$C$ is obviously a bilinear map $d\mathcal{A} \times d\mathcal{A} \to \Omega^1(\mathcal{A})$ which is symmetric, i.e.

$$C(df, dh) = C(dh, df) ,$$

as a consequence of our first equation. In the following, it will be shown that $C$ determines an $\mathcal{A}$-bilinear associative and commutative product in the space of 1-forms.

3.1 The canonical product in the space of universal 1-forms

For an associative and commutative algebra $\mathcal{A}$ also $\mathcal{A} \otimes \mathcal{A}$ with the canonical multiplication rule (2.4) is an associative commutative algebra. The map $\mu$ introduced in section 2.1 then becomes an algebra homomorphism so that $\tilde{\Omega}^1(\mathcal{A}) = \ker \mu$ is an ideal. As a consequence, in the space $\tilde{\Omega}^1(\mathcal{A})$ of 1-forms of the universal first order differential calculus on $\mathcal{A}$ there is a canonical associative and commutative product

$$\tilde{\Omega}^1(\mathcal{A}) \times \tilde{\Omega}^1(\mathcal{A}) \to \tilde{\Omega}^1(\mathcal{A}) , \quad (\tilde{\omega}, \tilde{\omega}') \mapsto \tilde{\omega} \cdot \tilde{\omega}'$$

which is $\mathcal{A}$-bilinear, i.e.,

$$(f\tilde{\omega}h) \cdot (f'\tilde{\omega}'h') = ff' (\tilde{\omega} \cdot \tilde{\omega}') hh'$$

(cf (2.5)). From

$$[\sum_a g_a \otimes h_a , f] = \left( \sum_a g_a \otimes h_a \right) (\mathbb{1} \otimes f - f \otimes \mathbb{1})$$

and (2.8) we deduce the following important property,

$$[\tilde{\omega}, f] = \tilde{\omega} \cdot \tilde{df} \quad \forall \tilde{\omega} \in \tilde{\Omega}^1(\mathcal{A}), \ f \in \mathcal{A} .$$
A simple calculation now leads to

\[ \tilde{d}(fh) = f \tilde{d}h + h \tilde{d}f + \tilde{d}f \cdot \tilde{d}h \]  

(3.8)

which is generalized in the following Lemma.

**Lemma 3.1**

\[ \tilde{d}(f_1 \cdots f_r) = \tilde{d}f_1 \cdot \cdots \cdot \tilde{d}f_r + \sum_{k=2}^{r} \frac{1}{(k-1)! (r-k+1)!} f_1 \cdots f_{k-1} \tilde{d}f_k \cdot \cdots \tilde{d}f_r \]  

(3.9)

where the indices on the rhs are totally symmetrised (indicated by brackets).

**Proof:** by induction, using the identity

\[ f_1 \cdots f_{k-2} \tilde{d}f_k \cdot \cdots \cdot \tilde{d}f_r = \frac{(k-1)!}{(k-2)!} f_{r+1} f_1 \cdots f_{k-2} \tilde{d}f_{k-1} \cdot \cdots \cdot \tilde{d}f_r \]

\[ + \frac{(r+1-k+1)!}{(r-k+1)!} f_1 \cdots f_{k-1} \tilde{d}f_k \cdot \cdots \cdot \tilde{d}f_r \cdot \tilde{d}f_{r+1}. \]

\[ \Box \]

A result about 2-forms is expressed next.

**Lemma 3.2**

\[ \tilde{d}(\tilde{d}f_1 \cdot \cdots \cdot \tilde{d}f_r) = - \sum_{k=1}^{r-1} \frac{1}{k! (r-k)!} (\tilde{d}f_1 \cdot \cdots \cdot \tilde{d}f_k) (\tilde{d}f_{k+1} \cdot \cdots \cdot \tilde{d}f_r). \]  

(3.10)

**Proof:** by induction. In order to show that (3.10) implies the corresponding formula with \( r \) replaced by \( r + 1 \), one may start with the rhs of the latter and write

\[ (\tilde{d}f_1 \cdot \cdots \cdot \tilde{d}f_k) (\tilde{d}f_{k+1} \cdot \cdots \cdot \tilde{d}f_{r+1}) \]

\[ = k! (r+1-k)! \sum_{\text{partitions}} (\tilde{d}f_{\ell_1} \cdot \cdots \cdot \tilde{d}f_{\ell_k}) (\tilde{d}f_{\ell_{k+1}} \cdot \cdots \cdot \tilde{d}f_{\ell_{r+1}}) \]

where the sum is taken over all partitions of \( 1, \ldots, r+1 \) into ordered tuples \( (\ell_1, \ldots, \ell_k) \), \( (\ell_{k+1}, \ldots, \ell_{r+1}) \). This sum splits into a sum over partitions with \( r+1 \in \{\ell_1, \ldots, \ell_k\} \) and a sum over partitions with \( r+1 \in \{\ell_{k+1}, \ldots, \ell_{r+1}\} \). The first of these sums can then be expressed as a sum over all partitions of \( 1, \ldots, r \) into ordered tuples \( (\ell_1, \ldots, \ell_{k-1}) \), \( (\ell_k, \ldots, \ell_r) \). The second sum is treated similarly. The further procedure is then quite evident. \[ \Box \]

### 3.2 The ring structure of a first order differential calculus

Let \((\Omega^1(\mathcal{A}), d)\) be a first order differential calculus on \(\mathcal{A}\). In the following, we show that the canonical product in the space \(\tilde{\Omega}^1(\mathcal{A})\) of universal 1-forms induces a corresponding product in \(\Omega^1(\mathcal{A})\).
Lemma 3.3 If \( \phi : \tilde{\Omega}^1(A) \rightarrow \Omega^1(A) \) is an \( A \)-bimodule homomorphism, then \( \ker \phi \) is an ideal in \( \tilde{\Omega}^1(A) \) as a ring with product \( \bullet \).

Proof: An arbitrary element of \( \tilde{\Omega}^1(A) \) can be written as \( \sum_a f_a (1 \otimes h_a - h_a \otimes 1) \) with \( f_a, h_a \in A \). Let \( \tilde{\omega} \in \ker \phi \). Then

\[
\phi(\tilde{\omega} \bullet \sum_a f_a (1 \otimes h_a - h_a \otimes 1)) = \sum_a f_a \phi([\tilde{\omega}, h_a]) = \sum_a f_a [\phi(\tilde{\omega}), h_a] = 0 .
\]

Since \( \bullet \) is commutative, this shows that \( \ker \phi \) is an ideal.

As a consequence of this Lemma and Theorem 2.1, we now obtain the following result.

Theorem 3.1 For every first order differential calculus \( (\Omega^1(A), d) \) there is a unique \( A \)-bilinear associative and commutative product \( \bullet \) in \( \Omega^1(A) \) such that \( [\omega, f] = \omega \bullet df \).

The next Lemma gives a characterization of inner differential calculi.

Lemma 3.4 The derivation \( d \) of a first order differential calculus is inner if and only if there is a unit with respect to \( \bullet \).

Proof: The statement is an immediate consequence of the relation \( \omega \bullet df = [\omega, f] \) taking into account that \( \bullet \) is \( A \)-bilinear.

If a first order differential calculus is inner, i.e., \( df = [\rho, f] \) \( \forall f \in A \) with an element \( \rho \in \Omega^1(A) \), then \( \rho \) is unique. This follows from Lemma 3.4 together with the fact that the unit of an algebra is unique. This in turn implies that, if \( d \) is inner, the center of the \( A \)-bimodule \( \Omega^1(A) \) is trivial, i.e., \( \{ \zeta \in \Omega^1(A) \mid [\zeta, f] = 0 \ \forall f \in A \} = \{0\} \).

Let \( I \) be the two-sided differential ideal in \( \tilde{\Omega}(A) \) generated by \( \ker \phi \). Now

\[
\Omega(A) := \tilde{\Omega}(A)/I
\]

(3.11)

and together with \( d := \pi \circ \tilde{d} \) is a differential calculus on \( A \). Here, \( \pi : \tilde{\Omega}(A) \rightarrow \Omega(A) \) is the canonical projection. The ideal \( I \) has a decomposition

\[
I = \bigoplus_{r=0}^{\infty} I^r \quad (3.12)
\]

where \( I^0 = \{0\} \) and \( I^1 = \ker \phi \), so that

\[
\Omega(A) = \bigoplus_{r=0}^{\infty} \Omega^r(A) \quad \text{with} \quad \Omega^r(A) = \tilde{\Omega}^r(A)/I^r. \quad (3.13)
\]

Example. \( \tilde{\Omega}^1(A)^2 := \tilde{\Omega}^1(A) \bullet \tilde{\Omega}^1(A) \) is an \( A \)-subbimodule and also a two-sided ideal in \( \tilde{\Omega}^1(A) \). Hence,

\[
\mathcal{K}^1(A) := \tilde{\Omega}^1(A)/\tilde{\Omega}^1(A)^2 \quad (3.14)
\]
carries an $\mathcal{A}$-bimodule structure too and the induced product is trivial, i.e., the product of any two elements of $\mathcal{K}^1(\mathcal{A})$ is equal to zero. Now Theorem 3.1 shows that all elements of $\mathcal{K}^1(\mathcal{A})$ commute with all elements of $\mathcal{A}$. The extension to forms of higher grade is called Kähler differential calculus $(\mathcal{K}(\mathcal{A}), d_K)$ on $\mathcal{A}$.

Let $\mathcal{A}$ be the algebra generated by $x$ with the relation $x^N = \mathbf{1}$ for some $N \in \mathbb{N}$. Acting on the latter with the Kähler derivation leads to

$$x^{N-1} d_K x = 0$$

which implies $d_K x = 0$ so that the Kähler derivation is trivial. In the presence of constraints one is therefore led to consider noncommutative differential calculi, where differentials do not commute with elements of $\mathcal{A}$ in general, in order to have a nontrivial $d$. In particular, this is so for differential calculi on finite sets.

Example. Let $\mathcal{A}$ be the commutative and associative algebra which is freely generated by elements $t$ and $x$ (and a unit $\mathbf{1}$). An example of a differential calculus on $\mathcal{A}$ which is not inner is determined by the commutation relations

$$[dx, x] = dt, \quad [dx, t] = 0 = [dt, t]$$

where we assume that $dx, dt$ is a basis of $\Omega^1(\mathcal{A})$ as a left- (and right) $\mathcal{A}$-module. For the associated product we have

$$dx \cdot dx = dt, \quad dx \cdot dt = 0, \quad dt \cdot dt = 0.$$ (3.17)

This product is then consistent with commutativity of differentials and elements of $\mathcal{A}$. A realization of this algebra is given by a stochastic time variable $t$ and a Wiener process $x = W_t$. The above relations are basic formulas in the Itô calculus of stochastic differentials (where $d$ is not a derivation). Our example is easily generalized to the case of several independent Wiener processes. See also

3.3 The case of a freely and finitely generated algebra

Let $\mathcal{A}$ be freely generated by elements $x^i$, $i = 1, \ldots, n$, and the unit $\mathbf{1}$. From Lemma 3.1 we can then deduce that the 1-forms

$$\tilde{\tau}^{i_1 \cdots i_r} := \tilde{d}x^{i_1} \cdot \cdots \cdot \tilde{d}x^{i_r} \quad (r = 1, \ldots)$$

generate $\tilde{\Omega}^1(\mathcal{A})$ as a left $\mathcal{A}$-module. $\tilde{\tau}^{i_1 \cdots i_r}$ is totally symmetric in the indices $i_1, \ldots, i_r$, so that we should restrict the latter by $i_1 \leq i_2 \leq \ldots \leq i_r$. $\mathcal{A}$ consists of finite linear combinations of monomials in $x^1, \ldots, x^n$ and $\mathbf{1}$ with coefficients in $\mathbb{C}$, i.e., $\mathcal{A} = \mathbb{C}[x^1, \ldots, x^n]$. Here, we will not discuss a possible extension to infinite sums (e.g., the case of analytic functions on $\mathbb{R}^n$).
Lemma 3.5 The set of 1-forms

\[ B := \{ \tilde{\tau}_{i_1 \cdots i_r} \in \tilde{\Omega}^1(\mathcal{A}) \mid i_1 \leq \ldots \leq i_r, r = 1, 2, \ldots \} \]  

(3.19)
is a basis of \( \tilde{\Omega}^1(\mathcal{A}) \) as a left \( \mathcal{A} \)-module.

**Proof:** We already know that \( B \) generates \( \tilde{\Omega}^1(\mathcal{A}) \) as a left \( \mathcal{A} \)-module. It is therefore sufficient to show that any finite subset of \( B \) is linearly independent over \( \mathcal{A} \). Let

\[ 0 = \sum_{r=1}^{n} \sum_{i_1 \leq i_2 \ldots \leq i_r} f_{i_1 \ldots i_r} \tilde{\tau}_{i_1 \cdots i_r} \]

with \( f_{i_1 \ldots i_r} \in \mathcal{A} \). Using

\[ \tilde{\tau}_{i_1 \cdots i_r} = 1 \otimes x^{i_1} \cdots x^{i_r} + \sum_{p=1}^{r-1} \frac{(-1)^p}{p!(r-p)!} x^{(i_1} \cdots x^{i_p} \otimes x^{i_{p+1}} \cdots x^{i_r)} + (-1)^r x^{i_1} \cdots x^{i_r} \otimes 1 \]

the above equation leads to

\[ 0 = \sum_{i_1 \leq i_2 \ldots \leq i_n} f_{i_1 \ldots i_n} \otimes x^{i_1} \cdots x^{i_n} + \text{rest} \]

where ‘rest’ consists of a finite sum of tensor products of which the second factor is a monomial of degree < \( n \) in the generators \( x^i \) of \( \mathcal{A} \). Since \( \mathcal{A} \) is freely generated, we conclude that \( f_{i_1 \ldots i_n} = 0 \). By repetition of this argument, \( f_{i_1 \ldots i_r} = 0 \) \( \forall i_1, \ldots, i_r \), \( r = 1, \ldots, n \). \( \square \)

Similarly, one can argue that the 2-forms \( \tilde{\tau}_{i_1 \cdots i_r} \tilde{\tau}_{i_1 \cdots i_s} \) \( (r, s = 1, \ldots) \) constitute a basis of \( \tilde{\Omega}^2(\mathcal{A}) \) as a left \( \mathcal{A} \)-module (see also Lemma 3.2), and correspondingly for \( \tilde{\Omega}^r(\mathcal{A}) \) with \( r > 2 \).

As a consequence of the preceding Lemma,

\[ \tilde{d} f = \sum_{r=1}^{\infty} (\tilde{D}_{i_1 \cdots i_r} f) \tilde{\tau}_{i_1 \cdots i_r} . \]  

(3.20)

with operators \( \tilde{D}_{i_1 \cdots i_r} : \mathcal{A} \rightarrow \mathcal{A} \), where the indices are totally symmetric. Inserted in \( (3.8) \) this leads to

\[ \tilde{D}_{i_1 \cdots i_r} (f h) = f \tilde{D}_{i_1 \cdots i_r} h + h \tilde{D}_{i_1 \cdots i_r} f + \sum_{k=1}^{r-1} \frac{1}{k!(r-k)!} (\tilde{D}_{i_1 \cdots i_k} f) (\tilde{D}_{i_{k+1} \cdots i_r} h) \]  

(3.21)

which, in particular, shows that the operators \( \tilde{D}_i \) are derivations. As a consequence of \( (3.20) \) they satisfy \( \tilde{D}_i x^i = \delta_j^i \) and therefore coincide with the ordinary partial derivatives\(^9\).

\[ \tilde{D}_i = \partial_i . \]  

(3.22)

\^9The ‘ordinary partial derivatives’ are the derivations \( \partial_k : \mathcal{A} \rightarrow \mathcal{A} \) \( (k = 1, \ldots, n) \) with \( \partial_k x^i = \delta_k^i \).
Applying $\tilde{d}$ to (3.20) using (3.10) in the form
\[
\tilde{d}^{i_1 \ldots i_r} = - \sum_{k=1}^{r-1} \frac{1}{k!(r-k)!} \tilde{\tau}^{(i_1 \ldots i_k \ k \ i_{k+1} \ldots i_r)}
\]
and $\tilde{d}^2 = 0$, we obtain
\[
\tilde{D}_{i_1 \ldots i_k} \tilde{D}_{i_{k+1} \ldots i_r} = \binom{r}{k} \tilde{D}_{i_1 \ldots i_r}.
\]
Together with (3.22) this implies
\[
\tilde{D}_{i_1 \ldots i_r} = \frac{1}{r!} \partial_{i_1} \cdots \partial_{i_r} \quad (r = 1, \ldots).
\]
So far we have treated the case of the universal differential calculus with its ring structure. For any other first order differential calculus $(\tilde{\Omega}^1(\mathcal{A}), \tilde{d})$ we can define $\tilde{\tau}^{i_1 \ldots i_r}$ as in (3.18) (with $\tilde{d}x_i$ replaced by $d x_i$). These 1-forms are then, however, not linearly independent. Nevertheless, the formulas derived above induce corresponding formulas for any differential calculus, as demonstrated in the following examples.

**Examples.** We evaluate (3.20) with (3.25) for some examples of differential calculi.

1. For the Kähler calculus, where $d x_i \cdot d x_j = 0$, we recover the familiar formula $df = (\partial_i f) dx_i$.

2. The lattice calculus in $\mathbb{R}^n$ is determined by $d x_i \cdot d x_j = \ell \delta^{ij} d x^j$ (no summation, $\ell \in \mathbb{R} \setminus \{0\}$). In this case we obtain
\[
d f = \sum_{i=1}^n \frac{1}{\ell} (\exp(\ell \partial_i) - 1) f d x_i
= \sum_{i=1}^n \frac{1}{\ell} \left[f(x^1, \ldots, x^i + \ell, \ldots, x^n) - f(x)\right] d x_i.
\]

In the universal differential calculus, the ideal by which we have to factorize $\tilde{\Omega}^1(\mathcal{A})$ in order to obtain the calculus under consideration is generated by $\tilde{d} x_i \cdot \tilde{d} x^j - \ell \delta^{ij} \tilde{d} x^j$. Representing the $x^i$ as coordinate functions on $\mathbb{C}^n$ (or $\mathbb{R}^n$) and evaluating the last expressions on $(a, b) \in \mathbb{C}^n \times \mathbb{C}^n$ using (2.8), we find
\[
(\tilde{d} x_i \cdot \tilde{d} x^j - \ell \delta^{ij} \tilde{d} x^j)(a, b) = (b^i - a^i)[b^j - a^j - \ell \delta^{ij}].
\]
Equated to zero, this precisely displays the lattice structure.

3. For $n = 1$ (for simplicity), the symmetric lattice calculus discussed in $\mathbb{F}$ can be defined by $d x \cdot d x \cdot d x = \ell^2 d x$. Then
\[
d f = \sum_{r=0}^{\infty} \frac{\ell^{2r}}{(2r+1)!} (\partial^{2r+1} f) d x + \sum_{r=1}^{\infty} \frac{\ell^{2r-1}}{(2r)!} (\partial^{2r} f) d x \cdot d x
= \bar{\partial} f d x + \frac{1}{2} \Delta f d x \cdot d x
\]

13
where
\[
\bar{\partial} f := \frac{1}{2 \ell} [f(x + \ell) - f(x - \ell)], \quad \Delta f := \frac{1}{\ell^2} [f(x + \ell) + f(x - \ell) - 2f(x)].
\]

With \(x\) as a coordinate function on \(\mathcal{C}\), we find
\[
(\tilde{dx} \bullet \tilde{dx} \bullet \tilde{dx} - \ell^2 \tilde{dx})(a, b) = (b - a)[(b - a)^2 - \ell^2].
\]

Equated to zero, this implies \(b = a\) or \(b = a + \ell\) or \(b = a - \ell\) which reveals the symmetric lattice structure (see [6]).

For \(\ell = 0\) one obtains
\[
\partial f = \frac{\partial f}{dx} + \frac{1}{2} \partial^2 f dx \bullet dx.
\]

The last type of calculus appears in the classical limit \((q \to 1)\) of bicovariant differential calculus on the quantum groups \(SL_q(n)\) [14, 5, 15]. Via \(dx \bullet dx \mapsto dt\) contact is made with the calculus of the last example in the previous subsection.

4. Generalizing the last two examples for \(n = 1\), we consider the ideal in \(\tilde{\Omega}^1(A)\) generated by
\[
(\tilde{dx})^{(k+1)} - \ell^k \tilde{dx}
\]
for some fixed \(k \in \mathbb{N}\). Evaluated on \((a, b) \in \mathcal{C} \times \mathcal{C}\), it leads us to the equation
\[
(b - a)[(b - a)^k - \ell^k] = 0.
\]

This defines an algorithm which, fixing a starting point \(a\), generates new points \(a + \ell q^r\) for \(r = 0, 1, \ldots, k\), where \(q\) is a primitive \(k\)th root of unity. In this way, a lattice is created in the complex plane and the differential calculus can be restricted to (the functions on) it.

Using \(\sum_{j=0}^{k-1} q^j = (q^k - 1)/(q - 1) = 0\) for \(k > 1\), we find
\[
\partial f = \sum_{r=0}^{\infty} \frac{\ell^{kr}}{(kr + 1)!} (\partial^{kr+1} f) dx + \sum_{r=0}^{\infty} \frac{\ell^{kr}}{(kr + 2)!} (\partial^{kr+2} f) dx \bullet dx
\]
\[
+ \ldots + \sum_{r=0}^{\infty} \frac{\ell^{kr}}{(kr + k)!} (\partial^{kr+k} f) (dx)^k
\]
\[
= \sum_{j=1}^{k-1} (D_j f) (dx)^j + (D_k - \ell^{-k}) f (dx)^k
\]
with
\[
D_j f = \frac{1}{k \ell^j} \sum_{m=0}^{k-1} q^{j(k-m)} f(x + \ell q^m).
\]

In terms of the 1-forms
\[
\theta^j := \frac{1}{k} \sum_{m=1}^{k} q^{j(k-m)} \ell^{-m} (dx)^m.
\]
this becomes
\[ df = \sum_{j=0}^{k-1} [f(x + \ell q^j) - f(x)] \theta^j. \]

Furthermore, we have the following simple commutation relations,
\[ \theta^j f(x) = f(x + \ell q^j) \theta^j. \]

For \( k = 3 \) the lattice is triangular and of the kind which underlies the hard hexagon model in statistical mechanics \([10]\). More precisely, it should be regarded as an oriented lattice and for \( k = 4 \) one obtains the corresponding symmetric lattice. The case \( k = 5 \) is related to a quasilattice \([17]\).

\[ \square \]

4 Deformations of the ordinary differential calculus on freely generated commutative algebras

Throughout this section \( \mathcal{A} \) denotes an associative and commutative algebra which is freely generated by \( x^1, \ldots, x^n \) and the unit \( 1 \). Furthermore, we restrict our considerations to \( n \)-dimensional first order differential calculi \((\Omega^1(\mathcal{A}), d)\). For those the differentials \( dx^i, i = 1, \ldots, n \), form a basis of \( \Omega^1(\mathcal{A}) \) as a left \( \mathcal{A} \)-module. Such calculi may be regarded as (algebraic) deformations of the ordinary (Kähler) differential calculus and are therefore of particular interest. (3.2) then yields
\[ \left[ dx^i, dx^j \right] = C^{ij} \, dx^k \]  \hspace{1cm} (4.1)

with \( C^{ij} \in \mathcal{A} \). From (3.3) and the Jacobi identity we obtain the following consistency conditions,
\[ C^{ij} = C^{ji}, \quad C^{ik} C^{jm} = C^{jk} C^{im} \]  \hspace{1cm} (4.2)

(see also \([3]\)). In terms of the (structure) matrices \( C^k \) with entries \((C^k)^i_j := C^{ki} \), the first of these conditions means that the \( j \)th row of \( C^i \) equals the \( i \)th row of \( C^j \). The second condition says that the \( C^i \) commute with each other:
\[ C^k C^\ell = C^\ell C^k. \]  \hspace{1cm} (4.3)

Remark. As described in the preceding section, a first order differential calculus induces a product in the space of 1-forms. In the case under consideration, the latter is determined by
\[ dx^i \bullet dx^j = C^{ij} \, dx^k. \]  \hspace{1cm} (4.4)
As a consequence of (4.2) this product is commutative and associative:

\[ dx^i \bullet dx^j = C^{ij}_k \, dx^k = C^{ji}_k \, dx^k = dx^j \bullet dx^i \]  

(4.5)

\[ (dx^i \bullet dx^j) \bullet dx^k = (C^{ij}_\ell \, dx^\ell) \bullet dx^k = C^{ij}_\ell \, C^{k_m}_m \, dx^m = C^{jk}_\ell \, C^{i\ell}_m \, dx^m \]

\[ = dx^i \bullet C^{jk}_\ell \, dx^\ell = dx^i \bullet (dx^j \bullet dx^k). \]  

(4.6)

The matrices \( C^i \) constitute a representation of this algebra since

\[ C^i C^j = C^{ij}_k \, C^k. \]  

(4.7)

As a consequence of the foregoing, the classification of first order differential calculi of the kind specified above with \( C^{ij}_k \in \mathcal{M} \) is equivalent to the classification of commutative and associative algebras over \( \mathbb{C} \).

Remark. More generally, when the conditions (4.2) are satisfied, (4.1) determines a (first order) differential calculus on any algebra \( \mathcal{A} \) which is freely generated by the \( x^i \) modulo commutation relations such that \([x^i, x^j]\) is constant with respect to \( d \) (for all \( i, j \)). Special examples are the Heisenberg algebras of quantum mechanics (see also [1, 8] for related work). Further examples are the algebras considered in [18] where \([x^k, x^\ell]\) = \( iQ^{k\ell} \) with an antisymmetric tensor operator \( Q^{ij} \) which is central in the algebra generated by the \( x^k \). The solutions of the consistency conditions presented in subsections 4.3 and 4.4 therefore also determine differential calculi on such noncommutative algebras.

In the following subsections we first introduce a notion of 'extension' of a differential calculus (following the general recipe of section 2.4). A procedure for the classification of differential calculi with constant structure functions is then outlined and applied to the cases where \( n = 2 \) and \( n = 3 \). The action of an exterior derivative on \( \mathcal{A} \) is determined by left- (or right-) partial derivatives, for which we derive some general formulas and which we calculate for several examples of differential calculi. Particular solutions of the consistency conditions for arbitrary \( n \) are discussed in the last two subsections.

4.1 Inner differential calculi and inner extensions of differential calculi

The following result gives a criterion for a differential calculus to be inner (in the sense of section 2.4).

**Lemma 4.1** \( d \) is inner if and only if there is a 1-form \( \rho = \rho_k \, dx^k \) with \( \rho_k \, C^k = 1 \) (the unit \( n \times n \) matrix).

\[ ^{10} \text{Here we have to make the assumption that } Q^{k\ell} \text{ is annihilated by } d. \]
Proof:
"⇒": follows immediately from (4.1) and $dx^i = [\rho, x^i]$.

"⇐":

\[
d f = \delta^j_i (D_i f) dx^j = \rho_k (D_i f) C^{ikj} dx^j = \rho_k (D_i f) [dx^i, x^k] = \rho_k [df, x^k] = \rho_k [dx^k, f] = [\rho, f].
\]

\[\blacksquare\]

Let $(\Omega^1(\mathcal{A}), d)$ be a first order differential calculus. To the generators $x^1, \ldots, x^n$ of $\mathcal{A}$ we adjoin an element $x^{n+1}$ to freely generate the larger commutative algebra $\tilde{\mathcal{A}} = \mathcal{A}[x^{n+1}]$. On the latter we introduce an $n$-dimensional first order differential calculus via structure matrices as follows. Define

\[
\tilde{C}^i := \begin{pmatrix}
C^i & 0 \\
\vdots & \\
0 & \\
e^i & 0
\end{pmatrix}
\text{ (i = 1, \ldots, n)}
\]  

where $C^i$ are the structure matrices of $(\Omega^1(\mathcal{A}), d)$ and $e^i$ is the row vector with entries $e^i_j = \delta^i_j, j = 1, \ldots, n$. Let $\tilde{C}^{n+1}$ be the $(n + 1) \times (n + 1)$ unit matrix. The matrices $\tilde{C}^I, I = 1, \ldots, n + 1$, then satisfy the consistency conditions (4.2) (if the $C^i$ satisfy them).

For the enlarged differential calculus $(\Omega^1(\tilde{\mathcal{A}}), \tilde{d}) =: \textbf{Ext}(\Omega^1(\mathcal{A}), d)$ the extended derivation is inner,

\[
\tilde{d} f = [dx^{n+1}, f] \quad (\forall f \in \tilde{\mathcal{A}}),
\]

i.e., we have (2.15) with $\rho = \tilde{d}x^{n+1}$. In particular, if $(\Omega^1(\mathcal{A}), d)$ is not inner, then there is always an extension of it which is inner. This observation is helpful since it is often much easier to carry out calculations with an inner exterior derivative.

4.2 Procedure for classification of constant structure functions

With the additional assumption that the structure functions are constant, i.e., $C^i_{jk} \in \mathbb{C}$, it is in principle possible to classify all first order differential calculi.\[\text{This has been done}\]

\[\text{All first order differential calculi with constant structure functions extend to higher orders with the usual anticommutation rule for the product of differentials, } dx^i dx^j = -dx^j dx^i. \text{ Of course, this simple rule does not extend to arbitrary 1-forms in case of a noncommutative differential calculus (where some of the } C^i_{jk} \text{ are different from zero).}\]
in [3] for the case \( n = 2 \). The methods used there are not applicable to the case \( n > 2 \), however, in contrast to the procedure which we outline below and which is then applied to the cases \( n = 2 \) and \( n = 3 \).

Under a \( GL(n, \mathbb{C}) \)-transformations

\[
x'^k = U^k \ell x^\ell \quad \text{with} \quad U = (U^k \ell) \in GL(n, \mathbb{C})
\]  

the commutation relations (4.1) are invariant if

\[
C'^{ij}_{k} = U^i_r U^j_s C^{rs}_{t} (U^{-1})^t_k
\]

respectively,

\[
C'^{ii} = U^i_j (U C^j U^{-1}).
\]

These transformations preserve the conditions (4.2). In order to classify differential calculi one should therefore determine all equivalence classes of structure matrices with respect to \( GL(n, \mathbb{C}) \)-transformations. Thanks to the commutativity of the matrices \( C^i \), there is a \( U \in GL(n, \mathbb{C}) \) such that, for all \( i = 1, \ldots, n \), the \( U C^i U^{-1} \) are triangular, i.e., have zeros everywhere above the diagonal. This is a consequence of the Jordan trigonalization theorem. But then also the \( C'^{ii} \) in (4.12) are triangular as linear combinations of triangular matrices.

Hence, in each \( GL(n, \mathbb{C}) \)-orbit of structure matrices there are representatives which are triangular and only for those we have to solve the \( GL(n, \mathbb{C}) \)-invariant conditions (4.2). The symmetry condition now reduces the \( C^i \) to the following form,

\[
C^1 = \begin{pmatrix}
C^{11}_{1} & 0 & \cdots & 0 \\
C^{12}_{1} & 0 & \cdots & 0 \\
\vdots & \vdots & \ddots & \vdots \\
C^{1n}_{1} & 0 & \cdots & 0
\end{pmatrix}, \quad
C^2 = \begin{pmatrix}
C^{21}_{2} & 0 & \cdots & 0 \\
C^{22}_{2} & 0 & \cdots & 0 \\
\vdots & \vdots & \ddots & \vdots \\
C^{2n}_{2} & 0 & \cdots & 0
\end{pmatrix}, \ldots
\]

\[
\ldots, \quad
C^n = \begin{pmatrix}
C^{n1}_{n} & 0 & \cdots & 0 \\
C^{n2}_{n} & \cdots & \ddots & \vdots \\
\vdots & \vdots & \ddots & 0 \\
C^{nn}_{n} & \cdots & \cdots & 0
\end{pmatrix}.
\]

Although we made use of the fact that the \( C^i \) have to commute with each other in order to derive (4.13), the commutativity is not yet built in completely. The further procedure may now be as follows. There are \( GL(n, \mathbb{C}) \)-transformations which preserve the above form of the matrices \( C^i \). They can be used to further simplify their structure. The remaining complex constants are then constrained by quadratic equations resulting from the condition (4.3) that the \( C^i \) have to commute with each other. These equations have to be solved.
In the simple case $n = 1$, where $[dx, x] = c dx$, there are two orbits. $c = 0$ represents the ordinary (Kähler) differential calculus. We refer to it as $\mathbb{K}$. The other orbit where $c \neq 0$ can be represented by $c = 1$. It describes a differential calculus on a 1-dimensional lattice $\mathbb{L}$ denoted by $\mathbb{L}$.

From these 1-dimensional calculi one can build differential calculi on algebras with more than one generator. The general construction has been recalled in section 2.3. Let $y^1, \ldots, y^r$ and $z^1, \ldots, z^s$ be the generators of two commutative algebras with, respectively, $r$- and $s$-dimensional (first order) differential calculi determined by

$$[dy^a, y^b] = C^{ab}_c dy^c, \quad [dz^{a'}, z^{b'}] = C^{a'b'}_{c'} dz^{c'}.$$  

(4.14)

For $x^a := y^a \otimes 1$ and $x^{r+a'} := 1 \otimes z^{a'}$ this implies

$$[dx^i, x^j] = \hat{C}^{ij} k d x^k \quad (i, j = 1, \ldots, r + s)$$  

(4.15)

where $\hat{C}^{ab}_c = C^{ab}_c$, $\hat{C}^{r+a', s+b'}_{r+c'} = C^{a'b'}_{c'}$ and $\hat{C}^{ij} k = 0$ otherwise. Conversely, if after some $GL(n, \mathbb{C})$-transformation the structure matrices of a differential calculus decompose in this way, the calculus is reducible and can be expressed as a skew tensor product of lower-dimensional calculi.

The $n$-dimensional irreducible calculi can be further classified into those which are extensions – in the sense of subsection 4.1 – of $(n-1)$-dimensional calculi and those which are not. This makes sense on the basis of the following result.

**Lemma 4.2** The extensions of all representatives of a $GL(n, \mathbb{C})$-orbit of $n$-dimensional differential calculi lie in the same $GL(n+1, \mathbb{C})$-orbit.

**Proof:** With the special $GL(n+1, \mathbb{C})$-matrix

$$\hat{U} = \begin{pmatrix} U & 0 \\ 0 & 1 \end{pmatrix}$$

where $U \in GL(n, \mathbb{C})$ we find

$$\hat{C}^{ij} = \hat{U}^i j \hat{U} \hat{C}^j \hat{U}^{-1} = U^i j \begin{pmatrix} U & 0 \\ 0 & 1 \end{pmatrix} \begin{pmatrix} C^j & 0 \\ e^j & 0 \end{pmatrix} \begin{pmatrix} U^{-1} & 0 \\ 0 & 1 \end{pmatrix}$$

$$= \begin{pmatrix} U^i j UC^j U^{-1} & 0 \\ U^i j e^j U^{-1} & 0 \end{pmatrix}.$$  

Since $U^i j e^j U^{-1} = e^i$, this is the extension of the $U$-transformed $C^i$. Furthermore, $\hat{C}^{n+1}_n = C^{n+1}$ (which is the $(n+1) \times (n+1)$ unit matrix).

\[\hat{C}^{n+1}_n = C^{n+1}\]

\[\square\]

To see this, one actually has to go beyond the algebra of polynomials since functions with period $c$ play an essential role in this case.\[\Box\]
4.3 Classification of 2-dimensional differential calculi

For $n = 2$ equation (4.13) becomes

$$C^1 = \begin{pmatrix} a & 0 \\ b & 0 \end{pmatrix}, \quad C^2 = \begin{pmatrix} b & 0 \\ c & d \end{pmatrix}. \quad (4.16)$$

The two matrices commute iff the complex constants $a, b, c, d$ are related by

$$b^2 - ac - bd = 0. \quad (4.17)$$

An arbitrary element of $GL(2, \mathbb{C})$ is given by

$$\begin{pmatrix} s & t \\ u & v \end{pmatrix} \quad (4.18)$$

with $D := sv - tu \neq 0$. It acts on the matrices $C^i$ as follows,

$$C'^1 = \frac{1}{D} \begin{pmatrix} s^2va + 2stvb + t^2vc - t^2ud & -s^2ta - 2stb - t^3c + st^2d \\ sua + v(sv + tu)b + tu^2c - tuvd & -stu - t(sv + tu)b - t^2vc + stvd \end{pmatrix},$$

$$C'^2 = \frac{1}{D} \begin{pmatrix} sua + v(tu + sv)b + tu^2c - tuvd & -stu - t(tu + sv)b - t^2vc + stvd \\ u^2va + 2uv^2b + v^3c - uv^2d & -tu^2a - 2tuvb - tv^2c + sv^2d \end{pmatrix}. \quad (4.19)$$

For $t = 0$ this transformation preserves the form of the matrices in (4.13),

$$C'^1 = \begin{pmatrix} sa & 0 \\ ua + vb & 0 \end{pmatrix}, \quad C'^2 = \frac{1}{s(u^2a + 2uvb + v^2c - uv^2d)} \begin{pmatrix} ua + vb & 0 \\ v(a^2a + 2uvb + v^2c - uv^2d) & vd \end{pmatrix}. \quad (4.20)$$

It can thus be used to further reduce the parameter freedom of the matrices $C^i$.

If $a \neq 0$, we set $s = 1/a$ and $u = -vb/a$. Then

$$C'^1 = \begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix}, \quad C'^2 = \begin{pmatrix} 0 & 0 \\ 0 & vd \end{pmatrix} \quad (4.21)$$

using (4.17). If $d = 0$ we have $C'^2 = 0$. Otherwise the choice $v = 1/d$ leads to

$$C'^2 = \begin{pmatrix} 0 & 0 \\ 0 & 1 \end{pmatrix} \quad (4.22).$$

If $a = 0$ and $b = 0$, so that $C'^1 = 0$, we can arrange either $C'^2 = 0$, $C'^2$ of the form (4.22), or

$$C'^2 = \begin{pmatrix} 0 & 0 \\ 1 & 0 \end{pmatrix} \quad (4.23).$$

In the remaining case $a = 0$ and $b \neq 0$ one can always reach

$$C'^1 = \begin{pmatrix} 0 & 0 \\ 1 & 0 \end{pmatrix}, \quad C'^2 = \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}. \quad (4.24)$$
In all these cases, (4.17) is automatically satisfied. It has still to be checked, with the help of (4.19), which of the representatives for $C_1$ and $C_2$ obtained in this way generate different orbits. In the following we list representatives from all distinct orbits. The respective complete orbit is then obtained via (4.19).

(1) For $C_1 = C_2 = 0$ we recover the commutative (Kähler) differential calculus. It is reducible since it is the skew tensor product of two 1-dimensional commutative differential calculi: $K \otimes K$.

(2) The pair of matrices

$$C^1 = \begin{pmatrix} 0 & 0 \\ 0 & 0 \end{pmatrix}, \quad C^2 = \begin{pmatrix} 0 & 0 \\ 0 & 1 \end{pmatrix}$$

represents $K \otimes L$.

(3) The matrix pair

$$C^1 = \begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix}, \quad C^2 = \begin{pmatrix} 0 & 0 \\ 0 & 1 \end{pmatrix}$$

corresponds to $L \otimes L = \text{Ext}(L)$.

(4) A further calculus is given by

$$C^1 = \begin{pmatrix} 0 & 0 \\ 0 & 0 \end{pmatrix}, \quad C^2 = \begin{pmatrix} 0 & 0 \\ 1 & 0 \end{pmatrix}.$$

It is neither reducible nor the extension of a 1-dimensional calculus. It therefore plays a role as a ‘building block’ for the construction of higher-dimensional differential calculi. We will refer to it via $\mathbf{I}$. This calculus is a special case of a class of calculi which has been investigated in [4, 5].

(5) Another irreducible calculus is determined by

$$C^1 = \begin{pmatrix} 0 & 0 \\ 1 & 0 \end{pmatrix}, \quad C^2 = \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}.$$

It is the extension of $K$ and shall hence be denoted as $\text{Ext}(K)$.

If we want to have an involution on the differential algebra, we have to decompose the calculi into orbits with respect to the action of $GL(2, \mathbb{R})$. The $GL(2, \mathbb{C})$-orbit of (3) then splits into two $GL(2, \mathbb{R})$-orbits (cf [3]).

\footnote{13}{The pair of matrices $C^i$ with $a = 1$ and $b = c = d = 0$ which we encountered above lies in the orbit of solution (2).}
4.4 Classification of 3-dimensional differential calculi

In this subsection we apply the procedure described in subsection 4.2 to the case of an algebra with three generators. (4.13) then reads

\[
C^1 = \begin{pmatrix}
  a & 0 & 0 \\
  b & 0 & 0 \\
  c & 0 & 0
\end{pmatrix}, \quad C^2 = \begin{pmatrix}
  b & 0 & 0 \\
  d & e & 0 \\
  f & g & 0
\end{pmatrix}, \quad C^3 = \begin{pmatrix}
  c & 0 & 0 \\
  f & g & 0 \\
  h & k & l
\end{pmatrix}.
\] (4.25)

The complex entries are subject to the relations

\[
\begin{align*}
b^2 - be - ad &= 0 \\
bc - af - bg &= 0 \\
c^2 - ah - bk - cl &= 0 \\
cd + ef - bf - dg &= 0 \\
 cf + fg - bh - dk - fl &= 0 \\
g^2 - ek - gl &= 0
\end{align*}
\] (4.26)

Proceeding as in the 2-dimensional case treated in the previous subsection, after a tedious calculation one ends up with the following list of representatives of $GL(3, \mathbb{C})$-orbits:

(1) $K \hat{\otimes} K \hat{\otimes} K$

\[
C^1 = \begin{pmatrix}
  0 & 0 & 0 \\
  0 & 0 & 0 \\
  0 & 0 & 0
\end{pmatrix}, \quad C^2 = \begin{pmatrix}
  0 & 0 & 0 \\
  0 & 0 & 0 \\
  0 & 0 & 0
\end{pmatrix}, \quad C^3 = \begin{pmatrix}
  0 & 0 & 0 \\
  0 & 0 & 1
\end{pmatrix}.
\]

(2) $K \hat{\otimes} K \hat{\otimes} L$

\[
C^1 = \begin{pmatrix}
  0 & 0 & 0 \\
  0 & 0 & 0 \\
  0 & 0 & 0
\end{pmatrix}, \quad C^2 = \begin{pmatrix}
  0 & 0 & 0 \\
  0 & 1 & 0 \\
  0 & 0 & 0
\end{pmatrix}, \quad C^3 = \begin{pmatrix}
  0 & 0 & 0 \\
  0 & 0 & 1
\end{pmatrix}.
\]

(3) $K \hat{\otimes} L \hat{\otimes} L$

\[
C^1 = \begin{pmatrix}
  0 & 0 & 0 \\
  0 & 0 & 0 \\
  0 & 0 & 0
\end{pmatrix}, \quad C^2 = \begin{pmatrix}
  0 & 0 & 0 \\
  0 & 1 & 0 \\
  0 & 0 & 0
\end{pmatrix}, \quad C^3 = \begin{pmatrix}
  0 & 0 & 0 \\
  0 & 0 & 1
\end{pmatrix}.
\]

(4) $L \hat{\otimes} L \hat{\otimes} L = \text{Ext}(L \hat{\otimes} L)$

\[
C^1 = \begin{pmatrix}
  1 & 0 & 0 \\
  0 & 0 & 0 \\
  0 & 0 & 0
\end{pmatrix}, \quad C^2 = \begin{pmatrix}
  0 & 0 & 0 \\
  0 & 1 & 0 \\
  0 & 0 & 0
\end{pmatrix}, \quad C^3 = \begin{pmatrix}
  0 & 0 & 0 \\
  0 & 0 & 1
\end{pmatrix}.
\]

(5) $I \hat{\otimes} K$

\[
C^1 = \begin{pmatrix}
  0 & 0 & 0 \\
  0 & 0 & 0 \\
  0 & 0 & 0
\end{pmatrix}, \quad C^2 = \begin{pmatrix}
  0 & 0 & 0 \\
  1 & 0 & 0 \\
  0 & 0 & 0
\end{pmatrix}, \quad C^3 = \begin{pmatrix}
  0 & 0 & 0 \\
  0 & 0 & 0
\end{pmatrix}.
\]

\[\text{\textsuperscript{14}}\text{Some more details are presented in [9]}.\]
(6) $\mathbf{I} \otimes \mathbf{L}$

\[
C^1 = \begin{pmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix}, \quad C^2 = \begin{pmatrix} 0 & 0 & 0 \\ 1 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix}, \quad C^3 = \begin{pmatrix} 0 & 0 & 0 \\ 0 & 0 & 1 \end{pmatrix}.
\]

(7) $\text{Ext}(\mathbf{K} \otimes \mathbf{K})$

\[
C^1 = \begin{pmatrix} 0 & 0 & 0 \\ 1 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix}, \quad C^2 = \begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 0 \end{pmatrix}, \quad C^3 = \begin{pmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix}.
\]

(8) $\text{Ext}(\mathbf{K} \otimes \mathbf{L}) = \text{Ext}(\text{Ext}(\mathbf{K})) = \text{Ext}(\mathbf{K} \otimes \mathbf{L})$

\[
C^1 = \begin{pmatrix} 0 & 0 & 0 \\ 1 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix}, \quad C^2 = \begin{pmatrix} 1 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix}, \quad C^3 = \begin{pmatrix} 0 & 0 & 1 \end{pmatrix}.
\]

(9) An irreducible calculus is given by

\[
C^1 = \begin{pmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix}, \quad C^2 = \begin{pmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \\ 1 & 0 & 0 \end{pmatrix}, \quad C^3 = \begin{pmatrix} 0 & 0 & 0 \\ 1 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix}.
\]

(10) Another irreducible calculus is determined by

\[
C^1 = \begin{pmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix}, \quad C^2 = \begin{pmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \\ 1 & 0 & 0 \end{pmatrix}, \quad C^3 = \begin{pmatrix} 0 & 0 & 0 \\ 1 & 0 & 0 \\ 0 & 1 & 0 \end{pmatrix}.
\]

(11) $\text{Ext}(\mathbf{K} \otimes \mathbf{K})$

\[
C^1 = \begin{pmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \\ 1 & 0 & 0 \end{pmatrix}, \quad C^2 = \begin{pmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 1 & 0 \end{pmatrix}, \quad C^3 = \begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix}.
\]

(12) $\text{Ext}(\mathbf{I})$

\[
C^1 = \begin{pmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \\ 1 & 0 & 0 \end{pmatrix}, \quad C^2 = \begin{pmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \\ 1 & 0 & 0 \end{pmatrix}, \quad C^3 = \begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix}.
\]

The last four of these calculi are irreducible. Only two calculi – (9) and (10) – are new in the sense that they cannot be obtained as a skew tensor product or an extension of lower-dimensional calculi. We shall see in subsection 4.5 that (9) is a special case of the calculus explored in $\mathbf{I} \otimes \mathbf{I}$ for arbitrary $n$, to which also the 2-dimensional calculus $\mathbf{I}$ belongs. A generalization of (10) to arbitrary $n$ is presented in subsection 4.6.
4.5 Left- and right-partial derivatives

Left-partial derivatives are defined as $\mathbb{C}$-linear maps $D_j : A \rightarrow A$ by

$$df =: (D_j f) \, dx^j \quad \forall f \in A.$$  \hspace{1cm} (4.27)

Using (4.1), one finds

$$[df, h] = (D_if) \, [dx^i, h] = (D_if) \, [dh, x^i] = (D_if)(D_jh) \, [dx^j, x^i]$$

$$= (D_if)(D_jh) C^{ij} \, C^k \, dx^k. \hspace{1cm} (4.28)$$

This leads to

$$D_j(fh) \, dx^j = d(fh) = f \, dh + h \, df + [df, h]$$

$$= \{(D_jf) \, h + f \, D_jh + (D_kf)(D_\ell h) \, C^{k\ell} \} \, dx^j \quad \forall f, h \in A \hspace{1cm} (4.29)$$

from which we can read off a twisted Leibniz rule for the $D_j$.

**Lemma 4.3** The left-partial derivatives are given by

$$D_j = \sum_{r=1}^{\infty} \frac{1}{r!} (C^{k_1} \cdots C^{k_{r-1}})^{k_r} j \, \partial_{k_1} \cdots \partial_{k_r} \hspace{1cm} (4.30)$$

in terms of ordinary partial derivatives.\footnote{\textsuperscript{15}The first summand on the rhs is $\partial_j$.}

**Proof:** First we note that $(C^{k_1} \cdots C^{k_{r-1}})^{k_r} j$ is totally symmetric in the indices $k_1, \ldots, k_r$, as a consequence of $C^{ij} k = C^{ij} k$ and the commutativity of the structure matrices $C^i$. Because of the $\mathbb{C}$-linearity of the $D_j$ it is sufficient to prove (4.30) on monomials in $x^i, i = 1, \ldots, n$. This will be done using induction with respect to the degree of monomials. Applied to $x^i$ the formula is obviously true. Let us assume that it holds for monomials up to degree $m$. If $u$ is a monomial of degree $m$, then

$$\sum_{r=1}^{\infty} \frac{1}{r!} (C^{k_1} \cdots C^{k_{r-1}})^{k_r} j \, \partial_{k_1} \cdots \partial_{k_r} (x^i u)$$

$$= \partial_j (x^i u) + \sum_{r=2}^{\infty} \frac{1}{(r-1)!} (C^{k_1} \cdots C^{k_{r-1}})^i j \, \partial_{k_1} \cdots \partial_{k_{r-1}} u$$

$$+ x^i \sum_{r=2}^{\infty} \frac{1}{r!} (C^{k_1} \cdots C^{k_{r-1}})^{k_r} j \, \partial_{k_1} \cdots \partial_{k_r} u$$

$$= \delta^i_j u + \sum_{r=2}^{\infty} \frac{1}{(r-1)!} (C^{k_1} \cdots C^{k_{r-2}})^{k_{r-1}} \ell C^{i\ell} j \, \partial_{k_1} \cdots \partial_{k_{r-1}} u + x^i D_j u$$

$$= \delta^i_j u + C^{i\ell} j \sum_{r=2}^{\infty} \frac{1}{r!} (C^{k_1} \cdots C^{k_{r-1}})^{k_r} \ell \, \partial_{k_1} \cdots \partial_{k_r} u + x^i D_j u$$

$$= \delta^i_j u + C^{i\ell} j \, D_\ell u + x^i D_j u$$

$$= (D_j x^i) u + x^i D_j u + C^{i\ell} j (D_\ell x^i) D_j u = D_j (x^i u).$$
where we used (4.29) and $D_j x^i = \delta^i_j$ in the last steps.

Remark. For any first order differential calculus $(\Omega^1(\mathcal{A}), d)$ we define $\tau^{i_1 \cdots i_r}$ as in (3.18) (with $\tilde{d}x^i$ replaced by $d x^i$). Then (4.4) leads to

$$
\tau^{i_1 \cdots i_r} = C^{i_1 i_2}_{k_1} C^{i_2 k_2}_{k_3} \cdots C^{i_r k_{r-2}} \ell_x \ell \ d\ell.
$$

(4.31)

Inserting this in (3.20), we obtain

$$
d f = D_k f d x^k,
$$

(4.32)

with

$$
D_k = \partial_k + \sum_{r=2}^{\infty} \frac{1}{r!} C^{i_1 i_2}_{j_1} C^{i_2 j_2}_{j_3} \cdots C^{i_r j_{r-2}}_{j_r} \partial_{i_1} \cdots \partial_{i_r}.
$$

(4.33)

This is our formula (4.30).

Lemma 4.4

$$
dx^i f = \exp \left( C^k(x) \frac{\partial}{\partial y^k} \right)^i_j f(y) \bigg|_{y=x} \ d x^j.
$$

(4.34)

Proof: We have

$$
[dx^i, f] = [df, x^i] = (D_j f) [dx^i, x^j] = (D_j f) C^{ij} d x^k.
$$

Inserting the expression (4.30) for $D_j$, we find

$$
[dx^i, f] = \sum_{r=1}^{\infty} \frac{1}{r!} (C^{k_1} \cdots C^{k_{r-1}} C^k)_{j_1} \partial_{k_1} \cdots \partial_{k_r} f \ d x^j
$$

$$
= \sum_{r=1}^{\infty} \frac{1}{r!} (C^{k_1} \cdots C^{k_r})_{j_1} \partial_{k_1} \cdots \partial_{k_r} f \ d x^j
$$

$$
= \left( \exp \left( C^k(x) \frac{\partial}{\partial y^k} \right)^i_j f(y) \bigg|_{y=x} - 1 \right) \ d x^j.
$$

Here we have stressed the possible $x^k$-dependence of the structure matrices which necessitates the introduction of the auxiliary variables $y^k$ in the last formula.

Let us suppose that $\Omega^1(\mathcal{A})$ considered as an algebra with the product $\bullet$ (see section 3) is nilpotent, i.e., there is a number $k \in \mathbb{N} \setminus \{0\}$ such that all products with $k$ factors vanish (see [19], for example). The smallest such number is called the index of the algebra. Since multiplication is determined through the $n \times n$ matrices $C^i$, the index can be maximally $n$. Then (4.30) shows that the left-partial derivatives are differential operators of at most $n$th order.
If $(\Omega_1^{1}(A), \bullet)$ is not nilpotent, then there is a nonvanishing idempotent element (see [19], for example). The sum in (4.30) is then not finite, so that the left-partial derivatives are non-local. This is the case, for example, for the ‘lattice calculus’ [L] and for each differential calculus which is an extension in the sense of section 4.1.

For the right-partial derivatives $D_{-j}$ defined by $df =: d x^j D_{-j}f$ the formula (4.30) is replaced by

$$D_{-j} = \sum_{r=1}^{\infty} \frac{(-1)^{r-1}}{r!} (C^{k_1} \cdots C^{k_{r-1}})^{r_j} \partial_{k_1} \cdots \partial_{k_r}. \tag{4.35}$$

**Examples.** In the following we examine the four irreducible calculi which we found in subsection 4.4 and present the corresponding left- and right-partial derivatives.

(9) In this case, the only nonvanishing commutators (1.1) are

$$[dx^2, x^3] = [dx^3, x^2] = dx^1. \tag{4.36}$$

The corresponding left- and right-partial derivatives are

$$D_{\pm 1} = \partial_1 \pm \partial_2 \partial_3, \quad D_{\pm 2} = \partial_2, \quad D_{\pm 3} = \partial_3 \tag{4.37}$$

in accordance with the fact that the index of the associated algebra is equal to 2. In terms of $y^1 := x^1, y^2 := \frac{i}{\sqrt{2}} (x^2 + x^3)$ and $y^3 := \frac{1}{\sqrt{2}} (x^2 - x^3)$ we obtain

$$[dy^\mu, y^\nu] = -\delta^{\mu\nu} dy^1 \quad (\mu, \nu = 2, 3). \tag{4.38}$$

This is a special case of a differential calculus which has been studied in [4, 5] (see also (1.3) and the second example in section 3.2).

(10) Here, the nonvanishing commutators are

$$[dx^2, x^3] = [dx^3, x^2] = dx^1, \quad [dx^3, x^3] = dx^2 \tag{4.39}$$

and the left- (right-) partial derivatives are

$$D_{\pm 1} = \partial_1 \pm \partial_2 \partial_3 + \frac{1}{6} \partial_3^3, \quad D_{\pm 2} = \partial_2 \pm \frac{1}{2} \partial_3^2, \quad D_{\pm 3} = \partial_3. \tag{4.40}$$

The differential of a function $f$ thus involves third order derivatives,

$$df = (\partial_1 + \partial_2 \partial_3 + \frac{1}{6} \partial_3^3) f \, dx^1 + (\partial_2 + \frac{1}{2} \partial_3^2) f \, dx^2 + \partial_3 f \, dx^3. \tag{4.41}$$

For the associated algebra the index is 3. A generalization of this new calculus to $n$ dimensions with up to $n$th order left-partial derivatives will be described in the next subsection.
In this case we have
\[ [dx^1, x^3] = [dx^3, x^1] = dx^1, \quad [dx^2, x^3] = [dx^3, x^2] = dx^2, \quad [dx^3, x^3] = dx^3 \]  
(4.42)
with the left- (right-) partial derivatives
\[ D_{\pm 1} = \partial_1 \exp(\pm \partial_3), \quad D_{\pm 2} = \partial_2 \exp(\pm \partial_3), \quad D_{\pm 3} = \pm (\exp(\pm \partial_3) - 1). \]  
(4.43)

Here we have the nonvanishing commutators
\[ [dx^1, x^3] = [dx^3, x^1] = dx^1, \quad [dx^2, x^3] = [dx^3, x^2] = dx^2 \]  
(4.44)
and the left- (right-) partial derivatives
\[ D_{\pm 1} = (\partial_1 \pm \frac{1}{2} \partial_2^2) \exp(\pm \partial_3), \quad D_{\pm 2} = \partial_2 \exp(\pm \partial_3), \quad D_{\pm 3} = \pm (\exp(\pm \partial_3) - 1). \]  
(4.45)

Let us consider a differential calculus which is an extension in the sense of subsection 4.1. \( \hat{D}_I, \ I = 1, \ldots, n + 1, \) are the corresponding left-partial derivatives and \( D_j, \ j = 1, \ldots, n, \) those of the \( n \)-dimensional calculus which generates the extension. Then we have the following result.

**Lemma 4.5**
\[ \hat{D}_j = D_j \exp(\partial_{n+1}) \quad (j = 1, \ldots, n) \]  
(4.46)
\[ \hat{D}_{n+1} = \exp(\partial_{n+1}) - 1. \]  
(4.47)

**Proof:** Recalling (4.34), we find
\[ df = [dx^{n+1}, f] = \left( \exp\left( \hat{\mathcal{C}}^i \frac{\partial}{\partial y^i} \right) - 1 \right)^{n+1}_j f(y) \bigg|_{y=x} dx^j \]  
using (4.34)
\[ = \left( \exp\left( \hat{\mathcal{C}}^i \frac{\partial}{\partial y^i} \right) \exp\left( \frac{\partial}{\partial y^{n+1}} \right) - 1 \right)^{n+1}_j f(y) \bigg|_{y=x} dx^j \]
\[ = \hat{D}_j f dx^j. \]

On functions which do not depend on \( x^{n+1} \) the \( \hat{D}_j \) coincide with the operators \( D_j. \) Hence,
\[ D_j = \left( \exp\left( \mathcal{C}^i \frac{\partial}{\partial y^i} \right) - 1 \right)^{n+1}_j f(y) \bigg|_{y=x}. \]  
(4.48)
With this observation, the conjectured formulas follow immediately.

In the last two examples – (11) and (12) – treated above we have special cases of this general result.

4.6 An \( n \)-dimensional differential calculus with up to \( n \)th order partial derivatives

The relations

\[
[d x^i, x^j] = \begin{cases} 
  d x^{i+j} & \text{if } i + j \leq n \\
  0 & \text{otherwise}
\end{cases} \quad (4.49)
\]

determine a consistent differential calculus on \( \mathcal{A} \). For \( n = 2 \) this is our calculus \( I \) and for \( n = 3 \) we recover the calculus (10) of section 4.4 (up to a renumbering of the \( x^i \)).

A partition \( p(m) \) of a positive integer \( m \) is a nonincreasing sequence of positive integers \( p_1, \ldots, p_r \) such that \( \sum_{s=1}^{r} p_s = m \). It is always possible to write \( p(m) \) in the form \( (1^{k_1}, 2^{k_2}, \ldots, m^{k_m}) \) where \( \ell^k \) means that \( \ell \) appears exactly \( k \) times in \( p(m) \). With the definitions

\[
p(m)! := (k_1)! \cdots (k_m)!, \quad \partial_{p(m)} := \partial_{p_1} \cdots \partial_{p_r} \quad (4.50)
\]

one finds

\[
d f = \sum_{m=1}^{n} \sum_{p(m)} \frac{1}{p(m)!} \partial_{p(m)} f \, d x^m . \quad (4.51)
\]

The first four left-partial derivatives are thus

\[
D_1 = \partial_1 \\
D_2 = \partial_2 + \frac{1}{2} \partial_1^2 \\
D_3 = \partial_3 + \partial_2 \partial_1 + \frac{1}{6} \partial_1^3 \\
D_4 = \partial_4 + \partial_3 \partial_1 + \frac{1}{2} \partial_2^2 + \frac{1}{2} \partial_2 \partial_1^2 + \frac{1}{24} \partial_1^4 . \quad (4.52)
\]

4.7 On some solutions of the consistency conditions

We can always decompose the structure functions \( C_{ij\,k} \) as follows,

\[
C_{ij\,k} = \frac{1}{n+1} \left( \delta_{k}^i \, C_{ij} + \delta_{k}^j \, C_{ij} \right) + P_{ij\,k} \quad (4.53)
\]

where

\[
C^i := C_{ij\,j}, \quad P_{ij\,j} = 0 . \quad (4.54)
\]
The first of the consistency conditions (4.2) requires that
\[ P^{ij} = P^{ji}_k, \] (4.55)
the second becomes
\[ P^{ik}_m P^{jm}_\ell - P^{jk}_m P^{im}_\ell + \frac{1}{n+1} C^m \left( \delta^i_\ell P^{jk}_m - \delta^i_\ell P^{ik}_m \right) + \frac{1}{(n+1)^2} C^k \left( \delta^i_\ell C^i - \delta^i_\ell C^j \right) = 0. \] (4.56)

For vanishing \( P^{ij}_k \) this implies \( C^i = 0 \) and thus \( C^{ij} = 0 \). A noncommutative differential calculus therefore has to have a nonvanishing traceless part of \( C^{ij} \).

In the following, we consider some solutions of the consistency conditions for general \( n \). With minor modifications these are taken from [20] where the consistency conditions (4.2) arose in a different context. Instead of using (4.53) it appears to be more convenient to use a corresponding decomposition with \( C^i \) replaced by vector components \( P^i \) and \( P^{ij}_k \) not necessarily traceless. A simple solution of (4.2) is then
\[ C^{ij} = \delta^i_k P^j + \delta^j_k P^i - P^i P^j U_k \] (4.57)
with an additional covector \( U \) subject to
\[ U_k P^i = 1. \] (4.58)

A generalization of this solution is given by
\[ C^{ij}_k = \frac{1}{\Delta} \begin{vmatrix} \delta^i_k P^j_1 + \delta^j_k P^i_1 - P^i P^j_1 U_k & \delta_{kl} P^j_1 & \delta_{kl} P^j_2 & \ldots & \delta_{kl} P^j_L \\ 0 & P_1 \cdot P_1 & P_1 \cdot P_2 & \ldots & P_1 \cdot P_L \\ - (P^i_1 - P^i_2) (P^j_1 - P^j_2) & P_2 \cdot P_1 & P_2 \cdot P_2 & \ldots & P_2 \cdot P_L \\ \vdots & \vdots & \vdots & \ldots & \vdots \\ - (P^i_1 - P^i_L) (P^j_1 - P^j_L) & P_L \cdot P_1 & P_L \cdot P_2 & \ldots & P_L \cdot P_L \end{vmatrix} \] (4.59)
in terms of a determinant (cf [20]). Here \( P_1, \ldots, P_L \) are \( L \leq n \) linearly independent vectors, all subjected to the condition (4.58). Furthermore, we have introduced the abbreviation \( P \cdot P' = \sum_{i=1}^n P^i P'^i \) and the subdeterminant
\[ \Delta := \begin{vmatrix} P_1 \cdot P_1 & P_1 \cdot P_2 & \ldots & P_1 \cdot P_L \\ P_2 \cdot P_1 & P_2 \cdot P_2 & \ldots & P_2 \cdot P_L \\ \vdots & \vdots & \ldots & \vdots \\ P_L \cdot P_1 & P_L \cdot P_2 & \ldots & P_L \cdot P_L \end{vmatrix}. \] (4.60)

\(^{16}\) \( P^i \) and \( U_j \) transform as the components of a vector and a covector, respectively, under \( GL(n, \mathfrak{c}) \)- or, more generally, \( GL(n, \mathcal{A}) \)-transformations, cf section 4.2.
The expression (4.59) is obviously symmetric in the two indices $i, j$. It satisfies $C^{ij} P^k = P^i \alpha \cdot P_j$, $\alpha = 1, \ldots, L$, which can then be used to prove that also the second condition in (4.2) is satisfied (cf. [20]). A different proof is given below which moreover provides us with a clear characterization of the differential calculi determined by (4.59).

**Lemma 4.6** Via a $GL(n, A)$-transformation, (4.59) is equivalent to

$$C^{ij} = \sum_{\alpha=1}^{L-1} \delta^{\alpha}_i \delta^{\alpha}_j + \sum_{J=L}^{n-1} \delta^{i}_J \delta^{j}_J + \delta^{i} \left( \delta^{\alpha}_n + \sum_{J=L}^{n-1} \delta^{i}_J \delta^{j}_J \right).$$

**(Proof:)** After a cyclic renumbering of the vectors $P_1, \ldots, P_L$, (4.59) takes the form

$$C^{ij} = \frac{1}{\Delta} \begin{vmatrix} \delta^i_k P^j_n + \delta^j_k P^i_n - P^i_n P^i_n U_k & \delta_{k\ell} P^\beta_{\ell} & \delta_{k\ell} P^\beta_n \\ -(P^i_n - P^i_{\alpha})(P^j_n - P^j_{\alpha}) & P_{\alpha} \cdot P_{\beta} & P_{\alpha} \cdot P_n \\ 0 & P_n \cdot P_{\beta} & P_n \cdot P_n \end{vmatrix}$$

where $\alpha, \beta = 1, \ldots, L - 1$. Now we complete the set of linearly independent vectors $P_{\alpha}, P_n$ to a linear frame (field) by adding vectors $P_J$, $J = L, \ldots, n - 1$, such that $P_{\alpha} \cdot P_J = P_n \cdot P_J = 0$. Then

$$C^{ij} P^k = P^i \alpha \cdot P^j, \quad C^{ij} P^k = P^i n \cdot P^j, \quad C^{ij} P^k = P^i n \cdot P^j V_J$$

where $V_J := U_k P^j$. Let $P \in GL(n, A)$ be the matrix with entries $P^j_i$. The transformation $x^k = (P^{-1})^k_i x^i$ preserves (4.4) if $C^{i\alpha} = (P^{-1})^i_j (P^{-1} C^j P)$. Here it leads to

$$C^{ij} = \sum_{\alpha} \delta^{\alpha}_i \delta^{\alpha}_j + \sum_J \delta^{i}_J \delta^{j}_J + \delta^{i} \left( \delta^{n}_n - \sum J V_j \delta^{j}_J \right)$$

so that

$$C^\alpha = \begin{pmatrix} E^\alpha & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix}, \quad C^J = \begin{pmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & e^J & 0 \end{pmatrix}, \quad C^n = \begin{pmatrix} 0 & 0 & 0 \\ 0 & I & 0 \\ 0 & -V & 1 \end{pmatrix},$$

where $(E^\alpha)^\beta_\gamma = \delta^\beta_\alpha \delta^\alpha_\gamma$ and $(e^J)^\gamma_K = \delta^J_K$. $I$ is the $(n-L) \times (n-L)$ unit matrix. A further $GL(n, A)$-transformation with

$$A = \begin{pmatrix} I & 0 & 0 \\ 0 & I & 0 \\ 0 & V & 1 \end{pmatrix}$$

eliminates the $V$-term.

\[ \square \]

\[17\] We were unable to verify the statement in [20] that certain linear combinations of terms of the form (4.59) (cf. (28) in [20]) also satisfy the nonlinear condition in (4.2). A counter example is given by $n = 3, L = 2$ with $P^i_1 = \delta_1^i, P^i_2 = \delta_2^i$ (and $U_k = \delta_k^i + \delta_k^j$).

30
According to the Lemma, the calculus determined by (4.59) is \( \otimes^n L \) for \( L = n \) and \( (\otimes^{L-1} L) \otimes \text{Ext}(\otimes^{n-L} K) \) for \( L < n \) where \( \text{Ext} \) indicates an extension in the sense of section 4.1. Comparison with the list of calculi in subsection 4.4 shows that the ansatz (4.59) by far does not exhaust the possibilities.

One can try other ansätze, but it is unlikely that this can be made into a systematic procedure to obtain the complete set of solutions of the consistency conditions (4.2).

## 5 Conclusions

In this work we have started a systematic exploration of differential calculi on commutative algebras and presented several new results.

A central part of this work is the classification of 3-dimensional differential calculi with constant structure functions (on a commutative algebra with three generators). Much of the additional material in this paper provides the necessary background or arose from insights obtained via this classification. Apart from having solved the classification problem for \( n \leq 3 \), we have presented generalizations to arbitrary dimension \( n \) for all the calculi found in this way.

Only four of the 3-dimensional calculi (more precisely: \( GL(3, \mathbb{C}) \)-orbits) obtained in section 4.4 turned out to be irreducible, i.e., they are not skew tensor products of lower-dimensional calculi. Two of these are extensions of 2-dimensional calculi (in the sense of section 4.1). They are ‘nonlocal’ in the sense that their left- (or right-) partial derivatives involve finite difference operators. The remaining two genuinely 3-dimensional calculi have local (though higher order) left- and right-partial derivatives. For one of them, a generalization to arbitrary dimension is already known \([4, 5]\). A corresponding generalization of the other calculus is presented in section 4.7, the left-partial derivatives are differential operators of up to \( n \)th order.

Our classification procedure extends to \( n > 3 \), but the corresponding calculations become much more involved. Computer algebra should then be helpful.

For the new calculi we were so far unable to find a relation with structures of interest in other branches of mathematics or in physics, similar to what we have for the examples mentioned in the introduction. Further investigation of these calculi is therefore required. There is, however, a general aspect which supports our investigation from a physical point of view. A study of differential calculi on finite sets has shown that the choice of a differential calculus assigns to a set a structure which should be regarded as an analogue of that of a differentiable manifold \([3]\). Our present paper provides new examples of such generalized spaces which can be regarded as deformations of \( \mathbb{R}^n \) with the ordinary differential calculus. Such a deformation induces (in a universal manner) corresponding deformations of models and theories built on the differential calculus (cf \([3, 4, 5]\)). There is the hope to obtain in this systematic way physical models which are somehow close to
known models but which improve the latter by properties like complete integrability or finiteness (of quantum perturbation theory, in particular for nonrenormalizable theories like gravity).

A On generalized differential calculi

Let $\mathcal{A}$ be a commutative associative algebra generated by $x^i$ ($i = 1, \ldots, n$), $\Theta$ an $\mathcal{A}$-bimodule which is free of rank $m$ as a left $\mathcal{A}$-module, and $d : \mathcal{A} \to \Theta$ a derivation. Here we do not assume that the $dx^i$ are a left $\mathcal{A}$-module basis (as we did in section 4). Moreover we will not even demand that $d\mathcal{A}$ generates $\Theta$ as an $\mathcal{A}$-bimodule. In this sense we generalize the notion of a (first order) differential calculus as defined in section 2.

Let $\theta^\mu$, $\mu = 1, \ldots, m$, be a left $\mathcal{A}$-module basis of $\Theta$. Every element $\varphi \in \Theta$ can then be expressed as $\varphi = \varphi_\mu \theta^\mu$ with $\varphi_\mu \in \mathcal{A}$. In particular, $dx^i = \gamma^i_\mu \theta^\mu$ where $\gamma$ is an $n \times m$-matrix with entries in $\mathcal{A}$. More generally,

$$df = (\nabla_\mu f) \theta^\mu \quad (\forall f \in \mathcal{A}) \quad (A.1)$$

which defines linear operators $\nabla_\mu : \mathcal{A} \to \mathcal{A}$. As a further consequence of the assumption that $\Theta$ is free as a left $\mathcal{A}$-module we have

$$[\theta^\mu, x^i] = C^{i\mu} \theta^\nu \quad (A.2)$$

with structure functions $C^{i\mu} \in \mathcal{A}$. The latter constitute a set of $m \times m$ matrices $C^i$. These have to satisfy the following consistency conditions which are derived in the same way as those in section 4,

$$\gamma^i_\mu C^{j\mu} = \gamma^j_\mu C^{i\mu} \quad (\forall i, j = 1, \ldots, n \quad \forall \mu = 1, \ldots, m),$$

$$C^{i\mu} C^{j\nu} = C^{i\nu} C^{j\mu} \quad (\forall i, j = 1, \ldots, n \quad \forall \mu, \nu = 1, \ldots, m). \quad (A.3)$$

The following is a generalization of Lemma 4.1.

Lemma A.1 The derivation $d$ is inner if and only if there are $\rho_\mu \in \mathcal{A}$ ($\mu = 1, \ldots, m$) such that $\rho_\mu C^{i\mu} = \gamma^i_\mu$. Then $df = [\rho_\mu \theta^\mu, f]$.

Proof:

$\Rightarrow$: follows from (A.2) and $dx^i = [\rho, x^i]$.

$\Leftarrow$: Define a derivation $d'$ by $d'f := [\rho, f]$. Then

$$d'x^i = [\rho, x^i] = \rho_\mu [\theta^\mu, x^i] = \rho_\mu C^{i\mu} \theta^\nu = \gamma^i_\nu \theta^\nu = dx^i$$

Such a generalization is encountered if one tries to extend the correspondence between differential calculi on finite (or discrete) sets and special digraphs (see [3]) to general digraphs (with multiple arrows and loops). This is of interest for the study of processes on (e.g., electrical) networks and will be discussed elsewhere.
shows that \(d'\) and \(d\) coincide on the generators of \(\mathcal{A}\). Since both are derivations, we have \(d' = d\).

The operators \(\nabla_\mu\) are not derivations, in general. If \(\mathcal{A}\) is freely generated by the \(x^i\), they satisfy the following twisted Leibniz rule,

\[
\nabla_\mu(fg) = (\nabla_\nu f) \left(\exp \left( C^i(x) \frac{\partial}{\partial y^i} \right) \right)^\nu_\mu g(y) \bigg|_{y=x} + f \nabla_\mu g \tag{A.4}
\]

(where \(y^i\) are auxiliary variables, cf section 4.5). We have the following generalization of Lemma 4.3.

**Lemma A.2** Let \(\mathcal{A}\) be freely generated by the \(x^i\). In terms of ordinary partial derivatives the linear operators \(\nabla_\mu\) are then given by

\[
\nabla_\mu = \gamma^i_\mu \partial_i + \sum_{r=2}^{\infty} \frac{1}{r!} \gamma^k_{\nu \mu} (C^{k_2} \ldots C^{k_r})^\nu_{\mu} \partial_{k_1} \ldots \partial_{k_r} . \tag{A.5}
\]

We omit the proof which is a minor modification of the proof of Lemma 4.3.

Using the construction of section 2.4 one obtains an extension \(\tilde{\Theta}\) of the \(\mathcal{A}\)-bimodule \(\Theta\) such that

\[
[\theta^\mu, x^i] = C^{ij}_{\mu \nu} \theta^\nu, \quad [\theta^{m+1}, x^i] = dx^i = \gamma^i_{\mu} \theta^\mu \tag{A.6}
\]

where \(\theta^{m+1}\) corresponds to \(\rho\) in section 2.4. The two relations can be combined to

\[
[\theta^\mu, x^i] = \tilde{C}^{ij}_{\mu \nu} \theta^\nu \tag{A.7}
\]

where the \(\tilde{C}^{ij}_{\mu \nu}\) are the entries of the \((m+1) \times (m+1)\) matrices

\[
\tilde{C}^i := \begin{pmatrix}
C^i & 0 \\
\vdots & \ddots \\
\gamma^i_1 \ldots \gamma^i_m & 0 \\
\end{pmatrix} . \tag{A.8}
\]

These matrices indeed satisfy the consistency conditions (A.3) (if the matrices \(C^i\) satisfy them).
