Abstract

We revisit partition functions of closed strings on toroidal backgrounds, including their $\mathbb{Z}_N$ shift orbifolds in the formalism where the dimension of the target space is doubled to make T-duality manifest. In such a T-duality covariant formalism, the constraint equation imposes a form of chiral factorization. Our computation furnishes a non-trivial consistency check for the quantum worldsheet theory of the doubled sigma model, when strings are placed on general toroidal backgrounds. The topological term that mixes the physical space and its T-dual is crucial in demonstrating that chiral factorization works, and that we obtain the correct partition function after imposing the constraints. Finally, we discuss how our results extend to $\mathcal{N} = 1$ worldsheet supersymmetry and string worldsheets of higher genus.
1 Introduction

This paper is devoted towards understanding some aspects of the doubled formulation of string theory of C.Hull [1] - a T-duality covariant framework that lives on an enlarged target space in which one can think of the extra coordinates as those conjugate to string winding numbers. Over the years, this formalism has attracted much attention primarily as a possible way to formulate our understanding of a class of non-geometric string backgrounds known as T-folds, itself being based on a series of earlier seminal works in the 80’s and 90’s. ([9, 10, 11, 12, 13]). String theory can be consistently defined on many non-geometric backgrounds which can nonetheless give rise to a conventional theory endowed with geometric four-dimensional spacetime (see for example [14]). An interesting class of non-geometric backgrounds are those which are constructed by duality twists [15]. In these twisted backgrounds, fibres are glued together with T-duality-valued

---

1 For a sampling of recent literature over the past decade, see for example [2, 3, 4, 5, 6, 7, 8].
transition functions - namely, the ‘T-folds’. More generally, we can have ‘U-folds’ with U-duality-valued transition functions. \[16\]  

Recall that T-duality was originally demonstrated to be a symmetry of the string sigma model with toroidal target spaces in which there is a $U(1)^d$ isometry and thus are principle $U(1)^d$ bundles. One can generalize the notion of T-duality to more generic torus bundles with less symmetry under some conditions, even in spaces devoid of globally defined Killing vectors (see \[20\] for details). This sets up the notion of a T-fold which locally resembles a conventional spacetime patch with a torus fibration over some open set in a base space, with T-duality-valued transition functions. The importance of these backgrounds arises from the fact that applying T-duality to geometric backgrounds with Kalb-Ramond $B$ fluxes can sometimes give rise to T-folds. To be more precise, the moduli of the string CFT which are related via an $O(d, d; \mathbb{Z})$ transformation gives essentially the same CFT, and the transition functions allow one to construct a bundle of torus CFT over some base space. The moduli can depend on the coordinates of the base space in general. Integrating over the base space target space fields gives the quantum string theory of the T-fold.

In this doubled formalism, we introduce an extra $d$ coordinates $\tilde{X}_i$ which are conjugate to the winding numbers. They can be understood as the coordinates which are T-dual to $X$ by the $O(d, d; \mathbb{Z})$ element $M$ which is the analogue of the $R \rightarrow \alpha' / R$ duality of a circle target space. When the closed string is endowed with the target space metric $G$ and coupled to the Kalb-Ramond field $B$, this T-duality element inverts a generalized background matrix $E = g + B$. The doubled sigma model has an expanded target space $\mathcal{M}$ of which coordinates patch together to form a $T^{2d}$ bundle over some base $N$. One then has to further impose a constraint which demands half of the $2d$ fields on $\mathcal{M}$ to be left-movers and the other half as right-movers. The ordinary theory is recovered after choosing half of $\{X^i, \tilde{X}^i\}$ to be the physical space. Such a choice of polarization $T^d \subset T^{2d}$ is generally done locally in each patch for an arbitrary well-defined T-fold. Being able to implement the constraint consistently is crucial. In \[1\], and as we shall review in Section 2, it was shown that this constraint requires a certain set of conserved currents $J$ to vanish and this could be imposed by gauging half of $J$’s via an auxiliary gauge field say $C$. Gauge-fixing and integrating out $C$ recovers the ordinary sigma model locally. The polarization then corresponds neatly to the choice of which $J$’s to gauge.

A crucial ingredient of the doubled sigma model is a topological interaction term included in the Lagrangian as

$$i\pi dX \wedge d\tilde{X} \quad (1.1)$$

and it was argued in \[1\] that at the level of the classical action, the above term is necessary to yield complete equivalence to the usual string sigma model formulation. Note that such

\[2\] See also \[17\] for a recent attempt at understanding an S-duality twisted gauge theory, \[18\] for a study of U-duality twists in toroidal compactifications, and \[19\] for non-geometric branes that can arise naturally in M-theory.
a term does not change the classical theory, but it introduces some relative signs when we sum up the cohomological sectors in evaluating the partition function. We will discuss more about this term in Section 2. Essentially, its presence preserves the invariance of the doubled sigma model’s action under large gauge transformations of the auxiliary coordinates.

Shortly after the appearance of [1], Berman and Copland explained in an elegant paper [21] that the constraints imposed to halve the degrees of freedom of the doubled formalism can be interpreted as those that determine chiral scalars. The one-loop partition function of the doubled target space is first computed without imposing any constraints but they keep track of certain left- and right-moving degrees of freedom encapsulated in each set of holomorphic variables $P$ and anti-holomorphic variables $Q$. After performing a series of Poisson resummations, the partition function can be expressed in the form of a chiral decomposition, i.e. a product of a holomorphic function and an anti-holomorphic function. Each chiral sector is then further decomposed into two separate blocks, and imposing the constraint is argued to be effectively equivalent to discarding one block in each of the two chiral sectors. The most significant observation made in [21] is that the one-loop closed string partition function can be reproduced from the doubled formalism via the chiral factorization procedure explained above provided the topological interaction term is included. This then yields a consistency test for the inclusion of this term in the doubled sigma model Langrangian.

Inspired by the results of [21], we will build on their work and as a first step forward, attempt to generalize their results to conventional non-T-fold backgrounds. We find that via the procedure of chiral factorization, we can reproduce the closed string partition functions of any worldsheet genus from the doubled sigma model for the generic toroidal background, including a non-vanishing $B$ field, and thus demonstrate explicitly the quantum equivalence to the usual formulation for toroidal backgrounds. We hope that this acts as a starting point for investigating whether generic well-defined T-folds can be understood at least partially by some principle of chiral block decomposition. We know that for asymmetric orbifolds, some have observed that the partition functions can be constructed by sewing together chiral blocks of associated symmetric orbifolds [22]. Most of our technical focus will on reassembling the classical instanton sums in the partition function via Poisson resummations. We will also discuss how chiral factorization works for the quantum part of the partition function that captures all the string’s oscillator modes. By partition function, we refer to the sum at each genus with a fixed worldsheet metric of unit determinant. The complete string partition function of course involves an integral over the moduli space.

Now, in [23], the simplest T-fold was studied in the doubled sigma model formulation. Corresponding to the only non-trivial element of $O(1,1;\mathbb{Z})$, an $S^1$ is fibred over a base $S^1$, with an asymmetric reflection acting on the right-movers augmented with a $\mathbb{Z}_2$ translational shift in the base. In that work, the doubled sigma model is analyzed in the operator
formalism, and it was shown that to recover a modular invariant partition function, one needs to impose the eigenvalues of the T-duality operator to be of certain values. Such a rule was derived in [24], but we do not know how it could be derived from first principles in the doubled formulation.

In our work, apart from the generalizations mentioned above, we will consider \( \mathbb{Z}_N \) orbifolds with the discrete orbifold action being independent translations in the left and right movers. Apart from being a simple class of orbifolds in its own right, such an orbifold action arises naturally in T-folds which admits description as asymmetric orbifolds. In these backgrounds which are sometimes called ‘interpolating orbifolds’ [25], the absence of singularities necessitates the orbifold action on the fibres to be augmented by a corresponding shift in the base. As an example where we take the base to be \( S^1 \), we can write the orbifold action as [26]

\[
G = e^{2\pi(F_L+F_R)}\delta_{a,b}
\]

where \( \delta_{a,b} \) is an order-\( N \) shift along the base circle and \( F_{L,R} \) are generators of the orbifold rotation on the fiber coordinates. If \( F_L \neq F_R \), this is an asymmetric orbifold [26] [27]. The shift along the base \( S^1 \) can be parametrized by a vector \( \lambda = \left( \frac{a}{N}, \frac{b}{N} \right) \) with \( a \) and \( b \) defined modulo \( N \). Let \( X \) denote the base circle target space variable and \( \tilde{X} \) its T-dual. Then \( \delta \) acts as

\[
\delta : X \rightarrow X + a\frac{2\pi R}{N}, \quad \delta : \tilde{X} \rightarrow \tilde{X} + b\frac{2\pi}{NR}
\]

In Section 2 we shall review these translational or shift orbifolds \( S^1/\mathbb{Z}_N \) with slightly more details. Formally speaking, we first need to specify in principle what defines the doubled orbifold that descends correctly to the physical one. A natural rule (that is assumed also in [24]) is that \( \tilde{X} \)'s are acted upon by an operator equivalent to the T-dual (defined by the element \( M \)) of the orbifolded \( X \). Thus, \( \mathbb{Z}_N \) translational/shift orbifolds is perhaps the most straightforward to study as a first example, since the action on \( X \) and \( \tilde{X} \) are just translations along each homological cycle of the worldsheet. Since \( \tilde{X} \sim X_L - X_R \), an asymmetric orbifold is obtained when we specify a non-zero shift for \( \tilde{X} \). Nonetheless, there is an important caveat that we should mention: namely that not all the asymmetric shift orbifolds on their own enjoy modular invariance which might demand among other things a certain number of spacetime dimensions (see [22] and [24] for a nice discussion on this). We reserve discussion of this important issue to future work [28], while maintaining our focus on studying the equivalence between the doubled formalism and the conventional sigma model.

We find that when strings are placed on an orbifold defined by translational shifts in \( X \) and \( \tilde{X} \), the signs induced by the topological term do lead us to the correct string partition function after chiral factorization. For a non-geometric asymmetric action, where there is an orbifold action on \( \tilde{X} \), in the Lagrangian representation of the partition function, this amounts to multiplying \( e^{-\mathcal{S}_{cl.}} \) with phase factors that parametrize the shifts on \( \tilde{X} \). This can be related after a Poisson resummation to the fact that while the momentum generates
translations in $X$, the winding number operator generates translations in $\tilde{X}$, and the latter manifests itself as phase factors. The fact that we can establish the equivalence of the partition functions rather easily (as we shall observe in this entire work) points swiftly to the underlying fact that in the doubled sigma model, $X$ and $\tilde{X}$ represent the Fourier transform duals of the momentum ($n$) and winding numbers ($w$). Thus, as explained in [20], we can write down the dual state

$$|X, \tilde{X}\rangle = \sum_{n,w} e^{inX} e^{iwR}\langle n, w|$$

where the dual $\tilde{X}$ corresponds to the T-dual of $X$ in which all original radii are inverted.

In the doubled Lagrangian, the natural metric on the fibre is given by $\mathcal{H}$ (see eqn. (2.2)), but this is precisely the matrix which defines a norm for $(n, w)$ that yields the string spectrum, i.e.

$$\frac{1}{2}M^2 = (n, w)\mathcal{H}(n, w)^T$$

We will see that our results for the $\mathbb{Z}_N$ shift orbifolds turn out to be very compatible with such a picture.

The plan of our paper is as follows. In Section 2, we briefly review the doubled geometry formalism of Hull and some basic aspects of the $\mathbb{Z}_N$ shift orbifolds. In Section 3, we demonstrate the equivalence of the partition function with that obtained in the conventional theory, following closely the technique introduced in [21] and [29]. At the same time, we present a slightly more efficient way to obtain the partition function which we will employ in the subsequent sections, but if desired, the reader can repeat the method in Section 3 for the latter computations and obtain identical conclusions too. Then in Section 4, we recover the partition function of the general toroidal background. We find that our narrative can be extended straightforwardly to higher-genus string worldsheets which we study explicitly in Section 5. In Section 6, we discuss how chiral factorization works for the ‘quantum part’ of the partition function - the part that counts all the oscillators’ modes and before we end with a concluding discussion, we briefly discuss the case of $\mathcal{N}=1$ worldsheet supersymmetry in Section 7. We emphasize that our various computations pertain not to the bundle structure of a T-fold with non-trivial $O(d, d; \mathbb{Z})$ transition functions, but simply a doubled toroidal geometry. A global choice of polarization can thus be made. We hope that this paper forms a starting point for future explorations of the role of chiral block decomposition in understanding T-folds in the doubled formalism [28]. Throughout our paper, we take $\alpha' = 1$. 
2 Preliminaries

2.1 On the action of the doubled sigma model

In the following, we shall give a quick review of the doubled sigma model following [1].

In this T-duality covariant framework, the toroidally compactified dimensions are doubled, and thus so are the number of degrees of freedom. This necessitates introducing constraints to remove the auxiliary ones. In its original formulation that involves a $T^{2d}$ bundle over some toroidal base of which coordinates we shall denote as $Y^n$, the Lagrangian reads

$$\mathcal{L} = \frac{\pi}{2} H_{ij} \partial_a X^i \partial^a X^j + \pi \partial_b X^i (A_{im} \partial^b Y^n + \bar{A}_{im} e^{bc} \partial_c Y^m) + \mathcal{L}_{base}(Y)$$  \hspace{1cm} (2.1)

where $X$ are the fibre coordinates, and the worldsheet one-forms $A^i \equiv A^i_m dY^m$ play the role of a connection. They are the conserved currents $J \equiv A^i_m dY^m + \bar{A}^i_n \ast dY^n$ under $M \in O(d, d; \mathbb{Z})$ transformations which leaves (2.1) invariant under

$$X \rightarrow MX, \quad H \rightarrow (M^{-1})^T H M^{-1}, \quad J \rightarrow (M^{-1})^T J$$

where the generalized metric reads

$$H \equiv \begin{pmatrix} G - BG^{-1}B & BG^{-1} \\ -G^{-1}B & G^{-1} \end{pmatrix}. \hspace{1cm} (2.2)$$

The constraint equation reads

$$\ast \partial X^i = L^{ik} H_{kj} \partial X^j + L^{im} J_m$$  \hspace{1cm} (2.3)

where in a certain basis, the $O(d, d; \mathbb{Z})$ metric reads

$$L_{ij} = \begin{pmatrix} 0 & \mathbb{1}_d \\ \mathbb{1}_d & 0 \end{pmatrix}.$$

One also needs to choose some splitting of $T^{2d}$ into a physical $T^d$ and a dual $\tilde{T}^d$ for each point in the $T^{2d}$ bundle, thus dividing the fibre coordinates into a physical $T^d(X)$ and a dual $\tilde{T}^d(\tilde{X})$. The theory can then be written in terms of $X$ alone after solving for $\tilde{X}$ in terms of $X$. In this paper, we shall restrict ourselves to backgrounds in which a global polarization can be chosen. We can set the connection to be zero, and the constraint equation then reads

$$\begin{pmatrix} \ast \partial X^i \\ \ast \partial \tilde{X}^i \end{pmatrix} = \begin{pmatrix} -G^{-1}B & G^{-1} \\ G - BG^{-1}B & BG^{-1} \end{pmatrix} \begin{pmatrix} \partial X^i \\ \partial \tilde{X}^i \end{pmatrix}$$  \hspace{1cm} (2.4)

Diagonalizing the matrix $LH$ above, we find that we can express the constraint in terms of self-dual and anti-self-dual equations for the fields (with components in a flat tangent space)

$$P^a = \frac{1}{\sqrt{2}} \left[ (e_a^i - B_{ij} e^j) dX^i + e^{jn} d\tilde{X}_j \right],$$
\[ Q^a = \frac{1}{\sqrt{2}} \left( (e_i^a + B_{ij} e^j) \, dX^i - e^j \, d\tilde{X}_j \right), \]

where we have introduced the vielbein by the relation \( G^{ij} = e^i_a e^j_b \eta^{ab} \). On the worldsheet, this implies the ‘chirality’ condition\(^3\)

\[ \partial_z P^a = \partial_{\bar{z}} Q_a = 0 \quad (2.6) \]

We find that the doubled Lagrangian can be written in terms of these variables as the sum of two kinetic terms

\[ L_{PQ} = \frac{\pi}{2} \eta_{ab} dP^a \wedge *dP^b + \frac{\pi}{2} \eta^{ab} dQ_a \wedge *dQ_b + \mathcal{L}_{\text{top}}. \quad (2.7) \]

Later in Section\(^4\) we shall see that for chiral factorization to work, it is rather important that the Lagrangian can be expressed in this manner. Note that there is also a topological term that we have added to (2.7) which we shall briefly review next. Recall that since we are restricting ourselves to globally well-defined splitting of the fibre in the doubled torus bundle, we set the \( O(d,d;\mathbb{Z}) \) connection to be zero. The conserved currents \( J_I \) read

\[ J_I = H_{IJ} \partial \tilde{X}^J - L_{IJ} * \partial \bar{X}^J \equiv \mathcal{J}_I - j_I \quad (2.8) \]

where \( J_I \) is the Noether current and \( j_I \) is trivially conserved. The field equations imply that \( d * J_I = 0 \) but the constraint equation sets the stronger condition \( J_I = 0 \). The current \( \mathcal{J}_I \) is the Noether current for the translational symmetries along the fibres which we parametrize as \( \delta \bar{X} = \alpha \). If we wish to write it with regards to left- and right-moving degrees of freedom, then the symmetries are \( \delta X_R = \alpha_R, \delta X_L = \alpha_L \), with \( J^i \) generating the anti-diagonal subgroup \( \alpha_L = -\alpha_R \), while \( J_i \) generates the diagonal subgroup \( \alpha_L = \alpha_R \).

To impose it, we gauge the symmetry by introducing a gauge field \( C \) which is a one-form on the worldsheet. We perform a minimal coupling procedure which amounts to replacing

\[ \partial \tilde{X}_i \rightarrow \partial \tilde{X}_i + C_i \quad (2.9) \]

Since this generates the linear coupling term \( \sim C_i \wedge *H_{ij} \partial X^j \), we add a term

\[ C_i \wedge \partial X^i \quad (2.10) \]

to yield the coupling \( C \wedge *J \). Under the gauge transformations \( \delta X_i = \alpha_i, \delta C_i = -\alpha_i \), the action is invariant up to a surface term. To remove this term, we add the topological term to the action

\[ \mathcal{L}_{\text{top}} = -i \pi d\tilde{X}_i \wedge dX^i \quad (2.11) \]

In \([1]\), it was noted that since after the inclusion of (2.9), (2.10) and (2.11), the doubled lagrangian can be written as

\[ \mathcal{L} = \pi G_{ij} \partial X^i \wedge *\partial X^j + \pi B_{ij} \partial X^i \wedge \partial X^j + \frac{\pi}{2} G^{ij} D_i \wedge *D_j, \]

\(^3\)We note that when the total spacetime dimension is just one, this reduces to the expressions found in \([21]\), namely \( P = \frac{1}{\sqrt{2}} \left( RdX + R^{-1}d\tilde{X} \right) \), \( Q = \frac{1}{\sqrt{2}} \left( RdX - R^{-1}d\tilde{X} \right) \).
$D_i \equiv C_i + d\bar{X}_j - G_{ij} \ast \partial X^j - B_{ij} \partial X^j \quad (2.12)$

Imposing the constraint is then equivalent to treating $D_i$ as the non-dynamical fields. The invariance under $\delta \bar{X}_i = \alpha_i$ implies that $\bar{X}$ can be completely gauged away including winding modes.

In this paper, we shall begin with the action by gauge-fixing $C$ to be zero, with thus only the topological term being added to the action (2.14). The non-dynamical degrees of freedom are removed from the partition function of the doubled sigma model by identifying and retaining the appropriate holomorphic and anti-holomorphic pieces following the constraint, rather than integrating over the auxiliary fields $D$ in (2.12). This procedure is sufficient for our purpose of reducing the partition function to the correct one, but would certainly need to be modified for T-folds in general. In these cases, the $O(d, d; \mathbb{Z})$ connection should act an integral role since they measure the non-trivial nature of the bundle.

### 2.2 On $S^1/\mathbb{Z}_N$ orbifolds: some generalities

In this subsection, we shall briefly discuss a somewhat different topic - closed string orbifolds, in anticipation of Section 3 where we discuss the $S^1/\mathbb{Z}_N$ case in detail. In particular, non-geometric backgrounds can be obtained when the orbifold action is asymmetric. Let us begin with the simplest example of a $S^1$ target space geometry on a toroidal worldsheet parametrized by periodic variables $\sigma_1, 2 \sim \sigma_1, 2 + 1$ and equipped with the following metric

$$ds^2 = \frac{1}{\tau_2} |d\sigma_2 + \tau d\sigma_1|^2$$

where $\sigma_1, 2$ are the periodic Euclidean time and space worldsheet coordinates respectively. Let the periodic boson be $X$, with $R$ being the compactification radius, and its T-dual be $\bar{X}$. In the following, we will absorb $R$ in the target space metric, and let $X$ be a dimensionless coordinate with unit period. First, let us recall some basic facts about abelian orbifolds defined by $\mathbb{Z}_N$ shifts of the form

$$\hat{s}X \rightarrow X + \frac{1}{N}.$$  \quad (2.13)

With regards to the left- and right-movers, the orbifold action acts symmetrically on both, with each of $X_L$ and $X_R$ being shifted by $\frac{1}{2N}$. The partition function can be written as a sum of partition traces

$$Z_{S^1/\hat{s}} = \frac{1}{N} \sum_{h,b=1} \hat{s}^{N-1} Z^g_h \quad (2.14)$$

where in the above notation, $h$ labels the twisted sector and $g$ is defined as the orbifold twist operator (in this case, a translation operator) inserted in the Hilbert space trace.
We can describe the shifted boundary conditions by the characteristics \( \delta = (\delta', \delta'') \) where \( \delta', \delta'' = 0, 1/N, 2/N, \ldots, (N-1)/N \). Corresponding to \( h = \hat{s}^N \delta' \) and \( g = \hat{s}^N \delta'' \), the twisted boundary conditions of \( X \) read

\[
X(\sigma_1 + 1, \sigma_2) = X(\sigma_1, \sigma_2) + \delta'' \pmod{1} \\
X(\sigma_1, \sigma_2 + 1) = X(\sigma_1, \sigma_2) + \delta' \pmod{1}.
\] (2.15)

The classical zero modes have winding numbers along each worldsheet direction which we denote by \( m, n \). Explicitly, we write

\[
X_{m,n}^\text{cl.}(\sigma) = \sigma_1 (m + \delta') + \sigma_2 (n + \delta'').
\] (2.16)

The string path integral, with Lagrangian \( \pi R^2 \partial^m X \partial_m X \) can be split up into a product of a quantum part capturing degrees of freedom of \( X - X^\text{cl.} \) coming from all the oscillators modes, and the classical zero modes (or string 'instantons') of which contributions read (we set \( \alpha' = 1 \))

\[
\sum_{m,n} e^{-\pi R^2/2 |\tau(n+\delta')-(m+\delta'')|^2}.
\] (2.17)

Together with the quantum part, the partition function in each twisted sector then reads

\[
Z^g_{h}(\tau) = \frac{R}{\sqrt{2\pi} |\eta(\tau)|^2} \sum_{m,n} e^{-\pi R^2/2 |\tau(n+\delta')-(m+\delta'')|^2}
\] (2.18)

where the factor \( R \) arises from integrating over the volume of the target space. There is another way to express the above partition function in terms of the chiral block structure of the theory, namely the left- and right-moving string degrees of freedom. One simply needs to perform a Poisson resummation in \( n \rightarrow w \), using the formula\(^4\)

\[
\sum_n \exp \left( -\pi A(n+c)^2 \right) = \frac{1}{\sqrt{\det A}} \sum_w \exp \left[ -\frac{\pi}{A} w^2 + 2\pi i c w \right]
\] (2.20)

which gives us

\[
Z^g_{h}(\tau) = \text{Tr}_h \left( g q^{1/2} \bar{q}^{1/2} \right) = \frac{1}{|\eta|^2} \sum_{w,n} e^{-2\pi i \delta'' w} q^{1/4 (\bar{w} + R(n+\delta')^2 q^{1/4 (\bar{w} - R(n+\delta'))^2}}.
\] (2.21)

In [2.21], we see that in the basis labelled by momentum number \( w \) and winding number \( n \), \( g = \hat{s}^N \delta'' = e^{-i(pL+pR)\delta X} = e^{-2\pi i \delta'' w} \). More generally, one can set up an orbifold by

\[
\sum_{m^1, \ldots, m^n \in \mathbb{Z}} \exp \left\{ -\pi A_{ij}(m^i + C^i)(m^j + C^j) + 2\pi i B_i (m^i + C^i) \right\}
\]

\[
= \frac{1}{\sqrt{\det A}} \sum_{m^1, \ldots, m^n \in \mathbb{Z}} \exp \left\{ -\pi (A^{-1})_{ij}(m_i - B_i)(m_j - B_j) + 2\pi i C^i (m_i - B_i) \right\}
\] (2.19)

where \( A \) is an invertible \( n \times n \) symmetric matrix and \( B, C \) are two \( n \)-column vectors.

\(^4\)This is a special case of
independent shifts in \( X \) and its T-dual \( \tilde{X} \) which has an inverted compactification radius. For definiteness, let us consider the case where the shifts are

\[
X \to X + a\, \frac{1}{N}, \quad \tilde{X} \to \tilde{X} + b\, \frac{1}{N}
\] (2.22)

where \( a, b = \{0, \pm 1\} \) are defining parameters of the translation orbifolds\(^5\), so for example, at the self-dual point \( R = 1 \), the orbifold of \((a, b) = (1, 1)\) would correspond to \( X_R \to X_R, X_L \to X_L + \frac{1}{N} \). We should introduce two other shift parameters \( \delta, \delta'' \), and thus altogether we have \( \delta, \delta'' = 0, 1/N, \ldots, a(N-1)/N \) and \( \delta, \delta'' = 0, 1/N, \ldots, b(N-1)/N \).

In each twisted sector labeled by \( \delta', \delta'' \), the instanton part of the partition function which corresponds to summing over all classical backgrounds with different winding modes reads

\[
Z_{(\delta'', \delta')}^{(\delta', \delta')} = \sum_{w, n} e^{-2\pi i \delta'' (w + \delta') - 2\pi i \delta'' (n + \delta')} \frac{1}{q} \left( \frac{w + \delta'}{N} + R (n + \delta') \right)^2 \frac{1}{\bar{q}} \left( \frac{w + \delta'}{N} - R (n + \delta') \right)^2.
\] (2.23)

Note that (2.21) corresponds to the case of \((a, b) = (1, 0)\). After a T-duality, we obtain the case of \((a, b) = (0, 1)\) which shifts the T-dual coordinate \( \tilde{X} \). This can be called a winding number shift, dual to the previous momentum shift. More generally, we can have both simultaneously. For example, when \( a = b = 1 \) or whenever \( b \neq 0 \), we have an asymmetric orbifold. This presents a rather natural setting for the doubled formalism where the parent sigma model includes \( \tilde{X} \) as a bona fide target space coordinate right from the outset. Nonetheless, one needs to understand how to consistently halve the degrees of freedom to arrive at the correct physical partition function. In the following Section, we will attempt to recover the partition function trace \( Z_{(\delta'', \delta')}^{(\delta', \delta')} \) in (2.23) in the doubled geometry formalism.

### 3 Closed string partition functions of \( S^1/\mathbb{Z}_N \) orbifolds

#### 3.1 Poisson resummations and chiral factorization

We begin with the action

\[
S = \frac{\pi}{2} R^2 dX \wedge dX + \frac{\pi}{2 R^2} d\tilde{X} \wedge d\tilde{X} + i\pi dX \wedge d\tilde{X}
\]

As discussed earlier, one needs to impose a suitable constraint to recover the physical theory. The natural variables for this constraint are

\[
P = \frac{1}{\sqrt{2}} \left( RX + \frac{1}{R} \tilde{X} \right), \quad Q = \frac{1}{\sqrt{2}} \left( RX - \frac{1}{R} \tilde{X} \right)
\] (3.1)

---

\(^5\)See [30] for a recent work in which these orbifolds are investigated from the viewpoint of gauged supergravities.
with the constraint being the chiral factorization
\[ \partial_z P = \partial_{\bar{z}} Q = 0. \] (3.2)

In terms of \( P, Q \), the action reads
\[ S = \frac{\pi}{2} dP \wedge *dP + \frac{\pi}{2} dQ \wedge *dQ. \] (3.3)

We now consider the different classical backgrounds differentiated by their cohomology classes as defined on the toroidal worldsheet with cycles \( \alpha_1, \alpha_2 \). Define
\[ L = dX + \omega, \quad \omega \in H^1(\sigma, \mathbb{Z}) \]

Imposing the translational twists by phases \( \delta \), we can explicitly write \( L \) as
\[ L = dX + (n + \delta') \alpha_2 + (m + \delta'') \alpha_1, \] (3.4)
\[ \tilde{L} = d\tilde{X} + (\tilde{n} + \delta') \alpha_2 + (\tilde{m} + \delta'') \alpha_1. \] (3.5)

In [21], the partition function was shown to be equivalent to the original \( S^1 \) partition function after keeping the relevant chiral modes by invoking the constraint. Here, we would like to extend the results to \( \mathbb{Z}_N \) orbifolds generated by translations in the \( S^1 \) and dual \( S^1 \). Roughly speaking, this amounts to studying whether the Poisson resummation steps which were used to reproduce the closed string partition functions are consistent with the addition of the twists. If the doubled formalism is quantum mechanically identical to the original closed string theory, the Poisson resummations should reproduce the phase factors in the shifted lattice sum \( Z^{(\delta', \delta'')}_{(\sigma, \delta)} \) in the closed string theory partition function after chiral factorization.

The instanton sector of the partition function reads
\[
Z = \sum_{\{n, \tilde{n}, m, \tilde{m}\}} \exp \left[ - \left( R(n + \delta') + R^{-1}(\tilde{n} + \tilde{\delta}') \right) \frac{2 \pi |\tau|^2}{4 \tau_2} \right. \\
+ \left. \left( R(m + \delta'') + R^{-1}(\tilde{m} + \tilde{\delta}'') \right) \frac{2 \pi |\tau|^2}{4 \tau_2} \right] \times \exp \left[ - \left( R(n + \delta') - R^{-1}(\tilde{n} + \tilde{\delta}') \right) \frac{2 \pi |\tau|^2}{4 \tau_2} \right. \\
+ \left. \left( R(m + \delta'') - R^{-1}(\tilde{m} + \tilde{\delta}'') \right) \frac{2 \pi |\tau|^2}{4 \tau_2} \right],
\] (3.6)

where the first factor corresponds to \( P \) and the second to \( Q \). The phase factors arising from the topological term read
\[
\exp \left[ i\pi((n + \delta')(\tilde{m} + \tilde{\delta}'') - (m + \delta'')(\tilde{n} + \tilde{\delta}')) \right]
\] (3.7)
In the absence of the twists, the topological term contributes a relative sign to each term in the partition sum. To separate the sum, we write
\[ R^2 = \frac{p}{q}, \quad p, q \text{ coprime integers}, \quad k = pq \]
and thus,
\[ (R(n + \delta') \pm R^{-1}(\bar{n} + \bar{\delta'})) = \sqrt{k} \left( \frac{n + \delta'}{q} \pm \frac{\bar{n} + \bar{\delta'}}{p} \right). \] (3.8)
Substituting \( n = q(c + \gamma_q), m = q'(d + \gamma'_q) \) and \( \bar{n} = p(\bar{c} + \gamma_p), \bar{m} = p'(\bar{d} + \gamma'_p) \), where \( c, \bar{c}, d, \bar{d} \in \mathbb{Z} \) and \( \gamma_k, \gamma'_k \in \{0, 1, \ldots, \frac{k-1}{k} \} \), and letting \( h = c + \bar{c}, l = c - \bar{c}, i = d + \bar{d}, j = d - \bar{d} \), the partition function then reads (below, the set of summation indices is \( I = \{ h, l, i, j, \gamma, \gamma'_\pm, \phi, \theta \} \))
\[
Z = \sum_{I} \frac{1}{2} \exp \left[ -\frac{k \pi}{4} \left\{ (h + \gamma)(i + \gamma') \frac{\tau_1}{\tau_2} + (i + \gamma') \frac{\tau_1}{\tau_2} + 2\pi i (\phi h + \theta i) \right\} \right]
\times \frac{1}{2} \exp \left[ -\frac{k \pi}{4} \left\{ (l + \gamma)(j + \gamma') \frac{\tau_1}{\tau_2} + (j + \gamma') \frac{\tau_1}{\tau_2} - 2\pi i (\phi l + \theta j) \right\} \right]
\exp \left[ \frac{i \pi k}{2} \left( (l + \gamma)(i + \gamma') - (h + \gamma)(j + \gamma') \right) \right] \] (3.9)
where we have defined
\[ \gamma_{\pm} \equiv \gamma_q + \delta' \pm (\gamma_p + \bar{\delta'}), \quad \gamma'_{\pm} \equiv \gamma'_q + \delta'' \pm (\gamma'_p + \bar{\delta''}), \] (3.10)
and we have inserted in the factors
\[ \sum_{\phi, \theta = 0, \frac{1}{2}} \frac{1}{2} \exp \left[ 2\pi i (\phi (h - l) + \theta (i - j)) \right] \]
since the terms \( h - l \) and \( i - j \) are even. Note that each square-bracketed term in (3.9) corresponds to the contributions from \( P, Q \) and the topological term respectively. Let us write
\[ Z = Z_P Z_Q Z_{\text{top}} \]
We now perform a Poisson resummation of \( i, j \), replacing them with \( r, s \) respectively. After some algebra, this yields (the topological term is absorbed into each of the following pieces)
\[
Z_P = \sum_{j_p} \frac{1}{2} \sqrt{\frac{4\tau_2}{k}} \exp \left[ -\frac{k \pi}{4} \left\{ (h + \gamma)(i + \gamma') \frac{\tau_1}{\tau_2} - 2\gamma(h + \gamma) \frac{\tau_1}{\tau_2} + (\gamma')^2 \frac{\tau_1}{\tau_2} \right\} + 2\pi i \phi h \right.
\left. + \frac{i \pi k}{2} \left( l + \gamma \right) \gamma' \right) \frac{\tau_2}{k} \left[ r - \theta + i k \frac{\tau_1}{4 \tau_2} \left( h + \gamma \right) \right] - \frac{i k \gamma'}{4 \tau_2} - \frac{i k \gamma'}{4 \tau_2} \left( l + \gamma \right) \right] \right) \]
\[ = \sum \sqrt{\frac{\tau_2}{k}} \exp \left[ \tau_2 \left( -\frac{k \pi}{4} (h + \gamma)^2 - 4\pi k \left( \frac{r - \theta}{k} - \frac{1}{4} (l + \gamma) \right)^2 \right) \right] \]
\[-2\pi i \tau_1 (h + \gamma_+) (r - \theta - \frac{k}{4} (l - \gamma_-)) + 2\pi i \phi h + 2\pi i (r - \theta) \gamma'_+ \]  
(3.11)

and similarly,
\[Z_Q = \sum_{J_q} \sqrt{\frac{\tau_2}{k}} \exp \left[ \tau_2 \left( -\frac{k \pi}{4} (l + \gamma_-)^2 - 4 \pi k \left( \frac{s - \theta}{k} - \frac{1}{4} (h + \gamma_+) \right)^2 \right) \right. \]
\[-2\pi i \tau_1 (l + \gamma_-) (s - \theta - \frac{k}{4} (h + \gamma_+)) - 2\pi i \phi l + 2\pi i (-r + \theta) \gamma'_- \]  
(3.12)

where the summation indices are \( J_p = \{h, l, r, s, \phi, \theta, \gamma_\pm, \gamma'_\pm\} \), \( J_q = \{h, l, r, s, \phi, \theta, \gamma_\pm, \gamma'_\pm\} \).

At this point, the above expressions are of the same form as that presented in [21], with the shift factors contained in the \( \gamma_\pm, \gamma'_\pm \) as shown in (3.10). We have used the Poisson summation formula in (2.20). Then, invoking
\[\tau_2 (a^2 + b^2) - 2i \tau_1 ab = \frac{1}{2i} \left( \tau (a + b)^2 - \tau (a - b)^2 \right)\]  
(3.13)

we can write the partition function as
\[Z = \sum \frac{\tau_2}{k} \exp \left[ i \pi k \tau \frac{p_R^2}{2} - i \pi k \bar{\tau} \frac{p_L^2}{2} + 2\pi i (\phi h + (r - \theta) \gamma'_+) \right] \times \exp \left[ i \pi k \tau \frac{q_R^2}{2} - i \pi k \bar{\tau} \frac{q_L^2}{2} + 2\pi i (-\phi l + (s + \theta) \gamma'_-) \right] \times \exp \left[ 2\pi i (w \delta'' + \bar{w} \bar{\delta}'') \right] \]  
(3.14)

where the left and right-moving momentas are defined as
\[p_L = \frac{1}{2} (h + \gamma_+) - 2 \left( \frac{r - \theta}{k} - \frac{1}{4} (l + \gamma_-) \right), \quad p_R = \frac{1}{2} (h + \gamma_+) + 2 \left( \frac{r - \theta}{k} - \frac{1}{4} (l + \gamma_-) \right)\]  
\[q_L = \frac{1}{2} (l + \gamma_-) - 2 \left( \frac{s + \theta}{k} + \frac{1}{4} (h + \gamma_+) \right), \quad q_R = \frac{1}{2} (l + \gamma_-) + 2 \left( \frac{s + \theta}{k} + \frac{1}{4} (h + \gamma_+) \right)\]  
(3.15)

We now sum over all \( \gamma'_q, \gamma'_p \). Since
\[\sum_{u=0}^{N-1} \exp \left( 2\pi i \alpha u / N \right) = \begin{cases} N & \text{if } \alpha \equiv 0 \mod N \\ 0 & \text{otherwise} \end{cases},\]  
(3.17)

the summation over \( \gamma'_q, \gamma'_p \) is reduced to a restricted sum over all \( r, s, \theta \) as follows
\[r + s \equiv 0 \mod q, \quad r - s - 2\theta \equiv 0 \mod p.\]  
(3.18)

with a factor of \( k = pq \) which cancels the \( 1/k \) factor in (3.14). From (3.18), we can introduce integers \( w, \bar{w} \in \mathbb{Z} \) to write the momenta neatly as
\[p_L = \frac{n + \delta'}{q} - \left( \frac{w}{p} + \frac{\bar{w}}{q} \right),\]  

14
\[ p_R = \frac{\bar{n} + \delta'}{p} + \left( \frac{w}{p + \bar{w}} \right) q \]
\[ q_L = -\frac{\bar{n} + \delta'}{q} - \left( \frac{w}{p - \bar{w}} \right) q \]
\[ q_R = \frac{n + \delta'}{q} + \left( \frac{w}{p - \bar{w}} \right) q \] (3.19)

But if we keep track of the phases \( \delta', \delta'' \), we see that in the momenta to be retained after the chiral projection, we should have both \( \bar{\delta}', \delta' \). Comparison with (2.23) reveals that since the phases \( \delta'', \bar{\delta}' \) couple to \( w, \bar{w} \), the latter are the integers that count the effective momenta and winding number modes. Consistency with the original orbifold partition function leads to stringent constraints on what are the appropriate modes to retain when we perform the chiral factorization in accordance with \( \partial_z P = \partial_z Q = 0 \).

In [21], the final step in demonstrating the equivalence between the ordinary partition function and that of the doubled CFT is to identify \( p_L \) and \( q_R \) as the appropriate chiral and anti-chiral pieces. This appears to be compatible with the constraint \( \partial_z P = \partial_z Q = 0 \), but we note that in the Poisson resummation process, the topological term does mix modes between \( P \) and \( Q \), and thus labeling the modes by either \( P \) or \( Q \) is a subtle procedure which has to be treated with care.

Consider first a \( \mathbb{Z}_N \) shift ‘symmetric’ orbifold which acts equally on the left-and right-moving sectors. In this case, there is no orbifold action on \( \tilde{X} \) which corresponds to taking \( \bar{\delta}' = \delta'' = 0 \). The independent modes to be summed over are \( n - \bar{w} \) and \( w \). Removing the parts which depend on \( p_R, q_L \) requires these contributions to be factorized out and this can be done since we can treat \( \bar{n} + w \) and \( \bar{w} \) as independent modes. After that, the partition function of this ‘symmetric’ orbifold reads (after relabeling \( w \rightarrow -w \))

\[ Z_{\text{sym}} = \sum_{n - \bar{w}, w} e^{-2\pi i \delta'' w} q^{\frac{1}{2} \bar{\nu}_L^2} q^{\frac{1}{2} \bar{\nu}_R^2} \] (3.20)

This is indeed the correct expression as we have briefly discussed in Section 2. Recall that (3.20) is nothing but \( \text{Tr}_{\delta'} \left( \hat{s}^{N \delta''} q^{\frac{1}{2} \bar{\nu}_L^2} q^{\frac{1}{2} \bar{\nu}_R^2} \right) \).

Unfortunately, such an equivalence appears to fail when we consider the case in which the orbifold shift acts asymmetrically, i.e. for non-zero \( \delta'', \bar{\delta}' \). If we insist on factorizing out \( p_R, q_L \), we can immediately see that we cannot capture the effect of \( \bar{\delta}' \). However, the factor \( e^{2\pi i \delta'' \bar{w}} \) is in the right place though, since the insertion of the dual translation operator couples to the winding modes (whereas as we have seen, the insertion of the translation (in \( X \)) operator couples to the momentum modes). Of course, this ought to be further augmented by multiplying a phase factor \( e^{-2\pi i \delta'' n} \) since it is \( n - \bar{w} \) that is present in the summation as winding numbers.

One may attempt to remedy this situation by studying if it’s possible to express the squares of sum in the exponential arguments of the various momenta differently, such that
we retain both $\delta', \bar{\delta}'$. For example, suppose we redefine the left- and right-moving degrees of freedom as

\[
\tilde{p}_L = \frac{1}{\sqrt{2}} \left( \frac{n + \delta'}{q} + \frac{n + \bar{\delta}'}{p} - 2\bar{w} \right), \\
\tilde{p}_R = \frac{1}{\sqrt{2}} \left( \frac{n + \delta'}{q} + \frac{n + \bar{\delta}'}{p} + 2w \right), \\
\tilde{q}_L = \frac{1}{\sqrt{2}} \left( \frac{n + \delta'}{q} - \frac{n + \bar{\delta}'}{p} - 2w \right), \\
\tilde{q}_R = \frac{1}{\sqrt{2}} \left( \frac{n + \delta'}{q} - \frac{n + \bar{\delta}'}{p} + 2\bar{w} \right),
\] (3.21)

and we attempt to retain the relevant parts of the partition function by some form of chiral factorization, the independent modes to sum over can only be \{\bar{n} + 2w, n\} and \{\bar{n}, n - 2\bar{w}\}. These two sets, unlike the earlier case of the symmetric orbifold, are not independent, but we can still separate them into chiral blocks by summing over even and odd $n, \bar{n}$ separately. Let’s define $u = \bar{n} + 2w, v = n - 2\bar{w}$. Then the parity of $u, v$ follows that of $n, \bar{n}$ respectively. Thus the complete partition function is a sum of four distinct sectors depending on whether $n, \bar{n}$ are even or odd, i.e.

\[
Z = \sum_{n, \bar{n} \in \mathbb{Z}, \mathbb{Z}+1} Z^{(\tilde{p}_L)} Z^{(\tilde{q}_R)} Z^{(\bar{\tilde{p}}_R)} Z^{(\bar{\tilde{q}}_L)},
\]

The chiral factorization procedure then amounts to setting $Z^{(\tilde{q}_L)} Z^{(\tilde{p}_R)} = 1$. Yet this is problematic because the phase factors $\delta'', \bar{\delta}''$ must couple to $w, \bar{w}$ with the latter being momentum and winding integral modes. This clearly does not agree with the expressions in (3.21).

Thus far, we have followed rather closely the approach in [21]. When the orbifold action acts purely on $X$, and is thus symmetric and geometric, the closed string partition function can be recovered in a consistent fashion by chiral factorization. When the orbifold action is asymmetric and thus non-geometric, we find that the same procedure seems to require some modification. It turns out that we need to couple additional phase factors to the partition trace when $\bar{\delta}', \bar{\delta}'' \neq 0$. As we shall shortly point out, exactly the same phase factors arise in the conventional theory too.

### 3.2 Some pairing phase factors

We have argued that it does not seem possible to reduce the instanton part of the doubled partition function to the correct physical one by merely assuming $d\tilde{X} = (\bar{n} + \bar{\delta}')\alpha_2 + (\bar{m} + \bar{\delta}'')\alpha_1$. Let us introduce some additional phase factors when computing $Z^{(\bar{\delta}'', \bar{\delta}'')}$ right from the outset. These phase factors measure the asymmetric (and hence non-geometric) nature of the orbifold. We now compute the doubled partition function with the inclusion
of the following phase factor
\[ \exp \left[ 2\pi i \left( \delta' m - \delta''(n + \delta') \right) \right] \] (3.22)
in the sum over all modes in the starting step (3.6). We find that we can indeed recover the appropriate doubled lattice sum reducible to (2.23) after chiral factorization. Since we have already illustrated in detail this procedure (a rather simple extension of what was done in [21]), we choose not to be repetitive and instead present a somewhat shorter derivation that leads to the same partition function. We will perform separate Poisson resummations \( m \to w, \bar{m} \to \bar{w} \) which are the winding modes along the Euclidean time direction. It turns out that after resumming, the Lagrangian admits a unique splitting into a sum of the square of four distinct momenta terms, two of which are multiplied to \( \tau \) and the other two to \( \tau' \), thus allowing us to interpret them as \( p_{L,R}; q_{L,R} \). Although this shorter derivation is presented mainly for the purpose of efficiency, we should bear in mind that for a slightly more rigorous argument that allows us to discard half of the chiral modes away in the final step, the longer derivation presented earlier is tighter in logic. In the next section on more general toroidal backgrounds, we shall follow the more expedient derivation, leaving the longer exercise for any keen reader.

In any case, the fact that the doubled partition function can be chirally factorized is not trivial. The inclusion of the topological term plays a crucial role. Its dependence on the winding numbers exactly accounts for its needed appearance to ensure that the doubled sigma model is invariant under large gauge transformations. On the other hand, in our computations, this topological term governs the correct mixture of the momenta and winding degrees of freedom of \( X \) and \( \tilde{X} \).

Including the phase factors (3.22), we thus begin with the instanton sum
\[
Z_{cl.} = \sum_{n,m,n,m} \exp \left[ -2\pi i (\delta''(n + \delta') + \delta''(\bar{n} + \bar{\delta}')) - \frac{\pi |\tau|^2}{2\tau_2} \left( R^2(n + \delta')^2 + R^{-2}(\bar{n} + \bar{\delta}')^2 \right) \right] \\
\times \exp \left[ -\frac{\pi R^2}{2\tau_2} (m + \delta'')^2 + 2\pi i \left( \frac{R\tau_1}{2iR\tau_2}(n + \delta') - \frac{1}{2R}(\bar{n} - \bar{\delta}') \right) R(m + \delta'') \right] \\
\times \exp \left[ -\frac{\pi}{2\tau_2 R^2}(\bar{m} + \bar{\delta}'')^2 + 2\pi i \left( \frac{\tau_1}{2iR\tau_2}(\bar{n} + \bar{\delta}') + \frac{R}{2}(n + \delta') \right) R^{-1}(\bar{m} + \bar{\delta}'') \right]
\] (3.23)

Then, we proceed to perform separate Poisson resummations \( m \to w, \bar{m} \to \bar{w} \) starting from (3.23). After some algebra, we arrive at\(^6\)
\[
Z_{cl.} = \sum_{n,w,n,\bar{w}} (2\tau_2) \exp \left[ -2\pi \tau_2 \left( \frac{w}{R} + \frac{\tau_1}{2iR\tau_2}(n + \delta') - \frac{1}{2R}(\bar{n} - \bar{\delta}') + i\frac{\delta'' R^2}{2\tau_2} \right)^2 - \frac{\pi \delta''^2 R^2}{2\tau_2} \right]
\]

\(^6\)Each of the Poisson resummation process generates \( \sqrt{2\tau_2/R^2} \) and \( \sqrt{2\tau_2 R^2} \) which combine to yield a pre-factor \( 2\tau_2 \) in (3.23). The absence of \( R \) holds some implications for higher-genus worldsheets and we shall discuss this later in Section 5.
Consider first the terms which are multiplied by the phase \( \delta'', \bar{\delta}'' \). They amount to the phase factors

\[
\exp \left[ -2\pi i \delta''(\bar{w} + \bar{\delta}') - 2\pi i \bar{\delta}''(\bar{w} + n + \delta') \right]
\]

which turns out to be the appropriate phase factors that should appear in the asymmetric orbifold partition function. The other terms in the exponential argument simplify to read

\[
-2\pi \tau_2 \left( \frac{\bar{w}}{R} + \frac{\tau_1}{2i\tau_2 R^2}(\bar{n} + \bar{\delta}') + \frac{R}{2}(n + \delta') + i\frac{\bar{\delta}''}{2}\tau_2 R \right)^2 - \frac{\pi \bar{\delta}''}{2\tau_2 R^2} \\
+ 2\pi i \left( \frac{\tau_1}{2i\tau_2 R^2}((\bar{n} + \bar{\delta}') + \frac{1}{2}(n + \delta')) \bar{\delta}'' + 2\pi i \left( \frac{\tau_1 R^2}{2i\tau_2}((n + \delta') - \frac{1}{2}(\bar{n} - \bar{\delta}') \right) \bar{\delta}'' \right) \\
- \frac{\pi |\tau|^2}{2\tau_2} \left( R^2(n + \delta')^2 + R^{-2}(\bar{n} + \bar{\delta}')^2 - 2\pi i(\bar{\delta}'' n + \delta'' \bar{n}) \right)
\]

(3.24)

Defining

\[
p_L = (n + \bar{w} + \delta') R + \frac{(w + \bar{\delta}')}{R}, \quad p_R = \frac{\bar{n} - w}{R} + \bar{w} R \]

\[
q_L = \frac{\bar{n} - w}{R} - \bar{w} R, \quad q_R = (n + \bar{w} + \delta') R - \frac{(w + \bar{\delta}')}{R}, \quad (3.27)
\]

we see that the doubled partition function, including the quantum fluctuations (see Section 4), can be simplified to read

\[
Z = \frac{1}{|\eta|^2} \sum_{n,\bar{n},w,\bar{w}} e^{-2\pi |\delta''(w + \bar{\delta}') + \bar{\delta}''(n + \delta')|} q^+_4(v_4^4 + q_L^4) q^+_4(v_4^2 + q_R^2).
\]

(3.28)

Factoring out \( p_R \) and \( q_L \), the complete partition function now agrees with what we would expect in a conventional computation. It is noteworthy that the discarded modes do not capture any of the orbifold phases \( \{\delta', \bar{\delta}', \delta'', \bar{\delta}''\} \). We view this as a simple consistency check of the chiral factorization procedure. Our result demonstrates that at the asymmetric orbifold point, one can consistently remove the unphysical states from the doubled theory to recover the spectrum of the asymmetric orbifold. The non-geometric action of the orbifold manifests itself as complex phase factors when one writes down the lattice sum.

Our introduction of the phase factors (3.22) might appear to be rather contrived, hence we must now point out that these factors actually arise in an identical fashion in the ordinary theory. Beginning from (2.23), one can check that a Poisson resummation of \( w \) yields the instanton sum

\[
Z_{cl.} \sim \sum_{m,n} e^{2\pi i((\delta' m - \bar{\delta}' n + \delta'))} e^{-\frac{|\eta|^2}{4} |\pi(n + \delta') - (m + \delta'')|^2}
\]

(3.29)
where we observe that the complex phase factors that arise are precisely (3.22). It was 
noted in [22] that generically, the partition functions of asymmetric orbifolds can be 
constructed from the chiral blocks of associated symmetric orbifolds where the orbifold 
action $G_{L,R}$ is symmetrized in each block $F$ and that sewing these blocks together requires, 
in general for modular covariance, a pairing matrix $K$.

Symbolically, as explained in [22], we can write the ‘block’ $Z^g_h$ of the asymmetric orbifold 
with $h = (h_L; h_R), g = (g_L; g_R)$ as

$$
Z^g_h(p_L, p_R; \tau, \bar{\tau}) = F^g_{h_L}(p_L; \tau)F^{g_R}_{h_R}(p_R; \tau)
$$

with the full partition function being

$$
Z_G(\tau, \bar{\tau}) = \frac{1}{|G|} \sum_{g,h} \sum_{p_L, p_R} K(p_L, p_R, h_L, h_R, g_L, g_R) F^g_{h_L}(p_L; \tau)F^{g_R}_{h_R}(p_R; \tau)
$$

where $|G|$ is the order of the orbifold group. It is interesting to see that the doubled sigma 
model presents a theory for which the computation of the one-loop partition function 
involves naturally a pairing of some left and right chiral blocks. In this picture, the 
phase factors in (3.25) appears as a pairing phase matrix that pairs up the blocks. It 
would be interesting to explore this connection genuinely by working in the operator 
formalism [28]. What we have demonstrated is the quantum equivalence between the 
doubled sigma model and the conventional one via a simple chiral factorization process. In 
the following Sections, we shall continue to extend our result in several natural directions: 
(i) the general toroidal background with $B$ field (ii) higher-genus worldsheet (iii) $\mathcal{N} = 1$ 
worldsheet supersymmetry.

## 4 More general toroidal compactifications

Now, we lift our analysis of the previous two sections to higher-dimensional toroidal 
backgrounds with the general metric $G_{mn}$ and the Kalb-Ramond field $B_{mn}$. Before that, 
let us first derive the lattice sum of such a background (without orbifolding) by resumming 
the winding modes along the Euclidean time direction. In the following treatment, all $X^i$ are dimensionless periodic coordinates. The $d-$dimensional torus is $T^d = \mathbb{R}^d/\Lambda^d$ where $\Lambda$ is the compactification lattice with metric $G_{mn}$. Similar to (3.4), we can write

$$
L^r = d X^r + n^r \alpha_2 + m^r \alpha_1,
\tilde{L}_r = d \tilde{X}_r + \tilde{n}_r \alpha_2 + \tilde{m}_r \alpha_1,
$$

with the choice of the position of the index $r$ being such that all winding numbers are 
integral in (4.1). The classical action reads

$$-
S_{cl} = \frac{\pi}{\tau_2} G_{mn} (w^m_2 - w^m_1 \tau) (w^n_2 - w^n_1 \bar{\tau}) + 2\pi i B_{mn} w^m_1 w^n_2 \tag{4.1}
$$
It turns out that the above sum takes a more illuminating form

\[
- S_{cl} = -\pi \left( n_m - R_m + i \frac{\tau_1 w_m}{\tau_2} \right) \tau_2 \sum_{n,m} G^m_n \left( n_n - R_n + i \frac{\tau_1 w_n}{\tau_2} \right) - \frac{w^2 |\tau|^2}{\tau_2} \]

where we have defined

\[
A_{mn} = \frac{G_{mn}}{\tau_2}, \quad R_m = B_{mn} w_n^1 - i \frac{G_{mn} w_1^m \tau_1}{\tau_2}
\]

A Poisson resummation of all \( w_m^2 \to n^m \) yields

\[
- S_{cl} = -\pi \left( n_m - R_m + i \frac{\tau_1 w_m}{\tau_2} \right) \tau_2 G^m_n \left( n_n - R_n + i \frac{\tau_1 w_n}{\tau_2} \right) - \frac{w^2 |\tau|^2}{\tau_2}
\]

It turns out that the above sum takes a more illuminating form

\[
- S_{cl} = \frac{\pi i \tau P_L^2}{2} - \frac{\pi i \bar{\tau} P_R^2}{2}
\]

where the left- and right-moving momenta depend on the fields and the vielbeins

\[
P_{(L,R)}^a = e^m_a \left( w_m \pm (G_m mn^k + B_{mn} w_n^1) \right), \quad G^m_n = \eta^{ab} \epsilon^m_a \epsilon^n_b
\]

Recall that the factorized T-duality element that relates \( \tilde{X} \) to \( X \) induces the following action on the metric and the \( B \) field.

\[
\tilde{G}^m_n = (G_{mn} - B_{ma} G^{ab} B_n )^{-1}, \quad \tilde{B}^m_n = \left( B_{mn} - G_{ma} (B^{-1})^{ab} G_{bn} \right)^{-1}
\]

We then proceed similarly to the \( S^1 \) target space case. To simplify the algorithm, we shall perform Poisson resummation of \( m \) and \( \tilde{m} \), replacing them with \( w \) and \( \tilde{w} \). As mentioned
earlier, this effectively turns out to be equivalent to resumming \( m \pm \bar{m} \) which was done for the \( S^1 \) case earlier. Let us first check the result in the simpler case of vanishing \( B \) field. One can see that when \( B = 0 \), the terms in \( m \) and \( \bar{m} \) do not mix, and the Poisson resummation can be done independently to yield

\[
Z_{cl} = (2\tau_2)^d \sum_{\{n,\bar{n},w,\bar{w}\}} \exp \left[ -2\pi \tau_2 G_{ij} \left( \bar{w}^i + \frac{1}{2} n^i - \frac{i \tau_1}{2\tau_2} G^{ki} \bar{n}_k \right) \left( \bar{w}^j + \frac{1}{2} n^j - \frac{i \tau_1}{2\tau_2} G^{kj} \bar{n}_k \right) \right.
\]

\[
-2\pi \tau_2 G^{ij} \left( w_i + \frac{1}{2} \bar{n}_i + \frac{i \tau_1}{2\tau_2} G_{ki} \bar{n}_k \right) \left( w_j + \frac{1}{2} \bar{n}_j + \frac{i \tau_1}{2\tau_2} G_{kj} \bar{n}_k \right)
\]

\[
-\frac{\pi |\tau|^2}{2\tau_2} \left( G_{ij} n^i n^j + G^{ik} \bar{n}_i \bar{n}_k \right)
\]

\[
= (2\tau_2)^d \sum_{\{n,\bar{n},w,\bar{w}\}} \exp \left[ -2\pi \tau_2 \left( G_{ij}(\bar{w}^i + \frac{1}{2} n^i)(\bar{w}^j + \frac{1}{2} n^j) + G^{ij}(w_i + \frac{1}{2} \bar{n}_i)(w_j + \frac{1}{2} \bar{n}_j) \right) \right.
\]

\[
+ \frac{1}{4} \left( G_{ij} n^i n^j + G^{ij} \bar{n}_i \bar{n}_j \right) \left. + 2\pi i \tau_1 \left( \bar{n}_i \bar{w}^i - n^i w_i \right) \right] .
\]

The last line of (4.8) is identical in form to what we have for the doubled sigma model for a circle target space, with the metric \( G_{ij} \) contracting the various indices. After factoring out the appropriate modes, and combining with the quantum part which comes from the oscillators, we again have the correct contribution to the partition function which reads

\[
Z = \frac{1}{|\eta|^{2d}} \sum_{P_L,P_R} e^{\frac{i}{2} \tau P^2_L e^{-\frac{i}{2} \tau P^2_R}}, \quad P_{(L,R)a} = \epsilon_a^m \left( w_m \pm G_{mk}(n^k + \bar{w}^k) \right), \quad P^2 \equiv \eta^{ab} P_a P_b
\]

We now include the \( B \) field. In (4.7), we can see that it mixes the \( m, \bar{m} \) terms. We find it more convenient to perform a Poisson resummation of \( \bar{m} \to \bar{w} \) first. To see this, let’s assemble the \( \bar{m} \) terms which read

\[
Z_{cl} = (2\tau_2)^d \sum_{\{n,\bar{n},m,\bar{m}\}} \exp \left[ -\frac{\pi}{2\tau_2} G^{ik} \bar{n}_i \bar{m}_k + \frac{\pi}{\tau_2} B_{ij} G^{jm} m^j + \frac{\pi \tau_1}{\tau_2} (\epsilon_m \bar{m}_m - B_{ij} e^j n^k) e^k + i\pi n^k \right] \bar{m}_k + \ldots
\]

After Poisson resuming \( \bar{m} \), the terms quadratic in \( m \) read \(-\frac{\pi}{2\tau_2} m^k m^l B_{kl} G^{jm} B_{ml} \) which cancels away an identical term coming from the \( P \) part of the action to yield the term \(-\frac{\pi}{2\tau_2} G_{ij} m^i m^j + \ldots \) in the argument of the exponential. Since the metric can be inverted explicitly, we can proceed to Poisson resum \( m \) easily. One can check that if we choose to Poisson resum \( m \) first, the quadratic term in \( m \) does not allow one to invert the matrix.
The Poisson resumming of $\bar{m}$ yields

$$Z_{cl.} = (2\tau_2)^d / 2\sqrt{\text{Det}(G)} \sum_{\{n, \bar{n}, m, \bar{w}\}} \exp \left[ -\frac{\pi}{2\tau_2} G_{ik} m^i m^k + 2\pi i \left(B_{ik} (\bar{w}^k + D^k) - \frac{1}{2} \bar{n}_i \right) ight. \\
+ \left. \frac{\tau_1}{4i\tau_2} \left( (e^{-i} e^{-i} + e^i e^i) n^i + (e^{-i} e^{-i} - e^i e^i) \bar{n}_i \right) \right] m^i \\
- 2\pi \tau_2 G_{ij}(\bar{w}^i + D^i)(\bar{w}^j + D^j) - \frac{\pi|\tau|^2}{4\tau_2} \left( (e^{-i} n^i + e^i \bar{n}_j)^2 + (e^{-i} n^i - e^i \bar{n}_j)^2 \right) \right]$$

where we have defined

$$D^k = \frac{\tau_1}{2i\tau_2} (G^m \bar{n}_m - B_{rm} G^{mk} n^k) + \frac{1}{2} n^k, \quad e^\pm_i = e_i \pm B_{ij} e^j.$$

The term linear in $\bar{m}$ simplify to read

$$K_i = B_{ik} (\bar{w}^k + \frac{1}{2} n^k) - \frac{1}{2} \bar{n}_i + \frac{\tau_1}{2i\tau_2} G_{ik} n^k.$$

After Poisson resumming $m \to \bar{w}$, the instanton partition function can be simplified to become

$$Z_{cl.} = (2\tau_2)^d \sum_{\{n, \bar{n}, w, \bar{w}\}} \exp \left[ -2\pi \tau_2 G^{ik}(w_i + K_i)(w_k + K_k) - 2\pi \tau_2 G_{ij}(\bar{w}^i + D^i)(\bar{w}^j + D^j) \\
- \frac{\pi|\tau|^2}{4\tau_2} \left( 2(n_a n^a + B_{am} G^{mk} B_{bk} n^a n^k) + 2\bar{n}_a \bar{n}_a - 4B_{im} G^{mk} n^i \bar{n}_k \right) \right]. \tag{4.11}$$

The terms in $\tau_1^2$ can be checked to cancel nicely, and it turns out that (4.11) can be massaged into the form

$$Z_{cl.} = (2\tau_2)^d \sum_{\{n, \bar{n}, w, \bar{w}\}} \exp \left[ -2\pi \tau_2 \left( G^{ik} w_i w_k + G_{ik} \bar{w}^i \bar{w}^k + \frac{1}{2} G_{ik} n^i n^k + \frac{1}{2} G^{ik} \bar{n}_i \bar{n}_k \\
- G^{ik} \bar{n}_i w_k + G_{ik} n^i \bar{w}^k + 2 w_k \bar{w}^m B^k n + w_i n^j B^i_j - \bar{w}^i \bar{n}_j B^i_j \\
+ [2\bar{w}^m \bar{w}^n + 2n^m \bar{w}^n + n^m n^n] B^k_m B_{kn} \right) + i\pi \tau_1 \left( 2n^i w_i + 2\bar{n}_i \bar{w}^i \right) \right] \tag{4.12}$$

More suggestively terms of $\tau, \tau$, (4.12) reads

$$Z_{cl.} = (2\tau_2)^d \sum_{\{n, \bar{n}, w, \bar{w}\}} \exp \left[ \frac{i\pi}{2} \tau \left( (n + \bar{w} + B(n + \bar{w}) + w)^2 + (\bar{n} - w - B\bar{w} + \bar{w})^2 \right) \\
- \frac{i\pi}{2} \tau \left( (\bar{n} - w - B\bar{w} - \bar{w})^2 + (-n + \bar{w}) + B(n + \bar{w}) + w)^2 \right) \right]. \tag{4.13}$$
where we have suppressed all indices (raised/lowered by metric $G$) to unveil the resemblance of the structure of the expression to that of the $S^1$ case. As was the case previously, we note that the splitting of the terms into sum of two squares is unique. Recall that in our presentation for the $S^1$ target space, apart from a small ambiguity that arises from the topological term, each term in the doubled sigma model’s action can be attributed to either $P$ or $Q$ neatly. This is as it should formally be. Although we have presented a shorter derivation, the final result is identical. The only caveat lies in identifying which terms belong to that of $P$ or $Q$ degrees of freedom. The expression in (4.12) can be seen to be the correct generalization of the result first presented in [21] for the $S^1$ target space. Just as in that scenario, we should identify the independent momentum and winding modes as

$$u \equiv n + \bar{w}, \bar{w}$$

$$w, v \equiv \bar{n} - w$$

Finally, restoring the indices, we can then identify all the left- and right-moving momenta as

$$p_{La} = e_{a}^{m} (w_{m} + B_{mk} u^{k} + G_{mk} u^{k})$$

$$p_{Ra} = e_{a}^{m} (v_{m} - B_{mk} \bar{w}^{k} - G_{mk} \bar{w}^{k})$$

$$q_{La} = e_{a}^{m} (v_{m} - B_{mk} \bar{w}^{k} + G_{mk} \bar{w}^{k})$$

$$q_{Ra} = e_{a}^{m} (w_{m} + B_{mk} u^{k} - G_{mk} u^{k})$$

and taking into account the quantum part due to the oscillators, the doubled partition function reads

$$Z = \frac{1}{|\eta|^{2d}} \sum_{p_{L,R}, q_{L,R}} \exp \left[ \frac{1}{2} i \pi \tau p_{L}^{2} - \frac{1}{2} i \pi \bar{\tau} p_{R}^{2} \right] \exp \left[ \frac{1}{2} i \pi \tau q_{L}^{2} - \frac{1}{2} i \pi \bar{\tau} q_{R}^{2} \right]$$

The constraint can then be implemented immediately by discarding the $q_{L}, p_{R}$ modes, similar to the $S^1$ case. We have thus shown that starting from the doubled sigma model action, we can arrive at the correct physical theory by chiral factorization. This generalizes the result in [21] to general toroidal backgrounds. In several aspects, this is not a trivial consistency check because this derivation is sensitive to how the $B$ field couples to the original $X$ and $\tilde{X}$ terms. The topological term plays an essential role here as well. That we recover the correct partition function at the end is a non-trivial evidence for the structure of the doubled sigma model’s Lagrangian and whether it allows us to implement the constraint, at least in this specific computation, as a form of chiral factorization.

Translational orbifolds can be defined via shifts in the torus lattice, similar to what was discussed in [3]. Proving the quantum equivalence is similar in spirit to the $S^1$ case, so we shall leave the exercise to the reader.
5 Higher-Genus worldsheets

Let $g$ denote the worldsheet genus. Then the complete string partition function reads

$$Z_g = \int dh \, dX \exp \left[ -\frac{1}{4\pi} \int_{M_g} d\tau d\sigma \sqrt{h} \, h^{mn} G_{ij} \partial_m X^i \partial_n X^j + \epsilon^{mn} B_{ij} \partial_m X^i \partial_n X^j \right]$$  \hspace{1cm} (5.1)

where we integrate over all worldsheet metrics $h$ that are compatible with genus $g$. Let us define the canonical homological cycles $(a_\alpha, b_\alpha)$ of $M_g$ as follows. Define $\omega_\alpha, \alpha = 1, 2, \ldots g$ be the holomorphic one-forms that span $H^{(1,0)}(M_g, \mathbb{Z})$, and the $g \times g$ period matrix $\tau$ be

$$\tau_{\alpha\beta} = \int_{a_\alpha} \omega_\beta, \quad \int_{b_\alpha} \omega_\beta = \delta_{\alpha\beta}, \quad \int_{a_\alpha} dX^i = 2\pi n^i_\alpha, \quad \int_{b_\alpha} dX^i = 2\pi m^i_\alpha$$  \hspace{1cm} (5.2)

where we have defined $n^i_\alpha, m^i_\alpha$ to be the $d \times g$-dimensional winding and momentum vector modes. The complete partition function in (5.1) can be written as an integral over all the $3g - 3$ modular parameters. In the following, we shall first consider the classical instanton sector of the partition function, reserving the discussion of the quantum part to Section 6.

The winding numbers along each cycle are now $d \times g$-dimensional vectors. The partition function reads

$$Z_{cl.}(G, B, \tau) = \sum_{n, m} \exp \left[ -\pi m^i_\alpha \left( \frac{1}{\tau_2} \right)_{\alpha\beta} G_{ij} m^j_\beta - \pi n^i_\alpha \left( \frac{1}{\tau_2} \right)_{\alpha\beta} G_{ij} n^j_\beta \right.$$

$$\left. + \pi 2n^i_\alpha \left( \frac{1}{\tau_2} \right)_{\alpha\beta} G_{ij} m^j_\beta + 2\pi m^i_\alpha B_{ij} n^j_\alpha \right]$$  \hspace{1cm} (5.3)

This can be Poisson resummed just as in the torus case. The result is known and the classical zero modes’ part can be cast into the familiar form

$$\text{Det}(\tau_2)^{d/2} \sum_{(\vec{k}, \vec{m}) \in \mathbb{Z}^{2dg}} q^{\frac{1}{4} P^a_{L\alpha} \tau_{\alpha\beta} P^a_{L\beta}} q^{\frac{1}{4} P^a_{R\alpha} \tau_{\alpha\beta} P^a_{R\beta}}$$  \hspace{1cm} (5.4)

where the dependence of $p_{L,R}$ on the winding and momentum vectors $(\vec{k}, \vec{m})$ and the fields $G, B$ are identical in form to (4.15).

Let us now recover (5.4) in the doubled formalism. In the following, to avoid cluttering of indices, we shall suppress the Greek indices, bearing in mind the matrix nature of $\tau$.

The various terms assemble to be a straightforward generalization of (4.7).

$$Z_{cl.} = \sum_{n, \bar{n}, m, \bar{m}} \exp \left[ -\frac{\pi}{4} \left( e^a_i - B_{im} e^{ma} \right) n^i + e^{ja} \bar{n}_j \right. \left( \tau_2 + \tau_1 \frac{1}{\tau_2} \right) \left. \left( e^a_i - B_{im} e^{ma} \right) n^i + e^{ja} \bar{n}_j \right]$$

$$-\frac{\pi}{4} \left( e^a_i - B_{im} e^{ma} \right) m^i + e^{ja} \bar{m}_j \left( \frac{1}{\tau_2} \right) \left( e^a_i - B_{im} e^{ma} \right) m^i + e^{ja} \bar{m}_j$$

$$+ \frac{\pi}{2} \left( e^a_i - B_{im} e^{ma} \right) n^i + e^{ja} \bar{n}_j \left( \tau_1 \frac{1}{\tau_2} \right) \left( e^a_i - B_{im} e^{ma} \right) m^i + e^{ja} \bar{m}_j$$

$$24$$
\[-\frac{\pi}{4} \left( (e_i^a + B_{i} m^a\bar{m}) n^i - e^a_j \bar{n}_j \right) \left( \tau_2 + \frac{\tau_1}{\tau_2} \right) \left( (e_i^a + B_{i} m^a) n^i - e^a_j \bar{n}_j \right) \]
\[-\frac{\pi}{4} \left( (e_i^a + B_{i} m^a\bar{m}) m^i - e^a_j \bar{n}_j \right) \frac{1}{\tau_2} \left( (e_i^a + B_{i} m^a) m^i - e^a_j \bar{n}_j \right) \]
\[+ \frac{\pi}{2} \left( (e_i^a + B_{i} m^a\bar{m}) n^i - e^a_j \bar{n}_j \right) \tau_1 \frac{1}{\tau_2} \left( (e_i^a + B_{i} m^a) m^i - e^a_j \bar{n}_j \right) \]
\[+ i\pi \left( n^j \bar{m}_j - \bar{n}_k m^k \right) \] (5.5)

Similar to the one-loop case, for the case of vanishing $B$ field, the terms in $m$ and $\bar{m}$ do not mix, and we can perform independent Poisson resummations to obtain

\[Z_{cl.} = \sum_{n,\bar{n},w,\bar{w}} \exp \left[ -2\pi \left( G_{ij} (\bar{w}^i + \frac{1}{2} n^i) \tau_2 (\bar{w}^j + \frac{1}{2} n^j) + G_{ij} (w_i + \frac{1}{2} \bar{n}_i) \tau_2 (w_j + \frac{1}{2} \bar{n}_j) \right. \right. \]
\[\left. \left. + \frac{1}{4} \left( G_{ij} \bar{n}_i \tau_2 n^j + G_{ij} \bar{n}_i \tau_2 \bar{n}_j \right) \right) + 2\pi i \left( \bar{n}_k \tau_1 \bar{w}^k - n^k \tau_1 w_k \right) \right] \] (5.6)

This form is essentially the same as the one-loop case, and after factoring out the appropriate modes, we obtain the expected partition function. We now proceed to include the $B$ field. The modes in $m, \bar{m}$ are now mixed, but performing a Poisson resummation of $\bar{m}$, we obtain

\[Z_{cl.} = (\text{Det}(G))^{-g/2} (\text{Det}(\tau_2))^{d/2} \sum_{n,\bar{n},m,\bar{w}} \exp \left[ -\frac{\pi}{2} G_{ik} m^i \frac{1}{\tau_2} m^k + 2\pi i \left( B_{ik} \left( \bar{w}^k + D^k \right) - \frac{1}{2} \bar{n}_i \right) \right. \]
\[+ \left[ (e_i^- e_i^- + e_i^+ e_i^+) n^i + (e_i^k e_i^- - e_i^k e_i^+) \bar{n}_k \right] \tau_1 \frac{1}{4i \tau_2} \left. \right] m^i \]
\[\left. - 2\pi G_{ij} (\bar{w}^i + D^i) \tau_2 (\bar{w}^j + D^j) - \frac{\pi}{4} \left( e_i^- n^j + e^j \bar{n}_j \right) \left( \tau_2 + \frac{\tau_1}{\tau_2} \right) (e_i^- n^i + e^j \bar{n}_j) \right] \]
\[+ (e_i^+ n^i - e^j \bar{n}_j) \left( \tau_2 + \frac{\tau_1}{\tau_2} \right) (e_i^+ n^i - e^j \bar{n}_j) \] (5.7)

where we have defined

\[D^k = (G^{rk} \bar{n}_r - B_{rm} G^{mk} n^k) \frac{1}{2i \tau_2} \left( \tau_2 + \frac{\tau_1}{\tau_2} \right) + \frac{1}{2} n^k, \quad e_i^\pm = e_i \pm B_{ij} e^j \]

The term linear in $\bar{m}$ simplifies to read

\[K_i = B_{ik} \left( \bar{w}^k + \frac{1}{2} \bar{n}^k \right) - \frac{1}{2} \bar{n}_i + G_{ii} n^i \tau_1 \frac{1}{2i \tau_2} \]

After Poisson resumming $m \to w$, the instanton part of the partition function can be simplified to read

\[Z_{cl.} = (\text{Det}(\tau_2))^d \sum_{n,\bar{n},w,\bar{w}} \exp \left[ -2\pi G^{ik} (w_i + K_i) \tau_2 (w_k + K_k) - 2\pi G_{ij} (\bar{w}^j + D^j) \tau_2 (\bar{w}^j + D^j) \right] \]
\(-\frac{\pi}{4} \left( 2(n_a \left( \tau_2 + \frac{1}{\tau_2} \right) n^a + B_{am} \bar{G}^{mk} B_{bk} \bar{n}^a \left( \tau_2 + \frac{1}{\tau_2} \right) n^b \right) + 2\bar{n}^a \left( \tau_2 + \frac{1}{\tau_2} \right) \bar{n}_a \\
-4B_{im} \bar{G}^{mk} n^i \left( \tau_2 + \frac{1}{\tau_2} \right) \bar{n}_k \right) \] (5.8)

It is straightforward to verify that (5.8) can be massaged into the form (again, just like in (4.13), we suppress all indices to let the form of the expression be more revealing)

\[
Z_{cl.} = (\text{Det}(\tau_2))^d \sum_{n, \bar{n}, w, \bar{w}} \exp \left[ i\pi \left( \frac{1}{2} \left( (n + \bar{w} + B(n + \bar{w}) + w) \tau(n + \bar{w} + B(n + \bar{w}) + w) \right) + \frac{i\pi}{2} \left( (\bar{n} - w - B\bar{w} + \bar{w}) \tau(\bar{n} - w - B\bar{w} + \bar{w}) \right) \right. \\
- \frac{i\pi}{2} \left( (\bar{n} - w - B\bar{w} - \bar{w}) \tau(\bar{n} - w - B\bar{w} - \bar{w}) \right) \\
- \frac{i\pi}{2} \left( -(n + \bar{w}) + B(n + \bar{w}) + w) \tau(-(n + \bar{w}) + B(n + \bar{w}) + w) \right) \right] (5.9)
\]

We can identify all left- and right-moving momenta as

\[
p^{\alpha}_{La} = e^m_a \left( u^\alpha_m + B_{mk} u^{\alpha k} + G_{mk} u^{\alpha k} \right) \\
p^{\alpha}_{Ra} = e^m_a \left( v^\alpha_m - B_{mk} \bar{u}^{\alpha k} - G_{mk} \bar{u}^{\alpha k} \right) \\
q^{\alpha}_{La} = e^m_a \left( v^\alpha_m - B_{mk} \bar{w}^{\alpha k} + G_{mk} \bar{w}^{\alpha k} \right) \\
q^{\alpha}_{Ra} = e^m_a \left( w^\alpha_m + B_{mk} u^{\alpha k} - G_{mk} u^{\alpha k} \right) \] (5.10)

where we have restored all the indices. Factoring out \( p_R, q_L \), we obtain the correct partition function. Thus, we see from this section that the evaluation of the classical instanton contribution to the higher-genus partition function is rather straightforward when all the winding and momenta zero modes are defined with respect to the canonical basis of cycles of the Riemann surface.

In the bulk of our discussion in all previous sections, we have been mostly deriving the classical instanton part of the doubled partition function. In the next section, we shall discuss the contribution of the string oscillators to the doubled partition functions. For the general toroidal background and even on higher-genus worldsheets, we shall see that the quantum part factorizes into a product of holomorphic and anti-holomorphic functions. Imposing the constraint amounts to a neat removal of half of the holomorphic (and anti-holomorphic) functions, and thus we obtain the correct contribution to \( Z \). We shall also see in Section 7 that for the supersymmetric theory, this is the case for the fermions as well.
6 On the contributions of the quantum oscillators to the partition function

In this section, we fill up the gap in all the previous sections where the focus was exclusively on understanding how half of the classical instantons or zero modes are retained consistently, so that upon chiral factorization of the Hamiltonian representation of the partition function, we recover the correct partition function. A definitive statement on the consistency of such an approach should of course be accompanied by checking that the quantum part of the partition function - due to the oscillator modes - can be reduced appropriately by chiral factorization.

In the doubled formalism, we have emphasized that it is crucial that the Lagrangian can be written as a sum of doubled sets of kinetic terms of $P$ and $Q$. We have seen explicitly that this is true for the $\mathcal{N} = 1$ worldsheet and for the general toroidal background. Chiral factorization means that we keep the holomorphic part of $P$ and the anti-holomorphic part of $Q$. This can be done straightforwardly if the quantum part of the partition function contains $|F(\tau)|^2$ for some complex function $F(\tau)$.

Nonetheless there is a rather important subtlety that arises when we think about higher-genus string worldsheets that is not so apparent from a one-loop computation. For each classical instanton sector, recall that after a Poisson resummation, we obtain some prefactors containing the determinants of the target space metric tensor and the imaginary part of the worldsheet’s complex structure. Explicitly,

$$Z_{cl.} = (\text{Det}(\tau_2))^{\frac{d}{2}} (\text{Det}(G))^{-\frac{d}{2}} \sum_{p_L,p_R} \exp \left[ \frac{i\pi}{2} (p_L)_\alpha \tau_{\alpha\beta} (p_L)_\beta - \frac{i\pi}{2} (p_R)_\alpha \bar{\tau}_{\alpha\beta} (p_R)_\beta \right]$$ (6.1)

On the other hand, the quantum part of the partition function that takes into account the oscillator modes reads

$$Z_q. = \frac{\sqrt{\text{Det}(G)}}{(\text{Det}(\tau_2))^{\frac{d}{2}} |\eta_\phi|^2}$$ (6.2)

where $\eta_\phi$ is an appropriate generalization of the eta-function that comes from computing the determinant of the scalar Laplacian on higher-genus surfaces. We note that the factor of $\sqrt{\text{Det}(G)}$ originates from the zero mode of $X^\mu$ and measures the volume of the target space. Taking the product of $Z_{cl.}$ and $Z_q.$, we see that while $\text{Det}(\tau_2)$ cancels away, there is a remnant factor of $(\text{Det}(G))^{(1-g)/2}$. This factor implies that on its own, the partition function is not T-duality invariant. As is well-known, this factor of $\text{Det}(G)$ precisely matches the T-duality covariance of the dilaton. Recall that the complete closed string partition function is a sum over all genus. Schematically, we can write

$$Z_{\text{string}} = \sum_{g=0}^{\infty} e^{(1-g)\Phi} Z_g$$ (6.3)
where $Z_g$ is $Z_{cl.} Z_q$, at each genus $g$. Under T-duality, the dilaton transforms such that the following quantity is a T-duality invariant.

$$\Phi + \log \sqrt{\text{Det} \ G}$$  \hspace{1cm} (6.4)

Thus, we see that at each genus, T-duality is a symmetry. In the doubled formalism, we have seen that in computing $Z_{cl.}$, the factor of $\text{Det}(G)$ cancels away and is absent after Poisson resumming the winding modes along the Euclidean time direction. (Note that we still have the factor of $(\text{Det}(\tau_2))^d$. ) On the other hand, for the quantum part, since the metric $G$ is just $1/2 \times 1_{2d \times 2d}$, we retrieve a factor of some power of 2 which cancels away an identical factor in $Z_{cl.}$. This leaves us simply with the function $|\eta_g|^2$ in the denominator and the sum of all left and right-moving momenta. We thus observe that there is no dependence on $\text{Det}(G)$. This point suggests that in the doubled formalism, the scalar field that plays the role of the dilaton should be invariant under T-duality.

Indeed, as was explained in [1], this is the case. In the doubled theory, the parent T-duality invariant dilaton field $\phi$ presents itself in a Fradkin-Tseytlin term that reads

$$S_{FT} = \int d^2 \sigma \sqrt{h} \phi R.$$  \hspace{1cm} (6.5)

where $R$ is the worldsheet’s Ricci scalar. The relation to the usual dilaton field that transforms under (6.4) is manifest after integrating over the auxiliary fields as contained in the term $1/4 G^{ij} D_i \wedge * D_j$. This yields a determinant which replaces the $\phi$-term in (6.5) with $\Phi = \phi - \frac{1}{2} \log(\text{Det}(G_{ij})).$  \hspace{1cm} (6.6)

T-duality transformation rule allows us to identify $\Phi$ as the dilaton field. To relate this fact to our calculations, we note that integrating out the auxiliary fields in the Lagrangian picture, the spectrum of the theory is what we should obtain after performing the chiral factorization. In the latter procedure, within the framework that we considered, there is no principle that dictates us to put in a factor of $(\text{Det}(G))^{-g/2}$ in $Z_q$. after imposing the constraint. Although the final result is consistent with a T-duality invariant $\phi$, it would be important to develop a thorough understanding of how the chiral factorization procedure applies to $\phi$. It was mentioned in [1] that the expectation value of $e^{-\phi}$ is the string field theory coupling constant of [1]. It appears that a more complete and natural language for the higher-genus worldsheet theory lies in string fields [33, 34]. Our results only demonstrates consistency for the theory as a perturbation series in the expectation value of $\phi$.

Finally, before we proceed to the next section, let us briefly describe $|\eta_g|$ that we alluded to in (6.2). We simply wish to point out that it is of the form $|F(\tau)|$ as this is necessary for chiral factorization to work. We leave pedagogical details to [35] since we will not need them and they are established results. Let us first write the one-loop result in a
slightly different form. For a flat torus with metric 
\[ ds^2 = -\frac{|dw|^2}{\tau_2}, \nabla^2(\tau) = -\tau_2 \frac{\partial^2}{\partial z \partial \bar{z}}. \]
After excluding the zero eigenvalues, and using zeta function regularization, we can write
\[
\text{Det}' (\nabla^2) = 4\tau_2 |\eta(\tau)|^4 = 4\tau_2 e^{-\frac{S(\tau)}{12\pi}} \prod_{m=1}^{\infty} |1 - q^m|^4 \tag{6.7}
\]
where
\[
S(\tau) = \frac{i}{2} \int \int_D \frac{\left| \partial \log \rho \right|^2}{\partial w} \, dw d\bar{w} = 4\pi^2 \tau_2, \quad \rho(w) = \frac{1}{4\pi^2 \tau_2 |w|^2}, \quad D = \{ w \in \mathbb{C} : |q| < |w| \leq 1 \} \tag{6.8}
\]
This is motivated by describing the torus as the Schottky uniformization of the elliptic curve \( \Gamma \setminus \mathbb{C} \) where \( \Gamma \) is the cycle group generated by the dilation \( w \to qw \), with \( D \) as the fundamental region, and \( w = e^{2\pi z} \), with the metric \( ds^2 = \rho(w)|dw|^2 \). The function \( S(\tau) \) is known as the classical Liouville action defined on the Schottky space that we just described. We can now write down the higher-genus generalization straightforwardly. Following [35], the determinant of the scalar Laplacian on the higher genus surface can be written as
\[
\text{Det}' \nabla^2 = (\text{Det} \tau_2) \exp \left( -\frac{S}{12\pi} \right) |F|^2, \quad F = \prod_{\{ \gamma \}} \prod_{m=0}^{\infty} (1 - q_\gamma^{1+m}) \tag{6.9}
\]
where \( q_\gamma \) is the multiplier of \( \gamma \in \Gamma \) and \( \gamma \) runs over all distinct primitive conjugacy classes in \( \Gamma \) excluding the identity, and \( S \) is the classical Liouville action defined on the higher-genus Schottky space (for the torus, \( S = -\pi \log |q|^2 \)). In the context of chiral factorization, imposing the constraint is effectively equivalent to taking the square root of the determinant, retaining the factors \( e^{-\frac{S}{24\pi} F(\tau)} \) and \( e^{-\frac{S}{24\pi} F(\tau)} \) for the oscillator contributions of the holomorphic \( P \) and anti-holomorphic \( Q \) respectively.

7 \( \mathcal{N} = 1 \) Worldsheet Supersymmetry

Let us attempt to generalize our results to the doubled formalism with supersymmetry. We first briefly review some basic aspects of the supersymmetric doubled sigma model following [1]. The \( \mathcal{N} = 1 \) generalization of the ordinary sigma model in \((1,1)\) superspace reads [36]
\[
S = \int d^2\sigma d^2\theta (G_{\mu\nu} C^{rs} + B_{\mu\nu} \gamma^{rs}) D_r \Phi^\mu D_s \Phi^\nu \tag{7.1}
\]
where \( \Phi^\mu(\sigma, \theta) \) is a superfield on the superspace worldsheet with coordinates \( \sigma^\alpha, \theta^r \), the latter being real anti-commuting coordinates that transform as a worldsheet spinor, \( r = 1, 2 \) and \( D_r \) are the supercovariant derivatives. We work with Majorana spinors, with \( \theta_{\alpha}, \alpha = 1, 2 \) parametrizing the \( \mathcal{N} = 1 \) worldsheet supersymmetry. We choose our Dirac matrices to be
\[
\rho^0 = \sigma_2, \rho^1 = i\sigma_1, \rho^2 = \sigma_3 \tag{7.2}
\]
where \( \sigma_i \) are the Pauli matrices and \( \bar{\theta}_\alpha = \theta_\beta \rho^0_{\beta \alpha} \), and our superfields and their covariant derivatives read

\[
X^I = X^I + \bar{\theta} \psi^I + \frac{1}{2} \bar{\theta} \theta f^I, \\
D_\alpha X^I = \psi^I_\alpha + \theta_\alpha f^I - i(\rho^m \theta)_\alpha \partial_m X^I + \frac{i}{2} \partial_m (\rho^m \psi_I)_\alpha \bar{\theta}.
\]  

(7.3)

Also, \( C \) is the charge conjugation matrix, and \( \rho_2 \) the chirality operator satisfying

\[
C^{rs} = \epsilon^{rs}, \quad \gamma = C \rho_2.
\]

Correspondingly, the action of the supersymmetric doubled sigma model reads

\[
S = \frac{1}{2} \int d^2 \sigma d^2 \theta \frac{1}{4} H_{IJ} C^{rs} [D_r X^I + A^I_m D_r Y^m] [D_s X^J + A^J_n D_s Y^n] \\
- \frac{1}{2} \gamma^{rs} L_{IJ} [D_r X^I + A^I_m D_r Y^m] A^J_n + \mathcal{L}(Y).
\]  

(7.4)

As in the bosonic case, we need to augment it with an appropriately supersymmetrized
topological term which reads

\[
\mathcal{L}_{top.} = \frac{1}{2} \gamma^{rs} \Omega_{IJ} D_r X^I D_s X^J
\]

(7.5)

whereas the constraint is supersymmetrized to be

\[
[D_s X^I + A^I_m D_s Y^m] = S (\gamma_3)_{sr} [D_r X^J + A^J_n D_r Y^n]
\]  

(7.6)

Below we shall restrict ourselves to the case where the source terms \( A \) vanish. After
expanding each superfield in its constituents and keeping only terms in \( \bar{\theta} \theta \) since
\( \int d^2 \theta (\bar{\theta} \theta) = 1 \), we find

\[
\mathcal{L} = H_{IJ} \left( \partial^a X^I \partial_a X^J + iv^J \rho^m \partial_m \psi^J + f^I f^J \right) \\
+ i \pi \Omega_{IJ} \left[ \partial_t X^I \partial_\sigma X^J + i \psi^J_2 (\partial_t - \partial_\sigma) \psi^J_2 + i \psi^J_1 (\partial_t + \partial_\sigma) \psi^J_1 \right]
\]

(7.7)

We note that since \( \Omega \) is anti-symmetric, the fermionic bilinear terms are total derivatives.
They do not contribute to the classical instanton sector of the partition function. On-shell, the auxiliary fields \( f \) vanish (in general, this is not true when we consider fibrations
with generic \( O(d, d; \mathbb{Z}) \) transition functions), and the real fermions satisfy the equations
of motion

\[
(\partial_t - \partial_\sigma) \psi_2 = 0, \quad (\partial_t + \partial_\sigma) \psi_1 = 0
\]  

(7.8)

We observe from (7.7) that the topological term contains fermionic bilinears which are
total derivatives. We should of course check the constraint terms too to ensure that the
bosonic contraints are recovered. Indeed they are, and we also have similar constraints
for the fermions which read

\[
\psi_1^I = -S^I_f \psi_1^f, \quad \psi_2^I = S^I_f \psi_2^f
\]

(7.9)

\^There is also another constraint that arises from the quadratic \( \theta \) term which we find to be equivalent
to the fermion’s equation of motion in (7.8).
Recall that when we compute the partition function in earlier sections, the fact that we are able to express the non-topological part of the Lagrangian as a sum of two kinetic terms (for $P$ and $Q$) is crucial in arguing that the quantum fluctuations that arise from the oscillators admit a chiral factorization, and that we can effectively take the square root of this portion of the doubled partition function. With the fermions, we can do likewise. For each of $\psi_{1,2}$, we find that if we define

$$\varphi^a = (e^a_i + B_{ij}e^j_i) \psi^i + e^j_i \bar{\psi}_j,$$
$$\eta^a = (e^a_i - B_{ij}e^j_i) \psi^i - e^j_i \bar{\psi}_j,$$

then in these variables, the constraints translates into simply $\varphi^a_1 = \eta^a_2 = 0$. Note that just like their bosonic counterparts, these fields are valued in the tangent space indices. Formally, this projection into half the degrees of freedom is an endomorphism of the target tangent bundle. The fermionic part of the Lagrangian can now be simply expressed as

$$L_{\text{fermions}} = \frac{1}{2} \varphi^a_2 \partial_z \varphi^a_2 + \frac{1}{2} \varphi^a_1 \partial_{\bar{z}} \varphi^a_1 + \frac{1}{2} \eta^a_2 \partial_z \eta^a_2 + \frac{1}{2} \eta^a_1 \partial_{\bar{z}} \eta^a_1$$

(7.11)

Like the bosonic fields, the fact that within the Lagrangian, the fermionic fields can be expressed as a sum of kinetic terms is crucial for establishing the equivalence of the doubled sigma model with the ordinary one. Even though the fermionic terms do not contribute to the classical instanton part, the quantum part can be written as

$$\sqrt{\text{Det} \nabla^2} = (\text{Det} \partial_z)(\text{Det} \partial_{\bar{z}})$$

For the fermions, imposing the constraint after evaluating the full partition function is even a simpler process. Since $\varphi^a_1, \eta^a_2$ are set to vanish, what is left is half of the doubled contribution.

8 Conclusion

In this work, we have demonstrated that the ordinary closed string partition function in a general toroidal compactification, including their shift orbifolds, can be reproduced by interpreting the constraint equation in Hull’s doubled geometry formalism as that of chiral scalars. This furnishes a non-trivial consistency check for the quantum equivalence to the ordinary theory\cite{31} and demonstrates that the result of \cite{21} does generalize nicely to more generic string backgrounds. Moreover, we presented explicit computations showing that this equivalence holds tight at all higher worldsheet genus, and also for the case of $\mathcal{N} = 1$ worldsheet supersymmetry.

The partition function at a fixed toroidal metric can be decomposed into a part that sums up the string’s zero modes and a part that takes into account the quantum fluctuations of the oscillators. For the instanton part, the topological term in the doubled

\footnote{See also \cite{37} for another crucial quantum check of the doubled sigma model.}
sigma model plays a crucial role in ensuring that chiral factorization can allow us to consistently reduce the doubled partition function to the corresponding instanton sums in the conventional string theories, after a relabelling of winding numbers. This term contributes certain relative signs in the instanton sum, and as explained in [1], it is needed to completely gauge away the auxiliary degrees of freedom. For the quantum part, the consistency of the chiral factorization procedure relies on a couple of prerequisites. Firstly the Lagrangian can be written in a form manifestly independent of the target space metric in terms of the new chiral variables, and secondly that it contains the sum of these variables’ kinetic terms. We illustrated clearly that this can be done for the general toroidal background and for fermions when the worldsheet is endowed with $\mathcal{N} = 1$ supersymmetry.

We have also shown that the interpretation of the constraint equations as that of chiral scalars works for string worldsheets of higher genus. Comparing the instanton sum to the ordinary case, we find that it differs from the latter by being independent of the determinant of the target space metric. This in turn implies that it is only consistent with an accompanying dilaton field $\phi$ that is T-duality invariant. Indeed, this is the case as was explained in [1] and [21]. However, our technique does not empower us to understand how to impose the constraint on the dilaton $\phi$. In [1], it was shown that when the auxiliary degrees of freedom are integrated away, the dilaton $\phi$ can be related to the ordinary dilaton field with the correct T-duality transformation rules. We do not know how or whether the principle of chiral factorization can allow us to derive this relationship. At this level of our approach, we can at best make a statement on the consistency of the doubled formalism as a perturbation series in $\phi$. At genus one, this problem is not as apparent since the instanton sum is manifestly T-duality invariant.

Indeed, as much as we have demonstrated the consistency of interpreting the constraints as that arising from chiral scalars, we have also learnt to be aware of the limitations of such an approach. Apart from the point about $\phi$ for the higher-genus worldsheets, we also found that the doubled formalism does not seem to ‘geometrize’ asymmetric orbifold action. In our exploration of $\mathbb{Z}_N$ shift orbifolds, chiral factorization reproduces the expected partition function when the shift is geometric and thus acts symmetrically on the left and right-movers. For asymmetric shifts, we find that we need additional pairing phase factors identical to the ordinary case. These factors do not have a clear origin in the Lagrangian picture, but after Poisson resumming to be in the Hamiltonian picture, they arise naturally when we compute the insertion of the translation operator. Although we have demonstrated that we still recover the expected result, it would be nice if these phase factors arise from a geometrical origin in the doubled sigma model. One of the main purpose of the doubled formalism is to furnish a framework for T-folds. This generically involves asymmetric orbifolds when the T-duality is a symmetry of the background’s moduli space. It is known that modular invariance imposes conditions on the allowed asymmetric orbifold action, and more generally for T-folds, the legitimate $O(d, d; \mathbb{Z})$ valued transition functions of the torus fibration. The simplest T-fold which
involves an asymmetric $\mathbb{Z}_2$ reflection on $S^1$ target space was previously investigated in [23], where it was found that to construct a modular-invariant partition function, we need to impose the values of the eigenvalues of the T-duality operator (in the higher-dimensional case, this corresponds to the $O(d, d; \mathbb{Z})$ element that inverts all the circles’ radii). These conditions were taken from the beautiful work of [24] but we think that it would be very interesting to see them arising naturally from the doubled formalism. Our result for the $\mathbb{Z}_N$ shift orbifolds suggest that a supplementary analysis in the operator formalism as, for example, undertaken in [23] is necessary to develop a deeper understanding of modular invariance when asymmetric orbifold action is involved.

Throughout our work, we have appeared to be able to demonstrate the principle of chiral factorization rather smoothly to the general toroidal background and on higher-genus worldsheets. That this procedure falls into place so delicately is related to the underlying fact that in the doubled sigma model, $X$ and $\tilde{X}$ represent the Fourier transform duals of the momentum and winding numbers. A natural future work would be to consider T-folds with non-trivial T-duality transition functions. Will the principle of chiral block decomposition continue to play some role in these non-geometric backgrounds? In general, quantization of chiral scalars contains many subtleties (see [38] for an elucidating discussion) and a more thorough analysis is warranted. We hope to report our progress in these directions in the near future [28].

Acknowledgments

It is a pleasure to thank David Berman for correspondence on his work in [21] and for reminding me about Witten’s work in [38]. I am grateful to Jan de Boer, Ori Ganor, and Masaki Shigemori for inspirations on various topics related to duality twists and non-geometric backgrounds. I acknowledge support from the Foundation for Fundamental Research on Matter (FOM) which is part of the Netherlands Organization for Scientific Research.
