Abstract

We consider a deformation of the BF theory in any dimension by means of the antifield BRST formalism. Possible consistent interaction terms for the action and the gauge symmetries are analyzed and we find a new class of topological gauge theories. Deformations of the world volume BF theory are considered as possible deformations of the topological open membrane. Therefore if we consider these theories on open membranes, we obtain noncommutative structures of the boundaries of open membranes, and we propose a generalization of the path integral representation of the star deformation.

1 Introduction

Kontsevich has given a general formula for the deformation quantization \[1\] of functions on the Poisson manifold in the paper \[2\]. Cattaneo and Felder \[3\] have obtained the path integral representation of that formula on the Poisson manifold as a perturbative expansion of a two-dimensional field theory on two-dimensional disk. The star product structure in the open string theory with non-zero background Neveu-Schwarz B-field appears essentially at the same mechanism \[4\].

The world sheet field theory in the paper \[3\] is called a nonlinear gauge theory or the Poisson sigma model in two-dimension \[5\][6]. It is one of Schwarz type (or BF type) topological field theory \[7\] and has the gauge symmetry, which is a generalization of the usual nonabelian gauge symmetry.

Izawa \[8\] has recently analyzed the nonlinear gauge theory from the viewpoint of a deformation of the gauge symmetry \[9\]. He has found that two-dimensional nonlinear gauge theory is the unique consistent deformation of two-dimensional abelian BF theory. The author has made the similar analysis in three dimension \[10\] † He has considered the abelian BF theory in three dimension and all their possible deformations which action has the ghost number zero, and has found the new topological gauge theory. In this paper, we make a similar analysis in any dimension. We consider the abelian BF theory and analyze all deformations by the antifield BRST formalism.

We consider the two-dimensional theory as a survey of our story. First we consider the following action of the abelian BF theory in two dimension:

\[
S_0 = \int \mathcal{L}_0, \quad \mathcal{L}_0 = B_a d\phi^a, \tag{1}
\]

where \(a, b, \text{ etc.} \) are Lie algebra indices (or the target space indices). \(\phi^a\) is a scalar field, \(B_a\) is a one-form gauge field. This theory has the following abelian gauge symmetry:

\[
\delta_0 B_a = d\epsilon_a, \quad \delta_0 \phi^a = 0. \tag{2}
\]

Of course, the commutation relation on the scalar field \(\phi\) is \([\phi^a, \phi^b] = 0\) and correlation functions of arbitrary functions of \(\phi\) are simply products of one-point functions.

†A deformation of the BF theories has analyzed in a special case by Dayi \[11\].
Here we find all the consistent interactions with the free action (2) up to field redefinition as a local field theory in two dimension with the aid of Barnich-Henneaux method in terms of the BRST cohomology based on the antifield (Batalin-Vilkovisky) formalism. We use the BRST formalism to deform the world sheet theory, in order to realize the “physical requirement”. In the papers [9], they have required locality, unitarity and gauge invariance of the deformed action and have given a method to analyze the BRST cohomology and obtained all deformations of the gauge theory.

The answer in two dimension is

\[ S = \int \mathcal{L}, \quad \mathcal{L} = B_a d\phi^a + \frac{1}{2} W^{ab} B_a B_b, \quad (3) \]

under the assumption that the ghost number of the action is zero, where \( W^{ab}(\phi) = -W^{ba}(\phi) \) is an arbitrary function of \( \phi^a \) [8]. The gauge symmetry is deformed to the nonlinear gauge symmetry:

\[ \delta_{NL} B_a = d\epsilon_a + \frac{\partial W^{bc}}{\partial \phi^a} B_b \epsilon_c, \quad \delta_{NL} \phi^a = W^{ba} \epsilon_b, \quad (4) \]

where \( W^{ab}(\phi) \) must satisfy the following identities:

\[ \frac{\partial W^{ab}}{\partial \phi^d} W^{cd} + \frac{\partial W^{bc}}{\partial \phi^d} W^{ad} + \frac{\partial W^{ca}}{\partial \phi^d} W^{bd} = 0, \quad (5) \]

in order for (4) to be a symmetry of the theory. This Eq.(4) is just the Jacobi identity if the following commutation relation holds:

\[ [\phi^a, \phi^b] = W^{ab}(\phi). \quad (6) \]

The commutation relation on the left hand side is realized as the Poisson bracket of the coordinates \( \phi^a \) and \( \phi^b \) on the Poisson manifold [6]. If we consider the theory on the two-dimensional disk, the correlation functions at the boundary of the disk of arbitrary functions of \( \phi \) are deformed to the star product \( F * G \) under the appropriate regularization and the appropriate boundary condition [3].

Recently, noncommutative geometry are widely used to analyze the string theory. If we consider the open string theory with the constant background NS B-field, the noncommutative geometry appears on the D-brane [4]. The generalization of the star product to the
nonconstant B-field has been analyzed in [12]. Some authors have analyzed generalizations of this theory to the higher dimension. Noncommutative geometry appears at the boundary of open 2-brane in M-theory [13] [14] [15]. In this paper, we propose one approach to analyze them. We consider that deformations of the world volume BF theory lead us to deformations of the boundaries of the topological open $n - 1$-brane, where $n - 1$ is the space dimension of the membrane. In fact, the star deformation formula is derived from the deformation of two-dimensional BF theory as the world sheet theory.

Deformations of the topological open string have been analyzed in [21]. Deformations of the topological open membrane in three dimension have been analyzed in [22] [23]. We will obtain a generalization of the path integral representation of the star deformation formula. However analysis of deformations of the BF theories are not still completed. In this paper, we analyze deformations of the BF theory.

This paper is organized as follows. In section 2, we construct the superfield antifield formalism of the abelian BF theory. In section 3, we analyze deformations of the abelian BF theory and obtain all possible deformations. In section 4, we consider two examples of our theory in the lower dimensions. In section 5, we consider the quantum BV formalism and quantize the theory. In section 6, we analyze the topological membrane action. Section 7 is conclusion and discussion.

2 The Superfield Formalism for the Batalin-Vilkovisky Action of the Abelian BF Theory

First, we consider the following $n$-dimensional abelian BF theory:

$$S_0 = \sum_{p=0}^{[\frac{n-1}{2}]} \int_{\Sigma} (-1)^{n-p} B_{n-p-1} \, dA_p^a,$$

where $A_p^a$ is a p-form gauge field and $B_{n-p-1}^a$ is a $n - p - 1$ form auxiliary fields. Indices $a, b, c$, etc. represent algebra indices. $\Sigma$ is a base manifold on which the theory is defined. The sign factors $(-1)^{n-p}$ are introduced for convenience. This action has the following abelian gauge symmetry:

$$\delta_0 A_p^a = d\epsilon_{p-1}^{(p)a},$$
\[ \delta_0 B_{n-p-1\ a} = dt_{n-p-2\ a}, \]  

where \( c^{(p)a}_{p-1} \) is a \( p-1 \)-form gauge parameter and \( t^{(n-p-1)}_{n-p-2\ a} \) is a \( n-p-2 \)-form gauge parameter. (p) in \( c^{(p)a}_{p-1} \) and \((n-p-1)\) in \( t^{(n-p-1)}_{n-p-2\ a} \) represent that \( c^{(p)a}_{p-1} \) is a gauge parameter for \( p \)-form \( A^a_{\ p} \) and \( t^{(n-p-1)}_{n-p-2\ a} \) is one for \( n-p-1 \)-form \( B_{n-p-1\ a} \), respectively. This gauge symmetry is reducible. Since \( A^a_{\ p} \) is a \( p \)-form and \( B_{n-p-1\ a} \) is a \( n-p-1 \)-form, we need the following towers of the 'ghost for ghosts' to analyze the complete gauge degrees of freedom:

\[
\begin{align*}
\delta_0 A^a_{\ p} &= dc^{(p)a}_{p-1}, \\
\delta_0 t^{(n-p-1)}_{n-p-2\ a} &= dt^{(n-p-1)}_{n-p-2\ a}, \\
\delta_0 t^{(p)a}_{p-2\ a} &= dt^{(p)a}_{p-2\ a}, \\
\delta_0 t^{(n-p-1)}_{n-p-3\ a} &= dt^{(n-p-1)}_{n-p-3\ a}, \\
\vdots \\
\delta_0 t^{(p)a}_{1\ a} &= dt^{(p)a}_{1\ a}, \\
\delta_0 t^{(n-p-1)}_0 &= dt^{(n-p-1)}_0, \\
\delta_0 c^{(p)a}_0 &= 0, \\
\delta_0 t^{(n-p-1)}_0 &= 0,
\end{align*}
\]  

where \( c^{(p)a}_i \) are \( i \)-form gauge parameters and \( t^{(n-p-1)}_j \) are \( j \)-form gauge parameters. \( i = 0, \cdots, p-1 \) and \( j = 0, \cdots, n-p-2 \).

We write the theory by the antifield BRST formalism. First we take \( c^{(p)a}_i \) to be the FP ghosts \( i \)-form with ghost number \( p-i \), and \( t^{(n-p-1)}_j \) to be a \( j \)-form with the ghost number \( n-p-1-j \). As usual, if the ghost number is odd, the fields are Grassmann odd, and if ghost number even, they are Grassmann even.

Next we introduce the antifields for all the fields. Let \( \Phi^+ \) denote the antifields for the field \( \Phi \). Note that the relations \( \text{deg}(\Phi) + \text{deg}(\Phi^+) = n \) and \( \text{gh}(\Phi) + \text{gh}(\Phi^+) = -1 \) are required, where \( \text{deg}(\Phi) \) and \( \text{deg}(\Phi^+) \) are the form degrees of the fields \( \Phi \) and \( \Phi^+ \) and \( \text{gh}(\Phi) \) and \( \text{gh}(\Phi^+) \) are the ghost numbers of them. For \( A^a_{\ p} \), we introduce the antifield \( A^{+ \ (p)}_{n-p\ a} \), which is \( n-p \)-form with the ghost number \(-1\). For \( B_{n-p-1\ a}, B^{+ \ (n-p-1)\ a} \), which is \( p+1 \)-form with the ghost number \(-1\). For \( c^{(p)a}_i, c^{\ (p)\ a}_{n-i} \), which is \( n-i \)-form with the ghost number \(-p-1+i\). For \( t^{(n-p-1)}_j, t^{+ \ (n-p-1)\ a}_n \), which is \( n-j \)-form with the ghost number \(-n+p+j\).

For functions \( F(\Phi, \Phi^+) \) and \( G(\Phi, \Phi^+) \) of the fields and the antifields, we define the antibracket as follows:

\[
(F, G) \equiv \frac{\partial F}{\partial \Phi} \frac{\partial G}{\partial \Phi^+} - (-1)^{\text{deg} \Phi} \frac{\partial F}{\partial \Phi^+} \frac{\partial G}{\partial \Phi},
\]  

(10)
where $\frac{\partial}{\partial \varphi}$ and $\frac{\partial}{\partial \varphi}$ are the right differentiation and the left differentiation with respect to $\varphi$, respectively. The following identity about left and right derivative is useful:

$$\frac{\partial F}{\partial \varphi} = (-1)^{(ghF-gh\varphi)+(\deg F-\deg \varphi)} \frac{\partial \Phi}{\partial \Phi}.$$

If $S, T$ are two functionals, the antibracket is defined as follows:

$$(S, T) \equiv \int_\Sigma \left( S \frac{\partial}{\partial \Phi} \frac{\partial}{\partial \Phi^+} - (-1)^{(n+1)} S \frac{\partial}{\partial \Phi} \frac{\partial}{\partial \Phi^+} T \right).$$

The antibracket satisfies the following identities:

$$(F, G) = (-1)^{(\deg F-n)(\deg G-n)+(ghF+1)(ghG+1)} (G, F),$$

$$(F, GH) = (F, G)H + (-1)^{(\deg F-n) \deg G+(ghF+1)ghG} G(F, H),$$

$$(FG, H) = F(G, H) + (-1)^{\deg G(\deg H-n)+ghG(ghH+1)} (F, H)G,$$

$$( -1)^{(\deg F-n)(\deg H-n)+(ghF+1)(ghH+1)} (F, (G, H)) + \text{cyclic permutations} = 0,$$

where $F, G$ and $H$ are functions on fields and antifields.

In order to simplify notations and calculations, we rewrite notations by the superfield formalism. We combine the field, its antifield and their gauge descendant fields as superfield components. For $A^a_p$ and $B^{n-p-1}a$, we define corresponding superfields as follows:

$$A^a_p = c^a_0 + c^a_1 + \cdots + c^a_{p-1} + A^a_p + B^{+(n-p-1)a}_{p+1} + t^{+(n-p-1)a}_{p+2} + \cdots + t^{+(n-p-1)a}_n,$$

$$B^{n-p-1}a = t^{(n-p-1)0}_a + t^{(n-p-1)1}_a + \cdots + t^{(n-p-1)n-1}_a + B^{n-p-1}a + A^{+(p)}_{n-p} a + \cdots + c^{+(p)}_{n-1} a + c^{+(p)}_{n} a.$$

Then we define the total degree $|F| \equiv ghF + \deg F$. The component fields in a superfield have the same total degree. The total degrees of $A^a_p$ and $B^{n-p-1}a$ are $p$ and $n-p-1$, respectively.

We take a notation $\cdot$ as the *dot product* among superfields in order to simplify the sign factors. The definitions and properties of the *dot product* are in the appendix. The *dot antibracket* of the superfields $F$ and $G$ is defined as

$$(F, G) \equiv (-1)^{(ghF+1)(deg G-n)} (-1)^{gh\Phi(deg \Phi-n)+n} (F, G),$$

5
Then the following identities are obtained from the equations (13) and (15):

\[(F, G) = -(-1)^{|F|+1-n}|G|+1-n)(G, F),\]

\[(F, GH) = (F, G) \cdot H + (-1)^{|F|+1-n}|G| \cdot (F, H),\]

\[(FG, H) = F \cdot (G, H) + (-1)^{|G|+1-n}(F, H) \cdot G,\]

\[-(-1)^{|F|+1-n}|H|+1-n)(F, (G, H)) + \text{cyclic permutations} = 0.\]

(16)

We define the dot differential as

\[\frac{\partial}{\partial \varphi} \cdot F \equiv (-1)^{gh\varphi \deg F} \frac{\partial F}{\partial \varphi},\]

\[F \cdot \frac{\partial}{\partial \varphi} \equiv (-1)^{ghF \deg \varphi} F \frac{\partial}{\partial \varphi}.\]

(17)

Then, from the equation (11), we can obtain the formula

\[\frac{\partial}{\partial \varphi} \cdot F = (-1)^{|F|+|\varphi|} F \cdot \frac{\partial}{\partial \varphi}.\]

(18)

Since \(A_p^a\) and \(B_{n-p-1} a\) are the field-antifield pair, we can rewrite the BV antibracket on two superfields \(F\) and \(G\) from (10) and (13) as follows:

\[\langle (F, G) \rangle \equiv \sum_{p=0}^{[n-1]} F \cdot \frac{\partial}{\partial A_p^a} \cdot \frac{\partial}{\partial B_{n-p-1} a} \cdot G - (-1)^{np} F \cdot \frac{\partial}{\partial B_{n-p-1} a} \cdot \frac{\partial}{\partial A_p^a} \cdot G.\]

(19)

We can construct the Batalin-Vilkovisky action for the abelian BF theory by the superfields as follows:

\[S_0 = \sum_{p=0}^{[n-1]} \int_\Sigma (-1)^{n-p} B_{n-p-1} a \cdot dA_p^a,\]

(20)

where we integrate only \(n\)-form part of the integrand. If we set all the antifields zero, (20) reduces to (7). The BRST transformation for the superfield \(F\) under the action above is defined as

\[\delta_0 F = (S_0, F) = \sum_{p=0}^{[n-1]} S_0 \cdot \frac{\partial}{\partial A_p^a} \cdot \frac{\partial}{\partial B_{n-p-1} a} \cdot F - (-1)^{np} S_0 \cdot \frac{\partial}{\partial B_{n-p-1} a} \cdot \frac{\partial}{\partial A_p^a} \cdot F,\]

(21)
Hence the BRST transformations on $A^a_p$ and $B_{n-p-1}^a$ are obtained as follows:

\[
\delta_0 A^a_p = \left( S_0, A^a_p \right) = (-1)^{n-p} \frac{\partial}{\partial B_{n-p-1}^a} \cdot S_0 = dA^a_p,
\]

\[
\delta_0 B_{n-p-1}^a = \left( S_0, B_{n-p-1}^a \right) = (-1)^{p(n-p)} \frac{\partial}{\partial A^a_p} \cdot S_0 = dB_{n-p-1}^a.
\]

If we expand the BRST transformations (22) above to the components by (14), we can obtain the BRST transformation on each field and antifield as follows:

\[
\delta_0 c_0^{(p)a} = 0,
\]

\[
\delta_0 c_1^{(p)a} = dc_0^{(p)a},
\]

\[
\vdots
\]

\[
\delta_0 c_{p-1}^{(p)a} = dc_{p-2}^{(p)a},
\]

\[
\delta_0 A_p^a = dc_{p-1}^{(p)a},
\]

\[
\delta_0 B_{p+1}^{+(n-p-1)a} = dA_p^a,
\]

\[
\delta_0 t_{p+2}^{+(n-p-1)a} = dB_{p+1}^{+(n-p-1)a},
\]

\[
\delta_0 t_{p+3}^{+(n-p-1)a} = dt_{p+2}^{+(n-p-1)a},
\]

\[
\vdots
\]

\[
\delta_0 t_{n}^{+(n-p-1)a} = dt_{n-1}^{+(n-p-1)a},
\]

\[
\delta_0 t_0^{(n-p-1)} = 0,
\]

\[
\delta_0 t_1^{(n-p-1)} = dt_0^{(n-p-1)},
\]

\[
\vdots
\]

\[
\delta_0 t_{n-p-2}^{(n-p-1)} = dt_{n-p-3}^{(n-p-1)},
\]

\[
\delta_0 B_{n-p-1} = dt_{n-p-2}^{(n-p-1)},
\]

\[
\delta_0 A_{n-p}^{+(p)} = dB_{n-p-1}^{a},
\]

\[
\delta_0 c_{n-p+1}^{+(p)} = dA_{n-p}^{a},
\]

\[
\delta_0 c_{n-p+2}^{+(p)} = dc_{n-p+1}^{+(p)},
\]

\[
\vdots
\]
\[ \delta_0 c_{n_a}^{+(p)} = dc_{n-1_a}^{+(p)} \]  

which reproduce the gauge transformations \((23)\).

\( S_0 \) must be BRST invariant. In fact,

\[ \delta_0 S_0 = \langle (S_0, S_0) \rangle = 2 \sum_{p=0}^{a-1} (-1)^{(n-p)} \int_\Sigma d(B_{n-p-1 a} \cdot dA_p^a) \]

\[ = 2 \sum_{p=0}^{a-1} \int_\Sigma d(B_{n-p-1 a} \cdot A_p^a), \]  

(24)

therefore if the base manifold \( \Sigma \) has no boundary, \( \delta_0 S_0 = 0 \). If \( \Sigma \) has a boundary (For example, the open string or the open membrane.), we can take two kinds of boundary conditions \( A_p^a/|_{\partial \Sigma} = 0 \) or \( B_{n-p-1 a}/|_{\partial \Sigma} = 0 \), where the notation \( // \) mean the components along the direction tangent to the boundary \( \partial \Sigma \). We can also take the different boundary condition on each field component so as to satisfy BRST invariant condition of the action. Two boundary conditions are used to construct A, B and C boundary conditions in the paper \([22]\). In the rest of this paper, we select appropriate boundary conditions so as to satisfy \( \delta_0 S_0 = 0 \).

It is simple to confirm \( \delta_0^2 = 0 \) on all superfields. Equations of motion are

\[ dA_p^a = 0, \quad dB_{n-p-1 a} = 0. \]  

(25)

### 3 Deformation of BF Theory

Let us consider a deformation of the action \( S_0 \) perturbatively,

\[ S = S_0 + gS_1 + g^2S_2 + \cdots, \]  

(26)

where \( g \) is a deformation parameter, or a coupling constant of the theory. The total BRST transformation is deformed to

\[ \delta A_p^a = \langle (S, A_p^a) \rangle = (-1)^{n-p} \frac{\overrightarrow{\partial}}{\partial B_{n-p-1 a}} \cdot S, \]

\[ \delta B_{n-p-1 a} = \langle (S, B_{n-p-1 a}) \rangle = (-1)^{p(n-p)} \frac{\overrightarrow{\partial}}{\partial A_p^a} \cdot S. \]  

(27)

In order for the deformed BRST transformation \( \delta \) to be nilpotent and make the theory consistent, the total action \( S \) has to satisfy the following classical master equation:

\[ \langle (S, S) \rangle = 0. \]  

(28)
Substituting (24) to (28), we obtain

\[
\langle S', S \rangle = \langle S_0, S_0 \rangle + 2g\langle S_0, S_1 \rangle + g^2[\langle S_1, S_1 \rangle + 2\langle S_0, S_2 \rangle] + O(g^3) = 0. \tag{29}
\]

We solve this equation order by order. At the 0-th order, we obtain \(\delta_0 S_0 = \langle S_0, S_0 \rangle = 0\), which is already satisfied from (24). At the first order of \(g\) in the Eq. (29),

\[
\delta_0 S_1 = \langle S_0, S_1 \rangle = 0, \tag{30}
\]

is required. Now we assume that \(S_1\) is given by a local Lagrangian:

\[
S_1 = \int_\Sigma L_1, \tag{31}
\]

where \(L_1\) is constructed from the superfields \(A_p^a\) and \(B_{n-p-1}^a\) with \(p = 0, \ldots, \lceil \frac{n-1}{2} \rceil\). If a monomial in \(L_1\) includes a differentiation \(d\), its term is proportional to the equations of motion (23). Therefore its term can be absorbed to the abelian BF theory action (20) by the local field redefinitions of \(A_p^a\) or \(B_{n-p-1}^a\), and that term is BRST trivial at the BRST cohomology [3]. Hence the nontrivial deformation terms must not include the differentiation \(d\) and we can write the candidate \(L_1\) as

\[
L_1 = \sum_{p_1, \ldots, p_k, q_1, \ldots, q_l} F_{p_1 \ldots p_k, q_1 \ldots q_l} a_{1 \ldots a_k} b_{1 \ldots b_l} (A_0^a) \cdot A_{p_1} a_{1} \ldots A_{p_k} a_{k} \cdot B_{q_1 b_1} \ldots B_{q_l b_l}, \tag{32}
\]

where \(F_{p_1 \ldots p_k, q_1 \ldots q_l} a_{1 \ldots a_k} b_{1 \ldots b_l} (A_0^a)\) is a function of \(A_0^a\), and \(p_r \neq 0, q_s \neq 0\) for \(r = 1, \ldots, k, s = 1, \ldots, l\). In order to consider the general deformations, we do not require the total degree of \(L_1\) is \(n\). Then (30) is calculated as follows:

\[
\delta_0 S_1 = \sum_{p_1, \ldots, p_k, q_1, \ldots, q_l} \int \langle dF_{p_1 \ldots p_k, q_1 \ldots q_l} a_{1 \ldots a_k} b_{1 \ldots b_l} (A_0^a) \cdot A_{p_1} a_{1} \ldots A_{p_k} a_{k} \cdot B_{q_1 b_1} \ldots B_{q_l b_l} \\
+ \sum_{r=1}^k (-1)^{p_1 + \ldots + p_r - 1} F_{p_1 \ldots p_k, q_1 \ldots q_l} a_{1 \ldots a_k} b_{1 \ldots b_l} (A_0^a) \cdot A_{p_1} a_{1} \ldots A_{p_r} a_{r} \ldots A_{p_k} a_{k} \cdot B_{q_1 b_1} \ldots B_{q_1 b_1} \\
+ \sum_{s=1}^l (-1)^{p_1 + \ldots + p_k + q_1 + \ldots + q_{s-1}} \\
\times F_{p_1 \ldots p_k, q_1 \ldots q_l} a_{1 \ldots a_k} b_{1 \ldots b_l} (A_0^a) \cdot A_{p_1} a_{1} \ldots A_{p_k} a_{k} \cdot B_{q_1 b_1} \ldots dB_{q_s b_s} \ldots B_{q_l b_l} \rangle \\
= \sum_{p_1, \ldots, p_k, q_1, \ldots, q_l} \int [dF_{p_1 \ldots p_k, q_1 \ldots q_l} a_{1 \ldots a_k} b_{1 \ldots b_l} (A_0^a) \cdot A_{p_1} a_{1} \ldots A_{p_k} a_{k} \cdot B_{q_1 b_1} \ldots B_{q_l b_l}], \tag{33}
\]

9
and $\delta_0 S_1 = 0$ if
\[ (F_{p_1 \cdots p_k, q_1 \cdots q_l, a_1 \cdots a_k} b_1 \cdots b_l (A_0^a_{\cdot}) \cdot A_{p_1^a} \cdots A_{p_k^a} \cdot B_{q_1 b_1} \cdots B_{q_l b_l})_{\mid \partial \Sigma} = 0. \] (34)

$S_1$ must be constructed from the terms which satisfy the requirements above. If there is no boundary, there is no restriction for $S_1$. If we take the boundary condition $A_{p}^a_{\mid \partial \Sigma} = 0$, then (34) is satisfied if the terms include at least one $A_{p}^a$. If we take $B_{n-p-1} a_{\mid \partial \Sigma} = 0$, then (34) is satisfied if the terms include at least one $B_{n-p-1} a$.

At the second order of $g$,
\[ \langle (S_1, S_1) \rangle + 2 \langle (S_0, S_2) \rangle = 0, \] (35)
is required. We cannot construct nontrivial $S_2$ to satisfy (35) from the integration of a local Lagrangian, because $\delta_0$-BRST transforms of the local terms are always total derivative. Therefore if we assume locality of the action, $S_2$ is a BRST trivial and we can set $S_i = 0$ for $i \geq 2$. Then the condition (35) reduces to
\[ \langle (S_1, S_1) \rangle = 0. \] (36)
This imposes the identities on the structure functions $F_{p_1 \cdots p_k, q_1 \cdots q_l, a_1 \cdots a_k} b_1 \cdots b_l (A_0^a_{\cdot})$ in (32). Now we have obtained the possible deformations of the BF theory in any dimension as
\[ S = S_0 + g S_1, \] (37)
where $S_0$ is (20) and $S_1$ is defined as (32). In the next section, we consider two nontrivial examples. General algebra structure underline the antifield BRST formalism is the $L_{\infty}$-algebra (the sh Lie algebra) [17] [18] which is derived from the analysis of the master equation. The gauge symmetry in our theory generally has extended structures of usual Lie algebra, and if a deformation satisfies the master equation (28), that is, (36), the symmetry of the deformed theory generally has $L_{\infty}$-algebra structure.

The total BRST transformations $\delta$ for the superfields are as follows:
\[ \delta A_p^a = (-1)^{n-p} \langle (S, A_p^a) \rangle \]
\[ = dA_p^a + (-1)^{n-p} \frac{\partial}{\partial B_{n-p-1} a} \cdot S_1, \]
\[ \delta B_{n-p-1} a = (-1)^{p(n-p)} \langle (S, B_{n-p-1} a) \rangle \]
\[ = dB_{n-p-1} a + (-1)^{p(n-p)} \frac{\partial}{\partial A_p^a} \cdot S_1. \] (38)
Equations of motion are obtained as
\[ dA_p^a + (-1)^{n-p} \frac{\partial}{\partial B_{n-p-1}^a} \cdot S_1 = 0, \]
\[ dB_{n-p-1}^a + (-1)^{p(n-p)} \frac{\partial}{\partial A_p^a} \cdot S_1 = 0, \]
(39)

If we set all antifields \( \Phi^+ = 0 \) in (39), we obtain the usual classical action.

4 Examples in The Lower Dimensions

In this section, we consider some nontrivial examples of the deformations in the lower dimensions. For simplicity, we only consider the action which total ghost number is zero.

In two dimension, (26) is written as
\[ S = S_0 + gS_1, \]
\[ S_0 = \int_{\Sigma} B_{1a} \cdot d\phi^a, \quad S_1 = \int_{\Sigma} \frac{1}{2} f_{ab}(\phi^a) \cdot B_{1a} \cdot B_{1b}, \]
(40)
where \( \phi^a = A_0^a \) and \( \frac{1}{2} f_{ab}(\phi^a) = F_{11}(A_0^a) \). The condition (36) imposes the following identity on \( f_{ab}^c \):
\[ \frac{\partial f_{ab}^c}{\partial \phi^d} f_{cd} + \frac{\partial f_{bc}^d}{\partial \phi^d} f_{ad} + \frac{\partial f_{ca}^d}{\partial \phi^d} f_{bd} = 0. \]
(41)

We find that this theory is nothing but two-dimensional nonlinear gauge theory (the Poisson sigma model)\[5\]\[6\]. We have deformed the abelian BF theory \( S_0 \) to \( S \) by the analysis of the BRST cohomology. If we relax the condition that the action has ghost number zero, we can generalize the theory to the polyvector fields, and we obtain \( L_\infty \)-algebra by the deformation of the abelian BF theory.

Next, we consider the theory in three dimension. We restrict \( S_1 \) to the ghost number zero for simplicity again. Then the total action (29) is deformed as follows:
\[ S = S_0 + gS_1, \]
\[ S_0 = \int_{\Sigma} [ -B_{2a} \cdot d\phi^a + B_{1a} \cdot dA_1^a ], \]
\[ S_1 = \int_{\Sigma} d^3\theta d^3 x [ f_{1a}^{bc}(\phi) \cdot A_1^a \cdot B_{2b} + f_{2a}^{ab}(\phi) \cdot B_{2a} \cdot B_{1b} + \frac{1}{3!} f_{3abc}(\phi) \cdot A_1^a \cdot A_1^b \cdot A_1^c + \frac{1}{2} f_{4ab}^c(\phi) \cdot A_1^a \cdot A_1^b \cdot B_{1c} + \frac{1}{2} f_{5a}^{bc}(\phi) \cdot A_1^a \cdot B_{1b} \cdot B_{1c} + \frac{1}{3!} f_{6abc}(\phi) \cdot B_{1a} \cdot B_{1b} \cdot B_{1c} ] \]
where we replace the notations as $f_{1a}^b = F_{1,2a}^b$, $f_{2a}^b = F_{2,1}^{ab}$, $\frac{1}{3!} f_{3abc} = F_{111,abc}$, $\frac{1}{2} f_{4ab}^c = F_{11,1ab}^c$, $\frac{1}{2} f_{5a}^{bc} = F_{111,abc}$, $\frac{1}{3!} f_{6}^{abc} = F_{111,abc}$, for clarity. The condition of the classical master equation (36) imposes the following identities on six $f_i$'s, $i = 1, \cdots, 6$:

\begin{align}
&f_{1e}^a f_{2}^b + f_{2e}^a f_{1}^b = 0, \quad (43) \\
&\frac{\partial f_{1e}^a}{\partial \phi^e} f_{1}^b - \frac{\partial f_{1b}^a}{\partial \phi^e} f_{1e}^a + f_{1e}^a f_{4b}^e + f_{2}^a f_{3e}^b = 0, \quad (44) \\
&-f_{1b}^e \frac{\partial f_{2}^a}{\partial \phi^e} + f_{2e}^a \frac{\partial f_{1b}^a}{\partial \phi^e} + f_{1e}^a f_{5b}^e - f_{2}^a f_{4e}^b = 0, \quad (45) \\
&f_{2e}^b \frac{\partial f_{2}^a}{\partial \phi^e} - f_{2e}^c \frac{\partial f_{2}^a}{\partial \phi^e} + f_{1e}^a f_{6b}^c + f_{2}^a f_{5e}^b = 0, \quad (46) \\
&f_{1[a}^a \frac{\partial f_{4]be}}{\partial \phi^e} - f_{2}^e \frac{\partial f_{3abc}}{\partial \phi^e} + f_{4e}^{[a} f_{4]be}^e + f_{3e[ab} f_{5e]}^c = 0, \quad (47) \\
&f_{1[a}^e \frac{\partial f_{5]}^{cd}}{\partial \phi^e} + f_{2}^e \frac{\partial f_{4a]^{cd}}}{\partial \phi^e} + f_{3e}^{[a} f_{5]}^{cd} + f_{4e}^{[a} f_{5]}^{cd} e + f_{4ab} e f_{5e}^{cd} = 0, \quad (48) \\
&f_{1a}^e \frac{\partial f_{6}^{bcd}}{\partial \phi^e} - f_{2}^e \frac{\partial f_{5}^{cd]} e}{\partial \phi^e} + f_{4e}^{[a} f_{6}^{cd] e} + f_{5e}^{[bc} f_{5a]}^{de} = 0, \quad (49) \\
&f_{2}^{[a} \frac{\partial f_{6}^{bcd]}}{\partial \phi^e} + f_{6}^{[ab} f_{5e}^{cd] e} = 0, \quad (50) \\
&f_{1[a}^a \frac{\partial f_{3abc]}^{cd]}}{\partial \phi^e} + f_{4]ab} e f_{3cde]} = 0, \quad (51)
\end{align}

where $[\cdots]$ on the indices represents the antisymmetrization for the indices. For example, $\Phi_{[ab]} = \Phi_{ab} - \Phi_{ba}$. We find that the action (42) with (43)-(51) is the same theory constructed in the paper [10], and a nontrivial consistent deformation of the three-dimensional BF theory. If $\Sigma$ has boundaries, possible terms are restricted according to the boundary conditions, which are discussed in section 3.

## 5 Quantum BV formalism

### 5.1 Quantum Master Equation

In this section, we consider the quantum theory. We introduce the Hodge dual fields of the antifields $\Phi^a = \ast \Phi^{-a}$. We define the BV Laplacian as follows:

$$\Delta_{BV} F \equiv \sum_a (-1)^{\delta\Phi_a} \frac{\delta}{\delta \Phi_a} \frac{\delta}{\delta \Phi_a^{*}} F, \quad (52)$$

$$\Delta_{BV} F$$
where $\frac{\delta}{\delta \varphi_a}$ and $\frac{\delta}{\delta \varphi^a}$ are differentiations with respect to coefficient functions of the forms. Then the following identity is satisfied:

$$\Delta_{BV}(FG) = (\Delta_{BV}F)G + (-1)^{\text{deg}F + n} dv(F, G) + (-1)^{\text{deg}F} \Delta_{BV}G,$$  \hspace{1cm} (53)$$

where $dv$ is the volume form on $\Sigma$.

In order for the generating functional to be gauge invariant, The following quantum master equation is required:

$$(S, S) - 2i\hbar \Delta_{BV}S = 0,$$  \hspace{1cm} (54)$$

for the quantum action $S$. $\mathcal{O}$ is an observable if an operator $\mathcal{O}$ satisfies the following equation:

$$(S, \mathcal{O}) - i\hbar \Delta_{BV}\mathcal{O} = 0.$$  \hspace{1cm} (55)$$

If we define an operator $\Omega_{BV}$ as $\Omega_{BV} \equiv S - i\hbar \Delta_{BV}$, then (53) is denoted as $\Omega_{BV}\mathcal{O} = 0$. In our BF theory, we can confirm $\Delta_{BV}S = 0$, therefore the quantum master equation (54) becomes

$$(S, S) = 0.$$  \hspace{1cm} (56)$$

Let us rewrite the above formulae on the superfields. We define the dot $BV$ Laplacian on the superfield as follows:

$$\Delta F \equiv (-1)^{\text{deg}F - n} \Delta_{BV}F,$$  \hspace{1cm} (57)$$

Then identity (53) is rewritten as

$$\Delta(F \cdot G) = (\Delta F) \cdot G + (-1)^{(n+1)|F|} dv(\langle F, G \rangle) + (-1)^{|F|} F \cdot \Delta G,$$  \hspace{1cm} (58)$$

The quantum master equation (54) is rewritten as

$$\langle S, S \rangle - 2i\hbar \Delta S = 0,$$  \hspace{1cm} (59)$$

and the observable condition (55) of an operator $\mathcal{O}$ becomes

$$\langle S, \mathcal{O} \rangle - i\hbar \Delta \mathcal{O} = 0.$$  \hspace{1cm} (60)$$

We define that $\Omega_{BV} = \delta - i\hbar \Delta$, then (61) is written as $\Omega_{BV}\mathcal{O} = 0$. (60) becomes that $\langle S, S \rangle = 0$. 

13
5.2 Gauge Fixing

In order to quantize the gauge theory, we must fix the gauge. We introduce the new fields: Fadeev-Popov antighosts and Lagrange multiplier fields (Nakanishi-Lautrup fields). Since $\mathcal{A}_p^a$ has the $p$-th order reducible gauge transformation, the following many antighosts and NL-fields are needed [19][20]. We introduce antighost and NL-field pairs, $\bar{c}_{p-1-L}^a$ and $\bar{b}_{p-1-L}^a$, where $k = 0, 2, \cdots, 2 \left[ \frac{L}{2} \right]$, and $c_{p-1-L}^{(p)a}$ and $b_{p-1-L}^{(p)a}$ where $k = 1, 3, \cdots, 2 \left[ \frac{L-1}{2} \right] + 1$ at the $L$-th reducible order, where $L = 0, 1, \cdots, p-1$. The four kinds of fields are all $p-1-L$-forms. $\bar{c}_{p-1-L}^a$ has the ghost number $k - L - 1$, $\bar{b}_{p-1-L}^a$ has the ghost number $k - L$, $c_{p-1-L}^{(p)a}$ has the ghost number $L - k$, and $b_{p-1-L}^{(p)a}$ has the ghost number $L - k + 1$. Moreover we introduce the antifields for the fields above as $\bar{c}_{n-p+1+L}^{+k(p)a}$ and $\bar{b}_{n-p+1+L}^{+k(p)a}$, where $k = 0, 2, \cdots, 2 \left[ \frac{L}{2} \right]$, $c_{n-p+1+L}^{k(p)a}$, and $b_{n-p+1+L}^{k(p)a}$, where $k = 1, 3, \cdots, 2 \left[ \frac{L-1}{2} \right] + 1$. The form degrees and the ghost numbers of the antifields are determined from the relations $\text{deg}(\Phi) + \text{deg}(\Phi^+) = n$ and $\text{gh}(\Phi) + \text{gh}(\Phi^+) = -1$.

For $B_{n-p-1}^a$, we also introduce antighost and NL-field pairs as $\bar{c}_{n-p-2-L}^{k(n-p-1)a}$ and $\bar{b}_{n-p-2-L}^{k(n-p-1)a}$, where $k = 0, 2, \cdots, 2 \left[ \frac{L}{2} \right]$, and $c_{n-p-2-L}^{k(n-p-1)a}$, and $b_{n-p-2-L}^{k(n-p-1)a}$, where $k = 1, 3, \cdots, 2 \left[ \frac{L-1}{2} \right] + 1$ at the $L$-th reducible order, where $L = 0, 1, \cdots, n - p - 2$. The four kinds of fields are all $n - p - 2 - L$-forms. $\bar{c}_{n-p-2-L}^{k(n-p-1)a}$ has the ghost number $k - L - 1$, $\bar{b}_{n-p-2-L}^{k(n-p-1)a}$ has the ghost number $k - L$, $c_{n-p-2-L}^{k(n-p-1)a}$ has the ghost number $L - k$, and $b_{n-p-2-L}^{k(n-p-1)a}$ has the ghost number $L - k + 1$. We introduce the antifields for the fields above as $\bar{c}_{p+2+L}^{+k(n-p-1)a}$ and $\bar{b}_{p+2+L}^{+k(n-p-1)a}$, where $k = 0, 2, \cdots, 2 \left[ \frac{L}{2} \right]$, and $c_{p+2+L}^{+k(n-p-1)a}$, and $b_{p+2+L}^{+k(n-p-1)a}$, where $k = 1, 3, \cdots, 2 \left[ \frac{L-1}{2} \right] + 1$.

We define the extended BV action including the antighosts and NL-fields as $S + S_{\text{aux}}$, where

\[
S_{\text{aux}} = (-1)^n \int \sum_{p=1}^{\lfloor \frac{n-1}{2} \rfloor} \sum_{k=0}^{p-1} \sum_{L=k}^{p-1} (-1)^{L-k} c_{p-1-L}^{k(p)a} b_{p-1-L}^{k(p)a} + \sum_{k=1}^{p-1} \sum_{L=k}^{p-1} (-1)^{L-k} c_{n-p+1+L}^{k(p)a} b_{n-p+1+L}^{k(p)a} + (2L-1) \sum_{k=0}^{\frac{n-2}{2}} \sum_{L=k}^{\frac{n-2}{2}} (-1)^{L-k} c_{n-p-2-L}^{k(n-p-1)a} b_{n-p-2-L}^{k(n-p-1)a} + \sum_{k=1}^{\frac{n-2}{2}} \sum_{L=k}^{\frac{n-2}{2}} (-1)^{L-k} c_{n-p-2-L}^{k(n-p-1)a} b_{n-p-2-L}^{k(n-p-1)a},
\]

(61)
Then the BRST transformations of the fields are calculated from the antibrackets as follows:

\[
\begin{align*}
\delta c_{p-1-L}^{k(p)} &= t_{p-1-L}^{k(p)}, & \delta b_{p-1-L}^{k(p)} &= 0, \\
\delta c_{p-1-L}^{k(p)a} &= b_{p-1-L}^{k(p)a}, & \delta b_{p-1-L}^{k(p)a} &= 0, \\
\delta t_{n-p-2}^{k(n-p-1)a} &= s_{n-p-2}^{k(n-p-1)a}, & \delta s_{n-p-2}^{k(n-p-1)a} &= 0, \\
\delta t_{n-p-2}^{k(n-p-1)} &= s_{n-p-2}^{k(n-p-1)}a, & \delta s_{n-p-2}^{k(n-p-1)} &= 0. 
\end{align*}
\]

We take the boundary condition as a constant at the boundary for antighosts, and as zero at the boundary for NL-fields. Now we fix the gauge as follows:

\[
S_{GF} = S + S_{\text{aux}}|_{\Phi^+ = \frac{\partial}{\partial \phi^+}},
\]

where \(\Psi\) is a gauge fixing fermion which is a function of the fields \(\Phi\) with ghost number \(-1\). For example, if we take the Landau gauge, the gauge fixing fermion is

\[
\Psi = \sum_{p=1}^{[\frac{d-1}{2}]} \int c_{p-1}^{(p)} a \star A_{p}^a + \sum_{L=1}^{p-1} \sum_{k=0}^{L} \delta c_{p-1-L}^{k(p)} a \star c_{p-1-L}^{k-1(p)a} + \sum_{L=1}^{p-1} \sum_{k=1 \text{ odd}}^{L} d \star c_{p-1-L}^{k-1(p)} c_{p-1-L}^{k(p)a}
\]

\[
+ \sum_{L=1}^{n-p-2} \sum_{k=0 \text{ even}}^{L} \delta t_{n-p-2}^{k(n-p-1)} a \star t_{n-p-2}^{k(n-p-1)} a
\]

\[
+ \sum_{L=1}^{n-p-2} \sum_{k=1 \text{ odd}}^{L} d \star t_{n-p-2}^{k-1(n-p-1)} t_{n-p-2}^{k(n-p-1)} a,
\]

where \(\star\) is the Hodge star operator.

### 5.3 Observables and a generalization of the star product

According to the discussion of the section 3, we can take two kinds of boundary conditions (i) \(\mathbf{A}_{p}^a |_{\partial \Sigma} = 0\) and (ii) \(\mathbf{B}_{n-p-1} a |_{\partial \Sigma} = 0\) consistently. We analyze the total BRST transformations \(\mathbf{B}_{\Sigma}\) of the fields under each boundary condition. If we take (i), the terms include at least one \(\mathbf{A}_{p}^a\). The total BRST transformation of \(\mathbf{A}_{p}^a\) at the boundary is as follows:

\[
\delta \mathbf{A}_{p}^a |_{\partial \Sigma} = d \mathbf{A}_{p}^a |_{\partial \Sigma}.
\]

On the other hand, if \(S_1\) has no terms which include only one \(\mathbf{A}_{p}^a\), \(\delta \mathbf{B}_{n-p-1} a\) becomes a total derivative:

\[
\delta \mathbf{B}_{n-p-1} a |_{\partial \Sigma} = d \mathbf{B}_{n-p-1} a |_{\partial \Sigma}.
\]
If we take (ii), the terms include at least one $B_{n-p-1}a$. Then if $S_1$ has no terms which include only one $B_{n-p-1}a$, the total BRST transformation of $A_p^a$ at the boundary becomes

$$
\delta A_p^a|_{\partial \Sigma} = dA_p^a|_{\partial \Sigma}.
$$

(67)

On the other hand, one of $B_{n-p-1}a$ becomes a total derivative:

$$
\delta B_{n-p-1}a|_{\partial \Sigma} = dB_{n-p-1}a|_{\partial \Sigma}.
$$

(68)

Now we assume that $S_1$ is constructed from terms to satisfy the condition above. Then we define

$$
O_{F,p_1\ldots p_k,q_1\ldots q_l} = \sum_{p_1\ldots p_k,q_1\ldots q_l} (F_{p_1\ldots p_k,q_1\ldots q_l}(A_0^a) \cdot A_{p_1}^{a_1} \cdots A_{p_k}^{a_k} \cdot B_{q_1b_1} \cdots B_{q_lb_l})|_{\partial \Sigma}.
$$

(69)

We can confirm that

$$
\Delta O_{F,p_1\ldots p_k,q_1\ldots q_l} = 0, \quad \delta O_{F,p_1\ldots p_k,q_1\ldots q_l} = \left( \left( S, O_{F,p_1\ldots p_k,q_1\ldots q_l} \right) \right) = dO_{F,p_1\ldots p_k,q_1\ldots q_l}.
$$

(70)

Especially

$$
\Delta O_{F,p_1\ldots p_k,q_1\ldots q_l}^{(0)} = 0, \quad \delta O_{F,p_1\ldots p_k,q_1\ldots q_l}^{(0)} = 0,
$$

(71)

where $O^{(0)}$ is the 0-form part of $O$. Therefore $O_{F,p_1\ldots p_k,q_1\ldots q_l}^{(0)}$ is a local observable with ghost number $|O| = p_1 + \cdots + p_k + q_1 + \cdots + q_l$. We can also construct Wilson-loop-like observables on the boundary manifold $\partial \Sigma$.

$$
\int_{\Sigma_r} O_{F,p_1\ldots p_k,q_1\ldots q_l}.
$$

(72)

where $\Sigma_r \subset \partial \Sigma$ is a $r$-dimensional closed subspace of $\partial \Sigma$ and $0 \leq r \leq |O|$. Actually $\Omega_{uv} \int_{\Sigma_r} O_{F,p_1\ldots p_k,q_1\ldots q_l} = 0$ because of the equation (70).

We consider simple cases. $\int_{\Sigma_r} A_p^a$ is an observable from (72). If we take (i), it is trivial. If we take (ii), it is an observable with ghost number $p-r$. $\int_{\Sigma_r} B_{n-p-1}a$ is also an observable from (72). If we take (i), it is an observable with ghost number $n-p-1-r$. On the other hand, if we take (ii), it is trivial. We consider another example:

$$
O_F \equiv F(A_0^a)|_{\partial \Sigma}.
$$

(73)
0-form part $\mathcal{O}_F^{(0)}$ of $\mathcal{O}_F$ is an local observable at the boundary with ghost number zero.

The generating functional is defined as

$$Z[\mathcal{O}_k] = \int \prod_{p=0}^{[\frac{n-1}{2}]} \mathcal{D}A_p \mathcal{D}B_{n-p-1} e^{\frac{i}{\hbar} \left( S + \sum_r J_r \mathcal{O}_r \right)},$$

(74)

where $J_k$ are source fields and $\mathcal{O}_k$ are observables. In two dimension, the correlation function of two local observables $\mathcal{O}_f^{(0)}$ and $\mathcal{O}_g^{(0)}$ leads the star product formula:

$$f \ast g(x) = \int_{\phi(\infty) = x} D\phi D\mathcal{B}_1 \mathcal{O}_f^{(0)}(\phi(1))\mathcal{O}_g^{(0)}(\phi(0)) e^{\frac{i}{\hbar} S},$$

(75)

where $\phi = A_0^a$ and 0, 1, $\infty$ are three distinct points at the boundary $\partial \Sigma$. We can propose a generalization of the star product to higher dimensions as follows:

$$m_k[\mathcal{O}_1, \mathcal{O}_2, \cdots, \mathcal{O}_k] = \int \prod_{p=0}^{[\frac{n-1}{2}]} \mathcal{D}A_p \mathcal{D}B_{n-p-1} \mathcal{O}_1 \mathcal{O}_2 \cdots \mathcal{O}_k e^{\frac{i}{\hbar} S},$$

(76)

under the appropriate regularization and the boundary conditions, where $S$ is the deformation (37) of the $n$-dimensional world volume BF theory and $\mathcal{O}_r$’s are observables at the boundary. The correlation functions satisfy the Ward-Takahashi identity derived from the gauge symmetry:

$$\int \prod_{p=0}^{[\frac{n-1}{2}]} \mathcal{D}A_p \mathcal{D}B_{n-p-1} \Delta \left( \mathcal{O} e^{\frac{i}{\hbar} S} \right) = 0,$$

(77)

where $\mathcal{O}$ is an observable. The WT identity leads $L_\infty$ structure on the correlation functions. Therefore the product (76) has the $L_\infty$ structure. In two dimension, $L_\infty$-algebra structure on the star deformation is certainly derived from the $L_\infty$-algebra structure of the BRST algebra [3]. We can generalize the structure to higher dimension as the WT identity on correlation functions of the higher dimensional BF theory.

6 Topological Open Membrane

We consider the theory on the $n - 1$-space-dimensional open membrane in $N$-dimensional target space. The open 2-brane theory with the background 3-form is analyzed at the paper [13] [14] [15].
First, we consider the topological membrane theory action with a background $n$-form field $C$ as follows:

$$ S = \int \Sigma C_{a_1 \cdots a_n}(\phi) d\phi^{a_1} \cdots d\phi^{a_n}, \quad (78) $$

there $C_{a_1 \cdots a_n}$ is a completely antisymmetric $n$-form. We rewrite the action (78) by first order formalism as follows:

$$ S = \int \Sigma B_{n-1} a d\phi^a + B_{n-1} a A_1^a + C_{a_1 \cdots a_n} A_1^{a_1} \cdots A_1^{a_n}, \quad (79) $$

where $A_1^a$ and $B_{n-1} a$ are auxiliary 1-form fields and $n-1$-form fields.

In two dimension, the action (79) is written as

$$ S = \int \Sigma B_{1} a d\phi^a + B_{1} a A_1^a + C_{ab} A_1^a A_1^b, $$

$$ = \int \Sigma B_1 a d\phi^a - \frac{1}{4} (C^{-1})^{ab} B_1 a B_1 b $$

$$ + C_{ab} \left( A_1^a - \frac{1}{2} (C^{-1})^{ac} B_1 c \right) \left( A_1^b - \frac{1}{2} (C^{-1})^{bd} B_1 d \right). \quad (80) $$

If we set $A_1^{a'} = A_1^a - \frac{1}{2} (C^{-1})^{ac} B_1 c$ and integrate out $A_1^{a'}$, we obtain the action of the nonlinear gauge theory in two dimension (3).

In higher dimensions than two, we can obtain (79) from our deformed action (37) by the following procedure. If we take the limit

$$ B_{n-p-1} a \rightarrow 0 \quad \text{for} \quad p \neq 0, $$

$$ A_p^a \rightarrow 0 \quad \text{for} \quad p \geq 2, \quad (81) $$

we obtain (79), where $\phi^a = A_0^a$ and

$$ F_{1,n-1} a^b = -\delta_a^b, \quad F_{1-1, a_1 \cdots a_n} = (-1)^n C_{a_1 \cdots a_n}(\phi). \quad (82) $$

The topological open membrane is derived as the above scaling limit of the deformed BF theory.

7 Conclusion and Discussion

We have considered all possible deformations of the BF theory in any dimension by the antifield BRST formalism. We have analyzed the BRST cohomology of the BF theory. It has
led us to a new gauge symmetry and a deformed action. We have considered quantum BV formalism and quantize the theory. We have taken the gauge fixing and found observables. This gauge symmetry gives an extension to higher dimension of the nonlinear gauge symmetry \cite{5,6} in two dimension, \cite{10} in three dimension. We have considered our theory as higher dimensional generalization of the two-dimensional nonlinear gauge theory, or the Poisson sigma model. It will be useful to analyze topological open membrane or noncommutative structure on higher dimensional open membrane. In fact, we have considered that our action tend to the topological \(n-1\)-brane action at a certain coupling zero limit.

Our key structure is \(L_\infty\)-algebra. Generally, the gauge algebra can be consistently deformed to the \(L_\infty\)-algebra (the strongly homotopy Lie algebra) in the antifield BRST formalism \cite{17,18}. On the other hand, \(L_\infty\)-algebra is the underline algebra in the deformation quantization or formality conjecture \cite{2}. \(L_\infty\)-algebra structure on the star deformation is certainly derived from the \(L_\infty\)-algebra structure of the BRST algebra at the path integral representation of the deformation quantization \cite{3}. Our extension has respected the similar \(L_\infty\)-algebra structure.

We can conjecture that if we consider the deformation \eqref{37} of the BF theory on the open membrane, the operator product expansions of the correlation function at the boundary are deformed and \eqref{76} is a deformation of \(n\)-algebra \cite{24}. The explicit calculations of the correlation functions are needed on the quantum theory.

In the Schwarz type topological field theory, such as the BF theory, observables are related to miscellaneous topological invariants and knot invariants \cite{7,23,26}. In our theory, geometrical meanings of correlation functions of observables are not still understood. More generally, whether deformation of correlation functions of a gauge theory is related to deformation of a mathematical structure or not is not still known.

Topological field theories called \(A\) model and \(B\) model are introduced to investigate the mirror symmetry \cite{27}. Different reduction of the topological open membrane theory leads us to the \(A\) model and \(B\) model \cite{22}. Our theory may be useful to analyze the mirror symmetry.

Appendix, Notation

For a superfield $F(\Phi, \Phi^+)$ and $G(\Phi, \Phi^+)$, The following identities are satisfied:

$$FG = (-1)^{gh_Fgh_G + \deg F \deg G} GF,$$
$$d(FG) = dF G + (-1)^{\deg F} F dG,$$  \hspace{1cm} (83)

at the usual products. The graded commutator of two superfields satisfies the following identities:

$$[F, G] = -(-1)^{gh_Fgh_G + \deg F \deg G} [G, F] ,$$
$$[F, [G, H]] = [[F, G], H] + (-1)^{gh_Fgh_G + \deg F \deg G} [G, [F, H]].$$  \hspace{1cm} (84)

We introduce the total degree of a superfield $F$ as $|F| = ghF + \deg F$. We define the dot product on superfields as

$$F \cdot G \equiv (-1)^{ghF \deg G} FG,$$  \hspace{1cm} (85)

and the dot Lie bracket

$$[F, G] \equiv (-1)^{ghF \deg G} [F, G].$$  \hspace{1cm} (86)

We obtain the following identities of the dot product and the dot Lie bracket from (83), (84), (85) and (86):

$$F \cdot G = (-1)^{|F| |G|} G \cdot F,$$
$$[F, G] = -(-1)^{|F| |G|} [G, F],$$
$$[F, [G, H]] = [[[F, G], H] + (-1)^{|F| |G|} [G, [F, H]],$$  \hspace{1cm} (87)

and

$$d(F \cdot G) \equiv dF \cdot G + (-1)^{|F|} F \cdot dG.$$  \hspace{1cm} (88)
