Aims. Autism Spectrum Disorder (ASD) is a common neurodevelopmental disorder associated with difficulties in social communication and language development, preoccupations, a need for routine, sensory sensitivities and emotional dysregulation. People with autism who have violently offended may be prescribed psychotropic medications to treat comorbidities, or off-license to manage aggressive or challenging behaviours. However, the evidence base for their use remains scarce.

Method. This was a retrospective audit at Broadmoor Hospital, a high security psychiatric hospital in the United Kingdom, into the safe and appropriate prescribing of psychotropic medicines in those with an ASD compared to guidance from the National Institute for Health and Care Excellence (CG142): “Autism spectrum disorder in adults: diagnosis and management”. This first cycle was undertaken during May and June 2020 and included all patients with a confirmed or equivocal diagnosis of ASD in the preceding five years.

Result. A total of 22 participants were included in this study. Of these, 17 participants had a confirmed diagnosis of ASD and five participants had a suspected diagnosis of ASD, but without formal confirmation with neurocognitive testing. A total of 13 (76.5%) participants with confirmed ASD were prescribed antipsychotic medication, nine of whom had an established comorbid mental disorder with psychotic symptoms. Of the remaining four, three had a diagnosis of a personality disorder. Three participants in this study had a confirmed diagnosis of ASD without any additional comorbid mental health diagnoses. No patients were prescribed psychotropic medicines for the core symptoms of ASD. The specific documentation of off-license use of antipsychotic medicines in those without a diagnosis of a psychotic disorder was poor. This was not recorded in any such participant in the preceding 12 months.

Conclusion. This audit highlighted that dual diagnoses of ASD alongside non-affective psychosis and personality disorder are over-represented in this high security setting. The NICE clinical guidelines CG142 guidelines state that “antipsychotic medications should only be used for behaviour that challenges if …. the risk to the person or others is very severe”. By definition, all patients admitted to high security are deemed to be a grave and imminent risk to the public. Psychotropic medicines may therefore be clinically indicated at a much earlier stage than in community patients, instigated alongside appropriate psychosocial interventions and treatment of comorbid conditions. It may be that catered guidelines need to be formulated to support the safe and appropriate prescribing of psychotropic medicine in forensic settings.

An audit into the management of diabetes mellitus at Broadmoor Hospital

Aims. Diabetes mellitus confers a twofold excess risk of cardiovascular disease - the leading cause of premature mortality in those with severe mental illness. Inpatients in forensic settings often have more severe, enduring and treatment-resistance forms of mental illness, sometimes necessitating combinations of prescribed antipsychotics. This audit aimed to assess adherence to National Institute for Health and Care Excellence (NICE) guidelines NG28 titled “type 2 diabetes in adults: management” and summarise the metabolic parameters of those with diabetes mellitus at Broadmoor hospital.

Method. This was a retrospective audit in a high secure forensic psychiatry hospital in the United Kingdom, into the management of patients with diabetes mellitus compared to guidance from NICE (NG28).

Result. We report data from over 30 inpatients (out of approximately 200) at a high secure forensic psychiatry hospital with a diagnosis of type 2 diabetes mellitus across two audit cycles. This audit identified improved adherence to national guidance regarding six monthly monitoring of HbA1c but with less than 50% of such patients having an HbA1c at or below the recommended target. This is in addition to high rates of other metabolic disorders such as obesity, dyslipidaemia and hypertension and a mean QRS3K score that was markedly higher than a healthy person with the same age, sex, and ethnicity. There was a prevalence of background diabetic retinopathy of 8%, diabetic nephropathy of 5.4%, no recorded cases of diabetic neuropathy and a macrovascular disease prevalence of 5.4%. There were no new diagnoses of microvascular or macrovascular disease between audit cycles. One of the key changes between audit cycles was the recruitment of a dietician to the hospital. By the time of undertaking the second audit cycle, 23 patients had documented evidence of having been offered a referral to the dietician.

Conclusion. This audit highlighted the marked cardiovascular risk in patients with type 2 diabetes mellitus at a high secure forensic psychiatry hospital. This includes suboptimal control of blood pressure, lipid profiles and HbA1c that increases the risk of premature mortality in these patients with severe mental illness. Wider, cultural changes in practice need to be implemented to improve the metabolic health of patients in the long-term inpatient setting of Broadmoor Hospital. This includes prescribers avoiding the most diabetogenic antipsychotics where possible, increasing the provision of sugar-free options at the on-site shop, examining the proportion of carbohydrate-rich foodstuffs in the shop and understanding the characteristics of its heaviest purchasers, and continued coordination between primary care and ward teams to support patients in making sustained changes to improve their metabolic health.

An audit into the management of COVID-19 in a high security psychiatric hospital

Aims. Comprehensive and timely data collection during a pandemic is crucial in developing guidelines and policy as well as evaluating their effectiveness. In turn, this will improve planning for future incidents. While this is being undertaken at a national level by Public Health England, more specific information as it relates to psychiatric care is important in understanding the neuropsychiatric, psychological and social effects of the pandemic. The management of patients with COVID-19 presents a
