Abstract In this paper, two semi-analytical solutions of force free fields (Low and Lou [1990]) have been used to test two nonlinear force-free extrapolation methods. One is the boundary integral equation (BIE) method developed by Yan and Sakurai (2000), and another is the approximate vertical integration (AVI) method developed by Song et al. (2006). Some improvements for the AVI method have been taken to avoid the singular points in the process of calculation. It is found that the correlation coefficients between the first semi-analytical field and extrapolated field by BIE, and also that by improved AVI, are greater than 90% below a height 10 of the 64 × 64 lower boundary. While for the second semi-analytical field, these correlation coefficients are greater than 80% below the same relative height. Although the differences between the semi-analytical solutions and the extrapolated fields exist for both BIE and AVI methods, these two methods can give reliable results for the height of about 15% of the extent of the lower boundary.

Keywords: Active Regions, Magnetic Fields, Photosphere

1. Introduction

It is well known that the magnetic field plays a key role in solar activity, particularly in eruptive phenomena such as filament eruptions, flares, and coronal mass ejections. However, so far the reliable measurements of the magnetic field are restricted to the photosphere, and the understanding of the magnetic field in the chromosphere and in the corona is a difficult problem due to both intrinsic physical difficulties and observational limitations. Instead of the direct measurement, the chromospheric and coronal magnetic field can be extrapolated from the photospheric magnetic field by assuming the magnetic field above photosphere is force-free (Aly [1989]). For the low-β corona where the plasma is tenuous, this is

possibly not a bad assumption. The force-free magnetic field satisfies the following equations:

\[ \nabla \times \mathbf{B} = \alpha(r)\mathbf{B}, \]
\[ \nabla \cdot \mathbf{B} = 0. \]

They imply that there is no Lorentz force and \( \alpha \) is constant along magnetic field lines. If \( \alpha = 0 \), the equations represent a potential field (a current-free field). If \( \alpha = \text{constant} \), they describe a current-carrying linear force-free (LFF) field, and if \( \alpha = f(r) \) it is a general force-free (NLFF) field.

Base on the force-free assumption, the magnetic field in the solar chromosphere and corona can be obtained from the photospheric magnetic field by extrapolation. For the potential field \( (\alpha = 0) \), the precise analytical solutions can be obtained from Equations (1) and (2), and several practical methods for solution have been proposed \( (e.g., \text{Schmidt}, 1964; \text{Newkirk et al.}, 1968) \). For the linear force-free field \( (\alpha = \text{constant}) \), the analytical solutions can also be obtained from Equations (1) and (2), but the unknown constant \( \alpha \) must be given in advance for the calculations. The value of \( \alpha \) can be determined by comparing the distribution of extrapolated magnetic field lines and the observed structures \( (e.g., \text{Wiegelmann et al.}, 2005) \). Several methods for linear force-free fields have been used to extrapolate the magnetic field \( (e.g., \text{Nakagawa and Raadu}, 1972; \text{Chiu and Hilton}, 1977; \text{Soehner}, 1978; \text{Alissandrakis}, 1981; \text{Gary}, 1989; \text{Aly}, 1992; \text{Yan}, 1995; \text{Song and Zhang}, 2005; \text{Song and Zhang}, 2006) \).

So far the extrapolation methods for the potential field and the linear force-free field have been developed well, but they describe the magnetic field above the photosphere in a very restricted manner. Therefore, the introduction of the nonlinear force-free field model is more reasonable. Recently several extrapolation methods for the nonlinear force-free field have been proposed \( (e.g., \text{Sakurai}, 1981; \text{Chodura and Schlueter}, 1981; \text{Wu et al.}, 1990; \text{Roumeliotis}, 1990; \text{Amari et al.}, 1997; \text{Amari et al.}, 1999; \text{Yan and Sakurai}, 2000; \text{Wheatland et al.}, 2000; \text{Valori et al.}, 2005; \text{Wiegelmann}, 2004; \text{Song et al.}, 2006) \). Although some differences exist among these methods \( (\text{Schrijver et al.}, 2006; \text{DeRosa et al.}, 2009) \), the extrapolated fields generally give the results that are consistent with the observations \( (e.g., \text{Regnier et al.}, 2002; \text{Wiegelmann et al.}, 2009) \). Therefore, the magnetic field extrapolation provides a promising tool for us to understand the magnetic field in the chromosphere and in the corona, and to study the mechanism of solar activity.

Since all the above methods, in principle, can be used to extrapolate the magnetic field in the chromosphere and corona from the photosphere \( (e.g., \text{Song et al.}, 2006; \text{Song et al.}, 2007; \text{He, Wang and Yan}, 2008; \text{Wang et al.}, 2008; \text{Guo et al.}, 2009) \), testing the validity of these models become an imperative subject. Generally speaking, the extrapolated results of the force-free models can be either compared to an analytical field or compared to some observed data such as X-rays, EUV, etc. The semi-analytical solutions of force-free and divergence-free equations given by \( \text{Low and Lou} (1990) \) can provide a 3D magnetic field easily, which create axially-symmetric numerical solutions satisfying the force-free and divergence-free equations in the spherical coordinates. Thus, a part
of the analytical field can be used for testing the validity of the extrapolation methods for nonlinear force-free magnetic fields.

In this paper we select two extrapolation methods by Yan and Sakurai (2000) and Song et al. (2006) and compare them to the semi-analytical field by Low and Loi (1990). Firstly, the principles and solution algorithms will be introduced in Section 2, the results and discussions are shown in Section 3, and finally the conclusions are given in Section 4.

2. Principles and Algorithms

2.1. BIE method

The method of boundary integral equation (BIE) was proposed by Yan and Sakurai (1997, 2000), and was subsequently developed by Yan and Li (2006), He and Wang (2008). The magnetic field can be obtained by direct integration of the magnetic field on the bottom boundary surface. As shown in Figure 1, one assumes a force-free field in the half-space Ω above the photospheric surface Γ. The boundary condition is

\[ \mathbf{B} = \mathbf{B}_0 \quad \text{on} \quad \Gamma, \]  

where \( \mathbf{B}_0 \) is the photospheric vector magnetic field. At infinity, an asymptotic constraint should be imposed to ensure a finite energy content in the half-space \( \Omega \) above \( \Gamma \)

\[ \mathbf{B} = O(r^{-2}) \quad \text{when} \quad r \to \infty, \]  

where \( r \) is the radial distance.

The method uses two constraint conditions (1) and (2) and two boundary conditions (3) and (4) to calculate the magnetic field above the photosphere.
The reference function $Y$ is introduced in this method (Yan and Li 2006),

$$ Y = \frac{\cos(\lambda \rho)}{4\pi \rho} - \frac{\cos(\lambda \rho^*)}{4\pi \rho^*}, \quad (5) $$

where $\rho = [(x-x_i)^2 + (y-y_i)^2 + (z-z_i)^2]^{1/2}$ is the distance between a variable point $(x, y, z)$ and the given field point $(x_i, y_i, z_i)$, $\rho^* = [(x-x_i)^2 + (y-y_i)^2 + (z+z_i)^2]^{1/2}$, and $\lambda$ is a factor dependent on the location of point $i$. After a series of derivations, the magnetic field $\mathbf{B}$ can be obtained from the following formula:

$$ \mathbf{B}(x_i, y_i, z_i) = \int_\Gamma z_i |\lambda r \sin(\lambda r) + \cos(\lambda r)| \mathbf{B}_0(x, y, 0) dxdy, \quad (6) $$

where $r = [(x-x_i)^2 + (y-y_i)^2 + z_i^2]^{1/2}$, $\mathbf{B}_0$ is the magnetic field on the photospheric surface, and $\lambda = \lambda(x_i, y_i, z_i)$ can be calculated from

$$ \int_{\Omega'} (Y \nabla^2 \mathbf{B} - \mathbf{B} \nabla^2 Y) d\Omega = \int_{\Omega''} Y(\lambda^2 \mathbf{B} - \alpha^2 \mathbf{B} - \nabla \alpha \times \mathbf{B}) d\Omega = 0, \quad (7) $$

where $\Omega$ is the half-space above the photospheric surface $\Gamma$, and $\Omega''$ is the same as $\Omega$ but excludes a small neighborhood where the point calculated is included (cf. Yan and Li 2006). Unlike $\alpha$, $\lambda$ is not constant along the magnetic field line; it is a function of position. The theories of BIE are described in detail in Li, Yan, and Song (2004) and Yan and Li (2006). The BIE method is to find the best $\lambda$ through iteration, and to obtain the magnetic field at the same time. When the magnetic field satisfies the following conditions (10) and (11), the corresponding $\lambda$ is a good value:

$$ f_i(\lambda_x, \lambda_y, \lambda_z) = \frac{|\mathbf{J} \times \mathbf{B}|}{|\mathbf{J}| |\mathbf{B}|}, \quad \text{with} \quad \mathbf{J} = \nabla \times \mathbf{B}, \quad (8) $$

$$ g_i(\lambda_x, \lambda_y, \lambda_z) = \frac{\delta \mathbf{B}_i}{\mathbf{B}_i} = \frac{|\nabla \cdot \mathbf{B}| \Delta V_i}{|\mathbf{B}| \Delta \sigma_i}, \quad (9) $$

and

$$ f_i(\lambda_{x^*}, \lambda_{y^*}, \lambda_{z^*}) = \min(f_i(\lambda_x, \lambda_y, \lambda_z)), $$

$$ g_i(\lambda_{x^*}, \lambda_{y^*}, \lambda_{z^*}) = \min(g_i(\lambda_x, \lambda_y, \lambda_z)). \quad (10) $$

We set the following constraints:

$$ f_i(\lambda_{x^*}, \lambda_{y^*}, \lambda_{z^*}) \leq \epsilon_f, \quad g_i(\lambda_{x^*}, \lambda_{y^*}, \lambda_{z^*}) \leq \epsilon_g, \quad (11) $$

where $\epsilon_f$ and $\epsilon_g$ are sufficiently small thresholds. In fact, $f_i(\lambda_x, \lambda_y, \lambda_z)$ indicates the angle between $\mathbf{B}$ and $\mathbf{J}$; if $f_i(\lambda_x, \lambda_y, \lambda_z) = 0$ there is no Lorentz force and Equation (1) is satisfied. Function $g_i(\lambda_x, \lambda_y, \lambda_z)$ stands for the divergence of $\mathbf{B}$; Equation (2) can be satisfied when $g_i(\lambda_x, \lambda_y, \lambda_z) = 0$. The BIE method uses a simple downhill technique to find $\lambda$, and then calculate $\mathbf{B}$ that satisfies Equations (11).
2.2. AVI Method

The vertical integration method \cite{Wu1990} uses a finite difference scheme to solve the height-dependent mixed elliptic-hyperbolic partial differential equations (12)-(15), which can be deduced from Equations (1) and (2):

\[ \frac{\partial B_x}{\partial z} = \frac{\partial B_z}{\partial x} + \alpha B_y, \]  
\[ \frac{\partial B_y}{\partial z} = \frac{\partial B_z}{\partial y} - \alpha B_x, \]  
\[ \frac{\partial B_z}{\partial z} = -\frac{\partial B_x}{\partial x} - \frac{\partial B_y}{\partial y}, \]  
\[ \alpha B_z = \frac{\partial B_y}{\partial x} - \frac{\partial B_x}{\partial y}. \]

However, they constitute an ill-posed problem and the solution diverges as the height increases \cite{Demoulin1992, Cuperman1990, Song2006}. Song et al. \cite{Song2006} proposed the approximate vertical integration (AVI) method, and tried to avoid those problems that the vertical integration method contains. In this method, at first they constructed the magnetic field by the following formulas, supposing the solutions with second-order continuous partial derivatives in a certain height range, \( 0 < z < H \) (\( z \) is the height calculated from the photospheric surface),

\[ B_x = \xi_1(x, y, z)F_1(x, y, z), \]  
\[ B_y = \xi_2(x, y, z)F_2(x, y, z), \]  
\[ B_z = \xi_3(x, y, z)F_3(x, y, z), \]

where \( \xi_1, \xi_2, \) and \( \xi_3 \) mainly depend on \( z \) and slowly vary with \( (x, y) \), \( F_1, F_2, \) and \( F_3 \) mainly depend on \( x \) and \( y \) while weakly vary with \( z \). Equation (16) is a mathematical representation of the similarity solutions and six derivatives \( \partial F_1/\partial x, \partial F_1/\partial y, \partial F_2/\partial x, \partial F_2/\partial y, \partial F_3/\partial x, \partial F_3/\partial y \) change slowly in the \( z \)-direction. In solar active regions, we cannot seek analytical solutions for the magnetic field due to a great variety of magnetic fields, but we can construct an analytical asymptotic solutions within a thin layer: \( \Gamma \) and \( z_k < z < z_{k+1} \) (\( \Gamma \) is the horizontal extension of an active region), \( z_k = k\Delta z \). Here \( \Delta z = H/K \) (\( H \) is the height calculated from the photospheric surface, \( K \) is the number of layers calculated) and \( k = 1, 2, 3, \ldots, K - 1, K \).
After constructing the similarity solutions for Equations (12)-(15), the equations can be written as follows:

\[
\frac{d\xi_1}{dz} F_1(x_i, y_j, z) = \xi_1 \frac{\partial F_3(x_i, y_j, z)}{\partial x} + \alpha(x_i, y_j, z) \xi_2 F_2(x_i, y_j, z),
\]

\[
\frac{d\xi_2}{dz} F_2(x_i, y_j, z) = \xi_1 \frac{\partial F_3(x_i, y_j, z)}{\partial y} - \alpha(x_i, y_j, z) \xi_1 F_1(x_i, y_j, z),
\]

\[
\frac{d\xi_3}{dz} F_3(x_i, y_j, z) = -\xi_1 \frac{\partial F_1(x_i, y_j, z)}{\partial x} - \xi_2 \frac{\partial F_2(x_i, y_j, z)}{\partial y},
\]

\[
\alpha(x_i, y_j, z) \xi_3 F_3(x_i, y_j, z) = \xi_2 \frac{\partial F_2(x_i, y_j, z)}{\partial x} - \xi_1 \frac{\partial F_1(x_i, y_j, z)}{\partial y},
\]

for \( 0 \leq z \leq \Delta z \).

The solutions of the above equations can be found in Song et al. (2006).

The AVI method uses the above technique to calculate the magnetic field from one layer to another, and at the same time the following artificial viscosity formulas are used:

\[
[(B_x)_{i,j}]_{\text{correct}} = (B_x)_{i,j} (1 - \omega_1) + \omega_1 \frac{1}{4} [(B_x)_{i-1,j} + (B_x)_{i+1,j} + (B_x)_{i,j-1} + (B_x)_{i,j+1}],
\]

\[
[(B_z)_{i,j}]_{\text{correct}} = (B_z)_{i,j} (1 - \omega_2) + \omega_2 \frac{1}{4} [(B_z)_{i-1,j} + (B_z)_{i+1,j} + (B_z)_{i,j-1} + (B_z)_{i,j+1}],
\]

where \( \omega_1 = 0.1, \omega_2 = 0.2 \). \([(B_x)_{i,j}]_{\text{correct}}\) can be defined as \([(B_z)_{i,j}]_{\text{correct}}\) above.

Due to the differential scheme used in the AVI method, the deviations of \( \alpha \) and \( \xi \) may be introduced at some points where the values of \( B_x \), \( B_y \), and \( B_z \) approach zero. This problem is unavoidable because the differential is used in this method. In the paper of Song et al. (2006), a reasonable value of \( B_z \) would be replaced when \( B_z \) is less than a threshold. However, this simple method cannot always give the good results. To improve this method, we replace \( B_z \), where the value of \( B_z \) of a point is close to zero, with the mean value of \( B_z \) of its nearest points (in this paper the number of its nearest points is 8), which means that we do a local integration at the points where \( B_z \) approaches zero. The same technique is used for \( B_x \) and \( B_y \) components as well. Here we refer to the AVI method of Song et al. (2006) as the original AVI method, and the AVI method in this paper as the improved AVI method.

2.3. Nonlinear Force-Free Magnetic Field Solutions

Low and Lou (1999) describe a special class of nonlinear force-free fields, which satisfy Equations (1)-(2), written as a second-order partial differential equation (19) in the spherical coordinate system

\[
B = \frac{1}{r \sin \theta} \left( \frac{1}{r} \frac{\partial A}{\partial \theta} - \frac{A}{r} \frac{\partial}{\partial \phi} - Q \frac{\partial}{\partial \phi} \right),
\]

(19)
where $A$ and $Q$ are two scalar functions. The force-free condition require $Q$ to be a strict function of $A$ with

$$\alpha = \frac{dQ}{dA}$$

and

$$\frac{\partial^2 A}{\partial r^2} + \frac{1 - \mu^2}{r^2} \frac{\partial^2 A}{\partial \mu^2} + Q \frac{dQ}{dA} = 0,$$

where $\mu = \cos \theta$. Mathematically the equation is a separable differential equation and the solutions are:

$$A = \frac{P(\mu)}{r^n},$$

$$Q(A) = a A^{1+1/n},$$

where $a$ and $n$ are constants and the Legendre polynomial function $P$ satisfies the nonlinear differential equation

$$(1 - \mu^2) \frac{d^2 P}{d\mu^2} + n(n+1)P + a^2 \frac{1 + n}{n} \mu^{1+2/n} = 0.$$  

For the magnetic field vanishing at infinity, it implies that

$$P = 0 \quad \text{at} \quad \mu = -1, 1.$$  

It can be seen that Equation (19) describes an axially symmetric magnetic field. [Low and Lou (1990)] pointed out that an arbitrary position of a plane determined by two parameters $l$ (the distance between the plane surface boundary and the point source) and $\phi$ (the angle between the normal direction of the surface and the $z$-axis associated with the spherical coordinate system), may represent the magnetic field of an active region on the solar photosphere. Therefore, it can be taken as the boundary conditions for the magnetic field extrapolation. When $n > 0$, the boundary equation (25) creates a discrete infinite set of eigenvalues, which can be denoted by $\alpha_{n,m}^2$, $m = 0, 1, 2, 3,...$, and $\alpha_{n,0}^2 = 0$, and the corresponding eigenfunctions is $P_{n,m}(\mu)$. For different values of $n$ and $m$, it can give different distributions of magnetic field in the spherical coordinate system, which meet the requirements of divergence-free and force-free equations. Then we specify the values of $l$ and $\phi$ for coordinate transformation since the magnetic field in the Cartesian coordinate is needed in our extrapolation. In this paper we choose such two of these solutions as test fields:

SAF1: the semi-analytical field with $n = 1, m = 1, l = 0.3$, and $\phi = \frac{\pi}{4}$, set $x \in [-0.5, 0.5], y \in [-0.5, 0.5]$ and $z \in [0, 1]$ in the Cartesian coordinate system.

SAF2: the semi-analytical field with $n = 3, m = 1, l = 0.3$, and $\phi = \frac{4\pi}{3}$, set $x \in [-0.5, 0.5], y \in [-0.5, 0.5]$ and $z \in [0, 1]$ in the Cartesian coordinate system. The mesh is 64 pixel $\times$ 64 pixel for those two solutions.

---

[Low and Lou (1990)]
3. Results and Discussion

3.1. Comparison of Metrics

Like Schrijver et al. (2006), Amari et al. (2006) and Valori et al. (2007), we also calculate some metrics that have been employed for checking the performance of the extrapolation in their papers. In the following, we will introduce them one by one.

$C_{\text{vec}}$ is used to quantify the vector correlation, which is defined as:

$$C_{\text{vec}} = \frac{\sum_i B_i \cdot b_i / (\sum_i |B_i|^2 \sum_i |b_i|^2)^{1/2}}{\sum_i |B_i|^2},$$  \hspace{1cm} (26)$$

where $B_i$ and $b_i$ are the field vector of the semi-analytical field and the extrapolated field at the grid point $i$, respectively. If the vector fields are identical, then $C_{\text{vec}} \equiv 1$; if $B_i \perp b_i$, then $C_{\text{vec}} \equiv 0$.

$C_{\text{cs}}$ is based on the Cauchy-Schwarz inequality and mostly used to measure the differences of the vector fields:

$$C_{\text{cs}} = \frac{1}{M} \sum_i B_i \cdot b_i / |B_i||b_i| = \frac{1}{M} \sum_i \cos \theta_i,$$  \hspace{1cm} (27)$$

where $M$ is the total number of vectors in the volume to be calculated, and $\theta_i$ is the angle between $B_i$ and $b_i$. $C_{\text{cs}} = 1$ indicates $B_i$ and $b_i$ are parallel; and contrarily, $C_{\text{cs}} = -1$ indicates $B_i$ and $b_i$ are anti-parallel; $C_{\text{cs}} = 0$ indicates $B_i$ and $b_i$ are mutually perpendicular.

$E_n$ is a normalized vector error:

$$E_n = \sum_i |b_i - B_i| / \sum_i |B_i|. \hspace{1cm} (28)$$

The fourth is a mean of the above normalized vector errors:

$$E_m = \frac{1}{M} \sum_i |b_i - B_i| / |B_i|. \hspace{1cm} (29)$$

When $E_m = E_n = 0$, the agreement is perfect, which is different from the first two metrics. However, in this work we will use $E_m(n) = 1 - E_m(n)$ instead of $E_m(n)$ for the comparisons.

The last one measures the fraction of the energy of the extrapolated field normalized to that of the semi-analytical field:

$$\epsilon = \frac{\sum_i |b_i|^2}{\sum_i |B_i|^2}. \hspace{1cm} (30)$$

For these metrics, if $B_i$ and $b_i$ are identical, $C_{\text{vec}}$, $C_{\text{cs}}$, $\epsilon$, $E'_n$ and $E'_m$ should be equal to unity. $E'_n$ and $E'_m$ are based on the differences between the semi-analytical field vectors and the extrapolated field vectors. They thus include the information on the agreement of two vectors both in direction and magnitude.
Table 1. The metrics of $C_{vec}$, $C_{cs}$, $E'_n$, $E'_m$ and $\epsilon$ for the extrapolated fields of BIE, original AVI and improved AVI methods in the calculated box ($64 \times 64 \times 64$).

|                | $C_{vec}$ | $C_{cs}$ | $E'_n$ | $E'_m$ | $\epsilon$ |
|----------------|-----------|----------|--------|--------|-------------|
| Low & Lou (SAF1) | 1.00      | 1.00     | 1.00   | 1.00   | 1.00        |
| BIE             | 0.978     | 0.956    | 0.770  | 0.721  | 0.990       |
| AVI (improved)  | 0.983     | 0.979    | 0.803  | 0.722  | 0.943       |
| AVI (original)  | 0.956     | 0.969    | 0.661  | 0.189  | 0.825       |
| Low & Lou (SAF2) | 1.00      | 1.00     | 1.00   | 1.00   | 1.00        |
| BIE             | 0.959     | 0.873    | 0.658  | 0.567  | 0.978       |
| AVI (improved)  | 0.958     | 0.864    | 0.651  | 0.403  | 0.728       |
| AVI (original)  | 0.939     | 0.858    | 0.402  | 0.214  | 0.678       |

On the other hand $C_{vec}$ and $C_{cs}$ are relatively more influenced by the directional differences between the semi-analytical field vectors and the extrapolated field vectors [Schrijver et al. 2006]. Moreover, $C_{vec}$ and $C_{cs}$ are less sensitive to the errors of the extrapolated field than the normalized vector error $E'_n$. The mean vector error $E'_m$, especially $E'_n$, is a sensitive and reliable indicator of extrapolation accuracy [Valori et al. 2007].

Results of these metrics for two semi-analytical fields (SAF1 and SAF2) are shown in Table 1. It also shows the results of the extrapolated fields of BIE, original AVI and improved AVI methods. We find the consistencies between the semi-analytical fields and the corresponding extrapolated fields of the improved AVI method are better than those by the original AVI method. Especially for $E'_n$ and $E'_m$, the existence of numerical singularities globally affects the accuracy of extrapolation because only a small number of points are used in the improved AVI method. The evident improvements on $E'_n$ and $E'_m$ also indicate that they are sensitive to the errors in the extrapolated field. For each method, the consistencies between SAF1 and the corresponding extrapolated fields are better than those between SAF2 and the corresponding extrapolated fields. These results are consistent with those obtained by other authors [Schrijver et al. 2006; Amari et al. 2006 and Valori et al. 2007]. Just as Amari et al. [2006] pointed out that SAF2 may be considered as a theoretical challenge to push the methods to their limits, because SAF2 actually represents an extreme nonlinear case in which $\alpha$ takes large values on a scale much larger than the distribution of $B_z$. In addition, we can find that the amplitudes of these metrics are comparable to those of other methods (e.g., Schrijver et al., 2006; Amari et al., 2006; Valori et al., 2007). Note that for our extrapolations, only the bottom boundary data from the semi-analytical fields are used, and these metrics only show their overall performance of the extrapolation methods.
Figure 2. Comparisons between the vector fields obtained by SAF1 and the BIE extrapolation. Rows 1, 3, and 5 are for $B_x$, $B_y$, and $B_z$ of SAF1, and rows 2, 4, and 6 are for $B_x$, $B_y$, and $B_z$ of the extrapolation, respectively. The height, $z$, is set from 2 to 10 in a step of $\Delta z = 2$.

3.2. SAF1

Figure 2 shows the image comparisons between SAF1 and the extrapolated field of the BIE method for three magnetic field components. Rows 1, 3, and 5 are for $B_x$, $B_y$, and $B_z$ of SAF1, and rows 2, 4, and 6 are for $B_x$, $B_y$, and $B_z$ of the extrapolated field, respectively. Here, the extrapolation height changes from $z = 2$ to 10 and the step is set $\Delta z = 2$. Generally, two classes of $B_x$, $B_y$, and $B_z$ match well and show no obvious differences when the height is lower (such as $z < 6$). However, the differences become evident as the height increases.

Similar to Figure 2, Figures 3 and 4 show the image comparisons between SAF1 and the extrapolated fields of the original AVI method and the improved AVI method, respectively. Due to the differential scheme used in the AVI method, the calculation errors of $\alpha$ and $\xi$ are introduced when the values of $B_x$, $B_y$, and $B_z$ are close to zero. For example, evident errors exist in Figure 3 near the points where $B_z$ are close to zero. It becomes the main error source for the original AVI extrapolation. However, after the improvement was introduced to this method,
Figure 3. Same as Figure 2, but for the original AVI method. The extrapolation errors mainly occur near the polarity inversion line.

evident differences between SAF1 and the extrapolated field disappear as shown in Figure 4.

The correlations of $B_x$, $B_y$, $B_z$ and azimuths ($\phi$) between SAF1 and the extrapolated fields of the BIE method, the original AVI and improved AVI methods are shown in Figure 5, where the solid, dotted and dashed lines indicate the BIE method, the original AVI and improved AVI methods, respectively. The $x$- and $y$-axes represent the extrapolated height and the correlation coefficient, respectively. For the BIE method, the correlation coefficients of $B_x$, $B_y$, and $\phi$ are greater than 95%, and those of $B_z$ are greater than 98% below $z = 10$. This suggests that the fields extrapolated with the BIE method are reliable for $z < 10$. Relative to the original AVI method, it can be seen that there are evident increases of the correlation coefficients between SAF1 and the extrapolated field of the improved AVI method. For example, there is an increase of 4% for the correlation coefficient of $B_x$ at $z = 10$. Furthermore, it can be found that for the improved AVI method, the correlation coefficients of $B_y$ and $B_z$ between SAF1 and the extrapolated field are greater than 95% below $z = 10$; while the correlation coefficients of $B_x$ and $\phi$ are less than 95% below $z = 10$. It may be
Figure 4. Same as Figure 2, but for the improved AVI method. After improvement, most extrapolation errors occurring near the polarity inversion line disappear.

concluded that the fields extrapolated with the improved AVI are reliable when the height is below $z = 10$, because all its correlation coefficients are greater than 90% within this height range.

The shapes of the selected magnetic field lines for SAF1 and the extrapolated fields of each method are shown in Figure 6, where the red and blue lines are for the closed and open magnetic field lines, respectively. It can be seen that the extrapolated field lines basically coincide with those of SAF1 at lower heights, but the differences become evident as the height increases, especially for the open magnetic field lines of the AVI method.

3.3. SAF2

Figure 7 is made in the same way as in Figure 2, but shows the image comparisons between SAF2 and the extrapolated field of BIE for three magnetic field components. We can find that the field components $B_x$ and $B_z$ match well with those of SAF2, while $B_y$ does not. There are evident differences for $B_y$ components when the height is larger than $z = 4$. 
Figure 5. Correlations of $B_x$, $B_y$, $B_z$ and azimuths ($\phi$) between SAF1 and the extrapolated fields (of the BIE, original and improved AVI methods) at various heights.

Figure 6. Representative magnetic field lines for SAF1 and the corresponding extrapolated fields of the BIE, original and improved AVI methods.
Similar to Figure 7, Figures 8 and 9 show the image comparisons of the magnetic field components between SAF2 and the extrapolated fields of the original AVI and improved AVI methods, respectively. Comparing two figures, we find the consistency of SAF2 with the fields extrapolated with the improved AVI method (Figure 9) are obviously superior to the fields extrapolated with the original AVI method (Figure 8). In Figure 8, evident difference appears for the $B_z$ components even when the height is just at $z = 2$. In Figure 9, we find that the field components $B_x$ and $B_z$ of SAF2 and the improved AVI method match well and they show negligible differences at the height lower than $z = 6$. Similar to the BIE method, the $B_y$ component of the improved AVI method also does not match well with that of SAF2.

Figure 10 shows the correlations of $B_x$, $B_y$, $B_z$ and azimuths ($\phi$) between SAF2 and the corresponding extrapolated fields of the BIE method, the original AVI and improved AVI methods at various heights. Comparing Figures 10 and 5, we find that all the correlation coefficients decrease evidently, of which for $B_x$, $B_z$, and $\phi$ they are greater than 90% below $z = 10$, but for $B_y$ it is less than 90%, and decline to 80% at $z = 10$ due to the complexity of $B_y$. The
poor correlation for $B_y$ can also be seen from Figure 7, in which the difference of $B_y$'s between SAF2 and the extrapolated field of the BIE method are very evident. The deviations of $B_y$'s from that of SAF2 can also affect the correlation coefficients of $\phi$ as the azimuth is directly derived from $B_x$ and $B_y$. Compared to the original AVI method, there are evident improvement for the correlation coefficients of the field components between SAF2 and the extrapolated field of the improved AVI method, especially for $B_y$, e.g., there is an increase of 6% at $z = 10$. For the improved AVI method, the correlation coefficients of $B_z$ are greater than 95% below $z = 10$, while those of $B_x$ and $B_y$ are less than 90%. The correlation of $B_y$ in the BIE method is the worst compared to the other methods. On the whole, the correlation coefficients of the magnetic field components between SAF2 and the extrapolated fields of the BIE method and the AVI method (original or improved) are greater than 80% below $z = 10$.

In Figure 11, selected magnetic field lines for SAF2 and the extrapolated field of each method are all drawn and their disagreements are evident. For example, the open field lines of three extrapolated fields all can reach higher relative to those of SAF2. The differences of the closed field lines between SAF2 and the extrapolated fields, either the BIE method or the AVI method, become more
Figure 9. Same as Figure 7, but for the improved AVI method.

Figure 10. Correlations of $B_x$s, $B_y$s, $B_z$s and azimuths ($\phi$) between SAF2 and the extrapolated field at various heights.
Study on two Methods for Nonlinear Force-free Extrapolation

evident as the height increases. Note that we cannot see more improvements in the field lines of the improved AVI method.

4. Conclusions

The magnetic field extrapolation is a main tool to study the properties of solar magnetic field in the chromosphere and corona. Thus, it is necessary to test the validity of different extrapolation methods. In this work, two semi-analytical fields are used to test two kinds of extrapolation fields derived from the BIE and AVI methods. In the AVI method, as the differential scheme is used to extrapolate the magnetic field, the numerical singularities cannot be removed completely. In this paper, we do some small scale smoothing to solve the problem and get better results than those obtained by [Song et al. (2006)]. However, by our analysis we find that the reliable results are only limited at the lower heights, and new improvements are still needed for this method. On the other hand, the benefit of this method is its time-saving in carrying out the extrapolation. In the case for our computer (Intel Pentium 4 CPU 3.00GHz, RAM 1.0GB), it takes only 10 min to extrapolate the magnetic field from \( z = 0 \) to 64 for a mesh 64 × 64, and produce 320 files (divided by different heights, \( \Delta z = 0.2 \)).

In the BIE method, it uses Green’s function to reduce the problem to the Helmholtz equation, and then the integral method is applied to solve the Helmholtz equation and extrapolates the magnetic field. Therefore, the problem of singularities in differential equations can be avoided. While the key problem for the BIE method is whether a reasonable \( \lambda \) can be found or not, which may strongly affect
the extrapolated results. For example, if we can increase our computer power, the better results could be obtained by modifying the iteration and computational accuracy. For our computer, it takes about 10 h to calculate the extrapolated field from $z = 0$ to 64 for a mesh $64 \times 64$, which may be a limitation of the BIE method and an urgent problem to solve.

From the metrics listed in Table 1 and the correlation analysis to each magnetic field component in the paper, it can be found that the improved AVI method is better than the original AVI method evidently. It can also be found that the poor results are obtained for the $B_x$ extrapolation in comparison with SAF1 and for the $B_y$ extrapolation in comparison with SAF2. It may be because the strong current density near or in weak field regions has a strong influence on the solutions of nonlinear force-free extrapolation.

Through comparisons, it is found that there are evident differences between the semi-analytical field and the extrapolated fields. However, for the lower heights, the two extrapolation methods can give reliable results. Finally, it should be noted that using the semi-analytical field of [Low and Lou (1990)] to test the validity of the extrapolation methods may have theoretical disadvantages as only the finite bottom boundary data are used in the extrapolations, but the semi-analytical field presents the global magnetic configurations.

Acknowledgements The authors wish to thank the anonymous referee for his/her helpful comments and suggestions. We thank Dr. Han He for his code of the BIE method and other helps.
