ABSTRACT: The richness of 5d $\mathcal{N}=1$ theories with a UV fixed point at infinite coupling is due to the existence of local disorder operators known as instanton operators. By considering the Higgs branch of SU(2) gauge theories with $N_f \leq 7$ flavours at finite and infinite coupling, we write down the explicit chiral ring relations between instanton operators, the glueball superfield and mesons. Exciting phenomena appear at infinite coupling: the glueball superfield is no longer nilpotent and the classical chiral ring relations are quantum corrected by instanton operators bilinears. We also find expressions for the dressing of instanton operators of arbitrary charge. The same analysis is performed for USp(2k) with an antisymmetric hypermultiplet and pure SU(N) gauge theories.

1 Introduction

The dynamics of five-dimensional supersymmetric gauge theories has many interesting features. From the Lagrangian perspective these field theories are not renormalisable. However, by using string theoretic methods along with field theory analysis, it was demonstrated that a number of such field theories can be considered as flowing from certain non-trivial superconformal field theories in the ultraviolet (UV) \cite{1-4}. Such UV fixed points at infinite gauge coupling may exhibit an enhancement of the global symmetry. In particular, in the seminal work \cite{1}, it was pointed out that the UV fixed point of 5d $\mathcal{N} = 1$ SU(2) gauge theory with $N_f \leq 7$ flavours exhibits $E_{N_f+1}$ flavour symmetry, which enhances from the global symmetry $SO(2N_f) \times U(1)$ apparent in the Lagrangian at finite coupling. Since then a large class of five dimensional supersymmetric field theories have been constructed using webs of five-branes \cite{5-7} and the enhancement of the global symmetry of these theories has been studied using various approaches, including superconformal indices \cite{8-19}, Nekrasov partition functions and (refined) topological string partition functions \cite{20-28}.

In five dimensions, instantons are particles charged under the the U(1) global symmetry associated with the topological conserved current $J = \frac{1}{8\pi^2} \text{Tr} *(F \wedge F)$; this global symmetry is denoted by $U(1)_I$ in the rest of the paper. In the UV superconformal field theory, the instanton particles are created by local operators known as instanton operators, that insert a topological defect at a spacetime point and impose certain singular boundary conditions on the fields \cite{29-31}. These operators play an important role in enhancing the global symmetry of the theory. For 5d $\mathcal{N} = 1$ field theories at infinite coupling, it was argued that instanton operators with charge $I = \pm 1$, form a multiplet under the supersymmetry and flavour symmetry \cite{31}. In 5d $\mathcal{N} = 2$ Yang-Mills theory with simply laced gauge group, it is believed that the instanton operators constitute the Kaluza-Klein tower that enhances the Poincaré symmetry and provides the UV completion by uplifting this five dimensional theory to the 6d $\mathcal{N} = (2,0)$ CFT \cite{29, 32, 33}.

Standard lore says that the Higgs branch of theories with 8 supercharges in dimensions 3 to 6 are classically exact, and do not receive quantum corrections. In 5 dimensions, this statement turns out to be imprecise, and should be corrected. In fact, one of the main points of the paper, is that there are three different regimes, given by 0, finite, and infinite gauge coupling. The hypermultiplet moduli space, which we always refer to as the Higgs branch, turns out to be different in each of these regimes, and hence our analysis corrects and sharpens the standard lore. The main goal of the paper is to understand how, at infinite coupling, instanton operators correct the chiral ring relations satisfied by the classical fields at finite coupling.

In order to perform such an analysis we start from the known Higgs branch at infinite coupling and write the Hilbert series of such a moduli space for various 5d $\mathcal{N} = 1$
theories. We mostly focus on the SU(2) gauge theories with \( N_f \) flavours, for which string theory arguments show that the Higgs branch at infinite coupling is the reduced moduli space of one \( E_{N_f+1} \) instanton on \( \mathbb{C}^2 \) \cite{1, 6}. The Hilbert series counts the holomorphic functions that parametrise the Higgs branch, graded with respect to the Cartan subalgebra of the (enhanced) flavour symmetry and the highest weight of the SU(2) \( R \)-symmetry of the theory:

\[
H(t, y) = \text{Tr}_H(t^{2R} y_H^A),
\]

where \( H \) is the Hilbert space of chiral operators of the SCFT, \( R \) the SU(2)\(_R\) isospin and \( H_A \) the Cartan generators of the enhanced global symmetry.

Such a Hilbert series can then be expressed in terms of the global symmetry of the theory at finite coupling — the latter is a subgroup of the enhanced symmetry at infinite coupling:

\[
H(t, y(x, q)) = \text{Tr}_H(t^{2R} q^I x_a^H_a),
\]

where \( I \) is the topological charge and \( H_a \) the Cartan generators of the SO(2\( N_f \)) flavour symmetry. This decomposition allows us to extract the contributions of the classical fields and the instanton operators to the Higgs branch chiral ring and explicitly write down the relations they satisfy.

The paper is organised as follows. In section 2 we study the Higgs branch of SU(2) gauge theories with \( N_f \leq 7 \) flavours, spell out the relations in the chiral ring in terms of mesons, glueball and instanton operators, and discuss the dressing of instanton operators. We generalise the analysis to pure USp(2\( k \)) Yang-Mills theories with an antisymmetric hypermultiplet in sections 3 and 4, and to pure SU(\( N \)) Yang-Mills in section 5. We close the paper with a discussion of our results and an outlook in section 6. Several technical results are relegated to appendices.

2 SU(2) with \( N_f \) flavours: one \( E_{N_f+1} \) instanton on \( \mathbb{C}^2 \)

The dynamics of 5d \( \mathcal{N} = 1 \) SU(2) gauge theory with \( N_f \leq 7 \) flavours was studied in detail in \cite{1}. In there it was argued that, despite being power counting non-renormalisable, these theories possess strongly interacting UV fixed points. Moreover a classification was proposed where the global symmetry, which at finite coupling is SO(2\( N_f \)) \( \times \) U(1)\(_f\), with U(1)\(_f\) the global symmetry associated with a topologically conserved current, enhances to \( E_{N_f+1} \), where \( E_1 = U(1) \), \( E_1 = SU(2) \), \( E_2 = SU(2) \times U(1) \), \( E_3 = SU(3) \times SU(2) \), \( E_4 = SU(5) \), \( E_5 = SO(10) \) and \( E_6, E_7, E_8 \) are the usual exceptional symmetries.

The analysis presented in this paper focuses on how the Higgs branch of these 5d theories changes along the RG flow. In particular we take care in distinguishing three different regimes for these theories, the operators that contribute to the chiral ring on the Higgs branch\(^1\) and the defining equations that these operators satisfy:

\(^1\)Even though we discuss theories with minimal \( \mathcal{N} = 1 \) supersymmetry (that is 8 Poincaré supercharges)
In the classical regime, where fermions are neglected, these 5d theories have the usual Higgs branch which is just given by $\hat{\mathcal{M}}_{1,SO(2N_f)}$, the centred (or reduced) moduli space of one SO($2N_f$) instanton. The gauge invariant operators that generate this space are mesons $M^{ab}$, constructed out of chiral matter superfields in the bifundamental of the SU(2) gauge group and SO($2N_f$) flavour group. The relations that these generators satisfy on the moduli space can be extrapolated from its description as the minimal nilpotent orbit of SO($2N_f$) [34]. They are the usual Joseph relations [35] and their transformation properties can be read off from the decomposition of the second symmetric product of the adjoint, the representation in which the generator transforms. Let $V(\theta)$ denote the adjoint representation. The decomposition

$$\text{Sym}^2 V(\theta) = V(2\theta) + \mathcal{J}_2$$

prescribes that the relations transform in the representation $\mathcal{J}_2$. For SO($2N_f$)

$$\mathcal{J}_2 = \text{Sym}^2[1,0,\ldots] + \wedge^4[1,0,\ldots].$$

(2.2)

We can construct these representations from the adjoint mesons $M^{ab}$ as follows. Take $M$ to be an antisymmetric $2N_f \times 2N_f$ matrix, $M^{ab} = -M^{ba}$, $a,b = 1,\ldots,2N_f$. Then the two terms of (2.2) correspond respectively to:

$$M^2 = 0$$

(2.3)

$$M^{[ab}M^{cd]} = 0.$$  

(2.4)

We call the last equation the rank 1 condition, since for an antisymmetric matrix it is equivalent to the vanishing of all degree 2 minors.

When the coupling is finite, one needs to take into account the contribution from the gaugino sector. In particular, the glueball superfield $S$, which is a chiral superfield bilinear in the gaugino superfield $W$, is now no longer suppressed and will de jure appear in the chiral ring. This operator satisfies a classical relation in the chiral ring as in four dimensions [36], namely

$$S^2 = 0,$$

(2.5)

hence $S$ is the only extra operator that one needs to consider at finite coupling. At first sight it might seem counterintuitive that $S$ contributes to the Higgs branch as it is a bilinear in the vector multiplet. In fact in 5d the Higgs branch is the only complex branch of the full moduli space. As such, any chiral operator, and in

in 5 dimensions, we are interested in the chiral ring as defined in terms of a subsuperalgebra with 4 supercharges, and the Higgs branch as a complex algebraic variety. We therefore use 4d $\mathcal{N} = 1$ notation and terminology throughout this paper. Even though this formalism is not consistent with Poincaré supersymmetry in five dimensions, it is necessary to discuss chiral operators and holomorphic functions on the Higgs branch.
particular the glueball superfield $S$, belongs to the class of Higgs operators. This will become even clearer later, when we recover the finite coupling Higgs branch from the one at infinite coupling.

Geometrically we interpret the operator $S$ as generating a 2-point space, which by a slight abuse of notation we denote by $\mathbb{Z}_2$. Algebraically the Hilbert series for this space is simply written as

$$HS(\mathbb{Z}_2; t) = 1 + t^2$$

(2.6)

where 1 signifies the identity operator and the $t^2$ term is associated to the quadratic operator $S$. The fugacity $t$ grades operators by their $SU(2)_R$ representation and the normalisation is chosen so that the power is twice the isospin. The meson $M^{ab}$ and the glueball superfield $S$ obey the chiral ring relation $[36, 37]$ $SM^{ab} = 0$.

(2.7)

This signifies that the spaces $\tilde{M}_{1,SO(2N_f)}$ and $\mathbb{Z}_2$ intersect only at the origin. From an algebraic perspective, when two moduli spaces $X$ and $Y$ intersect, the Hilbert series of their union is given by the surgery formula

$$H_{X \cup Y} = H_X + H_Y - H_{X \cap Y},$$

(2.8)

where the subtraction is done to avoid double counting [38]. Thus, when $\mathbb{Z}_2$ is glued to $\tilde{M}_{1,SO(2N_f)}$, the net effect on the Hilbert series is simply that of adding a $t^2$ to the Hilbert series of $\tilde{M}_{1,SO(2N_f)}$.

The plethystic logarithm\(^2\) of this newly obtained expression is interesting: it shows that at order $t^4$ there are two extra relations compared to the classical regime, one transforming in the singlet and one transforming in the adjoint of $SO(2N_f)$. The singlet relation is (2.5). For the adjoint relation the only possible extra operator that one can construct in such a representation is $SM^{ab}$. The adjoint relation is then precisely (2.7).

- At infinite coupling, the moduli space is a different space altogether. Instanton operators, carrying charge under $U(1)_I$, contribute to the chiral ring and are responsible for prompting symmetry enhancement: the Higgs branch in this regime becomes isomorphic to the reduced moduli space $\tilde{M}_{1,E_{N_f+1}}$ of one $E_{N_f+1}$ instanton on $\mathbb{C}^2$ [1]. In order for this to happen a crucial event on the chiral ring takes place: instanton and anti-instanton operators $I$ and $\bar{I}$ of $U(1)_I$ charge $\pm 1$ correct the relation (2.5).\(^3\)

\(^2\)The plethystic logarithm of a multivariate function $f(x_1, \ldots, x_n)$ such that $f(0, \ldots, 0) = 1$ is

$$PL[f(x_1, \ldots, x_n)] = \sum_{k=1}^{\infty} \frac{1}{k} \mu(k) \log f(x_1^k, \ldots, x_n^k)$$

(2.9)

where $\mu(k)$ is the Moebius function. The plethystic logarithm of the Hilbert series encodes generators and relations of the chiral ring.

\(^3\)We call the instanton operator $\bar{I}$ of topological charge $-1$ “anti-instanton operator”, even though it is mutually BPS with the positively charged instanton operator $I$.  

---

"The plethystic logarithm of a multivariate function $f(x_1, \ldots, x_n)$ such that $f(0, \ldots, 0) = 1$ is

$$PL[f(x_1, \ldots, x_n)] = \sum_{k=1}^{\infty} \frac{1}{k} \mu(k) \log f(x_1^k, \ldots, x_n^k)$$

(2.9)

where $\mu(k)$ is the Moebius function. The plethystic logarithm of the Hilbert series encodes generators and relations of the chiral ring.

"We call the instanton operator $\bar{I}$ of topological charge $-1$ “anti-instanton operator”, even though it is mutually BPS with the positively charged instanton operator $I".
This is the most dramatic dynamical mechanism happening at infinite coupling: the operator $S$ is no longer a nilpotent bilinear in the vector multiplet and it becomes, for all intents and purposes, a chiral bosonic operator on the Higgs branch. The contribution of $S$ to the chiral ring will no longer amount to (2.6), but instead an infinite tower of operators will appear generating a factor $(1 - t^2)^{-1}$ in the Hilbert series.

The purpose of this paper is to explore these statements quantitatively for known cases of UV-IR pairs of theories. We do this as follows. We start from the UV theory at infinite gauge coupling, which has $E_{N_f+1}$ symmetry acting on the hypermultiplet moduli space. As soon as the dimensionful gauge coupling becomes finite, a term is added to the scalar potential which is proportional to the norm squared of the moment maps of the broken symmetries in the breaking $E_{N_f+1} \to SO(2N_f) \times U(1)_I$. Consequently, the broken moment maps must vanish on the Higgs branch of the theory at finite coupling. In terms of the chiral ring, this sets to zero the instanton operators $I$ and $\tilde{I}$.

Computationally, one starts with the Hilbert series of the reduced one $E_{N_f+1}$ instanton moduli space written in terms of representations of $E_{N_f+1}$ [39] and decomposes them into representations of $SO(2N_f) \times U(1)_I$. For all theories of our interest, the Hilbert series after this decomposition admits a very simple expression in terms of the highest weight generating function [40]. This allows us to analyse the generators of the moduli space in terms of instanton operators and classical fields, and in many cases the relations between such generators are sufficiently simple to be written down explicitly.

2.1 $E_0$

The $E_0$ theory is the trivial case. There is no hypermultiplet moduli space. Consequently the Hilbert series for this theory is just given by 1, corresponding to the identity operator. The theory has no RG flow. Its interest lies in it being the limiting case of all the theories we consider in this section since none of the operators ($M, S, I$; $e, I$) makes an appearance.

2.2 $N_f = 0$

A pure SU(2) SYM theory with $\mathcal{N} = 1$ supersymmetry in 5d can be obtained by flowing from two UV fixed points which have different global symmetry. The existence of these two theories is dictated by a discrete $\theta$ parameter taking value in $\pi_1(\text{Sp}(1)) = \mathbb{Z}_2$ [2]. For the non-trivial element the global symmetry at infinite coupling is $\tilde{E}_1 = U(1)$ whilst for the identity element the global symmetry is $E_1 = SU(2)$.

2.2.1 The $\tilde{E}_1$ theory

For the theory with $\theta = \pi$ no enhancement of the global symmetry occurs: the global symmetry at finite and infinite coupling is the instanton charge symmetry $U(1)_I$. Here instanton operators are absent and the generator of the moduli space is just $S$ obeying $S^2 = 0$, both at infinite and finite coupling. The moduli space generated by this operator is simply $\mathbb{Z}_2$. Classically the moduli space is trivial.

\footnote{Although this argument applies to most of the theories we study in this paper, it is in general not useful for theories where instanton operators have SU(2)$_R$ spin higher than 1, e.g. as in section 5.}
2.2.2 The $E_1$ theory

For the theory associated to the trivial element of the $\mathbb{Z}_2$ valued $\theta$ parameter the $U(1)_I$ topological symmetry is enhanced to $SU(2)$ by instanton operators at infinite coupling. In this regime the Higgs branch of the theory is isomorphic to the reduced moduli space of one-SU(2) instanton $\hat{\mathcal{M}}_{1,\text{SU}(2)}$, which is the orbifold $\mathbb{C}^2/\mathbb{Z}_2$. This theory is the prototypical example of the class we study. Since there is no flavour symmetry, we can understand the three regimes by means of simple physical arguments.

As we flow away from the UV fixed point, the Higgs branch is lifted and its only remnant is a discrete $\mathbb{Z}_2$ space generated by $S$. Classically, even this contribution can be neglected and the Higgs branch is completely absent. This is a remarkable effect whereby from no Higgs branch in the classical regime a full Higgs branch opens up at infinite coupling.

Algebraically we start from the Hilbert series for $\mathbb{C}^2/\mathbb{Z}_2$ and decompose it in representations of $U(1)_I$ so that we can identify the contribution from instanton operators, as well as the finite coupling chiral operators, and their relations.

The Hilbert series for $\mathbb{C}^2/\mathbb{Z}_2$ can be written as

$$H[\hat{\mathcal{M}}_{1,\text{SU}(2)}](t; x) = \sum_{n=0}^{\infty} [2n]_x t^{2n} = \frac{1 - t^4}{(1 - t^2)(1 - t^2 x^{-2})},$$

(2.10)

where $t$ is the fugacity for the SU(2)$_R$ symmetry, $x$ is the fugacity for the SU(2) global symmetry acting on $\mathbb{C}^2/\mathbb{Z}_2$, and $[2n]_x$ stands for the character, as a function of $x$, of the representation of SU(2) with such a Dynkin label. Identifying the Cartan subalgebra of the SU(2) symmetry with U(1)$_I$, we obtain

$$H[\hat{\mathcal{M}}_{1,\text{SU}(2)}](t; q^{1/2}) = \frac{1 - t^4}{(1 - t^2 q)(1 - t^2)(1 - t^2 q^{-1})},$$

(2.11)

$$= \frac{1}{1 - t^2} \sum_{j=-\infty}^{\infty} t^{2|j|} q^j.$$

2.2.3 The generators and their relations

Eq. (2.11) has a natural interpretation in terms of operators at infinite coupling:

- Each term in the sum $t^{2|j|} q^j$ corresponds to an instanton operator $I_{+|j|}$ for $j > 0$ and an anti-instanton operator $I_{-|j|}$ for $j < 0$ that is the highest weight state of the SU(2)$_R$ representation with highest weight $2|j|$.\footnote{Notice how the SU(2)$_R$ spin of an instanton operator of charge $\pm j$ is $|j|$. Whilst we can easily extract the SU(2)$_R$ spin as a function of instanton number, it is not clear how to do so for the representation under the global symmetry, as will be seen for the cases with higher number of flavours.} $q$ is the fugacity for the instanton number U(1)$_I$. The plethystic logarithm of the Hilbert series shows that the instanton operator $I_{+|j|}$ is generated by the charge 1 operator $I_{+1} \equiv I$ through the relation $I_{+|j|} = (I)^j$. Similarly $I_{-|j|} = (\bar{I})^j$ where $\bar{I} \equiv I_{-1}$.

- The tower of operators generated by $S$ can be identified with the factor $(1 - t^2)^{-1}$. This enhancement in the number of operators constructed from powers of $S$ is crucial:
at infinite coupling $S$ is a full-on operator on the Higgs branch and, together with
the instanton and anti-instanton operators $I, \bar{I}$, forms a triplet of the SU(2) that
generates $\mathbb{C}^2/\mathbb{Z}_2$.

From this form of the Hilbert series we can also give another interpretation to the Higgs
branch at infinite coupling. Instanton operators on the Higgs branch in 5d $\mathcal{N} = 1$ theories
play a similar role to monopole operators in 3d $\mathcal{N} = 4$ [41] and $\mathcal{N} = 2$ theories [42, 43]: in
this sense (2.11) can be interpreted as the space of dressed instanton operators, where the
factor $\frac{1}{1-x^2}$ is the dressing from the operator $S$ and it is freely generated.

The numerator in the rational function of (2.11) signifies a relation quadratic in the
operators which can only be given by

$$S^2 = II,$$  \hfill (2.12)

the defining equation for $\mathbb{C}^2/\mathbb{Z}_2$.

At finite coupling, where $I, \bar{I} = 0$, we recover the known chiral ring relation (2.5), i.e.
the nilpotency of the operator $S$. As we have explained, the only remnant of $\mathbb{C}^2/\mathbb{Z}_2$ is a
residual $\mathbb{Z}_2$ generated precisely by $S$.

Classically, we can set $S = 0$ and lift the Higgs branch entirely.

2.3 $N_f = 1$

For $N_f = 1$ and $N_f = 2$ the infinite coupling Higgs branch is the moduli space of one
instanton for a product gauge group. In such cases the moduli space is given by the
union of the one instanton moduli space for each factor. For the case of $N_f = 1$, i.e
$E_2 = SU(2) \times U(1)$, the Higgs branch at infinite coupling is thus the union of the one
SU(2) and the one U(1) instanton moduli spaces.

For the U(1) instanton moduli space, there are two possible ADHM constructions that
one may consider: (1) USp(2) gauge theory with one flavour, and (2) U(1) gauge theory
with one flavour. As analysed below, the Higgs branch of the former is $\mathbb{Z}_2$ whereas the
Higgs branch of the latter is a point. A priori it might not be apparent which option is the
correct one but consistency with the finite coupling regime points out that the right choice
is the former. We provide an independent argument below.

Let us begin with the first option. The Higgs branch of the ADHM gauge theory given
by USp(2) with one flavour describes the moduli space of one SO(2) instanton.\footnote{To be precise, the flavour symmetry of the quiver gauge theory is $O(2)$, not $SO(2)$. (We thank the referee for raising this point.) However the moduli space of instantons in question is insensitive to the difference between the two groups.} There is
only one operator in the chiral ring, $P$, subject to a quadratic nilpotency relation, $P^2 = 0$.
The moduli space of one SO(2) instanton is thus $\mathbb{Z}_2$.\footnote{Note that as rings $\mathbb{C}[P]/(P^2) \neq \mathbb{C}[P]/\langle P \rangle$.}

On the other hand, one may consider a U(1) gauge theory with one flavour, whose
Higgs branch is often referred to as “the moduli space of one U(1) instanton”. The gauge
invariant quantity is $QQ$ but is set to zero by the F-terms. The moduli space is thus trivial:
it consists of one point only rather than two.
The reduced moduli space \( \hat{\mathcal{M}}_{1,E_2} \) of one \( E_2 \) instanton is thus either isomorphic to the space \( \mathbb{C}^2/\mathbb{Z}_2 \cup \mathbb{Z}_2 \) or to \( \mathbb{C}^2/\mathbb{Z}_2 \cup \{1\} \), depending on which of the above options is correct.

With the first option, the Hilbert series of \( \hat{\mathcal{M}}_{1,E_2} \) can be written using (2.8) as:

\[
H[\hat{\mathcal{M}}_{1,E_2}](t; x) = H[\hat{\mathcal{M}}_{1,\text{SU}(2)}] + H[\mathbb{Z}_2] - 1 = \frac{1 - t^4}{(1 - x^2t^2)(1 - t^2)(1 - x^{-2}t^2)} + t^2
\] (2.13)

where \( H[\mathbb{Z}_2] = 1 + t^2 \) is generated by \( P \).

With the second option, the Hilbert series of \( \hat{\mathcal{M}}_{1,E_2} \) is

\[
H[\hat{\mathcal{M}}_{1,E_2}](t; x) = H[\hat{\mathcal{M}}_{1,\text{SU}(2)}] = \frac{1 - t^4}{(1 - x^2t^2)(1 - t^2)(1 - x^{-2}t^2)} .
\] (2.14)

The generator of the \( \mathbb{C}^2/\mathbb{Z}_2 \) factor is \( \Phi^{ij}, i = 1, 2 \), with \( \Phi^{ij} = \Phi^{ji} \) and it obeys the quadratic nilpotency:

\[
\Phi^{ij} \epsilon_{jk} \Phi^{kl} = 0
\] (2.15)

where \( \epsilon_{ij} \) is defined by its antisymmetry property and \( \epsilon_{12} = 1 \).

The extra generator, \( P \), is there only in the case of a union of \( \mathbb{C}^2/\mathbb{Z}_2 \) with a two point moduli space. In its presence, beside (2.15), two further relations hold:

\[
P^2 = 0
\]

\[
P \Phi^{ij} = 0
\] (2.16)

(2.15) is the usual Joseph relation for the SU(2) minimal nilpotent orbit \( \mathbb{C}^2/\mathbb{Z}_2 \). The last equation encodes the fact that the two spaces, \( \mathbb{C}^2/\mathbb{Z}_2 \) and \( \mathbb{Z}_2 \), only intersect at one point, the origin of the moduli space.

Let us proceed without making any assumption on whether \( \hat{\mathcal{M}}_{1,E_2} \) is given by \( \mathbb{C}^2/\mathbb{Z}_2 \cup \mathbb{Z}_2 \) or \( \mathbb{C}^2/\mathbb{Z}_2 \cup \{1\} \). In the next subsection, we show that consistency with the finite coupling result tells us that the correct choice is the former.

2.3.1 The generators and their relations

The theory at finite coupling has a Higgs branch which is isomorphic to the union of \( \hat{\mathcal{M}}_{1,\text{SO}(2)} \) with \( \mathbb{Z}_2 \), the former generated by a meson, \( M \), subject to a quadratic nilpotency and the latter by the glueball superfield \( S \), itself quadratically nilpotent. The finite coupling chiral ring is thus defined by:

\[
M^2 = S^2 = SM = 0
\] (2.17)

where the last equation signifies that the two spaces, \( \hat{\mathcal{M}}_{1,\text{SO}(2)} \) generated by \( M \) and \( \mathbb{Z}_2 \) generated by \( S \), are orthogonal to each other and intersect only at the origin. Moreover since \( \hat{\mathcal{M}}_{1,\text{SO}(2)} \cong \mathbb{Z}_2 \), the Higgs branch at finite coupling is given by \( \mathbb{Z}_2 \cup \mathbb{Z}_2 \).
The goal is to reproduce the set of equations (2.17) from the ones at infinite coupling by setting the instanton operators appearing there to zero. This can be achieved as follows. Decompose the generators $\Phi^{ij}$ of $\tilde{M}_{1,E_2}$ by letting
\begin{align}
\Phi^{11} &= I \\
\Phi^{12} &= M \\
\Phi^{22} &= -\tilde{I}
\end{align}
where $M$ is the SO(2) mesonic operator and $I, \tilde{I}$ are the instanton and anti-instanton operators respectively. The relation in (2.15) can then be rewritten as:
\begin{equation}
M^2 = I \tilde{I} .
\end{equation}
It is clear that, by setting the instanton operators to zero, only one of the three equations in (2.17) can be recovered for the finite coupling limit. However, if the extra operator $P$ and the extra relations in (2.16) are also taken into account, the classical regime can be precisely recovered. To this avail, let $P$ be decomposed as:
\begin{equation}
P = S - M ,
\end{equation}
i.e. a linear combination of the meson $M$ and the glueball $S$. Then (2.15) and (2.16) together can be rewritten as:
\begin{align}
M^2 &= \tilde{I} I \\
S^2 &= \tilde{I} I \\
SM &= \tilde{I} I \\
MI &= SI \\
\tilde{I} M &= \tilde{I} S .
\end{align}
This time, setting $I, \tilde{I} = 0$, the finite coupling relations (2.17) are finally recovered.

In the classical regime, where we neglect the contribution from $S$, we recover the space $\mathbb{Z}_2$, the reduced moduli space of one SO(2) instanton generated by $M$, such that $M^2 = 0$.

This is the required consistency that we mentioned above: $\tilde{M}_{1,E_2}$ is indeed $\mathbb{C}^2/\mathbb{Z}_2 \cup \mathbb{Z}_2$, the latter being given by the ADHM construction of USp(2) with 1 flavour.

Let us provide a complementary argument based on symmetries that supports the identification of $\tilde{M}_{1,E_2}$ with $C^2/\mathbb{Z}_2 \cup \mathbb{Z}_2$. The ADHM construction for $U(1)$ with $N_f$ flavours provides the moduli space of $U(N_f)/U(1)$ instantons, which for $N_f = 1$ corresponds to an empty symmetry group and thus a trivial moduli space. Furthermore, in the presence of a flavour symmetry, an SU(2)$_R$ spin-1 operator is a necessary requirement for the existence of a linear hypermultiplet containing the conserved current. For a U(1) gauge theory with 1 flavour, there is no flavour symmetry and hence no associated generator. Identifying $\tilde{M}_{1,E_2}$ with $\mathbb{C}^2/\mathbb{Z}_2 \cup \{1\}$, there would be only three generators transforming in the adjoint representation of SU(2) associated with $\mathbb{C}^2/\mathbb{Z}_2$ but no extra generator associated with the aforementioned U(1) symmetry, as in (2.14). On the other hand, for a USp(2) gauge theory
with 1 flavour, there is an SO(2) $\cong$ U(1) flavour symmetry; hence there is a generator at order $t^2$ associated with this symmetry. We see that only when we identify $\tilde{M}_{1,E_2}$ with $\mathbb{C}^2/\mathbb{Z}_2 \cup \mathbb{Z}_2$ there are four generators transforming in the adjoint representation of the global symmetry SU(2) $\times$ U(1) $\cong$ E$_2$ as one can see explicitly in (2.13).

### 2.3.2 Expansion in the instanton fugacity

It is instructive to rewrite (2.13) as an expansion in $q$, the U(1)$_I$ fugacity. Replacing $x$, the fugacity for SU(2), by $q^{1/2}$ we have that:

$$H[\tilde{M}_{1,E_2}](t; y, q^{1/2}) = \frac{1}{(1 - t^2)} \sum_{n=-\infty}^{\infty} q^n t^{2n} + t^2.$$  

Hence a bare instanton operator with U(1)$_I$ charge $n$ is the highest weight state of the spin $j$ representation of the SU(2)$_R$ symmetry. For $n \neq 0$, the tower of states originating from the glueball $(1 - t^2)^{-1}$, i.e the space $\mathbb{C}$, acts as a dressing for the instanton operators. For $n = 0$, the dressing is a different space, due to the presence of an extra piece of the moduli space unaffected by instantons. It is in fact the space generated by $S$ and $M$, subject to the relations $SM = 0$ and $M^2 = 0$, i.e $\mathbb{C} \cup \mathbb{Z}_2$.

### 2.4 $N_f = 2$

The reduced moduli space of one $E_3 = SU(3) \times SU(2)_A$ instanton\footnote{The subscript $A$ is used to differentiate from SU(2)$_B$ which is defined in the next paragraph.} is isomorphic to the union of two hyperKähler cones, the reduced moduli space of one SU(3) instanton, $\tilde{M}_{1,SU(3)}$, and the reduced moduli space of one SU(2)$_A$ instanton $\tilde{M}_{1,SU(2)_A}$, meeting at a point. As an algebraic variety it is generated by operators transforming in the reducible adjoint representation subject to the Joseph relations, which can be extracted from (2.1). The Hilbert series can again be written using the surgery formula (2.8) as

$$H[\tilde{M}_{1,E_3}](t; x, y) = H[\tilde{M}_{1,SU(3)}](t; x) + H[\tilde{M}_{1,SU(2)_A}](t; y) - 1$$

$$= \sum_{m_1=0}^{\infty} [m_1, 1]_{x}^{SU(3)} t^{2m_1} + \sum_{m_2=0}^{\infty} [2m_2]_{y}^{SU(2)_A} t^{2m_2} - 1,$$  

where $x = (x_1, x_2)$ are the fugacities for SU(3) and $y$ is the fugacity for SU(2)$_A$.

The SU(3) factor of the enhanced global symmetry $E_3$ is broken to SU(2)$_B \times$ U(1)$_I$ when one flows away from the fixed point. The U(1) factor is identified with the topological symmetry U(1)$_I$, up to a normalisation of charges that is explained below. The SU(2)$_B$ factor instead combines with the SU(2)$_A$ factor in $E_3$, which acts as a spectator for the breaking, and together they form a global symmetry SO(4). Hence, we decompose the representations of SU(3) in (2.29), whilst keeping the representations of SU(2)$_A$, i.e we break:

$$SU(3) \times SU(2)_A \supset SU(2)_B \times SU(2)_A \times U(1)_I \cong SO(4) \times U(1)_I$$  

(2.30)
A possible projection matrix that maps the weights of SU(3) to SU(2)_B × U(1) is given by

\[
P_{\text{SU(3)} \to \text{SU(2)}_B \times \text{U(1)}} = \begin{pmatrix} 0 & 1 \\ 2 & 1 \end{pmatrix},
\]

(2.31)

Let \( x = (x_1, x_2) \) be the fugacities of SU(3); \( z \) and \( w \) be those of SU(2)_B and U(1) respectively (the fugacity \( w \) for the U(1) factor will be related to the fugacity \( q \) for U(1)_I shortly).

Under the action of this matrix, the weights of the fundamental representation of SU(3) are mapped as follows:

\[
(1, 0) \rightarrow (0, 2), \quad (-1, 1) \rightarrow (1, -1).
\]

(2.32)

In other words, we have

\[
x_1 = w^2, \quad x_2 = zw^{-1} \quad \Leftrightarrow \quad x_1 = w^2, \quad x_2 = zw.
\]

(2.33)

The character of the fundamental representation of SU(3) is mapped to that of SU(2)_B × U(1) as

\[
[1, 0] = x_1 + x_2x_1^{-1} + x_2^{-1} = w^2 + zw^{-1} + z^{-1}w^{-1} = [0_2] + [1_{-1}],
\]

(2.34)

while the adjoint representation decomposes as

\[
[1, 1] \rightarrow [0_0] + [2_0] + [1_3] + [1_{-3}].
\]

(2.35)

The U(1) charge is a multiple of 3 for states in the root lattice. To obtain integer instanton numbers \( I \in \mathbb{Z} \), we set \( w^3 = q \), where \( q \) is the fugacity for U(1)_I.

Under this map, the Hilbert series of the reduced moduli space of one SU(3) instanton becomes

\[
H[\widetilde{M}_{1, \text{SU(3)}}](t; z, q) = \sum_{m=0}^{\infty} \sum_{n_1=0}^{m} \sum_{n_2=0}^{m} [n_1 + n_2]z^{n_1}q^{-n_2}t^{2m},
\]

(2.36)

where \( z \) is the SU(2)_B fugacity and \( q \) is the U(1)_I fugacity.

The highest weight generating function\(^9\) [40] associated to this Hilbert series is

\[
G[\widetilde{M}_{1, \text{SU(3)}}](t; \mu, q) = \text{PE} \left[ (1 + \mu q + \mu q^{-1} + \mu^2) t^2 - \mu^2 t^4 \right],
\]

(2.38)

where \( \mu \) is the fugacity for the highest weight of SU(2)_B.

---

\(^9\)The highest weight generating function for group of rank \( r \) is defined as follows:

\[
G(t; \mu_i) = \sum_{n_i, k} b_{n_1, \ldots, n_r, k} \mu_1^{n_1} \cdots \mu_r^{n_r} t^k
\]

(2.37)

where \( \{\mu_i\}_{i=1}^r \) are highest weight fugacities s.t. \( [n_1, \ldots, n_r] \mapsto \mu_1^{n_1} \cdots \mu_r^{n_r} \) and \( \{b_{n_1, \ldots, n_r, k}\} \) are the series coefficients.
Thus, the highest weight generating function for (2.29) becomes

\[
G[f_{M;E_3}](t; \mu, \nu, q) = \text{PE} [(1 + \mu q + \mu q^{-1})t^2 - \mu^2 t^4] + \text{PE} [\nu^2 t^2] - 1 ,
\]

where \( \mu \) and \( \nu \) are the fugacities corresponding to the highest weights of \( \text{SO}(4) \cong \text{SU}(2)_A \times \text{SU}(2)_B \).

The highest weight generating function (2.39) provides five dominant representations that generate the highest weight lattice in a simple way. The information can be read as follows. Inside the first \( \text{PE} \) we can identify the \( \text{SU}(2)_R \) spin 2 generators: the singlet \( S \), the instanton operator \( q \) which we denote by \( I \), the anti-instanton operator \( q^* \) which we denote by \( \bar{e}_I \), and the meson transforming in the adjoint of \( \text{SU}(2)_B \), which we denote by \( T \) and is subject to the traceless condition \( T_{\alpha\beta} = 0 \). We also identify a relation quadratic in the generators and transforming in the adjoint representation of \( \text{SU}(2)_B \), the term \(-\mu^2 t^4\). The second \( \text{PE} \) is the contribution from the spectator \( \text{SU}(2)_A \), with the only representation \( \text{SU}(3)_{\text{adj}} \), the inert meson that we denote by \( \bar{e}_T \).

Eq. (2.39) is an expression that carries information about the representation theory more concisely than the Hilbert series and furthermore the lattice it encodes is a complete intersection. However in order to write the relations between the operators on the chiral ring explicitly, we consider what the Joseph relations for \( \widetilde{M}_{1,E_3} \) imply.

2.4.1 The generators and their relations

For the \( \widetilde{M}_{1,E_3} \) case, the generators are \( \Phi^i_j \), with \( i = 1, 2, 3 \) and \( \Phi^i_i = 0 \), transforming in the \([1,1;0] \) of \( \text{SU}(3) \times \text{SU}(2)_A \), and \( \tilde{T}^{\alpha\beta} \) with \( \tilde{T}^{\alpha\beta} \epsilon_{\alpha\beta} = 0 \), transforming in the \([0,0;2] \) of \( \text{SU}(3) \times \text{SU}(2)_A \). The relations can be read off from (2.1):

\[
\begin{align*}
\text{Sym}^2([1,1;0] + [0,0;2]) &= \text{Sym}^2[1,1;0] + \text{Sym}^2[0,0;2] + [1,1;2] \quad \text{where} \\
\text{Sym}^2([1,1;0]) &= [2,2;0] + [1,1;0] + [0,0;0] \\
\text{Sym}^2([0,0;2]) &= [0,0;4] + [0,0;0]
\end{align*}
\]

Hence the generator \( \Phi^i_j \) obeys a quadratic relation transforming in the reducible representation \([1,1;0] + [0,0;0] \) whilst \( \tilde{T}^{\alpha\beta} \) obeys a singlet relation. This is to be expected, since the minimal nilpotent orbit of traceless \( 2 \times 2 \) matrix is the subset of matrices with zero determinant. There is also a quadratic relation mixing \( \Phi^i_j \) and \( \tilde{T}^{\alpha\beta} \) transforming in the \([1,1;2] \). We can write these relations as follows:

\[
\begin{align*}
\text{Sym}^2([1,1;0] + [0,0;2]) &= \text{Sym}^2[1,1;0] + \text{Sym}^2[0,0;2] + [1,1;2] \\
\text{Sym}^2([1,1;0]) &= [2,2;0] + [1,1;0] + [0,0;0] \\
\text{Sym}^2([0,0;2]) &= [0,0;4] + [0,0;0]
\end{align*}
\]

where the indices of \( \tilde{T} \) are contracted by the epsilon tensor, e.g. \( (\tilde{T}^2)^{\alpha\beta} = \tilde{T}^{\alpha\beta} \epsilon_{\alpha\beta} \tilde{T}^{\rho\sigma} \).

\[\text{For } \tilde{T} \text{ a symmetric } 2 \times 2 \text{ matrix, i.e. } \tilde{T}^{\alpha\beta} \epsilon_{\alpha\beta} = 0, \text{ the following statements are equivalent: } \tilde{T}^2 = 0, \det \tilde{T} = 0 \text{ and } \text{Tr} \tilde{T}^2 = 0.\]
The glueball operator, the instanton and anti-instanton operators and the meson are embedded into the generator \( \Phi_{ij} \) since this is the one transforming nontrivially under the SU(3) factor that breaks into SU(2)\(_B\) \( \times \) U(1). We choose the following embedding:

\[
\begin{align*}
\Phi^{\alpha\beta} &= T^{\alpha\gamma} \epsilon_{\gamma\beta} - \frac{1}{2} S \delta^{\alpha\beta} \quad \alpha, \beta = 1, 2 \\
\Phi^{\alpha \bar{3}} &= I^\alpha \\
\Phi^{3 \alpha} &= \epsilon_{\alpha\beta} \bar{T}^\beta \\
\Phi^{3 \bar{3}} &= S
\end{align*}
\]

where \( T^{\alpha\beta} \) is a traceless \( 2 \times 2 \) matrix, \( T^{\alpha\beta} \epsilon_{\alpha\beta} = 0 \). Notice that the choice of \( \Phi^{\alpha\beta} \) ensures that \( \Phi^{ij} \) is traceless since \( \epsilon_{ii}^{\alpha\beta} + \epsilon_{33}^{\alpha\beta} = 0 \).

The aim is to decompose the relations in the first and third equations of (2.41). Under SU(3) \( \times \) SU(2)\(_A\) \( \supset \) SU(2)\(_B\) \( \times \) U(1) \( \times \)SU(2)\(_A\) the representations decompose as

\[
\begin{align*}
[1,1;0] + [0,0;0] &\rightarrow [2;0] + [1,1;0] + [1,-1;0] + 2[0,0;0] \\
[1,1;2] &\rightarrow [2;0] + [1,1;2] + [1,-1;2] + [0,2;0].
\end{align*}
\]

Thus the relations in the first equation of (2.41) decompose into the five relations

\[
\begin{align*}
[2;0]: \quad ST^{\alpha\beta} &= -I^\alpha \bar{T}^\beta + \frac{1}{2} (I^\rho \epsilon_{\rho\sigma} I^\sigma) \epsilon_{\alpha\beta} \\
[1,1;0]: \quad I^\beta \epsilon_{\beta\gamma} T^{\gamma\alpha} &= \frac{1}{2} I^\alpha S \\
[1,-1;0]: \quad \bar{T}^\beta \epsilon_{\beta\gamma} T^{\gamma\alpha} &= -\frac{1}{2} I^\alpha S \\
[2;0]: \quad S^2 &= \epsilon_{\alpha\beta} I^\alpha I^\beta = 2 \text{Tr}(T^2).
\end{align*}
\]

The relations in the second line of (2.43) can be explicitly written as:

\[
\begin{align*}
[2;0]: \quad T^{\alpha\beta} \bar{T}^{\dot{\alpha} \dot{\beta}} &= 0 \\
[1,1;2]: \quad I^\alpha \bar{T}^{\dot{\alpha} \dot{\beta}} &= 0 \\
[1,-1;2]: \quad \bar{T}^\alpha \bar{T}^\beta &= 0 \\
[0,0;2]: \quad ST^{\alpha\beta} &= 0.
\end{align*}
\]

Recall also from (2.41) that

\[
[0,0;0]: \quad \text{Tr}(\bar{T}^2) = 0.
\]

In total there are thus 10 equations, namely (2.44), (2.45) and (2.46).\(^\text{11}\)

The finite coupling result that \( S \) be nilpotent is obtained by virtue of the last equation of (2.44) when we set \( I, \bar{I} = 0 \). Consequently we also restore the condition \( \text{Tr}(T^2) = 0 \), which, for a traceless \( 2 \times 2 \) matrix, is equivalent to \( T^2 = 0 \), the classical relation. Moreover (2.7) is also recovered.

\(^{11}\)Notice that the meson \( \bar{T}^{\dot{\alpha} \dot{\beta}} \), the generator for the spectator SU(2)\(_A\), is made up of the same fundamental fields (quarks) as the meson \( T^{\alpha \beta} \). Before considering gauge invariant combinations, the quarks \( Q^{\alpha \dot{\alpha} a} \) with \( \alpha, \dot{\alpha} = 1, 2 \) and \( a = 1, 2 \), transform in the vector representation of the global symmetry SO(4) \( \cong \) SU(2)\(_A\) \( \times \)SU(2)\(_B\) and in the fundamental representation of the gauge group SU(2). Out of these quarks the following gauge invariant mesons can be constructed:

\[
T^{\alpha \beta} = Q^{\alpha a} \bar{Q}^{\beta \dot{b}} \epsilon_{a \dot{b}} \text{ and } \bar{T}^{\dot{\alpha} \dot{\beta}} = Q^{\dot{a} \dot{\alpha}} Q^{\beta b} \epsilon_{\dot{a} b}.
\]

The difference between these two mesons is in the relations they satisfy at infinite coupling, one being quantum corrected whilst the other being unaffected: \( \text{Tr}(\bar{T}^2) = 0 \) vs \( 2 \text{Tr}(T^2) = S^2 = I \cdot \bar{I} \).
Another approach to see these 10 relations between the operators at infinite coupling is to rewrite (2.29) in terms of characters of representations of SO(4) × U(1) and compute its plethystic logarithm. For reference, we present such a Hilbert series up to order \( t^4 \) as follows:

\[
H\left[ E_3 \right](t; x_1, x_2, q) = 1 + \left( 1 + [2, 0] + [0, 2] + (q + q^{-1})[1, 0] \right) t^2 \\
+ \left( 1 + [2, 0] + [4, 0] + [0, 4] + (q + q^{-1})([1, 0] + [3, 0]) + (q^2 + q^{-2})[2, 0] \right) t^4 \\
+ \ldots . \tag{2.47}
\]

The plethystic logarithm of this Hilbert series is

\[
\text{PL} \left[ H\left[ E_3 \right](t; x_1, x_2, q) \right] = 1 + [2; 0] + [0; 2] + (q + q^{-1})[1; 0] t^2 + \\
- \left( 3 + [2, 0] + [0, 2] + [2, 2] + (q + q^{-1})([1, 2] + [1, 0]) \right) t^4 \tag{2.48}
\]

Indeed, the 10 relations listed in (2.44), (2.45) and (2.46) are in correspondence with the terms at order \( t^4 \) in (2.48). We emphasise here that the computation of the plethystic logarithm provides an efficient way to write down the relations that are crucial to describe the moduli space. This method is applied for the cases of higher \( N_f \) in subsequent sections.

We can rewrite these relations in terms of a \( 4 \times 4 \) adjoint matrix \( M^{ab} \), with \( a, b, c, d = 1, \ldots, 4 \) vector indices of SO(4), such that

\[
M^{ab} = -M^{ba}, \tag{2.49}
\]
as follows:

\[
[2, 2] + [0, 0]: \quad M^{ab}M^{bc} = (\epsilon_{\alpha\beta} I^a I^b) \delta^{ac} \tag{2.50}
\]
\[
[0, 0]: \quad \epsilon_{abcd}M^{ab}M^{cd} = \epsilon_{\alpha\beta} I^a I^b \tag{2.51}
\]
\[
[0, 0]: \quad S^2 = \epsilon_{\alpha\beta} I^a I^b \tag{2.52}
\]
\[
[2, 0]: \quad SM^{ab}(\gamma^{ab})^{\alpha\beta} = \tilde{I}^a I^b \tag{2.53}
\]
\[
[0, 2]: \quad SM^{ab}(\gamma^{ab})^{\bar{\alpha}\bar{\beta}} = 0 \tag{2.54}
\]
\[
q([1, 2] + [1, 0]): \quad M^{ab}\tilde{I}^\beta (\gamma^b)^{\beta\alpha} = S I^\beta (\gamma^a)^{\bar{\alpha}} \tag{2.55}
\]
\[
q^{-1}([1, 2] + [1, 0]): \quad M^{ab}\tilde{I}^\beta (\gamma^b)^{\beta\bar{\alpha}} = S I^\beta (\gamma^a)^{\bar{\alpha}} . \tag{2.56}
\]

The gamma matrices \( \gamma^a \) for SO(4) take the following index form:

\[
(\gamma^a)_{\alpha\bar{\alpha}} \tag{2.57}
\]
and the product of two gamma matrices is defined as:

\[
(\gamma^{ab})_{\alpha\beta} \equiv (\gamma^a)^{\alpha\alpha}(\gamma^b)^{\beta\beta} \epsilon^{\alpha\beta} \quad \text{and} \quad (\gamma^{ab})_{\bar{\alpha}\bar{\beta}} \equiv (\gamma^a)^{\bar{\alpha}\bar{\alpha}}(\gamma^b)^{\bar{\beta}\bar{\beta}} \epsilon^{\alpha\beta} ; \tag{2.58}
\]
where the spinor indices are raised and lowered with the epsilon tensor.
2.4.2 Expansion in the instanton fugacity

It is useful to rewrite (2.39) in terms of an expansion in $q$:

$$G[M_1,E_3](t;\mu,\nu,q) = \frac{1}{(1-t^2)(1-t^2\mu^2)} \sum_{n=-\infty}^{\infty} q^{n+2|n|} \mu^{|n|} + \frac{1}{1-\nu^2t^2} - 1$$

(2.59)

From here, we can extract the transformation properties of instanton operators of charge $n$ under the $U(1)_I$. They transform as spin $|n|$ highest weight states for $SU(2)_R$ and as spin $|n|/2$ representations of $SU(2)_B$.

The classical dressing for each $q^n$ instanton operator, the factor outside the sum, is, for $n \neq 0$, a space generated by the $SU(2)_B$ adjoint meson $T^{\alpha\beta} = M^{ab}(\gamma^{ab})_{\alpha\beta}$ and the glueball operator $S$ obeying the relation:

$$\text{Tr}(T^2) = S^2$$

(2.60)

For $n = 0$ there is a contribution coming from the $SU(2)_A$, the second term in (2.59), which modifies the classical dressing entirely. The latter is in fact, for this charge zero sector, generated by $M^{ab}$ and $S$ subject to the following relations:

$$[2,2] + [0,0] : M^{ab}M^{kc} = S^2\delta^{ac}$$

(2.61)

$$[0,0] : \epsilon_{abcd}M^{ab}M^{cd} = S^2$$

(2.62)

$$[0,2] : SM^{ab}(\gamma^{ab})_{\alpha\beta} = 0$$

(2.63)

These relations are a subset of (2.50) - (2.56) constructed in the following way: we take the first two equations and we substitute the instanton bilinear on the right hand side with the glueball operator by means of (2.52). Moreover we keep (2.54) as it is a relation not corrected by instanton operators.

2.5 $N_f = 3$

The moduli space of the reduced one $E_4 = SU(5)$ instanton, $\tilde{M}_{1,E_4} = SU(5)$, is the nilpotent orbit generated by the adjoint representation of $SU(5)$. Its associated Hilbert series can thus be written as

$$H[M,_{SU(5)}](t;\chi) = \sum_{n=0}^{\infty} [n,0,0,n]_\chi t^{2n},$$

(2.64)

where $[1,0,0,1]_\chi$ is the character of the adjoint representation of $SU(5)$ with fugacities $\chi = (x_1,x_2,x_3,x_4)$. In order to proceed with a decomposition from weights of $SU(5)$ representations to those of $SO(6) \times U(1)$, we choose the projection matrix

$$P_{A_4 \rightarrow D_3 \times U(1)} = \begin{pmatrix}
0 & 0 & 1 & 0 \\
0 & 0 & 0 & 1 \\
0 & 1 & 0 & 0 \\
4 & 3 & 2 & 1
\end{pmatrix},$$

(2.65)
which gives the fugacity map

\[
x_1 = w^4, \quad x_2 x_1^{-1} = y_3 w^{-1}, \quad x_3 x_2^{-1} = y_1 y_3^{-1} w^{-1}, \quad x_4 x_3^{-1} = y_1^{-1} y_2 w^{-1}, \quad \Leftrightarrow \quad x_1 = w^4, \quad x_2 = y_3 w^3, \quad x_3 = y_1 w^2, \quad x_4 = y_2 w.
\]

(2.66)

States in the root lattice carry a charge multiple of 5 for the U(1) associated to the fugacity \( w \), hence we set \( w^5 = q \) in the following, where \( q \) is the fugacity for the integer quantized instanton number \( U(1)_I \). Then (2.64) can be written in terms of the character expansion of \( SO(6) \times U(1) \supset SU(5) \) as

\[
H[\hat{\mathcal{M}}_{1, SU(5)}](t; y, q) = \sum_{n=0}^{\infty} \sum_{n_1=0}^{n} \sum_{n_2=0}^{n} [0, n_1, n_2] y q^{n_1-n_2} t^{2n},
\]

(2.67)

where \([p_1, p_2, p_3]_y \) is the character of a representation of \( SO(6) \) as a function of fugacities \( y = (y_1, y_2, y_3) \). The information contained in this equation can be carried compactly by means of the associated highest weight generating function

\[
G[\hat{\mathcal{M}}_{1, SU(5)}](t; \mu_2, \mu_3; q) = PE \left[ t^2 (1 + \mu_2 q + \mu_3 q^{-1} + \mu_2 \mu_3) - t^4 \mu_2 \mu_3 \right]
\]

(2.68)

where at \( t^2 \) we can again recognise the contribution of \( S \), a singlet of \( SO(6) \), the instanton and the anti-instanton operators in the spinor \([0, 1, 0]\) and cospinor \([0, 0, 1]\) representations, and the meson in the adjoint representation \([0, 1, 1]\), while at order \( t^4 \) is the basic relation between the operators. Notice that (2.68) is a generating function for a lattice with conifold structure.

### 2.5.1 The generators and their relations

The generators and the relations can be extracted from the plethystic logarithm of the Hilbert series. The Hilbert series of the reduced moduli space of 1 \( E_4 \) instanton can be written in terms of characters of \( SO(6) \times U(1) \) up to \( O(t^4) \) as:

\[
H[E_4](t; x, q) = 1 + (1 + [0, 1, 1] + q^{-1}[0, 0, 1] + q[0, 1, 0]) t^2 + \left( 1 + [0, 1, 1] + [0, 2, 2] + q^{-1}([0, 0, 1] + [0, 1, 2]) \right. \\
+ q([0, 1, 0] + [0, 2, 1]) + q^{-2}[0, 0, 2] + q^2[0, 2, 0] \left) t^4 + \ldots \right. \\
\]

(2.69)

The plethystic logarithm of this Hilbert series is

\[
\text{PL} [H[E_4](t; x, q)] = (1 + [0, 1, 1] + q^{-1}[0, 0, 1] + q[0, 1, 0]) t^2 \\
- \left( 2 + 2[0, 1, 1] + [2, 0, 0] + q([1, 0, 1] + [0, 1, 0]) \right. \\
+ q^{-1}([1, 1, 0] + [0, 0, 1]) \left) t^4 + \ldots \right.
\]

(2.70)

Below we write down the generators corresponding to the terms at \( t^2 \) and the explicit relations corresponding to the terms at order \( t^4 \) of (2.70).
For SO(6), we use $a, b, c, d = 1, \ldots, 6$ to denote vector indices and use $\alpha, \beta, \rho, \sigma = 1, \ldots, 4$ to denote spinor indices. Note that the spinor representation of SO(6) is complex. The delta symbol carries has one upper and one lower index:

$$\delta^\alpha_\beta .$$

(2.71)

The gamma matrices $\gamma^a$ can take the following forms:

$$(\gamma^a)_{\alpha\beta} \quad \text{and} \quad (\gamma^b)_{\alpha\beta},$$

(2.72)

where the $\alpha, \beta$ indices are antisymmetric. The product of two gamma matrices has one lower spinor index and one upper spinor index:

$$(\gamma^{ab})_{\alpha} \equiv (\gamma^a)^{\alpha\beta} (\gamma^b)_{\beta\rho} .$$

(2.73)

From (2.70) the generators of the moduli space are $M^{ab}$, a $6 \times 6$ antisymmetric matrix, the instanton operators $I^a$ and $\bar{I}_a$ and the gaugino bilinear $S$. The relations corresponding to the terms at order $t^4$ of (2.70) can be written as follows:

2.5.2 Expansion in the instanton fugacity

We rewrite (2.68) as an expansion in $q$ as follows:

$$G[M_{1,\text{SU}(5)}(t; \mu_2, \mu_3, q)] = \frac{1}{(1-t^2)(1-t^2\mu_2\mu_3)} \left( \sum_{n \geq 0} q^n (t^2 \mu_2)^n + \sum_{n < 0} q^n (t^2 \mu_3)^{-n} \right).$$

(2.81)

Two very interesting features emerge from the $q$ expansion. Firstly, an instanton operator of charge $n$ has SU(2)$_R$ spin $|n|$ and it transforms as an $|n|$-spinor — a representation with $|n|$ on a spinor Dynkin label — of the global flavour group SO(6). Whilst in [31] it was found that this result holds for $n = 1$, here we find a prediction for all $n$.

Secondly the instanton operators are dressed by a factor, the one in front of the sum, which is generated by $S$ and $M^{ab}$, subject to the following relations:

$$M^{ab} = M^{\alpha}_{\beta} (\gamma^{ab})^{\beta\alpha} .$$

(2.80)

As can be seen, the classical relations are corrected by instanton bilinears and this is a recurrent feature for all number of flavours. These relations can also be rewritten in terms of an SU(4) matrix $M^{\alpha}_{\beta}$ using the following relation:

$$M^{ab} = S^{\alpha}_{\beta} (\gamma^{ab})^{\beta\alpha} .$$

(2.82)

(2.83)
Interestingly, such relations can be extracted directly from (2.74) - (2.79) by keeping only those relations that are not corrected by the instanton operators. This feature is a recurrent theme for higher number of flavours.

2.6 $N_f = 4$

The Higgs branch at infinite coupling for an SU(2) theory with $N_f = 4$ flavours is isomorphic to the reduced moduli space of one $E_5 = SO(10)$ instanton $\tilde{M}_{1,E_5=SO(10)}$, which is given by the minimal nilpotent orbit of SO(10). Its Hilbert series is

$$H[\tilde{M}_{1,SO(10)}](t; x) = \sum_{n=0}^{\infty} [0, n, 0, 0, 0]_x t^{2n}, \quad (2.84)$$

where $[0, 1, 0, 0, 0]_x$ is the character of the adjoint representation of SO(10).

At finite coupling the theory has a global symmetry $SO(8) \times U(1)$. Hence we rewrite this Hilbert series in terms of an $SO(8) \times U(1)$ character expansion as

$$H[\tilde{M}_{1,SO(10)}](t; y, q) = \frac{1}{1 - t^2} \sum_{n_1, n_2, n_3 \geq 0} [0, n_1, 0, n_2 + n_3] y^{n_2 - n_3} t^{2n_1 + 2n_2 + 2n_3}, \quad (2.85)$$

where we decompose representations of $SO(8) \times U(1) \subset SO(10)$ using a projection matrix that maps the weights of SO(10) representations to those of SO(8) $\times U(1)$ as follows

$$P_{D_5 \rightarrow D_4 \times U(1)} = \begin{pmatrix}
0 & 0 & 0 & 0 & 1 \\
0 & 0 & 1 & 0 & 0 \\
0 & 0 & 0 & 1 & 0 \\
0 & 1 & 0 & 0 & 0 \\
-2 & -2 & -2 & -1 & -1
\end{pmatrix}. \quad (2.86)$$

Under the action of this matrix, the fugacities $x$ of SO(10) are mapped to the fugacities $y$ of SO(8) and $w$ of U(1) as follows:

$$(x_1, x_2 x_1^{-1}, x_3 x_2^{-1}, x_4 x_5 x_3^{-1}, x_5 x_4^{-1}) = \left(\frac{1}{w^2}, y_4, y_2 y_4^{-1}, y_1 y_2^{-1} y_3, y_1 y_3^{-1}\right)$$

$$\Leftrightarrow \quad (x_1, x_2, x_3, x_4, x_5) = \left(\frac{1}{w^2}, \frac{y_4}{w^2}, \frac{y_2}{w^2}, \frac{y_3}{w}, \frac{y_1}{w}\right). \quad (2.87)$$

In (2.85) we set $w^2 = q$ to have integer instanton numbers, rather than even.

The corresponding highest weight generating function is

$$G[\tilde{M}_{1,SO(10)}](t; \mu_2, \mu_4; q) = PE \left[t^2 (1 + \mu_2 + \mu_4 q + \mu_4 q^{-1})\right] \quad (2.88)$$

where we recognise the usual SU(2)$_R$ spin-2 generators: the glueball superfield $S$, a singlet of SO(8), the instanton operators $I_a$ and $\tilde{I}_a$ associated to $\mu_4 q$ and $\mu_4 q^{-1}$, both transforming in the same spinor representation of SO(8) with opposite U(1) charge, as well as the meson $M^{ab}$, associated to $\mu_2$. The highest weight lattice is freely generated as we see from the lack of relations at order $t^4$. 
2.6.1 The generators and their relations

The expansion of (2.85) up to order $t^4$ is given by

$$H_E[5](t; x, q) = 1 + \left( 1 + [0, 1, 0, 0] + (q + q^{-1})[0, 0, 0, 1] \right) t^2$$
$$+ \left( 1 + [0, 1, 0, 0] + [0, 0, 0, 2] + [0, 2, 0, 0] \right.\left. \right.$$
$$+ (q + q^{-1})([0, 0, 0, 1] + [0, 1, 0, 1]) + (q^2 + q^{-2})[0, 0, 0, 2] \right) t^4$$
$$+ \ldots .$$

The plethystic logarithm of this Hilbert series is

$$\text{PL}[H_E[5](t; x, q)] = \left( 1 + [0, 1, 0, 0] + (q + q^{-1})[0, 0, 0, 1] \right) t^2$$
$$- \left( 2 + [2, 0, 0, 0] + [0, 1, 0, 0] + [0, 0, 2, 0] + [0, 0, 0, 2] \right.\left. \right.$$
$$+ (q + q^{-1})([1, 0, 1, 0] + [0, 0, 0, 1]) + (q^2 + q^{-2}) \right) t^4 + \ldots .$$

(2.89)

From this collection of representations we can write the defining equations for the Higgs branch at infinite coupling by constructing the relevant operators. For SO(8), we use $a, b, c, d = 1, \ldots , 8$ to denote the vector indices, $\alpha, \beta, \rho, \sigma = 1, \ldots , 8$ to denote those in the spinor representation $[0, 0, 0, 1]$ and $\dot{\alpha}, \dot{\beta}, \dot{\rho}, \dot{\sigma} = 1, \ldots , 8$ to denote those in the conjugate spinor representation $[0, 0, 1, 0]$. The delta symbol has the following forms:

$$\delta^{\alpha \beta} \quad \text{or} \quad \delta_{\alpha \beta} \quad \text{or} \quad \delta^{\dot{\alpha} \dot{\beta}} \quad \text{or} \quad \delta_{\dot{\alpha} \dot{\beta}} .$$

(2.91)

The gamma matrices $\gamma^a$ can take the following forms:

$$\left( \gamma^a \right)_{\alpha \dot{\alpha}} \quad \text{or} \quad \left( \gamma^a \right)^{\alpha \dot{\alpha}} .$$

(2.92)

The product of two gamma matrices has the following forms:

$$\left( \gamma^{ab} \right)_{\alpha \beta} \equiv \left( \gamma^a \right)_{\alpha \dot{\alpha}} \left( \gamma^b \right)^{\beta \dot{\beta}} \quad \text{and} \quad \left( \gamma^{ab} \right)^{\dot{\alpha} \dot{\beta}} \equiv \left( \gamma^a \right)^{\alpha \dot{\alpha}} \left( \gamma^b \right)^{\beta \dot{\beta}}$$

(2.93)

and similarly for both upper indices; the indices $\alpha, \beta$ and $\dot{\alpha}, \dot{\beta}$ are antisymmetric. The product of four gamma matrices has the following forms:

$$\left( \gamma^{abcd} \right)_{\alpha \beta} \equiv \left( \gamma^a \right)_{\alpha \dot{\alpha}} \left( \gamma^b \right)^{\beta \dot{\beta}} \left( \gamma^c \right)^{\gamma \rho \sigma} (\gamma_d)_{\beta \sigma}$$
$$\left( \gamma^{abcd} \right)^{\dot{\alpha} \dot{\beta}} \equiv \left( \gamma^a \right)^{\alpha \dot{\alpha}} \left( \gamma^b \right)^{\beta \dot{\beta}} \left( \gamma^c \right)^{\gamma \rho \sigma} (\gamma_d)^{\rho \sigma}$$

(2.94)

and similarly for both upper indices; the indices $\alpha, \beta$ and $\dot{\alpha}, \dot{\beta}$ are symmetric.

The generators of the moduli space are $M^{ab}$, which is a $8 \times 8$ antisymmetric matrix; the instanton operators $I_\alpha$ and $\tilde{I}_{\dot{\alpha}}$; and the glueball superfield $S$.

The relations corresponding to terms at order $t^4$ of (2.90) can be written as

$$[2, 0, 0, 0] + [0, 0, 0, 0] : \quad M^{ab} M^{bc} = (I_\alpha \tilde{I}_{\dot{\alpha}}) \delta^{ac}$$
$$[0, 0, 2, 0] : \quad M^{ab} M^{cd} (\gamma^{abcd})^{\dot{\alpha} \dot{\beta}} = 0$$

(2.95)

(2.96)
\[
M^{ab} M^{cd} (\gamma^{abcd})_{\alpha\beta} = I_{(\alpha} \bar{I}_{\beta)} - \frac{1}{8} (I_{\mu} \bar{I}_{\rho}) \delta_{\alpha\beta} \tag{2.97}
\]

\[
S^2 = I_{\alpha} \bar{I}_{\beta} \delta^{\alpha\beta} \tag{2.98}
\]

\[
SM^{ab} = I_{\alpha} \bar{I}_{\beta} (\gamma^{ab})_{\alpha\beta} \tag{2.99}
\]

\[
q([1, 0, 1, 0] + [0, 0, 0, 1]) : M^{ab} I_{\beta} (\gamma^{b})_{\beta\delta} = S I_{\beta} (\gamma^{a})_{\beta\delta} \tag{2.100}
\]

\[
q^{-1}([1, 0, 1, 0] + [0, 0, 0, 1]) : M^{ab} I_{\beta} (\gamma^{b})_{\beta\delta} = S I_{\beta} (\gamma^{a})_{\beta\delta} \tag{2.101}
\]

\[
(q^2 + q^{-2})[0, 0, 0, 0] : I_{\alpha} I_{\beta} I_{\delta} I_{\gamma} = 0 . \tag{2.102}
\]

### 2.6.2 Expansion in the instanton fugacity

In terms of an expansion in \(q\), (2.88) can be written as

\[
G[\mathcal{M}_{1,SO(10)}(t; \mu_2, \mu_4; q) = \frac{1}{(1 - t^2)(1 - \mu_2 t^2)(1 - \mu_4^2 t^2)} \sum_{n=-\infty}^{\infty} q^n \mu_2^{[n]} t^{2|n|} . \tag{2.103}
\]

Here again we find that instanton operators of charge \(n\) are spin \(|n|\) of SU(2)\(_R\) and transform in \(|n|\)-spinor representations of SO(8).

However the interpretation of the classical dressing is more subtle than in previous cases. The prefactor in the \(q\) expansion signifies a space which is algebraically determined by some of the conditions that define the moduli space of one SO(8) instanton; in particular it is a space generated by two operators, \(M^{ab}\), in the adjoint representation \([0, 1, 0, 0]\) of SO(8), and \(S\), in the singlet \([0, 0, 0, 0]\), subject to relations that transform in the representations \([2, 0, 0, 0]\), \([0, 0, 0, 0]\) and \([0, 0, 2, 0]\). Explicitly these relations are:

\[
[2, 0, 0, 0] + [0, 0, 0, 0] : M^{ab} M^{bc} = S^2 \delta^{ac} \tag{2.104}
\]

\[
[0, 0, 2, 0] : M^{ab} M^{cd} (\gamma^{abcd})_{\alpha\beta} = 0 . \tag{2.105}
\]

The following features can be observed. Whilst the classical moduli space of one SO(8) instanton is generated by (2.3) and (2.4), here the anti-self-dual 4th rank antisymmetric representation is missing.\(^{12} \) Such a space has complex dimension 13 and, by adding the dimension originating from the sum over the instanton number, the correct 14 dimensional moduli space of one SO(10) instanton is recovered. Again, the classical dressing can be guessed from the set of equations in (2.95)-(2.102) by keeping only the relations that are not corrected by the instanton operators.

### 2.7 \(N_f = 5\)

The Hilbert series of \(\mathcal{M}_{1,E_6}\) can be written as

\[
H[\mathcal{M}_{1,E_6}](t; x) = \sum_{n=0}^{\infty} \left[ \begin{array}{c} n \\ 0 0 0 0 0 \end{array} \right] t^{2n} \cdot \tag{2.106}
\]

\(^{12}\)Recall that for SO(8), \(\wedge^4[1, 0, 0, 0] = [0, 0, 2, 0] + [0, 0, 0, 2]\) is a reducible representation.
A projection matrix that maps the weights of $E_6$ to those of $D_5 \times U(1)$ is given by

$$P_{E_6 \rightarrow D_5 \times U(1)} = \begin{pmatrix} 0 & 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 & 0 & 0 \\ -4 & -3 & -5 & -6 & -4 & -2 \end{pmatrix}. \quad (2.107)$$

Under the action of this matrix, the fugacities of $x$ of $E_6$ are mapped to the fugacities $y$ of $SO(10)$ and $w$ of $U(1)$ as follows:

$$\begin{pmatrix} x_1, x_1x_2^{-1}, x_1x_3^{-1}, x_2x_6^{-1}, x_3x_5^{-1}, x_3x_4^{-1} \end{pmatrix} = \begin{pmatrix} \frac{1}{w^4}, \frac{1}{wy_5}, \frac{w}{y_4}, \frac{y_5}{wy_1}, \frac{y_4}{wy_2}, \frac{wy_4}{y_3} \end{pmatrix} \quad (2.108)$$

The fugacity of $U(1)_I$ is $q = w^4$. Thus, the Hilbert series $H[\tilde{M}_1, E_6]$ can be written in terms of characters of representations of $SO(10) \times U(1)_I$ as

$$H[\tilde{M}_1, E_6](t; y, q) = \frac{1}{1 - t^2} \sum_{n_1, n_2, n_3 \geq 0} [0, n_1, 0, n_2, n_3]y^{n_2-n_3}t^{2n_1+2n_2+2n_3}, \quad (2.109)$$

The corresponding highest weight generating function is

$$G[\tilde{M}_1, E_6](t; \mu_2, \mu_4; q) = PE\left[t^2(1 + \mu_2 + \mu_4q + \mu_5q^{-1})\right]. \quad (2.110)$$

### 2.7.1 The generators and their relations

The expansion of (2.109) up to order $t^4$ is given by

$$H[E_6](t; x, q) = 1 + (1 + [0, 1, 0, 0, 0] + q^{-1}[0, 0, 0, 0, 1] + q[0, 0, 0, 1, 0])t^2 +$$

$$+ \left(1 + [0, 1, 0, 0, 0] + [0, 2, 0, 0, 0] + [0, 0, 0, 1, 1]ight.$$  

$$+ q^{-1}([0, 0, 0, 0, 1] + [0, 1, 0, 0, 1]) + q([0, 0, 0, 1, 0] + [0, 1, 0, 1, 0])$$

$$+ q^{-2}[0, 0, 0, 2] + q^2[0, 0, 0, 2])t^4 + \ldots.$$  

(2.111)

The plethystic logarithm of this Hilbert series is

$$\text{PL}\left[H[E_6](t; x, q)\right] = (1 + [0, 1, 0, 0, 0] + q^{-1}[0, 0, 0, 0, 1] + q[0, 0, 0, 1, 0])t^2$$

$$- \left(2 + [0, 1, 0, 0, 0] + [2, 0, 0, 0, 0] + [0, 0, 0, 1, 1]ight.$$  

$$+ q([1, 0, 0, 0, 1] + [0, 0, 0, 1, 0]) + q^{-1}([1, 0, 0, 1, 0] + [0, 0, 0, 0, 1])$$

$$+ (q^2 + q^{-2})[1, 0, 0, 0, 0])t^4 + \ldots.$$  

(2.112)
For SO(10), we use $a, b, c, d = 1, \ldots, 10$ to denote vector indices and $\alpha, \beta, \rho, \sigma = 1, \ldots, 16$ to denote spinor indices. Note that the spinor representation of SO(10) is complex. The delta symbol has the following form:

$$\delta_{\beta}^\alpha.$$  \hfill (2.113)

The gamma matrices $\gamma^a$ can take the following forms:

$$\left(\gamma^a\right)_{\alpha\beta} \quad \text{and} \quad \left(\gamma^a\gamma^{\alpha\beta}\right),$$  \hfill (2.114)

where the $\alpha, \beta$ indices are symmetric. The product of two gamma matrices has the following form:

$$\left(\gamma^{ab}\right)^{\alpha\beta}_\rho \equiv \left(\gamma^a|^{\alpha\beta}\left(\gamma^b\right)_\beta\rho\right).$$  \hfill (2.115)

The product of four gamma matrices has the following form:

$$\left(\gamma^{abcd}\right)^{\alpha\beta}_\gamma \equiv \left(\gamma^a|^{\alpha\beta}\gamma^b|^{\sigma_1\sigma_2}\gamma^c|^{\sigma_3\sigma_4}\gamma^d\right)_{\sigma_3\beta}.$$  \hfill (2.116)

The generators of the moduli space are $M^{ab}$, which is a $10 \times 10$ antisymmetric matrix; the instanton operators $I^{a}$ and $\tilde{I}_a$; and the gaugino superfield $S$.

The relations appearing in the plethystic logarithm (2.112) are as follows:

$$\begin{align*}
(2,0,0,0,0) + [0,0,0,0,0] & : M^{ab}M^{bc} = (I^a\tilde{I}_a)\delta^{ac}, \\
[0,0,0,1,1] & : M^{[a_1a_2}M^{a_3a_4]} = \tilde{I}_a(\gamma^{a_1\cdots a_4})^a_{\beta}I^\alpha, \\
[0,0,0,0,0] & : S^2 = I^a\tilde{I}_a, \\
[0,1,0,0,0] & : SM^{ab} = \tilde{I}_a(\gamma^{ab})_\alpha^a I^\alpha, \\
qu([1,0,0,1,0] + [0,0,0,1,0]) & : M^{ab}I^a(\gamma^b)^\beta_\alpha = SI^a(\gamma^a)^\beta_\alpha, \\
q^{-1}([1,0,0,1,0] + [0,0,0,1,0]) & : M^{ab}\tilde{I}_a(\gamma^b)^\beta_\alpha = \tilde{S}\tilde{I}_a(\gamma^a)^\beta_\alpha, \\
(q^2 + q^{-2})[1,0,0,0,0] & : I^a\tilde{I}_a(\gamma^a)^\alpha_\beta = 0.
\end{align*}$$  \hfill (2.117-2.123)

### 2.7.2 Expansion in the instanton fugacity

The highest weight generating function (2.110) can be expanded in the instanton number fugacity $q$ as

$$G[\mathcal{M}_{1,\bar{E}_0}](t; \mu_2, \mu_4, \mu_5; q) = \frac{1}{(1-t^2)(1-t^2\mu_2)(1-t^4\mu_4\mu_5)} \times \left(\sum_{n \geq 0} q^n(t^2\mu_4)^n + \sum_{n < 0} q^n(t^2\mu_5)^{-n}\right).$$  \hfill (2.124)

From this formula we see that the instanton operators of charge $n$ are spin $|n|$ highest weight states under SU(2)$_R$ and transform in the $n$-spinor representation $[0,0,0,n,0]$ of SO(10) for $n > 0$ and the conjugate $|n|$-spinor representation $[0,0,0,0,|n|]$ for $n < 0$. 

\newpage

- 23 -
The dressing factor has the features previously encountered in that is generated by the classical operators $M^{ab}$ and $S$, subject to the relations

$$[2, 0, 0, 0, 0] + [0, 0, 0, 0, 0] : M^{ab} M^{bc} = S^2 \delta^{ac}.$$  (2.125)

Comparing this space to the moduli space of one SO(10) instanton given by (2.3) and (2.4), it is clear that here the rank-1 condition (2.4) is missing altogether. As we have explained in the previous case, this can be at once read off from the relations (2.117)-(2.123), by keeping only the ones which are not corrected by instanton bilinears. The classical dressing is a space of dimension 21 and again, by adding the contribution from the sum over instantons, we recover the correct 22-dimensional moduli space of one $E_6$ instanton.

2.8 $N_f = 6$

The Hilbert series of $\tilde{M}_{1, E_7}$ can be written as

$$H[\tilde{M}_{1, E_7}](t; x) = \sum_{n=0}^{\infty} \begin{bmatrix} n & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 \end{bmatrix}_x t^{2n}.$$  (2.126)

The $E_7$ representations can be decomposed into those of SO(12) $\times$ U(1) using the projection matrix:

$$P_{E_7 \rightarrow D_6 \times U(1)} = \begin{pmatrix} 0 & 0 & 0 & 0 & 0 & 0 & 1 \\ 0 & 0 & 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 & 0 & 0 & 0 \\ -2 & -2 & -3 & -4 & -3 & -2 & -1 \end{pmatrix}.$$  (2.127)

Under the action of this matrix, the fugacities $x$ of $E_7$ are mapped to the fugacities $y$ of SO(12) and the fugacity $q$ of U(1) as

$$x = \left( \frac{1}{q^2}, \frac{y_6}{q^2}, \frac{y_5}{q^3}, \frac{y_4}{q^3}, \frac{y_3}{q^3}, \frac{y_2}{q^2}, \frac{y_1}{q} \right).$$  (2.128)

We then have the following highest weight generating function:

$$G[\tilde{M}_{1, E_7}](t; \mu_2, \mu_4, \mu_5; q) = \text{PE} \left[ (1 + \mu_2 + \mu_5(q + q^{-1}) + (q^2 + q^{-2})t^2 + \mu_4 t^4) \right].$$  (2.129)

where at order $t^2$ we recognise the contributions of: $S$, which is a singlet of SO(12); the instanton and the anti-instanton operators with U(1)$_I$ charge $\pm 1$ in the spinor representation $[0, 0, 0, 0, 1, 0]$; the instanton and the anti-instanton operators with U(1)$_I$ charge $\pm 2$ which are singlets of SO(12); the meson in the adjoint representation $[0, 1, 0, 0, 0, 0]$. In addition there is a fourth-rank antisymmetric tensor of SO(12) at order $t^4$. 

- 24 -
2.8.1 The generators and their relations

The expansion up to order $t^4$ of (2.129) is given by

$$H[E_\gamma](t; x, q) = 1 + \left(1 + [0, 1, 0, 0, 0, 0] + (q + q^{-1})[0, 0, 0, 1, 0] + (q^2 + q^{-2})t^2ight) + \left(2 + [0, 0, 0, 0, 0] + [0, 0, 0, 2, 0] + [0, 0, 1, 0, 0] + [0, 1, 0, 0, 0, 0]\right)
+ (q + q^{-1})[2[0, 0, 0, 1, 0] + [0, 1, 0, 1, 0])
+ (q^2 + q^{-2})(1 + [0, 0, 0, 0, 2, 0] + [0, 1, 0, 0, 0, 0])
+ (q^3 + q^{-3})[0, 0, 0, 0, 1, 0] + (q^4 + q^{-4})t^4 + \ldots .$$

(2.130)

The plethystic logarithm of this Hilbert series is given by

$$\text{PL}[H[E_\gamma](t; x, q)] = \left(1 + [0, 1, 0, 0, 0, 0] + (q + q^{-1})[0, 0, 0, 1, 0] + (q^2 + q^{-2})t^2ight) - \left(2 + [0, 0, 0, 1, 0, 0] + [0, 1, 0, 0, 0, 0] + [2, 0, 0, 0, 0, 0]\right)
+ (q + q^{-1})[0, 0, 0, 0, 1, 0] + [1, 0, 0, 0, 0, 1])
+ (q^2 + q^{-2})[0, 1, 0, 0, 0, 0]t^4 + \ldots .$$

(2.131)

For SO(12), we use $a, b, c, d = 1, \ldots, 12$ to denote vector indices, $\alpha, \beta, \rho, \sigma = 1, \ldots, 32$ to denote indices of the spinor representation $[0, 0, 0, 1, 0]$, and $\dot{\alpha}, \dot{\beta}, \dot{\rho}, \dot{\sigma} = 1, \ldots, 32$ to denote indices of the conjugate spinor representation $[0, 0, 0, 0, 1]$. The spinor representation of SO(12) is pseudoreal, hence all contractions of the spinor indices are made with the epsilon tensor, which takes the forms

$$\epsilon_{\alpha\beta} \quad \text{or} \quad \epsilon^{\alpha\beta} \quad \text{or} \quad \epsilon_{\dot{\alpha}\dot{\beta}} \quad \text{or} \quad \epsilon^{\dot{\alpha}\dot{\beta}}.$$  

(2.132)

Gamma matrices $\gamma^a$ take the forms

$$(\gamma^a)_{\alpha\dot{\beta}}.$$  

(2.133)

The product of two gamma matrices has the following forms:

$$(\gamma^{ab})_{\alpha\beta} \equiv (\gamma^a)_{\alpha\dot{\alpha}}(\gamma^b)_{\beta\dot{\beta}}\epsilon^{\dot{\alpha}\dot{\beta}} \quad \text{and} \quad (\gamma^{ab})_{\dot{\alpha}\dot{\beta}} \equiv (\gamma^a)_{\alpha\dot{\alpha}}(\gamma^b)_{\beta\dot{\beta}}\epsilon^{\alpha\beta},$$  

(2.134)

where the spinor indices are symmetric. The product of four gamma matrices has the following forms:

$$(\gamma^{abcd})_{\alpha\sigma} \equiv (\gamma^a)_{\alpha\dot{\alpha}}(\gamma^b)_{\beta\dot{\beta}}(\gamma^c)_{\rho\dot{\rho}}(\gamma^d)_{\sigma\dot{\sigma}}\epsilon^{\dot{\alpha}\dot{\beta}\dot{\rho}\dot{\sigma}} \quad \text{and} \quad (\gamma^{abcd})_{\dot{\alpha}\dot{\sigma}} \equiv (\gamma^a)_{\dot{\alpha}\alpha}(\gamma^b)_{\dot{\dot{\beta}}\beta}(\gamma^c)_{\dot{\rho}\rho}(\gamma^d)_{\dot{\sigma}\sigma}\epsilon^{\alpha\beta\rho\sigma},$$  

(2.135)

(2.136)

where the spinor indices are antisymmetric.

The generators of the moduli space are $M^{ab}$, which is a $12 \times 12$ antisymmetric matrix, the instanton operators $I^n_{1+}, I^n_{1-}$ and $I^2_{2+}, I^2_{2-}$, and the glueball superfield $S$. 

---

- 25 -
From (2.131), we have the following sets of relations:

\[
\begin{align*}
[2, 0, 0, 0, 0] & + [0, 0, 0, 0, 0] : \quad M^{ab} M^{bc} = (I^a_{1^+} \epsilon_{\alpha \beta} I^\beta_{1^-}) \delta^{ac} \quad (2.137) \\
[0, 0, 0, 1, 0] & : \quad M^{[a1a2} M^{a3a4]} = I^a_{1^+} I^b_{1^-} (\gamma^{a1\cdots a4})_{\alpha \beta} \quad (2.138) \\
[0, 0, 0, 0, 0] & : \quad S^2 + I_{2^+} I_{2^-} = I^a_{1^+} I^\beta_{1^-} \epsilon_{\alpha \beta} \quad (2.139) \\
[0, 1, 0, 0, 0] & : \quad SM^{ab} = I^a_{1^+} I^\beta_{1^-} (\gamma^{ab})_{\alpha \beta} \quad (2.140) \\
(q^2 + q^{-2})[0, 1, 0, 0, 0] & : \quad (q + q^{-1})[1, 0, 0, 0, 0, 1] + [0, 0, 0, 1, 0] : \quad M^{ab} I^a_{1^\pm} (\gamma^b)_{\alpha \beta} = (SI^a_{1^\pm} + I_{2^\pm}) (\gamma^a)_{\alpha \beta} \quad (2.142)
\end{align*}
\]

To aid computations it is useful to rewrite (2.130) and (2.131) in terms of characters of $SO(12) \times SU(2)$. The reader can find the relevant formulae in appendix B.

### 2.8.2 Expansion in the instanton fugacity

The highest weight generating function (2.129) can be expanded in powers of the instanton number fugacity $q$ as

\[
G[\widetilde{M}_{1,E_b}](t; \mu_2, \mu_4, \mu_5; q) = \frac{1}{(1-t^2)(1-\mu_2 t^2)(1-\mu_4 t^4)(1-\mu_5^2 t^4)(1-t^4)} \sum_{m \in \mathbb{Z}} (t^2 \mu_5)^{|m|} q^{|m|} \sum_{n \in \mathbb{Z}} t^{2|m|} q^{2n} \\
= \text{PE}[\{\mu_2^2 + 1 + \mu_2 t^2 + \mu_4 t^4 + \mu_5^2 t^6\}] \times \left( \frac{1 + \mu_5^2 t^4}{1-t^4} \sum_{m \text{ even}} t^{2|m|} q^{|m|} - \frac{(t \mu_5)^2}{1-\mu_5^2 t^4} \sum_{m \text{ even}} \mu_5^{|m|} t^{2|m|} q^{|m|} \\
+ \frac{(1 + \mu_5^2) t^{2t}}{1-t^4} \sum_{m \text{ odd}} t^{2|m|} q^{|m|} - \frac{(t \mu_5)^2}{1-\mu_5^2 t^4} \sum_{m \text{ odd}} \mu_5^{|m|} t^{2|m|} q^{|m|} \right) 
\]  

(2.143)

The first equality is a $q$ expansion in terms of a double sum. This separates the classical dressing from the one and two instanton contributions. It is precisely the presence of both types of instantons as quadratic generators that, for $N_f > 5$, complicates the features of the $q$ expansion in terms of a one sum only. We still write such an expansion in the second equality, splitting it into odd and even terms.

### 2.9 $N_f = 7$

The Hilbert series of $\widetilde{M}_{1,E_b}$ can be written as

\[
H[\widetilde{M}_{1,E_b}](t; x) = \sum_{n=0}^{\infty} \left[ \begin{array}{cc} 0 & 0 \\
0 & 0 & 0 & 0 & n \\
\end{array} \right] t^{2n} x.
\]

(2.144)
The $E_8$ representations can be decomposed into those of $\text{SO}(14) \times \text{U}(1)$ using the projection matrix

$$
P_{E_8 \rightarrow D_7 \times U(1)} = \begin{pmatrix}
0 & 0 & 0 & 0 & 0 & 0 & 0 & 1 \\
0 & 0 & 0 & 0 & 0 & 0 & 1 & 0 \\
0 & 0 & 0 & 0 & 0 & 1 & 0 & 0 \\
0 & 0 & 0 & 0 & 1 & 0 & 0 & 0 \\
0 & 0 & 1 & 0 & 0 & 0 & 0 & 0 \\
0 & 1 & 0 & 0 & 0 & 0 & 0 & 0 \\
-4 & -5 & -7 & -10 & -8 & -6 & -4 & -2
\end{pmatrix}
$$

(2.145)

Under the action of this matrix, the fugacities $x$ of $E_8$ are mapped to the fugacities $y$ of $\text{SO}(14)$ and the fugacity $q$ of $\text{U}(1)$ as

$$
x = \left( \frac{1}{q^4}, \frac{1}{q^5}, \frac{1}{q^7}, \frac{1}{q^{10}}, \frac{1}{q^8}, \frac{1}{q^6}, \frac{1}{q^4}, \frac{1}{q^2} \right)
$$

(2.146)

We then have the following highest weight generating function:

$$
G[\tilde{M}_{1,E_8}](t; \mu; q) = \text{PE} \left[ t^2 \left( 1 + \mu_2 + \mu_6 q + \mu_7 q^{-1} + \mu_4 (q^2 + q^{-2}) \right) + t^4 \left( 1 + \mu_2 + \mu_4 + \mu_6 q + \mu_7 q^{-1} + \mu_5 (q^2 + q^{-2}) \right) + t^6 (\mu_4 + \mu_5 (q^2 + q^{-2})) \right].
$$

(2.147)

2.9.1 The generators and their relations

The Hilbert series of the reduced moduli space of 1 $E_8$ instanton can be written in terms of characters of $\text{SO}(14) \times \text{U}(1)$ as

$$
H[E_8](t; x, q) = 1 + \left( (1 + [0, 1, 0, 0, 0, 0, 0, 0]) + [0, 0, 0, 0, 0, 1, 0, 0] q + [0, 0, 0, 0, 0, 0, 1] q^{-1} \right) t^2 + \left( 2 + [0, 0, 0, 0, 0, 0, 1, 0] + [0, 0, 0, 1, 0, 0, 0] \right) t^4 + \left( [0, 0, 0, 0, 0, 0, 1] + [0, 0, 0, 1, 1, 0, 0] + \right. \left. [0, 2, 0, 0, 0, 0, 0, 0] + [2, 0, 0, 0, 0, 0, 0, 0] \right) q^{-1}
$$

$$
+ \left( [0, 0, 0, 0, 0, 0, 0, 0] + [0, 1, 0, 0, 0, 0, 0, 0] + [1, 0, 0, 0, 0, 0, 1] q \right) t^6 + \left( [0, 0, 0, 0, 0, 0, 0, 1] + [0, 0, 0, 0, 0, 0, 1, 0] q^{-1} \right) t^8 + \ldots.
$$

(2.148)

The plethystic logarithm of this Hilbert series is given by

$$
\text{PL} \left[ H[E_8](t; x, q) \right] = \left( (1 + [0, 1, 0, 0, 0, 0, 0, 0]) + [0, 0, 0, 0, 0, 1, 0, 0] q + [0, 0, 0, 0, 0, 0, 1] q^{-1} \right) t^2 + \ldots
$$
\[ + [1, 0, 0, 0, 0, 0, 0] (q^2 + q^{-2}) t^2 - \left( 2 + [2, 0, 0, 0, 0, 0, 0] + [0, 0, 0, 1, 0, 0, 0] \\
+ [0, 1, 0, 0, 0, 0, 0] + ([0, 0, 0, 0, 1, 0] + [1, 0, 0, 0, 0, 1]) q \\
+ ([0, 0, 0, 0, 0, 0, 1] + [1, 0, 0, 0, 0, 1]) q^{-1} \\
+ ([0, 0, 1, 0, 0, 0, 0] + [1, 0, 0, 0, 0, 0])(q^2 + q^{-2}) \\
+ [0, 0, 0, 0, 0, 0, 1] q^3 + [0, 0, 0, 0, 0, 1, 0] q^3 + (q^4 + q^{-4}) t^4 + \ldots \] (2.149)

It is also useful to write the Hilbert series written in terms of characters of representations of SO(16):

\[
H[E_8](t; z) \\
= 1 + ([0, 0, 0, 0, 0, 0, 0, 1] + [0, 0, 0, 0, 0, 0, 0, 0]) t^2 \\
+ (1 + [0, 0, 0, 0, 0, 0, 0, 1] + [0, 0, 0, 0, 0, 0, 0, 2] \\
+ [0, 0, 0, 1, 0, 0, 0, 0] + [0, 1, 0, 0, 0, 0, 0, 0, 1] + [0, 2, 0, 0, 0, 0, 0, 0, 0]) t^4 + \ldots . 
\]

(2.150)

The plethystic logarithm of this Hilbert series is

\[
\text{PL}[H[E_8](t; z)] \\
= ([0, 0, 0, 0, 0, 0, 0, 1] + [0, 1, 0, 0, 0, 0, 0, 0]) t^2 - (1 + [0, 0, 0, 1, 0, 0, 0, 0] \\
+ [1, 0, 0, 0, 0, 0, 1, 0] + [2, 0, 0, 0, 0, 0, 0, 0]) t^4 + \ldots . 
\]

(2.151)

Note that the spinor representation \([0, 0, 0, 0, 0, 0, 0, 1]\) of SO(16) branches to those of SO(14) \(\times\) U(1) as

\[
[0, 0, 0, 0, 0, 0, 0, 1] \longrightarrow [0, 0, 0, 0, 0, 0, 1]_{-1} + [0, 0, 0, 0, 0, 1, 0]_{+1}, 
\]

(2.152)

corresponding to the charge \(\pm 1\) instanton operators \(I_{1-}\) and \(I_{1+}\), whereas the field \(X\) in the adjoint representation \([0, 1, 0, 0, 0, 0, 0, 0]\) of SO(16) contains the charge \(\pm 2\) instanton operators \(I_{2+}, I_{2-}\), the glueball superfields \(S\) and \(M\) in \(X\). The adjoint field \(X\) of SO(16) satisfies the matrix relation

\[
X^2 = 0, 
\]

(2.153)

transforming in the rank two symmetric representation \([2, 0, 0, 0, 0, 0, 0, 0] + [0, 0, 0, 0, 0, 0, 0, 0]\) of SO(16). This representation branches into those of SO(14) \(\times\) U(1) as

\[
[2, 0, 0, 0, 0, 0, 0, 0] \longrightarrow 1 + [0, 0, 0, 0, 0, 0, 0]_{-4} + [0, 0, 0, 0, 0, 0, 0]_{+4} \\
+ [1, 0, 0, 0, 0, 0, 0, 0]_{-2} + [1, 0, 0, 0, 0, 0, 0, 0]_{+2} + [2, 0, 0, 0, 0, 0, 0, 0]_0. 
\]

(2.154)

Upon expanding (2.153) in components, we see that the vanishing components \((X^2)_{15,15}\), \((X^2)_{16,16}\) and \((X^2)_{15,16}\) imply that

\[
I_{2+}^a I_{2+}^a = 0, \quad I_{2-}^a I_{2-}^a = 0, \quad S^2 + I_{2+}^a I_{2-}^a = 0. 
\]

(2.155)

These relations are collected in (2.165) and (2.175).
The generators of the moduli space are symmetric in the spinor indices. The product of four gamma matrices is

\[ \gamma_a \gamma_b \gamma^c \gamma_d \]

The delta symbol has the form

\[ \delta_\beta^\alpha \].

The gamma matrices \( \gamma^a \) can take the following forms:

\[ (\gamma^a)_{\alpha\beta} \quad \text{or} \quad (\gamma^a)^{\alpha\beta} \]

where the \( \alpha, \beta \) indices are antisymmetric. The product of two gamma matrices is

\[ (\gamma^{ab})_{\rho} \equiv (\gamma^{[a})_{\alpha\beta} (\gamma^{b]}_{\beta\sigma})_{\rho\sigma} \]

The product of three gamma matrices has the forms

\[ (\gamma^{abc})_{\alpha\rho} \equiv (\gamma^{[a})_{\alpha\beta} (\gamma^{b})_{\beta\sigma} (\gamma^{c]}_{\sigma\rho})_{\alpha\rho} \]

The relations corresponding to order \( t^4 \) of (2.149) are as follows:

\[ (2, 0, 0, 0, 0, 0) + [0, 0, 0, 0, 0, 0, 0] : M^{ab}M^{bc} + I_2^{[a} I_2^{b]} = I_{1+}^a (I_{1-})_b \delta^{ac} \]

\[ [0, 0, 0, 1, 0, 0, 0] : M^{a1a2} M^{a3a4} = (I_{1-})_{\beta} (\gamma^{a1-a4})_{\alpha} I_{1+}^a \]

\[ [0, 0, 0, 0, 0, 0, 0] : S^2 + I_2^a I_2^b = 0 \]

\[ [0, 1, 0, 0, 0, 0, 0] : SM^{ab} + I_2^{[a} I_2^{b]} = I_{1+}^a (I_{1-})_{\beta} (\gamma^{ab})_{\alpha} \]

\[ q([0, 0, 0, 0, 1, 0] + [1, 0, 0, 0, 0, 1]) : M^{ab} I_{1+}^a (\gamma^b)_{\alpha} \]

\[ = S I_{1+}^a (\gamma^a)_{\alpha} + I_2^a (I_{1-})_{\beta} \]

\[ q^{-1}([0, 0, 0, 0, 0, 1] + [1, 0, 0, 0, 0, 1]) : M^{ab} (I_{1-})_{\alpha} (\gamma^b)_{\alpha} \]

\[ = S (I_{1-})_{\alpha} (\gamma^a)_{\alpha} + I_2^a I_{1+}^b \]
The corresponding highest weight generating function is (see (4.25) of [40])

\[ q^2[0, 0, 1, 0, 0, 0, 0] : M^{ab} I^a_2 = I^a_1 (\gamma^{abc})_{\alpha\beta} t^\beta_1 \]

(2.169)

\[ q^{-2}[0, 0, 1, 0, 0, 0, 0] : M^{ab} I^a_2 = (I_{1-})_a (\gamma^{abc})_{\alpha\beta} (I_{1-})_b \]

(2.170)

\[ q^2[0, 0, 0, 0, 0, 0, 0] : M^{ab} I^a_2 = S I^a_2 \]

(2.171)

\[ q^{-2}[0, 0, 0, 0, 0, 0, 0] : M^{ab} I^a_2 = S I^a_2 \]

(2.172)

\[ q^3[0, 0, 0, 0, 0, 0, 0, 1] : I^a_2 + I^a_2 (\gamma^a)_{\alpha\beta} = 0 \]

(2.173)

\[ q^{-3}[0, 0, 0, 0, 0, 0, 0, 1] : I^a_2 (I_{1-})_a (\gamma^a)_{\alpha\beta} = 0 \]

(2.174)

\[ (q^3 + q^{-4})[0, 0, 0, 0, 0, 0, 0, 0] : I^a_2 + I^a_2 = I^a_2 - I^a_2 = 0 . \]

(2.175)

2.9.2 Expansion in the instanton fugacity

The highest weight generating function (2.147) can be rewritten in terms of an implicit expansion in \( q \) involving 5 sums:

\[
\mathcal{G}[\widetilde{M}_{1, E_8}](t; \mu; q) = \text{PE} \left[ (1 + \mu_2) t^2 + (1 + \mu_2 + \mu_4) t^4 + \mu_4 t^6 \right]
\times \text{PE} \left[ (\mu_6 \mu_7 + \mu_1^2) t^4 + (\mu_6 \mu_7 + \mu_5^2) t^8 + \mu_5^2 t^{12} \right]
\times \left( \sum_{n_1 \geq 0} (\mu_6 t^2 q^{n_1}) \sum_{n_2 \in \mathbb{Z}} (\mu_7 t^2)^{-n_1} q^{n_1} \right) \sum_{n_2 \in \mathbb{Z}} (\mu_1 t^2)^{n_2} q^{2n_2}
\times \left( \sum_{n_3 \geq 0} (\mu_6 t^4 q^{n_3}) \sum_{n_4 \in \mathbb{Z}} (\mu_7 t^4)^{-n_3} q^{n_3} \right)
\times \sum_{n_4 \in \mathbb{Z}} (\mu_5 t^6)^{n_4} q^{2n_4} \sum_{n_5 \in \mathbb{Z}} (\mu_5 t^6)^{n_5} q^{2n_5} .
\]

(2.176)

3 USp(4) with one antisymmetric hypermultiplet

In this theory, we pick the trivial value of the discrete theta angle for the USp(4) gauge group. The Higgs branch at infinite coupling of this theory is identified with the reduced moduli space of 2 SU(2) instantons on \( \mathbb{C}^2 \) [4], whose global symmetry is SU(2) \( \times \) SU(2). The Hilbert series is given by (3.14) of [44]. For reference, we provide here the explicit expression of the Hilbert series up to order \( t^6 \):

\[
H[\widetilde{M}_{2, SU(2)}](t; y, x) = 1 + ([0; 2] + [2; 0]) t^2 + [1; 2] t^3 + (1 + [0; 4] + [2; 2] + [4; 0]) t^4
\]
\[
+ ([1; 2] + [1; 4] + [3; 2]) t^5 + ([0; 2] + [0; 6] + [2; 0]
\]
\[
+ 2[2; 4] + [4; 2] + [6; 0]) t^6 + \ldots .
\]

(3.1)

The plethystic logarithm of this expression is

\[
\text{PL} \left[ H[\widetilde{M}_{2, SU(2)}](t; y, x) \right] = \gamma^{(0; 2) + [2; 0] t^2 + [1; 2] t^3 - t^4 - ([1; 2] + [1; 0]) t^5
\]
\[
- ([2; 0] + [0; 2]) t^6 + \ldots .
\]

(3.2)

The corresponding highest weight generating function is (see (4.25) of [40])

\[
\mathcal{G}[\widetilde{M}_{2, SU(2)}](t; \mu_1, \mu_2) = \text{PE} \left[ (\mu_1^2 + \mu_2^2) t^2 + \mu_1 \mu_2 t^3 + t^4 + \mu_1 \mu_2 t^5 - \mu_1^2 \mu_2 t^{10} \right] ,
\]

(3.3)
where $\mu_1$ and $\mu_2$ are respectively the fugacities for the highest weights of the SU(2) acting on the centre of instantons and the SU(2) associated with the internal degrees of freedom.

Let us use the indices $a, b, c, d = 1, 2$ for the first SU(2) and $i, j, k, l = 1, 2$ for the second SU(2). The generators of the moduli space are as follows.

- **Order $t^2$:** the rank two symmetric tensors $P_{ab}$ and $M_{ij}$ in the representation $[2; 0]$ and $[0; 2]$ of SU(2) × SU(2):
  \[ P_{ab} = P_{ba} \quad M_{ij} = M_{ji} \, . \]  
  \[ \text{(3.4)} \]

- **Order $t^3$:** a doublet of rank two symmetric tensors $(A_a)_{ij}$, with
  \[ (A_a)_{ij} = (A_a)_{ji} \, , \]  
  in the representation $[1; 2]$ of SU(2) × SU(2).

The singlet relation at order $t^4$ can be written as
\[ [0; 0]t^4 : \quad \text{Tr}(P^2) = \text{Tr}(M^2) \, . \]  
\[ \text{(3.6)} \]

The relations at order $t^5$ are
\[ [1; 0]t^5 : \quad e^{i'i'}(A_a)_{ij}M_{i'j'} = 0 \, ; \]  
\[ \text{(3.7)} \]
\[ [1; 2]t^5 : \quad e^{bb'}P_{ab}(A_{b'})_{ij} = e^{kk'}M_{ik}(A_a)_{k'j} + (i \leftrightarrow j) \, . \]  
\[ \text{(3.8)} \]

The relations at order $t^6$ are
\[ [2; 0]t^6 : \quad \text{Tr}(P^2)P_{ab} = e^{i'i'}(A_a)_{ij}(A_b)_{i'j'} \, ; \]  
\[ \text{(3.9)} \]
\[ [0; 2]t^6 : \quad \text{Tr}(M^2)M_{ij} = e^{ab}e^{kk'}(A_a)_{ik}(A_b)_{k'j} \, . \]  
\[ \text{(3.10)} \]

Let us now rewrite the above statements in SU(2) × U(1) language. Up to charge normalisation, we identify the Cartan subalgebra of the latter SU(2) associated with $\mu_2$ with the U(1) symmetry. More precisely, if $w$ is the fugacity associated to the Cartan generator of the latter SU(2), then $q = w^2$ is the fugacity for the topological symmetry. The highest weight generating function can then be written as
\[ G[M_{SU(2)}(t; \mu_1; q)] = \text{PE} \left[ \left( 1 + \mu_1^2 + (q + q^{-1}) \right)t^2 + \left( \mu_1 + \mu_1(q + q^{-1}) \right)t^3 \right. \]  
\[ - \mu_1 t^5 - \mu_1^2 t^6 \]  
\[ \left. \text{PE} \left[ \left( 1 + \mu_1^2 + (q + q^{-1}) \right)t^2 + \left( \mu_1 + \mu_1(q + q^{-1}) \right)t^3 \right. \right. \]  
\[ - \mu_1 t^5 - \mu_1^2 t^6 \right] \, . \]  
\[ \text{(3.11)} \]

This can be written as a power series in $q$ as
\[ G[M_{SU(2)}(t; \mu_1; q)] = \frac{1}{(1 - t^2)(1 - t^4)(1 - \mu_1 t)(1 - \mu_1^2 t^2)(1 - \mu_1^3 t^3)} \]  
\[ \times \left( 1 - \mu_1^2 t^6 \right) \left( 1 - \mu_1^2 t^6 \right) \sum_{j=-\infty}^{\infty} q^j t^{2|j|} - (1 - t^4) \sum_{j=-\infty}^{\infty} q^j t^{2|j|}(\mu_1 t)^{|j+1|} \, . \]  
\[ \text{(3.12)} \]
The Hilbert series up to order $t^6$ can be written explicitly as follows:

\[
H_{\mathcal{M}_{\text{SU}(2)}}(t; y, q) = 1 + \left(1 + [2] + (q + q^{-1})\right)t^2 + \left([1] + [1](q + q^{-1})\right)t^3 \\
+ \left(2 + [2] + [4] + (1 + [2])(q + q^{-1}) + (q^2 + q^{-2})\right)t^4 \\
+ \left(2[1] + [3] + (2[1] + [3])(q + q^{-1}) + [1](q^2 + q^{-2})\right)t^5 \\
+ \left(2 + 3[2] + [4] + [6] + (2 + 2[2] + [4])(q + q^{-1}) + (1 + 2[1])(q^2 + q^{-2}) + (q^3 + q^{-3})\right)t^6 + \ldots .
\] (3.13)

The plethystic logarithm of this Hilbert series is given by

\[
\text{PL} \left[H_{\mathcal{M}_{\text{SU}(2)}}(t; y, q)\right] = 1 + [2] + (q + q^{-1})t^2 + \left([1] + [1](q + q^{-1})\right)t^3 - t^4 \\
- \left(2[1] + [1](q + q^{-1})\right)t^5 + \left(1 + [2] + (q + q^{-1})\right)t^6 \\
+ \ldots .
\] (3.14)

**The generators.** At order $t^2$, the generators are

\[
\begin{align*}
[2] : & \quad P_{ab} \quad \text{with} \quad P_{ab} = P_{ba} , \\
q, q^{-1} , 1 : & \quad I , \bar{I} , S .
\end{align*}
\] (3.15) (3.16)

The generators $P_{ab}$ are identified as a product of two antisymmetric tensors:

\[
P_{ab} = \text{Tr}(X_a X_b) .
\] (3.17)

At order 3, the generators are denoted by

\[
q[1], q^{-1}[1], [1] : \quad J_a , \quad \bar{J}_a , \quad T_a .
\] (3.18)

where the generators $T_a$ are identified as a product of two gauginos and one antisymmetric tensor

\[
T_a = \text{Tr} (X_a WW) .
\] (3.19)

**The relations.** The relation at order $t^4$ can be written as

\[
[0]t^4 : \quad \text{Tr}(P^2) + S^2 = I\bar{I} .
\] (3.20)

The relations at order $t^5$ can be written as

\[
\begin{align*}
[1]t^5 : & \quad ST_a = \bar{I}J_a + I\bar{J}_a , \\
q[1]t^5 : & \quad P_{ab} J' \epsilon^{bb'} + I T_a + S J_a = 0 , \\
[1]t^5 : & \quad P_{ab} T' \epsilon^{bb'} + 2ST_a = 0 , \\
q^{-1}[1]t^5 : & \quad P_{ab} \bar{J}_b \epsilon^{bb'} + I T_a + S\bar{J}_a = 0 .
\end{align*}
\] (3.21) (3.22) (3.23) (3.24)
The relations at order $t^6$ can be written as

$$[2]t^6 : S^2 P_{ab} + T_a T_b = J_{(a} \tilde{J}_{b)} + I \bar{I} P_{ab},$$

$$qt^6 : S^2 I = \varepsilon^{ab} J_a T_b + t^2 \bar{I},$$

$$t^6 : S^3 = \varepsilon^{ab} J_a \tilde{J}_b + S I \bar{I},$$

$$q^{-1} t^6 : S^2 \bar{I} = \varepsilon^{ab} \tilde{J}_a T_b + \bar{T}^2 \bar{I}.$$  \hspace{1cm} (3.25)

$$qt^6 : S^2 I = \varepsilon^{ab} J_a T_b + t^2 I,$$

$$t^6 : S^3 = \varepsilon^{ab} J_a \tilde{J}_b + S I \bar{I},$$

$$q^{-1} t^6 : S^2 \bar{I} = \varepsilon^{ab} \tilde{J}_a T_b + \bar{T}^2 \bar{I}.$$  \hspace{1cm} (3.26)

$$t^6 : S^3 = \varepsilon^{ab} J_a \tilde{J}_b + S I \bar{I},$$

$$q^{-1} t^6 : S^2 \bar{I} = \varepsilon^{ab} \tilde{J}_a T_b + \bar{T}^2 \bar{I}.$$  \hspace{1cm} (3.27)

$$qt^6 : S^2 I = \varepsilon^{ab} J_a T_b + t^2 I,$$

$$t^6 : S^3 = \varepsilon^{ab} J_a \tilde{J}_b + S I \bar{I},$$

$$q^{-1} t^6 : S^2 \bar{I} = \varepsilon^{ab} \tilde{J}_a T_b + \bar{T}^2 \bar{I}.$$  \hspace{1cm} (3.28)

4 USp$(2k)$ with one antisymmetric hypermultiplet

As in the previous sections, we pick the trivial value of the discrete theta angle for USp$(2k)$ gauge group. The Higgs branch of the conformal field theory at infinite coupling is identified with the moduli space of $k$ SU(2) instantons on $\mathbb{C}^2$ [4]. Below we consider the moduli space of the theory at finite coupling.

For $k = 1$, the Higgs branch at finite coupling is

$$\mathbb{C}^2 \times \mathbb{Z}_2,$$  \hspace{1cm} (4.1)

where $\mathbb{C}^2$ is the classical moduli space of a USp(2) gauge theory with 1 antisymmetric hypermultiplet and $\mathbb{Z}_2$ is the moduli space generated by the glueball superfield $S$ such that $S^2 = 0$. The Hilbert series is then given by

$$H_{k=1}(t; w) = H[\mathbb{Z}_2](t; w) H[\mathbb{C}^2](t; x)$$

$$= (1 + w^2 t^2) \text{PE} \left[ (t + x^{-1}) \right] = \frac{1 + w^2 t^2}{(1 - tx)(1 - tx^{-1})},$$  \hspace{1cm} (4.2)

where the fugacity $w$ corresponds to the number of gaugino superfields.

For higher $k$, the theory in question can be realised as the worldvolume theory of $k$ coincident D4-branes on an $O8^-$ plane. Hence, the moduli space is expected to be the $k$-th symmetric power of $\mathbb{C}^2 \times \mathbb{Z}_2$, whose Hilbert series is given by

$$H_k(t; x, w) = \int_{|\nu| = 1} \frac{d\nu}{2\pi i \nu^{k+1}} \exp \left( \sum_{m=1}^{\infty} \frac{\nu^m}{m} \eta_{k-1}(t^m; x^m, w^m) \right)$$

$$= \sum_{j=0}^{k} (wt)^{2j} H[\text{Sym}^j \mathbb{C}^2](t, x) H[\text{Sym}^{k-j} \mathbb{C}^2](t, x),$$  \hspace{1cm} (4.3)

where $H[\text{Sym}^n \mathbb{C}^2](t, x)$ is the Hilbert series for the $n$-th symmetric power of $\mathbb{C}^2$:

$$H[\text{Sym}^n \mathbb{C}^2](t, x) = \int_{|\nu| = 1} \frac{d\nu}{2\pi i \nu^{n+1}} \exp \left( \sum_{m=1}^{\infty} \frac{\nu^m}{m} \frac{1}{(1 - t^m x^m)(1 - t^m x^{-m})} \right).$$  \hspace{1cm} (4.4)

We tested the result for $k = 2$ directly from the field theory side using Macaulay2; the details are presented in appendix A.

Note that this result also holds for USp$(2k)$ gauge theory with 1 antisymmetric hypermultiplet and 1 fundamental hypermultiplet. This is because the classical moduli space
of this theory is the moduli space of $k$ SO(2) instantons on $\mathbb{C}^2$ — this space is in fact the $k$-symmetric power of the moduli space of 1 SO(2) instanton on $\mathbb{C}^2$, which is identical to $\mathbb{C}^2$.

Since the symmetric product $\text{Sym}^k(\mathbb{C}^2 \times \mathbb{Z}_2)$ has a $\mathbb{C}^2$ component that can be factored out, it is natural to define the Hilbert series $\tilde{H}_k(t; x, w)$ of the reduced moduli space as follows:

$$H_k(t; x, w) = H[\mathbb{C}^2](t; x)\tilde{H}_k(t; x, w) = \frac{1}{(1 - tx)(1 - tx^{-1})} \tilde{H}_k(t; x, w). \quad (4.5)$$

**Examples.** For $k = 2$, we have

$$\tilde{H}_{k=2}(t, x, w) = (1 + w^4 t^4)(1 - t^4) \text{PE}[(x^2 + 1 + x^{-2}) t^2] + (w t)^2 \text{PE}[(x + x^{-1}) t]$$

$$= 1 + (2 + w^2) t^2 + [1] w^2 t^3 + ([4] + [2] w^2 + w^4) t^4 + ([3] w^2) t^5$$

$$+ ([6] + [4] w^2 + [2] w^4) t^6 + \ldots. \quad (4.6)$$

The plethystic logarithm of this Hilbert series is

$$\text{PL}[\tilde{H}_{k=2}(t, x, w)] = ([2] + w^2) t^2 + [1] w^2 t^3 - t^4 - [1] (w^2 + w^4) t^5 - ([2] w^4 + w^6) t^6 + \ldots. \quad (4.7)$$

For $k = 3$, we have

$$\tilde{H}_{k=3}(t, x, w) = 1 + ([2] + w^2) t^2 + ([3] + [1] w^2) t^3 + (1 + [4] + 2[2] w^2 + w^4) t^4$$

$$+ ([3] + [5] + ([1] + 2[3]) w^2 + [1] w^4) t^5 + ([2] + 2[6])$$

$$+ ([1] + [2] + 3[4]) w^2 + 2[2] w^4 + w^6) t^6 + \ldots. \quad (4.8)$$

The plethystic logarithm of this Hilbert series is

$$\text{PL}[\tilde{H}_{k=3}(t, x, w)] = ([2] + w^2) t^2 + ([3] + [1] w^2) t^3 + [2] w^2 t^4 - [1] t^5$$

$$- ([2] + (1 + [2]) w^2 + [2] w^4) t^6 + \ldots. \quad (4.9)$$

**General $k$.** For general $k$, we have two sets of generators transforming in:

1. representation $[p]$ at order $t^p$, for all $2 \leq p \leq k$;
2. representation $[p] w^2$ at order $t^{p+2}$, for all $0 \leq p \leq k - 1$;

these follow from the generators of the moduli space of two instantons, given by section 8.5 of [45]. Explicitly, these generators are

$$\text{Tr}(X_{a_1} X_{a_2}), \text{Tr}(X_{a_1} X_{a_2} X_{a_3}), \ldots, \text{Tr}(X_{a_1} X_{a_2} \cdots X_{a_k}), \quad (4.10)$$

$$\text{Tr}(WW), \text{Tr}(X_{a_1} WW), \text{Tr}(X_{a_1} X_{a_2} WW), \ldots, \text{Tr}(X_{a_1} \cdots X_{a_{k-1}} WW)$$

where $a_1, a_2, \ldots, a_k = 1, 2$. The set of relations with the lowest dimension transform in the representation $[k - 2]$ at order $t^{k+2}$.

In the limit $k \to \infty$, the moduli space is thus freely generated by $(4.10)$. A similar situation was considered in [46], where it was pointed out that the generating function of multi-trace operators for one brane is equal to that of single trace operators for infinitely many branes.

---

\textsuperscript{13} We would like to express our thanks to Nick Dorey for his nice presentation at the Swansea workshop and especially for discussing this point.
5 Pure super Yang-Mills theories

For 5d $\mathcal{N} = 1$ pure Yang-Mills theory, the Higgs branch at infinite coupling takes a simple orbifold structure. Field theoretic and stringy arguments can be provided for this statement.

In [31] it was argued by counting zero modes that for an $SU(N)$ gauge group the instanton operators transform in the spin-$\frac{N}{2}$ representation of $SU(2)_R$. In [17] the result was generalised to arbitrary gauge groups. Using the observation of [9] that the instanton contribution to the superconformal index is given by an “$SU(2)$-covariantized” version of the Hilbert series, the $SU(2)_R$ spin of instanton operators in pure Yang-Mills theories is given by $\frac{1}{2} h^\vee_G$, where $h^\vee_G$ is the dual Coxeter number of the group $G$. It is then straightforward to construct the relation between the instanton operators and the glueball operator:

$$S^{h^\vee_G} = I \hat{I}
\tag{5.1}$$

which reduces to the standard nilpotency for $S$ [36] at finite coupling where the instanton operators are set to zero. The Higgs branch at infinite coupling is thus the orbifold $\mathbb{C}^2/\mathbb{Z}_{h^\vee_G}$.

For $SU(N)$ pure Yang-Mills a stringy construction provides a complementary viewpoint. For this theory, an $SL(2,\mathbb{Z})$ transformation on the 5-brane web can be exploited to set the charges of the external 5-brane legs to $(p_1, q_1) = (N, -1)$ and $(p_2, q_2) = (0, 1)$. In this basis, the web can be depicted as follows (this example is for $N = 3$):

At infinite coupling, the two 5-branes intersect and move apart, giving a one quaternionic dimensional Higgs branch, which has a cone structure. Using the classification of hyperKähler cones of dimension 1, the space has to be an ADE singularity. The existence in the chiral ring of the operator $S$, which has spin-1 under $SU(2)_R$, rules out the D and E cases, implying that the Higgs branch has to be $\mathbb{C}^2/\mathbb{Z}_m$, for some $m$. The value of $m$ can be deduced by considering the intersection number, which is given by:

$$p_1 q_2 - p_2 q_1 = N
\tag{5.3}$$

The Higgs branch at infinite coupling is therefore $\mathbb{C}^2/\mathbb{Z}_m$.

The generators of the Higgs branch at infinite coupling are $I$, $S$, $\hat{I}$, singlets under $SU(N)$, and with $U(1)_I$ charge +1, 0 and −1 respectively. For $N > 2$, the isometry group of $\mathbb{C}^2/\mathbb{Z}_m$ is identified with $U(1)_I$. For $N = 2$, the isometry of the Higgs branch is enhanced to $SU(2)$ and the operators form a triplet $(I, S, \hat{I})$.

The construction can be generalised by means of orientifold planes [6] to give analogous results for the case of classical gauge groups.

---

We thank Cumrun Vafa for discussions about this point.
6 Discussion

A coherent picture of the Higgs branch of 5d $\mathcal{N} = 1$ theories for all values of the gauge coupling emerges from this paper. In particular, we have presented explicit relations that define the chiral ring at infinite coupling and are consistent with those at finite coupling. A crucial result of this paper is the correction to the glueball superfield, $S$, which at finite coupling is a nilpotent bilinear in the gaugino superfield and at infinite coupling becomes an ordinary chiral operator on the Higgs branch.

For pure SU(2) theories with $N_f \leq 7$ flavours a nice pattern was established. The finite coupling relations involving mesons and the glueball operator are corrected at infinite coupling by bilinears in the instanton operators, in the obvious way dictated by representation theory. New relations also arise which exist uniquely at infinite coupling.

By expanding the highest weight generating function of the Hilbert series at infinite coupling in powers of $q$, we have analysed the dressing of instanton operators by mesons and gauginos. For $N_f \leq 5$ the defining equations for the space associated to the dressing can be obtained by keeping the relations at infinite coupling which are not corrected by the instanton operators. For $N_f = 6, 7$, the presence of charge $\pm 2$ instanton operators as generators independent from the charge $\pm 1$ ones complicates the picture and leaves the interpretation of the classical dressing in a preliminary and unsatisfactory stage.

The techniques developed in this paper could also be applied to other 5d $\mathcal{N} = 1$ theories with known Higgs branch at infinite coupling. We leave this to future work. The long term goal is to better understand supersymmetric instanton operators and their dressing from first principles and use such knowledge to derive a general formula for the Hilbert series associated to the Higgs branch at infinite coupling. We hope that the results of this paper can shine some light in this direction.

A Hilbert series of chiral rings with gaugino superfields

In this appendix we present a method to compute the Hilbert series of the Higgs branch at finite coupling. In this computation we include the classical chiral operators as well as the gaugino superfield \( \mathcal{W} \).

In five dimensions, the gaugino \( \lambda^A_I \) carries the USp(4) spin index \( A = 1, \ldots, 4 \) and the SU(2)_R index \( I = 1, 2 \). Since we focus on holomorphic functions, which are highest weights of SU(2)_R representations, we restrict ourselves to \( I = 1 \). In 4d \( \mathcal{N} = 1 \) language, which we adopt throughout the paper, the fundamental representation of USp(4) decomposes to \([1; 0] + [0; 1]\) of SU(2) \( \times \) SU(2). These are usually denoted by undotted and dotted indices, respectively. Since the latter correspond to non-chiral operators in the 4d \( \mathcal{N} = 1 \) holomorphic approach, we adhere to the undotted SU(2) spinor index. The gaugino superfield is henceforth denoted as \( \mathcal{W}_a \).

We will see that the 4d \( \mathcal{N} = 1 \) formalism adopted in this appendix yields results for the Hilbert series that are consistent with the chiral ring obtained by setting instanton and anti-instanton operators to zero in the five dimensional UV fixed point, which is discussed in the main body of the paper.

A.1 SU(2) gauge theory with \( N_f \) flavours

Let us denote the chiral matter fields appearing in the Lagrangian by \( Q^i_a \), with \( i = 1, \ldots, 2N_f \) and \( a = 1, 2 \). The \( F \)-terms relevant to the classical Higgs branch are\(^{15}\)

\[
\epsilon^{ab} \epsilon^{cd} Q^i_a Q^j_d = 0.
\]  

(A.1)

These relations are symmetric under the interchange of the indices \( b \) and \( c \).

Now let us discuss the inclusion of the gaugino superfield \( (\mathcal{W}_a)_{ab} \). \( \mathcal{W}_a \) is adjoint valued and is chosen to be a traceless symmetric 2-index tensor:

\[
(\mathcal{W}_a)_{ab} = 0.
\]  

(A.2)

Moreover, we impose the following conditions (see section 2 of [36]):

\[
\epsilon^{bc}(\mathcal{W}_a)_{ab}(\mathcal{W}_d)_{cd} + (\beta \leftrightarrow \alpha) = 0 \quad \forall \, \alpha, \beta = 1, 2, \ a, d = 1, 2,
\]  

(A.3)

\[
\epsilon^{bc}(\mathcal{W}_a)_{ab}Q^i_c = 0 \quad \forall \, \alpha = 1, 2, \ a = 1, 2, \ i = 1, \ldots, N_f.
\]  

(A.4)

The condition (A.3) follows from the fact that the lowest component of the gaugino superfield is fermionic. The relation (A.4) follows from gauge invariance and supersymmetry. The relation (A.5) indicates how the gaugino superfield acts on fundamental fields.

The Hilbert series of the ring of variables \( Q^a_i \), \( (\mathcal{W}_a)_{ab} \) subject to the conditions (A.1), (A.2), (A.3), (A.4) and (A.5) can be computed using Macaulay2. For reference, we provide the Macaulay2 code for the case of \( N_f = 3 \) in source code (SC) 1.

\(^{15}\)Here and in the main body of the paper, our relations are valid in the chiral ring. As operator relations, they hold up to a superderivative.
After integrating over the SU(2) gauge group and restricting to the scalar sector under the Lorentz group, we obtain the Hilbert series of the space
\[ \widetilde{\mathcal{M}}_{1,SO(2N_f)} \cup \mathbb{Z}_2, \]
where \( \widetilde{\mathcal{M}}_{1,SO(2N_f)} \) is the reduced moduli space of one SO(2\(N_f\)) instanton on \( \mathbb{C}^2 \) and \( \mathbb{Z}_2 \) is the moduli space generated by the glueball superfield \( S \) such that \( S^2 = 0 \).

\[ H[\widetilde{\mathcal{M}}_{1,SO(2N_f)} \cup \mathbb{Z}_2](t; w) = H[\mathbb{Z}_2](t; w) + H[\widetilde{\mathcal{M}}_{1,SO(2N_f)}](t; x) - 1 \]
\[ = w^2 t^2 + \sum_{p=0}^{\infty} |0, p, 0, \ldots, 0| t^{2p}, \]

where the fugacity \( w \) counts the number of gaugino superfields \( \mathcal{W} \) and \( x \) are the fugacities of SO(2\(N_f\)). The plethystic logarithm up to order \( t^4 \) of this is
\[ \text{PL} \left[ H[\widetilde{\mathcal{M}}_{1,SO(2N_f)} \cup \mathbb{Z}_2](t; x, w) \right] = ([0, 1, 0, \ldots, 0] + w^2) t^2 - \left(1 + [2, 0, \ldots, 0] + [0, 0, 0, 1, 0, \ldots, 0] + w^2[0, 1, 0, \ldots, 0] + w^4 \right) t^4 \]
\[ + \ldots. \]

This shows that the generators are the meson \( M^{ij} = -M^{ji} \), in the adjoint representation of SO(2\(N_f\)), and the glueball \( S = -\frac{1}{32 \pi^2} \text{Tr} \mathcal{W}_a \mathcal{W}^a \), subject to the relations
\[ M^{ij} M^{jk} = 0, \quad M^{[ij} M^{kl]} = 0, \quad SM^{ij} = 0, \quad S^2 = 0. \]

A.2 USp(2\(k\)) gauge theory with one antisymmetric hypermultiplet

The analysis is similar to the previous subsection. Let us denote the antisymmetric fields by \( X^{ij}_a \), where \( a = 1, 2 \) and \( i, j = 1, \ldots, 2k \) are the USp(2\(k\)) gauge indices. The \( F \)-terms associated to the classical Higgs branch is
\[ J_{ij} J_{jl} J_{kl} \epsilon_{a}^{ab} X^{ij}_a X^{kl}_b = 0, \]

where \( J_{ij} \) is the symplectic matrix associated with USp(2\(k\)).

For the gaugino superfield \( \mathcal{W}^{ij}_a \) (with \( \alpha = 1, 2 \)), we impose the conditions [36]
\[ \mathcal{W}^{ij}_a = \mathcal{W}^{ji}_a, \quad (A.11) \]
\[ \text{each component of } \mathcal{W}^{ij}_a \text{ is an anti-commuting variable}, \quad (A.12) \]
\[ J_{jk} \mathcal{W}^{ij}_a \mathcal{W}^{kl}_b = 0, \quad (A.13) \]
\[ J_{jk}(\mathcal{W}^{ij}_a X^{kl}_a - X^{ij}_a \mathcal{W}^{kl}_a) = 0. \quad (A.14) \]

After integrating over the USp(2\(k\)) gauge group and restricting to the scalar sector under the Lorentz group, we obtain the Hilbert series of the space
\[ \text{Sym}^k (\mathbb{C}^2 \times \mathbb{Z}_2), \]

In particular, for \( k = 2 \), we recover the Hilbert series (4.6).
Figure 1. A Macaulay2 code to compute the Hilbert series of the ring of variables $Q^i_a, (W_{ab})$, with $N_f = 3$, subject to the conditions (A.1), (A.2), (A.3), (A.4) and (A.5). Here we write $Q^i_a$ as $Qai$ and $(W_{ab})$ as $wab$. The ring $R$ is multi-graded with respect to the following charges (in order): 1. the $R$-charge associated with the fugacity $t$, 2. the number of gaugino superfields associated with the fugacity $w$, 3. the weights of the SU(2) gauge group, and 4. the weights of the SU(2) symmetry associated with the index $\alpha$.

B $N_f = 6$ in representations of $SO(12) \times SU(2)$

Here we rewrite (2.130) and (2.131) in terms of characters of representations of $SO(12) \times SU(2)$:

$$H[E_7](t; x, y) = 1 + ([0, 0, 0, 0, 0, 0, 2] + [0, 0, 0, 0, 1, 0; 1] + [0, 1, 0, 0, 0, 0; 0])t^2$$
$$+ (1 + [0, 0, 0, 0, 0, 0; 4] + [0, 0, 0, 0, 1, 0; 1] + [0, 0, 0, 0, 1, 0; 3] + [0, 0, 0, 2, 0; 2]$$
$$+ [0, 0, 0, 0, 1, 0, 0; 0] + [1, 0, 0, 0, 0; 2] + [0, 1, 0, 0, 1, 0; 1] + [0, 2, 0, 0, 0, 0; 0])t^4$$
$$+ \ldots.$$  

(B.1)

The plethystic logarithm of (B.1) is

$$\text{PL}[H[E_7](t; x, y)] = ([0, 0, 0, 0, 0, 0, 2] + [0, 0, 0, 0, 1, 0; 1] + [0, 1, 0, 0, 0, 0; 0])t^2 - \left(2 + [0, 0, 0, 1, 0, 0; 0]\right)$$
\[ + [2, 0, 0, 0, 0, 0; 0] + [0, 0, 0, 1, 0; 1] + [1, 0, 0, 0, 0, 1; 1] + [0, 1, 0, 0, 0; 2] \cdot t^4 \]
\[ + \ldots \]  

(B.2)

The representation \([0, 0, 0, 0, 0; 2]\) corresponds to \(I_{2+}, I_{2-}\) and \(S\), \([0, 0, 0, 1, 0; 1]\) to \(I_{1\pm}\) and \([0, 1, 0, 0, 0; 0]\) to \(M\). In the Hilbert series (B.1) there is only one independent singlet at order \(t^4\); this means that the singlets coming from these three sets of operators must be proportional to each other. These indeed correspond to the trace part of (2.137) and the relation (2.139).
