**ABSTRACT:** We show that in boundary CFTs, there exists a one-to-one correspondence between the boundary operator expansion of the two-point correlation function and a power series expansion of the layer susceptibility. This general property allows the direct identification of the boundary spectrum and expansion coefficients from the layer susceptibility and opens a new way for efficient calculations of two-point correlators in BCFTs. To show how it works we derive an explicit expression for the correlation function $\langle \phi_i \phi^i \rangle$ of the $O(N)$ model at the extraordinary transition in $4-\epsilon$ dimensional semi-infinite space to order $O(\epsilon)$. The bulk operator product expansion of the two-point function gives access to the spectrum of the bulk CFT. In our example, we obtain the averaged anomalous dimensions of scalar composite operators of the $O(N)$ model to order $O(\epsilon^2)$. These agree with the known results both in $\epsilon$ and large-$N$ expansions.
1 Introduction

Boundary conformal field theories (BCFTs) are an invaluable tool in studies of critical phenomena in semi-infinite systems. From the theoretical standpoint, in such systems the two-point correlation function is one of the most interesting observables, similar to the four-point function in infinite systems. The two-point correlator admits two powerful expansions: The boundary operator expansion (BOE) where each operator is expanded into a sum of boundary fields, and the bulk operator product expansion (OPE) where the product of two operators is expanded into a sum of bulk fields. The BOE was first explicitly formulated in [1]. Its early development in the context of the traditional field-theoretical renormalization-group approach [2, 3] has been summarized in [4]. A crucial step in the development of short-distance operator expansions in semi-infinite systems has been done by McAvity and Osborn [5] who recognized the powerful additional possibilities provided by the conformal invariance. They have taken into account all possible contributions from an infinite set of descendant derivative
operators originating from a given operator appearing in a short-distance operator expansion. This has led to contributions to BOE and OPE expressed in terms of Gaussian hypergeometric functions (see e.g. [6]), which are nowadays called boundary- and bulk-channel conformal blocks [7].

The perturbative calculation of two-point functions to high loop orders is a challenging task as it involves many complicated Feynman diagrams. It was shown in [5] that the connected two-point function in a BCFT can be mapped to another quantity called the layer susceptibility, which contains the same information concerning the scaling dimensions and short-distance properties. Both functions are related by an integral transformation. At the same time, the Feynman-graph calculation of the layer susceptibility is much simpler than that of the two-point correlation function. The central result of the current paper is that there is an infinite power series expansion of the layer susceptibility which is in one-to-one correspondence with the BOE of the two-point function. This means that one can directly read off the conformal dimensions and BOE coefficients from this expansion and obtain the two-point correlator in terms of the BOE.

Recently [8], the layer susceptibility for $(4 - \epsilon)$-dimensional $\phi^4$ theory at the extraordinary transition was computed in a Feynman-graph expansion to order $O(\epsilon)$. In the present paper we extend this calculation to the $O(N)$ models. Using the susceptibility-correlator correspondence, we derive the corresponding two-point function of the order-parameter field. Further, using the OPE we constrain the bulk CFT spectrum up to $O(\epsilon^2)$.

The paper is organized as follows. In Sec. 2 we discuss the layer susceptibility for generic BCFTs, derive the relation between the layer susceptibility and the boundary operator expansion of the two-point function and state our main result on page 6. These ideas are applied to the $O(N)$ model at the extraordinary transition in Sec. 3. We conclude with some future directions and give calculational details in two appendices.

2 The two-point function and layer susceptibility in BCFT

We shall consider two-point correlation functions of basic fields in a $d$-dimensional boundary conformal field theory BCFT$_d$. They are defined in a $d$-dimensional Euclidean semi-infinite space $\mathbb{R}^d_+ = \{x = (r, z) \in \mathbb{R}^d \mid r \in \mathbb{R}^{d-1}, z \geq 0\}$ bounded by a flat $(d - 1)$-dimensional hyper-surface at $z = 0$. The presence of a boundary at $z = 0$ breaks the translational invariance along the $z$ axis, while this invariance remains present in the parallel $r$-directions for any $z \geq 0$.

2.1 Correlation functions and operator product expansions

We assume that the theory is invariant under restricted conformal transformations that preserve the boundary of the system [9, 10]. In this case the two-point correlation function $\langle \phi(x)\phi(x') \rangle = G(r; z, z')$ of identical scalars $\phi$ with scaling dimension $\Delta_\phi$ at positions
The argument of the conformal scaling function \( F(\xi) \) is the cross-ratio
\[
\xi = \frac{(x - x')^2}{4zz'} = \frac{r^2 + (z' - z)^2}{4zz'},
\]
one of the possible conformal invariants involving two points \( x \) and \( x' \) in \( \mathbb{R}^d \).

There are two natural limiting configurations that lead to powerful operator expansions which restrict the structure of the correlation function. In the first case, both the operators are close to the boundary but far from each other. This is the limit \( \xi \to \infty \), where each operator can be expanded in a sum of boundary operators \( \hat{O}(r) \) with scaling dimensions \( \hat{\Delta} \) and their own two-point functions on the boundary. This is the boundary operator expansion (BOE). It is given by an infinite series of “boundary blocks” \( G_{\text{boe}}(\hat{\Delta}; \xi) \) with BOE coefficients \( \mu^2_{\hat{\Delta}} \)
\[
F(\xi) = \sum_{\hat{\Delta} \geq 0} \mu^2_{\hat{\Delta}} G_{\text{boe}}(\hat{\Delta}; \xi).
\]

The \( \hat{\Delta} = 0 \) term corresponds to the contribution of the identity operator on the boundary which is responsible for the appearance of the disconnected part of the two-point function. The boundary blocks \([5, (7.6)], [7, (2.20)]\) are given in terms of Gauss hypergeometric functions
\[
G_{\text{boe}}(\hat{\Delta}; \xi) = \xi^{-\hat{\Delta}} \, _2F_1\left(\hat{\Delta}, \hat{\Delta} + 1 - \frac{d}{2}; 2(\hat{\Delta} + 1 - \frac{d}{2}); -\xi^{-1}\right).
\]

The \( _2F_1 \) function results from summing the contributions of the boundary operator itself and all its descendent derivative operators generated by the action of parallel gradients within the boundary plane.\(^1\) A possible non-trivial mixing of subleading operators with the same scaling dimensions is not taken into account. An explicit example of such boundary-operator mixing can be found in [11].

The other important limiting case is \( \xi \to 0 \) and describes operators which are close to each other, but far from the boundary. In this case one can expand the product of operators using the usual bulk operator product expansion (OPE). Due to the presence of the boundary, the scalar operators emerging in the OPE (and not just the identity operator) can have a non-vanishing one-point function and thus contribute to the two-point correlator. The OPE of \( F(\xi) \) with OPE coefficients \( \lambda_{\Delta} \)
\[
F(\xi) = \xi^{-\Delta_{\phi}} \sum_{\Delta \geq 0} \lambda_{\Delta} G_{\text{ope}}(\Delta; \xi)
\]
\(^1\)Operators containing more inner normal derivatives at \( z = 0 \) than \( \hat{O} \) are subleading (quasi-primary) with respect to \( \hat{O} \).
involves the bulk blocks \[5, (6.5)], \[7, (2.15)]

\[
G_{\text{ope}}(\Delta; \xi) = \xi^{\Delta/2} F_1\left(\frac{\Delta}{2}, \frac{\Delta}{2}; \Delta + 1 - \frac{d}{2}; -\xi\right),
\]

(2.6)

The \(\Delta = 0\) term represents the contribution of the bulk identity operator which is responsible for the correct infinite-bulk limit of the two-point function as \(\xi \to 0\).

An identification of these two different expansions with just the same function \(F(\xi)\) constitutes the bootstrap equation

\[
\xi^{-\Delta_{\phi}} \sum_{\Delta \geq 0} \lambda_{\Delta} G_{\text{ope}}(\Delta; \xi) = \sum_{\hat{\Delta} \geq 0} \mu_{\hat{\Delta}}^2 G_{\text{boe}}(\hat{\Delta}; \xi).
\]

(2.7)

Using the bootstrap equation (2.7) one can reproduce the explicit expressions for two-point functions at the ordinary and special transitions to order \(O(\epsilon)\) of the \(\epsilon\)-expansion \[5, 7, 12, 13\]. The \(O(\epsilon^2)\) contributions were derived from this equation in \[14\]. In \[7, \text{Sec.} \ 3.2\] some preliminary results have been also obtained in the case of the extraordinary transition. The numerical bootstrap in this setting has been explored in \[15\], where the ordinary, extraordinary and special transitions in three dimensions were considered. In this setting the extraordinary transition is somewhat more constrained than the other two due to the large gap between the identity and the displacement operator in the boundary channel. In this work we will use the bootstrap equation to extract the bulk CFT data from the correlator derived in terms of the BOE. In the next section we will explain how to derive the two-point function from the layer susceptibility once it is known.

### 2.2 The layer susceptibility and Radon transformation

Let us introduce the layer (or parallel) susceptibility \(\chi(z, z')\) \[16–19\] and discuss some important properties of this function that follow from conformal invariance. It will play a crucial role in our further development.

The layer susceptibility is defined as an integral of the (connected) two-point correlation function over parallel coordinates \(r \in \mathbb{R}^{d-1}\) within the layer confined between parallel planes located at \(z\) and \(z'\)

\[
\chi(z, z') = \int d^{d-1}r \, G(r; z, z').
\]

(2.8)

An interesting direct connection between the layer susceptibility and the two-point function has been pointed out in the context of BCFT in \[5, \text{Sec.} \ 4\] (see also \[20\]). A straightforward integration (2.8) of the correlation function (2.1) shows that the layer susceptibility \(\chi(z, z')\) can be expressed in the form

\[
\chi(z, z') = (4zz')^{\lambda-\Delta_{\phi}} \hat{F}(\rho), \quad \text{where} \quad \lambda \equiv \frac{d-1}{2},
\]

(2.9)

in terms of a scaling function \(\hat{F}(\rho)\) depending on the cross-ratio

\[
\rho = \frac{(z' - z)^2}{4zz'}. \quad (2.10)
\]
This combination is simply the cross-ratio $\xi$ from (2.2) at $r = 0$, that is in a “perpendicular configuration” (used in [13], [21, p. 26]) where the points $x$ and $x'$ lie on a line orthogonal to the boundary plane. Another expression for the exponent in (2.9) is $\lambda - \Delta_\phi = (1 - \eta)/2$. One can use (2.8) to show that the function $\hat{F}(\rho)$ is given by

$$
\hat{F}(\rho) = \frac{S_{d-1}}{2} \int_0^\infty du u^{-1+\lambda} F(u + \rho),
$$

where the integration variable $u$ is related to $r$ via $u = r^2/(4zz')$. The geometric factor $S_{d-1}$ is the surface area of a unit sphere embedded in $\mathbb{R}^{d-1}$ and given by a specialization of the general formula

$$
S_d = \frac{2\pi^{d/2}}{\Gamma(d/2)}.
$$

In [5, Sec. 4]), the equation (2.11) has been identified as the Radon transform [22–25] which has the inverse

$$
F(\xi) = \frac{S^{-(d-1)}}{2} \int_0^\infty d\rho \rho^{-1-\lambda} \hat{F}(\rho + \xi).
$$

The pair of integral transformations (2.11) and (2.13) has been used in [5] to study correlation functions of the non-linear $O(N)$ sigma model in the framework of the large-$N$ expansion; in [20] to formulate a new approach to calculations of conformal integrals; and recently in [8] to compute the layer susceptibility at the extraordinary transition in a scalar $\phi^4$ theory to order $O(\epsilon)$. In the context of holography an inverse Radon transform was used in [26] to reconstruct two-point functions in the bulk of dS or AdS spaces from boundary correlators.

### 2.3 Layer susceptibility vs BOE

Let us now come to our main result, a direct relation between the layer susceptibility and the BOE of the two-point function given in (2.3) in terms of boundary-channel conformal blocks (2.4).

Consider just a single BOE block $G_{\text{boe}}(\hat{\Delta}; \xi)$ from (2.4) and let us derive its (direct) Radon transform using (2.11). We have

$$
\hat{F}_\Delta(\rho) = \frac{S_{d-1}}{2} \int_0^\infty du u^{-1+\lambda} (u + \rho)^{-\hat{\Delta}} F_1(\hat{\Delta} + 1 - \frac{d}{2}; 2(\hat{\Delta} + 1 - \frac{d}{2}); -\frac{1}{u + \rho}).
$$

One can use the series representation of the hypergeometric function here and integrate term by term. The result is

$$
\hat{F}_\Delta(\rho) = \frac{S_{d-1}}{2} B(\hat{a}, \lambda) \rho^{-\hat{a}} F_1(\hat{a}, \hat{a} + \frac{1}{2}; 2\hat{a} + 1; -\rho^{-1}), \quad \text{where} \quad \hat{a} \equiv \hat{\Delta} - \lambda,
$$

and

$$
B(a, b) = \frac{\Gamma(a) \Gamma(b)}{\Gamma(a + b)}, \quad (a, b \neq 0, -1, -2, \ldots)
$$

- 5 -
is the beta function. The specific set of parameters in the last Gauss function reduces it to a simple algebraic expression via \[27, 7.3.1.105\] and then, introducing the variable

\[
\zeta = \frac{\min(z, z')}{\max(z, z')} = \frac{z + z' - |z' - z|}{z + z' + |z' - z|} = \frac{\sqrt{\rho + 1} - \sqrt{\rho}}{\sqrt{\rho + 1} + \sqrt{\rho} + 1} = \left(\sqrt{\rho + \sqrt{\rho + 1}}\right)^{-2},
\]

(2.17)

to a single power of this variable. Hence,

\[
\hat{F}_\Delta(\rho) = 2^{2\hat{a}-1} S_{d-1} B(\hat{a}, \lambda) \left(\sqrt{\rho + \rho + 1}\right)^{-2\hat{a}} = \sigma_{\hat{\Delta}}^{-1} \zeta^\hat{a}.
\]

(2.18)

Here we denote by \(\sigma_{\hat{\Delta}}^{-1}\) the coefficient in front of \(\zeta^\hat{a}\)

\[
\sigma_{\hat{\Delta}}^{-1} = 4^{\hat{\Delta}-\lambda} \pi^\lambda \frac{\Gamma(\hat{\Delta} - \lambda)}{\Gamma(\hat{\Delta})}.
\]

(2.19)

The variable \(\zeta\) naturally arises both in ordinary scaling considerations \[17\], and in explicit calculations \[8, 18\] where the layer susceptibility has been obtained in terms of powers of \(\zeta\).

In fact, we can calculate the inverse Radon transform \(F_a(\xi)\) of \(\zeta_a\) with any \(a \neq 0\) via (2.13). To do this we need to express \(\zeta\) in terms of \(\rho\) by using (2.17), apply \[27, 7.3.1.105\] to produce the hypergeometric function, and integrate:

\[
F_a(\xi) = 2^{-1-2a} S_{-(d-1)} \int_0^\infty d\rho \rho^{-1-\lambda} (\rho + \xi)^{-a} _2F_1\left(a, a + \frac{1}{2}; 2a + 1; -\frac{1}{\rho + \xi}\right).
\]

(2.20)

Proceeding as before, we obtain

\[
F_a(\xi) = 2^{-1-2a} S_{-(d-1)} B(a + \lambda, -\lambda) \xi^{-a-\lambda} _2F_1\left(a + \lambda, a + \frac{1}{2}; 2a + 1; -\xi^{-1}\right).
\]

(2.21)

Then, after the identification \(a \mapsto \hat{a} = \hat{\Delta} - \lambda\) we arrive at

\[
F_a(\xi) = \sigma_{\hat{\Delta}} G_{\text{boe}}(\hat{\Delta}; \xi),
\]

(2.22)

where \(G_{\text{boe}}(\hat{\Delta}; \xi)\) is the boundary conformal block from (2.4). In summary:

\begin{center}

There is a one-to-one correspondence between the scaling functions of the connected two-point function and layer susceptibility

\[
G^\text{con}(x_1, x_2) = (4zz')^{-\Delta_\phi} F^\text{con}(\xi) \quad \text{and} \quad \chi(z, z') = (4zz')^\lambda - \Delta_\phi \ X(\zeta),
\]

with \(X(\zeta) = \hat{F}(\rho(\zeta))\), given by

\[
F^\text{con}(\xi) = \sum_{\hat{\Delta} > 0} \mu^2_{\hat{\Delta}} G_{\text{boe}}(\hat{\Delta}; \xi) \quad \leftrightarrow \quad X(\zeta) = \sum_{\hat{\Delta} > 0} C_{\hat{\Delta}} \zeta^{\hat{\Delta} - \lambda},
\]

(2.24)

where the BOE coefficients \(\mu^2_{\hat{\Delta}}\) of \(F(\xi)\) are related to coefficients \(C_{\hat{\Delta}}\) of the power expansion of \(X(\zeta)\) via

\[
\mu^2_{\hat{\Delta}} = C_{\hat{\Delta}} \sigma_{\hat{\Delta}} \quad \text{where} \quad \sigma_{\hat{\Delta}} = 4^{\hat{\Delta}+\lambda} \pi^{-\lambda} \frac{\Gamma(\hat{\Delta})}{\Gamma(\hat{\Delta} - \lambda)} \quad \text{and} \quad \lambda = \frac{d - 1}{2}.
\]

(2.25)
\end{center}
This has some important consequences. First, the existence of the BOE (2.3) implies that the layer susceptibility has a representation as a power series in $\zeta$, with powers according to the scaling dimensions of the boundary operators in the BOE. The power structure of $\chi(z,z')$ has been observed previously [8, 18] but was not seen to be a consequence of the BOE.

Second, given any layer susceptibility as a power series in $\zeta$, one can directly read off the boundary operator expansion (2.3) of the two-point function. Apart from being a nice conceptual advantage, this can be viewed as an essential computational shortcut in calculations of two-point correlators. One only needs to sum the BOE with coefficients obtained from the layer susceptibility. In the following we shall show how it works by performing explicit calculations for the $O(N)$ model at the extraordinary transition.

3 The $O(N)$ model and the extraordinary transition

We will now apply the steps outlined above for a general BCFT to a concrete physical system. To this end we assume isotropic short-range interactions throughout the system, which are generally different in its bulk when $z > 0$, and at the boundary when $z = 0$. External fields can be present as well, and they also may have different values in the bulk and the boundary of the system. With an $O(N)$-symmetric order parameter, the critical behavior of such systems is described by the effective Landau-Ginzburg-Wilson Hamiltonian (see e.g. [4])

$$
\mathcal{H}[\phi] = \int d^{d-1}r \int_0^\infty dz \left[ \frac{1}{2} |\nabla \phi|^2 + \frac{\tau_0}{2} |\phi|^2 + \frac{u_0}{4!} (|\phi|^2)^2 - h \phi^1 \right] + \int d^{d-1}r \left( \frac{c_0}{2} |\phi_s|^2 - h_1 \phi_s^1 \right).
$$

Here $\phi = \phi(r,z)$ is an $N$-component vector of scalar order-parameter fields, $\phi = \{\phi^i, i = 1, \ldots, N\}$, and the notation $\phi_s = \phi(r,0)$ is used for the surface field located at the boundary.

The parameter $\tau_0$ is a linear function of the temperature $T$, and $u_0 > 0$ is the usual bulk coupling constant of the $\phi^4$ term. The “surface enhancement” $c_0$ is a local boundary parameter that controls deviations of the strength of surface interactions with respect to the ones in the bulk. We also included terms related to the external fields. They are generally different in the bulk of the system ($h$) and in its boundary ($h_1$). We have assumed that both of them couple to the first component of the field. Note that we do not assume any coupling between the directions in the $d$-dimensional configuration space and the $N$-dimensional parametric space.

In the absence of external fields, the phase transitions with different types of surface critical behavior occur at bulk $T_c$ depending on the relation of bulk and surface interactions — see e.g. [28, p. 19-23], [4, p. 85-87]. Our Fig. 3 reproduces the main features of the phase diagram carefully discussed in these references:

1) When $c_0$ is greater than a certain special value $c_0^{sp}$, the surface interactions are not sufficient to produce the surface ordering at $T = T_c$. The surface is called free and the phase transition from the completely disordered phase to the ordered one goes through the line of ordinary transitions. The order-parameter field vanishes at the surface, and the Dirichlet boundary conditions are fulfilled.
2) When $c_0 = c_0^{sp}$ and $T \rightarrow T_c$ (i.e. $\tau_0 \rightarrow \tau_{0c}$), the surface and the bulk order simultaneously. This is the special transition, the Neumann boundary conditions apply.

3) When $c_0 < c_0^{sp}$, the surface interactions are strong enough to induce the surface order even at temperatures higher than $T_c$. Thus the system goes to the surface ordered/bulk disordered (SO/BD) phase through the surface transition.

4) As the temperature is further lowered down to $T = T_c$, the bulk ordering occurs in the presence of the order at the boundary. This is the extraordinary transition. In $N$-component systems with $N \neq 1$, the surface order breaks the $O(N)$ symmetry both above and below the transition temperature. Thus, the longitudinal and transverse components of the order-parameter field have to be distinguished, they correlate in different ways.

As far back as in 1977, Bray and Moore [29, p. 1933] argued that it is not important for the extraordinary transition how the surface order was achieved: it could be also induced by an application of an external surface field $h_1$ at any value of $c_0$. Moreover, using scaling arguments they concluded that the surface critical exponents at the extraordinary transition are expressed in terms of the bulk exponents and the space dimension $d$ [29, p. 1956]. In particular, the critical exponents of longitudinal and transverse correlations along directions parallel and perpendicular with respect to the boundary are given by

$$
\eta^L_\parallel = d + 2, \quad \eta^L_\perp = \frac{1}{2}(d + 2 + \eta),
$$

(3.2)

---

2Physically, one has to distinguish between the “extraordinary” and “normal” transitions [30, 31]. In the renormalized theory, the extraordinary transition occurs at the fixed point with $h_1 = 0$ and $c < 0$. At the normal transition (as in the case of the critical adsorption) generically $h_1 \neq 0$, while $c$ can be both positive and negative. Just at the fixed point the correlations are identical. However, away from the fixed point, there are different corrections in both cases. We thank H. W. Diehl for stressing this physical difference.
and \[32, (1.1)\]
\[
\eta^T_\parallel = d, \quad \eta^T_\perp = \frac{1}{2}(d + \eta),
\]
(3.3)
where \(\eta\) is the infinite-bulk correlation function exponent. In terms of this exponent the scaling dimension of the bulk field is \(\Delta_\phi = (d - 2 + \eta)/2\). The exponents appearing in our explicit calculations below, will agree with those of (3.2) and (3.3).

### 3.1 The one- and two-point functions

As discussed in the previous section, at the extraordinary transition the \(O(N)\) symmetry is broken due to the presence of the long-range order in the boundary. To implement this, we singled-out the first component of the field, \(\phi^1\). The expectation value of this longitudinal component is given by
\[
\langle \phi^1(x) \rangle = m(z) \neq 0.
\]
(3.4)
Its \(z\) dependence is fixed by scaling
\[
m(z) = \frac{\mu_0}{(2z)^{\Delta_\phi}}.
\]
(3.5)
The remaining \(N - 1\) transverse components \(\phi^i\) with \(i = 2, \ldots N\) have zero expectation values throughout the transition:
\[
\langle \phi^i(x) \rangle = 0, \quad i = 2, \ldots N.
\]
(3.6)
The two-point correlation functions of the longitudinal and transverse components are also different. For a pair of longitudinal fields we have
\[
G_L(r; z, z') = \langle \phi^1(x)\phi^1(x') \rangle = \langle \phi^1(x) \rangle \langle \phi^1(x') \rangle + \langle \phi^1(x)\phi^1(x') \rangle_{\text{con}}.
\]
(3.7)
The disconnected part of \(G_L(r; z, z')\) is given by a product of one-point functions (3.4), and the last term in (3.7) represents the connected part \(G_{L,\text{con}}^L(r; z, z')\) of this function.

When \(i > 1\), the two-point function of transverse fields is given by
\[
G_T(r; z, z') = \langle \phi^i(x)\phi^i(x') \rangle, \quad i = 2, \ldots N.
\]
(3.8)
Its disconnected part vanishes due to (3.6). The full correlator is
\[
G^{ij}(r; z, z') = \langle \phi^i(x)\phi^j(x') \rangle = \delta^{i1}\delta^{j1}G_L(r; z, z') + (\delta^{ij} - \delta^{i1}\delta^{j1})G_T(r; z, z').
\]
(3.9)
In the following we shall study the contracted correlation function
\[
G(r; z, z') = \delta_{ij}G^{ij}(r; z, z') = G_L(r; z, z') + (N - 1)G_T(r; z, z'),
\]
(3.10)
\[\text{\footnote{In statistical physics the value } m(z) \text{ is called the order-parameter profile, or magnetization profile in terminology appropriate for magnetic systems. An extensive study of this value in a scalar theory both above and below } T_c \text{ can be found in [33].}}\]
right at the extraordinary transition, that is at $T = T_c^{bulk}$. Using the scaling representation (2.1) in (3.10) we can write

$$F(\xi) = F_L(\xi) + (N - 1) F_T(\xi) = \mu^2 + F_L^{con}(\xi) + (N - 1) F_T(\xi).$$

The constant term $\mu^2$ stems from the disconnected part of $G_L(r; z, z')$ given by the square of the one-point function (3.5).

The layer susceptibility inherits the same structure as the two-point function by its definition (2.8), i.e.

$$\chi^{ij}(z, z') = \delta^{ij} \chi_L(z, z') + (\delta^{ij} - \delta^{11}) \chi_T(z, z').$$

The leading contributions are the free-theory results which are easily obtained as $p \to 0$ limits (cf. (3.21)) of the transverse and longitudinal free propagators from [34, p. 4671],

$$\chi^L_0(p = 0; z, z') = \frac{1}{10} \frac{\min(z, z')^3}{\max(z, z')^2} = \sqrt{4zz'} \frac{1}{10} \zeta^2,$$

$$\chi^T_0(p = 0; z, z') = \frac{1}{6} \frac{\min(z, z')^2}{\max(z, z')} = \sqrt{4zz'} \frac{1}{6} \zeta^2,$$

where $\tilde{G}(p; z, z')$ is the Fourier transform of $G(r; z, z')$ in $r \in \mathbb{R}^{d-1}$, and $p \in \mathbb{R}^{d-1}$ is the "parallel" momentum conjugate to $r$. They are independent of $d$, and are also valid in mean-field theory whose results are reproduced from $d$-dependent quantities at the upper critical dimension $d = d^* = 4$: we have $\chi^{L,T}_0(z, z') = \chi^{L,T}_{MF}(z, z')$.

The inverse Radon transformation of the free-theory susceptibilities (3.13) via (2.13) yields the $d$-dependent functions

$$G^{L,T}_0(r; z, z') = \frac{1}{(4zz')^{(d-2)/2}} \frac{S_{d-1}}{d - 2} g^{L,T}_0(\xi),$$

where (cf. [8, (30)])

$$g^L_0(\xi) = \xi^{-d/2} - (\xi + 1)^{1-d/2} + \frac{12}{4 - d} \left( \xi^{2-d/2} + (\xi + 1)^{2-d/2} + \frac{4}{6 - d} \left( \xi^{3-d/2} - (\xi + 1)^{3-d/2} \right) \right),$$

$$g^T_0(\xi) = \xi^{-d/2} + (\xi + 1)^{1-d/2} + \frac{4}{4 - d} \left( \xi^{2-d/2} - (\xi + 1)^{2-d/2} \right).$$

In the next section these functions will be used as free propagators in our Feynman-graph expansion in $d = 4 - \epsilon$. While only their leading terms in the $\epsilon$ expansion

$$G^L_0 = \frac{\sigma_4}{40zz'} G_{boe}(4; \xi) + O(\epsilon) = \frac{1}{16\pi^2} \frac{1}{zz'} \left( \frac{1}{\xi} \frac{1}{\xi + 1} + 12 + 6(\xi + 1) \log \frac{\xi}{\xi + 1} \right) + O(\epsilon),$$

$$G^T_0 = \frac{\sigma_3}{24zz'} G_{boe}(3; \xi) + O(\epsilon) = \frac{1}{16\pi^2} \frac{1}{zz'} \left( \frac{1}{\xi} \frac{1}{\xi + 1} + 2 \log \frac{\xi}{\xi + 1} \right) + O(\epsilon)$$

\footnote{These $d = 4$ terms agree with the corresponding mean-field two-point functions. The longitudinal one agrees with [7, (B.35)], [8, (34)] and is compatible with [35, (4.96)] known long time ago and transcribed incorrectly in [36, (12)], [37, (5.48)].}
will contribute to the Feynman diagrams, it is useful to keep the \( \epsilon \)-dependence in (3.15) to simplify the evaluation of Feynman integrals. Terms originating at order \( O(\epsilon) \) in (3.15) will drop out in the final expansion in \( \epsilon \). In (3.16) we used the \( d = 4 \) values \( \sigma_4 = 1/(4\pi^2) \) and \( \sigma_3 = 1/(2\pi^2) \).

3.2 The layer susceptibility and Feynman graphs

Before turning to explicit calculations let us consider the general structure of Feynman-graph expansions for the layer susceptibility \( \chi(z, z') \).

An important feature is that its Feynman-graph calculations are considerably simpler than the ones for the correlation function. In order to see this consider the following two types of Feynman diagrams that can appear in a two-point function \( G(x_1, x_2) \). Either the two external propagators are connected to the same vertex

\[
G_1(r_{12}, z_1, z_2) = \int_0^\infty dz \int d^{d-1}r A(z) , \tag{3.17}
\]

or they are connected to different vertices

\[
G_2(r_{12}, z_1, z_2) = \int_0^\infty dzdz' \int d^{d-1}r d^{d-1}r' A(x, x') . \tag{3.18}
\]

Both equations are defined up to some amputated diagrams \( A(x) \) and \( A(x, x') \) which we do not need to specify here. However due to translation invariance in the \( r \) directions, \( A(x) = A(z) \) can only depend on \( z \) and \( A(x, x') = A(r - r', z, z') \). The corresponding layer susceptibility for \( G_1 \) is

\[
\chi_1(z_1, z_2) = \int_0^\infty dz \int d^{d-1}r_{12} d^{d-1}r G_0(r_1 - r, z_1, z)G_0(r - r_2, z, z_2)A(z) \]
\[
= \int_0^\infty dz \chi_0(z_1, z) \chi_0(z, z_2)A(z) , \tag{3.19}
\]

where \( \chi_0 \) is given by (2.8) with the propagator \( G_0 \). Similarly for the diagrams of type \( G_2 \) we obtain

\[
\chi_2(z_1, z_2) = \int_0^\infty dzdz' \int d^{d-1}r_{12} d^{d-1}r d^{d-1}r' G_0(r_1 - r, z_1, z)G_0(r' - r_2, z', z_2)A(r - r', z, z') \]
\[
= \int_0^\infty dzdz' \chi_0(z_1, z) \chi_0(z', z_2) \int d^{d-1}r A(r, z, z') . \tag{3.20}
\]

\(^5\)For clarity of presentation we use in this subsection the notation \( z_1 \) and \( z_2 \) for perpendicular coordinates of external points instead of the usual \( z \) and \( z' \). We hope that this will not lead to any confusion.
In both cases we shifted integration variables and used translational invariance in the parallel directions. Thus, in a graphical expansion of $\chi(z_1, z_2)$ two of the integrals in the $r$ directions are absorbed by replacing the external propagators with the corresponding layer susceptibilities.

When the momentum representation in parallel directions is used, the definition (2.8) is equivalent to

$$\chi(z, z') = \tilde{G}(p = 0; z, z').$$

(3.21)

In constructing the perturbation theory for $\chi(z, z')$, we could alternatively use the definition (3.21), write down the Feynman-graph expansion for the two-point function $\tilde{G}(p; z_1, z_2)$ in the “mixed” $(p,z)$-representation and follow the simplifications occurring at zero external parallel momentum $p$. The calculational simplifications that occur when considering the layer susceptibility rather than the two-point function are essential.

### 3.3 Perturbation theory for the layer susceptibility

In this section we calculate the layer susceptibility via Feynman-graph expansion to one-loop order starting from the effective Hamiltonian (3.1) in $d = 4 - \epsilon$. Similarly as in Sec. 3.2, we use the usual rules for Feynman diagrams in position space. With the $O(N)$-symmetric interaction in (3.1), we have the following associations for the lines and vertices,

$$\begin{align*}
\frac{\longrightarrow}{\longleftarrow} &= G^{ij}_0(r_1 - r_2; z_1, z_2), \\
\times &= u^{ijkl}_0 \int_0^{\infty} dz \int d^{d-1}r \quad \text{with} \quad u^{ijkl}_0 = -\frac{u_0}{3} \left( \delta^{ij} \delta^{kl} + \delta^{ik} \delta^{jl} + \delta^{il} \delta^{jk} \right),
\end{align*}$$

(3.22)

where $G^{ij}_0(r_1 - r_2; z_1, z_2)$ is the free propagator with the longitudinal and transverse components given in (3.14).

The non-vanishing one-point function (3.4)-(3.5) is represented by

$$\begin{align*}
0 \frac{\longrightarrow}{\longleftarrow} &= \delta^{i1} m_0(z), \\
1 \frac{\longrightarrow}{\longleftarrow} &= \delta^{i1} m_1(z),
\end{align*}$$

(3.23)

where $m_0(z)$ and $m_1(z)$ are its leading and subleading terms in the loop expansion. The one-loop correction $m_1(z)$ given by

$$m_1(z) = 0.$$  

(3.24)

Explicit expressions for $m_0(z)$ and $m_1(z)$, as well as the $\epsilon$ expansion of $m(z)$ can be found in Appendix A.

The one-loop expansion for the connected two-point function from (3.9) reads

$$G^{ij}(r_1 - r_2; z_1, z_2) = (A) + (B) + (C) + (D).$$

(3.25)
The corresponding contributions to the layer susceptibility are obtained as in (3.19) and (3.20). Thus

\[
\chi_{ij}^A(z,z') = \chi_{ij}^0(z,z'),
\]

\[
\chi_{ij}^B(z,z') = \int_0^\infty dy \chi_0^{ik}(z,y)\chi_0^{jl}(y,z') u_{kldmn}m_0^n(y)m_1^m(y),
\]

\[
\chi_{ij}^C(z,z') = \frac{1}{2} \int_0^\infty \int_0^\infty dy(dy') \chi_0^{ik}(z,y)\chi_0^{jl}(y',z') u_{kmpn}u_{lqrms}m_0^n(y)m_0^m(y') \int d^{d-1}G_0^mq(r,y,y')G_0^{nr}(r,y,y').
\]

(3.26)

Finally, we use (3.12) for susceptibilities and (3.9) for propagators and do contractions to express everything in terms of longitudinal and transverse quantities. In this reformulation of our expansion we use the following graphical definitions for the free propagators and mean-field susceptibilities:

\[
\begin{align*}
\begin{aligned}
\hline & = G_0^L, \\
\begin{aligned}
\begin{aligned}
\hline & = \chi_0^L, \\
\begin{aligned}
\hline & = G_0^T, \\
\begin{aligned}
\hline & = \chi_0^T.
\end{aligned}
\end{aligned}
\end{aligned}
\end{aligned}
\end{align*}
\]

(3.27)

The longitudinal and transverse susceptibilities can then be written as

\[
\chi_L(z,z') = -(a) - u_0 - (b) - \frac{u_0}{2} (c) - \frac{u_0}{6}(N-1) -(c') - \frac{u_0^2}{2} (d) - \frac{u_0^2}{18}(N-1) -(d'),
\]

(3.28)

and

\[
\begin{align*}
\chi_T = -(a_T) - \frac{u_0}{3} (b_T) - \frac{u_0}{6} (c_T) - \frac{u_0}{6}(N+1) -(c'_T) - \frac{u_0^2}{9} (d_T) - \frac{u_0^2}{27}(N+1) -(d'_T).
\end{align*}
\]

(3.29)

Here the integrations for each diagram are as in the corresponding expression in (3.26). Only the diagrams of type \((D)\) include inner integrals over parallel directions.

In order to derive the \(\epsilon\) expansions in an efficient way we use dimensional regularization in each of the individual graphs. The pole terms arising at intermediate steps all cancel in
the final results. Following the approach of [8], we use the inverse Radon transforms (3.14) of
the mean-field layer susceptibilities (3.13) in the role of the free longitudinal and transverse
propagators $G^L_0$ and $G^T_0$ in (3.27)-(3.29). In contrast to their $d \to 4$ limits in (3.16), which
correspond to the mean-field approximation, the functions (3.14)-(3.15) are well-structured
and simple to use. In fact, all actual calculations reduce to evaluations of Euler integrals and
combining them into the final results. Details are shown in Appendix B.

3.4 The layer susceptibility to $O(\epsilon)$

In this section we write down the results of the $\epsilon$ expansion for $\chi_L(z, z')$ and $\chi_T(z, z')$, that
follow from the diagrammatic expansions discussed just above.

The final result for the longitudinal part of the layer susceptibility is

$$
\chi_L(z, z') = \sqrt{4zz'} \zeta^{\frac{d+1}{2}} C_d \left[1 + \epsilon h(\zeta)\right] + O(\epsilon^2),
$$

(3.30)

where we exponentiated the $\epsilon \log \zeta$ term that appeared in the $\epsilon$ expansion. This is in accord
with the enhanced scaling form (see [8, (63)] and related references)

$$
\chi(z, z') = (4zz')^{\frac{1-d}{2}} \zeta^{\frac{\eta-1}{2}} Y(\zeta),
$$

(3.31)

which takes into account more information on inner structure of the scaling function $X(\zeta)$ from (2.23).\(^6\)

The function $h(\zeta)$ in (3.30) is given by

$$
h(\zeta) = h_0(\zeta) + h_1(\zeta) + h_1(-\zeta),
$$

(3.32)

with

$$
h_0(\zeta) = \frac{1}{140(N+8)} \left[203N + 3140 - 10(7N + 96)\zeta^{-2} + 20(7N + 128)\zeta^{-4}\right],
$$

(3.33)

$$
h_1(\zeta) = -\frac{72(1 + \zeta^4) - (21N + 204)\zeta(1 + \zeta^2) - 4(7N + 74)\zeta^2}{42(N+8)\zeta^6} (1 - \zeta)^3 \log(1 - \zeta).
$$

(3.34)

The reason for calling the overall constant in (3.30) $C_d$ will become clear quite soon, its
explicit expression is given in (3.37).

The longitudinal part of the layer susceptibility in (3.30) represents a generalization of
$\chi(z, z')$ calculated in [8, Sec. 3.2] in the scalar theory with $N = 1$. As $\zeta \to 0$, the function
$h(\zeta)$ starts with

$$
h(\zeta) = \frac{5(N-1)}{63(N+8)} \zeta^2 + \frac{5N + 28}{360(N+8)} \zeta^4 + O(\zeta^6)
$$

(3.35)
in agreement with [8, (62)].

As discussed in Sec. 2.3, the expression (3.30) has the form (2.23) where the scaling
function $X(\zeta)$ can be written as a power series

$$
X_L(\zeta) = \zeta^{-\frac{d+1}{2}} \sum_{\Delta=d,k} C_{\Delta} \zeta^{\Delta} + O(\epsilon^2), \quad k = 6, 8, 10, \ldots
$$

(3.36)

\(^6\)We recall that in the present case $\eta_\parallel = \eta_\parallel' = d + 2$ (see (3.2)) and $\eta = O(\epsilon^2)$.
with coefficients
\[ C_d = \frac{1}{10} \left( 1 + \epsilon \frac{76 - N}{60(N + 8)} \right), \] (3.37)
\[ C_k = 2 \frac{k(k - 3)(N + 8) - 2(5N + 76)}{(k - 5)(k - 3)(N + 8)} \epsilon, \quad k = 6, 8, 10, \ldots , \] (3.38)
where \((a)_k = a(a+1) \ldots (a+k-1)\) denotes the Pochhammer symbol (by convention, \((0)_0 = 1\)).

The explicit expression for coefficients \(C_k\) has been obtained from the sequence of the Taylor-expansion coefficients of the function \(h(\zeta)\) from (3.30) and (3.32).

Remembering the relation (2.24) we see that the only operator that contributes to the connected longitudinal two-point function both at leading and subleading order in \(\epsilon\) is the displacement operator \(T_{zz}\) with dimension \([38]\), which emerges due to the breaking of the translation symmetry by the boundary. This matches the critical exponent of parallel correlations \(\eta_L^\parallel = d + 2\) from (3.2) through the relation \(\hat{\Delta} = (d - 2 + \eta_L^\parallel)/2\). Besides the contribution of \(T_{zz}\), at order \(O(\epsilon)\) an infinite tower of operators with dimensions \(6, 8, 10, \ldots \) contributes as well. At \(N = 1\) the \(\hat{\Delta} = 6\) term drops out because its coefficient is proportional to \(N - 1\) (3.35).

For the transverse part of the layer susceptibility we obtain
\[ \chi_T(z, z') = \sqrt{4zz'} \zeta^{\frac{d - 1}{2}} \tilde{C}_{d-1} [1 + \epsilon j(\zeta)] + O(\epsilon^2), \] (3.39)
where
\[ j(\zeta) = \frac{451}{30(N + 8)} + \frac{\zeta^{-4}}{5(N + 8)} \left( 47\zeta^2 + j_1(\zeta) + j_1(-\zeta) \right), \]
\[ j_1(\zeta) = -(3\zeta^2 - 16\zeta + 3)(1 - \zeta)^3 \log(1 - \zeta), \] (3.40)
and the coefficient \(\tilde{C}_{d-1}\) is given in (3.43).

As in the previous case of \(h(\zeta)\), the function \(j(\zeta)\) is also regular at the origin and we have
\[ j(\zeta) = \frac{3}{140(N + 8)} \zeta^4 + O(\zeta^6). \] (3.41)

Again, the expression (3.39) can be written in terms of a power series
\[ X_T(\zeta) = \zeta^{\frac{d - 1}{2}} \sum_{\Delta = d-1, k} \tilde{c}_\Delta z^\Delta + O(\epsilon^2), \quad k = 7, 9, 11, \ldots \] (3.42)
with coefficients
\[ \tilde{c}_{d-1} = \frac{1}{6} \left( 1 + \epsilon \frac{15 + 2N}{6(N + 8)} \right), \] (3.43)
\[ \tilde{c}_k = 4 \frac{(k + 2)(k - 5)}{(k - 4)(N + 8)} \epsilon, \quad k = 7, 9, 11, \ldots . \] (3.44)

– 15 –
At order $O(\epsilon^0)$, the only operator contributing to the connected two-point function is an operator with dimension $d - 1$, in agreement with (3.3). We expect this operator to be the analogue of the displacement operator for the broken rotation current $j_{\mu}^{[1]}$.\footnote{We thank Marco Meineri for pointing this out.} The conservation equation for this current is broken by a delta function on the boundary which is multiplied by a scalar boundary operator that is a vector of the preserved $O(N-1)$ subgroup. Similar to the displacement operator (see [39]), this operator should obey a Ward identity that relates its coupling $\mu_{d-1}$ to the bulk field $\phi^1$ with the one-point function coefficient $\mu_0$ of this field. It would be interesting to derive this Ward identity to confirm the nature of this operator. Similar protected defect operators appeared for instance in [40] in the context of a BPS defect which breaks part of the R-symmetry in a supersymmetric theory. At order $O(\epsilon)$ there are additional contributions from an infinite set of boundary operators with dimensions $\hat{\Delta} = 7, 9, 11, \ldots$.

### 3.5 From susceptibility to two-point function

We will now use the results for the layer susceptibility from the previous section to derive the correlation function. Owing to the relations (2.24)-(2.25), we now know the BOE coefficients and can compute the connected part of the two-point function. However, in order to significantly simplify the presentation, in what follows we shall use the normalized scaling function

$$F(\xi) = S_d F^{\text{con}}(\xi),$$

where $S_d$ is defined in (2.12). To relate the scaling function of any layer susceptibility $X(\zeta)$ to the newly introduced $F(\xi)$, we rephrase the relation (2.24) as

$$X(\zeta) = \zeta^{-\frac{d-1}{2}} \sum_{\Delta > 0} C_\Delta \zeta^{\hat{\Delta}} \rightarrow \bar{F}(\xi) = \sum_{\Delta > 0} S_d \sigma_\Delta C_\Delta \mathcal{G}_{\text{boe}}(\hat{\Delta}; \xi).$$

(3.46)

The new normalization is convenient for the present purpose because the normalized coefficients $\sigma_\Delta \equiv S_d \sigma_{\hat{\Delta}}$ are simple for the scaling dimensions of the leading boundary operators $\hat{\Delta} = d$ and $\hat{\Delta} = d - 1$. In particular, we have $\sigma_d = \frac{1}{2}$ and $\sigma_{d-1} = 1$ for any $d$, without $\epsilon$-corrections in $d = 4 - \epsilon$. Thus, the scaling functions to be found are

$$\bar{F}_L(\xi) = \sigma_d C_d \mathcal{G}_{\text{boe}}(4 - \epsilon; \xi) + \sum_{k=0}^{\infty} \sigma_k C_k \mathcal{G}_{\text{boe}}(k; \xi) + O(\epsilon^2),$$

(3.47)

and

$$\bar{F}_T(\xi) = \sigma_{d-1} \hat{C}_{d-1} \mathcal{G}_{\text{boe}}(3 - \epsilon; \xi) + \sum_{k=7}^{\infty} \sigma_k \hat{C}_k \mathcal{G}_{\text{boe}}(k; \xi) + O(\epsilon^2).$$

(3.48)

A convenient way to derive the $\epsilon$-expansion of the conformal blocks $\mathcal{G}_{\text{boe}}(4 - \epsilon; \xi)$ and $\mathcal{G}_{\text{boe}}(3 - \epsilon; \xi)$ is to use the Mathematica package HypExp [41, 42]. This yields

$$\mathcal{G}_{\text{boe}}(4 - \epsilon; \xi) = \mathcal{G}_{\text{boe}}(4; \xi) + \mathcal{G}_{\text{boe}}^{(1)}(4; \xi) \epsilon + O(\epsilon^2),$$

(3.49)
where
\[
G_{\text{boe}}(4; \xi) = 10 \left( \frac{1}{\xi} - \frac{1}{\xi + 1} + 12 + 6(2\xi + 1) \log \frac{\xi}{\xi + 1} \right),
\]
(3.50)
and
\[
G_{\text{boe}}^{(1)}(4; \xi) = \frac{3 + 5 \log [\xi(\xi + 1)]}{\xi(\xi + 1)} - 2 \log \xi + 122 \log(\xi + 1) - 4 - 124 \xi \log \frac{\xi}{\xi + 1} + 15(2\xi + 1) \left( \log [\xi^3(\xi + 1)] \log \frac{\xi}{\xi + 1} + 4 \text{Li}_2 \left( -\frac{1}{\xi} \right) \right).
\]
(3.51)
Here \( \text{Li}_2 \) is the dilogarithm function [6, Sec. 2.6], [43]. Similarly,
\[
G_{\text{boe}}(3 - \epsilon; \xi) = G_{\text{boe}}(3; \xi) + G_{\text{boe}}^{(1)}(3; \xi) \epsilon + O(\epsilon^2),
\]
(3.52)
where
\[
G_{\text{boe}}(3; \xi) = 3 \left( \frac{1}{\xi} + \frac{1}{\xi + 1} + 2 \log \frac{\xi}{\xi + 1} \right),
\]
(3.53)
and
\[
G_{\text{boe}}^{(1)}(3; \xi) = \frac{2\xi + 1}{2\xi(\xi + 1)} (1 + 6 \log \xi) - \frac{10\xi^2 + 16\xi + 3}{2\xi(\xi + 1)} \log \frac{\xi}{\xi + 1} + \frac{3}{2} \log [\xi^3(\xi + 1)] \log \frac{\xi}{\xi + 1} + 6 \text{Li}_2 \left( -\frac{1}{\xi} \right).
\]
(3.54)
The leading terms of the \( \epsilon \) expansions (3.49) and (3.52) are essentially the mean-field correlation functions in (3.16).

To proceed, we have to perform the infinite sums in (3.47) and (3.48). These are of order \( O(\epsilon) \) owing to the definitions of their coefficients in (3.38) and (3.44). The sums can be done using the standard Euler integral representation for Gauss hypergeometric functions in \( G_{\text{boe}}(k; \xi) \) from (2.4) (see e.g. [6, Sec. 2.2], [27, 7.2.1.2]),
\[
\mathbf{2F}_1(a, b; c; z) = \frac{1}{B(c - b, b)} \int_0^1 dt \, t^{c-1}(1-t)^{b-1}(1-tz)^{-a},
\]
(3.55)
where \( B \) is the beta function encountered in (2.16), \( \Re c > \Re b > 0 \) and \( |\text{arg}(1-z)| < \pi \). After performing the sums with the known coefficients, the resulting integrals over \( t \) can be done order by order in an expansion in powers of \( 1/\xi \). Resumming this expansion yields
\[
\sum_{k=6}^{\infty} \sigma_k C_k \, G_{\text{boe}}(k; \xi) = \frac{\epsilon}{N + 8} \left[ \frac{13N + 20}{120\xi(\xi + 1)} + \frac{23N + 220}{10} - \frac{37N + 620}{20} (2\xi + 1) \log \frac{\xi}{\xi + 1} \right.
\]
\[
+ \frac{1}{2} (72\xi^2 + 132\xi + 52 + (3\xi + 2)N) \log^2 \frac{\xi}{\xi + 1} + 3(N + 20)(2\xi + 1) \text{Li}_2 \left( -\frac{1}{\xi} \right),
\]
(3.56)
and
\[ \sum_{k \text{ odd}}^{\infty} \pi_k \hat{C}_k \mathcal{G}_{boe}(k; \xi) = \frac{\epsilon}{N + 8} \left[ \frac{2\xi + 1}{12(\xi + 1)} - \frac{41}{6} \log \frac{\xi}{\xi + 1} + (3\xi + 4) \log \frac{\xi}{\xi + 1} + 10 \text{Li}_2 \left( -\frac{1}{\xi} \right) \right]. \]  

(3.57)

Collecting all expansions via (3.47) and (3.48), we obtain the final results for the connected longitudinal and transverse correlators in the form
\[ F_{L,T}(\xi) = F_{L,T}^{(0)}(\xi) + \epsilon F_{L,T}^{(1)}(\xi) + O(\epsilon^2). \]  

(3.58)

Here, for the connected longitudinal correlation function we have
\[ F_{L}^{(0)}(\xi) = \frac{1}{2\xi} - \frac{1}{2(\xi + 1)} + 6 + 3(2\xi + 1) \log \frac{\xi}{\xi + 1}, \]  

(3.59)

\[ F_{L}^{(1)}(\xi) = \frac{1 + \log \left[ \frac{\xi(\xi + 1)}{4\xi(\xi + 1)} \right]}{4\xi(\xi + 1)} + 6 \log \xi + 3(2\xi + 1) \log \xi \cdot \log \frac{\xi}{\xi + 1} + \frac{1}{N + 8} \left[ \frac{72(2\xi + 3) + N + 80}{4} \log \frac{\xi}{\xi + 1} - 2((5N + 52)\xi + 2(2N + 19)) \right] \log \frac{\xi}{\xi + 1} + 2 \frac{N + 14}{N + 8} \left[ 1 + 3(2\xi + 1) \text{Li}_2 \left( -\frac{1}{\xi} \right) \right]. \]  

(3.60)

At \( N = 1 \) it reduces to the connected two-point function at the extraordinary transition in the scalar \( \phi^4 \) theory with a broken \( \mathbb{Z}_2 \) symmetry. For the transverse correlation function the leading and the \( O(\epsilon) \) terms are given by
\[ F_{T}^{(0)}(\xi) = \frac{1}{2\xi} + \frac{1}{2(\xi + 1)} + \log \frac{\xi}{\xi + 1}, \]  

(3.61)

\[ F_{T}^{(1)}(\xi) = \frac{1}{4\xi(\xi + 1)} \left( 2\xi + 1 + \log \left[ \frac{\xi(\xi + 1)}{4\xi(\xi + 1)} \right] + 4\xi \log \xi \right) + \log \xi \cdot \log \frac{\xi}{\xi + 1} + \frac{N + 18}{N + 8} \text{Li}_2 \left( -\frac{1}{\xi} \right) + \frac{1}{2(N + 8)} \left[ \frac{1}{2} \left( 12\xi + 8 - N \right) \log \frac{\xi}{\xi + 1} - \frac{\xi(N + 22) + 2(2N + 15)}{\xi + 1} \right] \log \frac{\xi}{\xi + 1}. \]  

(3.62)

In the limit \( \xi \to 0 \) the very first terms of \( F_{L}(\xi) \) and \( F_{T}(\xi) \) are
\[ F_{L,T}(\xi) = \frac{1}{2\xi} + \frac{1 + \log \xi}{4\xi} \epsilon + O(\xi^0) + O(\epsilon^2) = \frac{\xi^{-1+\frac{\epsilon}{2}}}{2 - \epsilon} + O(\epsilon^2), \]  

(3.63)

as expected in view of (2.5).\(^8\)

The final result for the normalized connected two-point function (3.45) in the \( O(N) \) symmetric theory is given by
\[ \mathcal{F}(\xi) = \mathcal{F}^{(0)}(\xi) + \epsilon \mathcal{F}^{(1)}(\xi) + O(\epsilon^2), \]  

(3.64)

\(^8\)In the presently obscured opposite limit \( \xi \to \infty \) the functions \( F_{L}(\xi) \) and \( F_{T}(\xi) \) behave as \( \sim \xi^{-4+\epsilon} \) and \( \sim \xi^{-3+\epsilon} \) as they should.
with
\[
\mathcal{F}^{(0)}(\xi) = \frac{N}{2\xi} - \frac{2 - N}{2(\xi + 1)} + 6 + (6\xi + N + 2) \log \frac{\xi}{\xi + 1},
\]
\[
\mathcal{F}^{(1)}(\xi) = \frac{2\xi(N - 1) + N}{4\xi(\xi + 1)} \left( 1 + \log \left[ \xi(\xi + 1) \right] \right) + 6\log \xi + (6\xi + N + 2) \log \xi \cdot \log \frac{\xi}{\xi + 1}
\]
\[
- \frac{1}{N + 8} \left( 2(5N + 52)\xi + \frac{N^2 + 37N + 130}{2} \right) \log \frac{\xi}{\xi + 1}
\]
\[
+ \frac{1}{N + 8} \left( 36\xi^2 + 3(N + 17)\xi + \frac{72 + 10N - N^2}{4} \right) \log^2 \frac{\xi}{\xi + 1}
\]
\[
+ 2 \frac{N + 14}{N + 8} \left[ 1 + \left( 6\xi + \frac{N^2 + 23N + 66}{2(N + 14)} \right) \text{Li}_2 \left( -\frac{1}{\xi} \right) \right].
\]  
(3.66)

This function also shares the behavior \((3.63)\) when \(\xi \to 0\).

3.6 The bulk-channel expansion

The two-point correlation function \(\mathcal{F}(\xi)\) from \((3.64)-(3.66)\) can be used to compute the bulk CFT data up to \(O(\epsilon^2)\) via the bootstrap equation \((2.7)\). In order to expand in bulk blocks we use the full correlator including its disconnected part and multiply it by the overall factor \(\xi^{\Delta_\phi}\). Thus we define the function

\[
\mathcal{F}_{\text{ope}}(\xi) \equiv \xi^{\Delta_\phi} \left( \mathcal{F}_0^2 + \mathcal{F}(\xi) \right)
\]

where the contribution from the disconnected part

\[
\mathcal{F}_0^2 = S_d \mu_0^2 = 2 \frac{N + 8}{\epsilon} - \frac{N^2 + 46N + 244}{N + 8} + O(\epsilon)
\]

is determined by the one-point function \((3.4)-(3.5)\) and calculated in Appendix A. Since the \(\epsilon\) expansion of \(\mathcal{F}_0^2\) in \((3.68)\) starts with \(O(\epsilon^{-1})\) we have to use

\[
\Delta_\phi = 1 - \frac{\epsilon}{2} + \frac{N + 2}{4(N + 8)^2} \epsilon^2 + O(\epsilon^3)
\]

for the scaling dimension of \(\phi\). The bulk-channel expansion \(\sum_{\Delta \geq 0} \lambda_\Delta \mathcal{G}_{\text{ope}}(\Delta; \xi)\) in \((2.7)\) will give us new information about the spectrum of operators in the bulk theory, which is of interest beyond the context of boundary CFT.

This expansion turns out to be simpler if we use a slightly different convention for the OPE coefficients and conformal blocks introduced in \((2.6)-(2.7)\) and write it as

\[
\mathcal{F}_{\text{ope}}(\xi) = \sum_{\Delta \geq 0} a_\Delta \xi^{\Delta} \mathcal{G}_{\text{ope}}(\Delta; \xi).
\]

Here we define the functions \(\mathcal{G}_{\text{ope}}(\Delta; \xi)\) via\(^9\)

\[
\mathcal{G}_{\text{ope}}(\Delta; \xi) = \Gamma(\Delta + 1 - \frac{d}{2}) \Gamma(\frac{d}{2}) \Gamma(\frac{\Delta}{2} + 2 - \frac{d}{2}) \xi^{\frac{d}{2}} g_{\text{ope}}(\Delta; \xi).
\]

\(^9\)For the identity operator the prefactor is singular and we define instead \(g_{\text{ope}}(0; \xi) = 1\).
The gamma functions are chosen to cancel (up to a factor) the beta function in the Euler-integral representation (3.55) of the Gauss functions in the OPE blocks. This results in a simplification of the OPE coefficients and their \( \epsilon \) expansions.

For the bulk scaling dimensions \( \Delta \) and OPE coefficients \( a_\Delta \) we write the formal \( \epsilon \) expansions

\[
\Delta_n = 2 + 2n + \gamma_n^{(1)} \epsilon + \gamma_n^{(2)} \epsilon^2 + O(\epsilon^3), \quad a_\Delta = a_n^{(-1)} \epsilon^{-1} + a_n^{(0)} + a_n^{(1)} \epsilon + O(\epsilon^2). \tag{3.72}
\]

The initial terms \( 2 + 2n \) in \( \Delta_n \) associate with the \( d = 4 \) values of the scaling dimensions of operators \( \phi^{2(1+n)} \). The \( \epsilon \) expansion of the scaling function \( \mathcal{F}_{\text{ope}}(\xi) \) in the bulk channel then becomes

\[
\mathcal{F}_{\text{ope}}(\xi) = \epsilon^{-1} \mathcal{F}_{\text{ope}}^{(-1)}(\xi) + \mathcal{F}_{\text{ope}}^{(0)}(\xi) + \epsilon \mathcal{F}_{\text{ope}}^{(1)}(\xi) + O(\epsilon^2) \tag{3.73}
\]

with\(^\text{10}\)

\[
\mathcal{F}_{\text{ope}}^{(-1)}(\xi) = \sum_{n=0}^{\infty} \xi^{n+1} (a_n^{(-1)}) \ g_{\text{ope}}(2n + 2; \xi), \tag{3.74}
\]

\[
\mathcal{F}_{\text{ope}}^{(0)}(\xi) = \sum_{n=-1}^{\infty} \xi^{n+1} \left( \frac{1}{2} \langle a_n^{(-1)} \gamma_n^{(1)} \rangle \log \xi + \langle a_n^{(-1)} \rangle \partial_\xi + \langle a_n^{(0)} \rangle \right) g_{\text{ope}}(2n + 2; \xi), \tag{3.75}
\]

\[
\mathcal{F}_{\text{ope}}^{(1)}(\xi) = \sum_{n=-1}^{\infty} \xi^{n+1} \left[ \frac{1}{2} \langle a_n^{(-1)} \gamma_n^{(1)} \rangle \log^2 \xi + \langle a_n^{(1)} \rangle \partial_\xi + \langle a_n^{(0)} \rangle \partial_\xi + \frac{1}{2} \langle a_n^{(-1)} \rangle \partial_\xi^2 
\right.
\]

\[
+ \frac{1}{2} \left( \langle a_n^{(-1)} \gamma_n^{(2)} \rangle + \langle a_n^{(0)} \gamma_n^{(1)} \rangle + \langle a_n^{(-1)} \gamma_n^{(1)} \rangle \partial_\xi \right) \log \xi \right] g_{\text{ope}}(2n + 2; \xi). \tag{3.76}
\]

The brackets indicate sums over possible degenerate operators,

\[
\langle x \rangle = \sum_k x_k. \tag{3.77}
\]

From (3.74)-(3.76) one can easily deduce the expansions for certain discontinuities of \( \mathcal{F}_{\text{ope}}(\xi) \) by noting that \( g_{\text{ope}}(\Delta; \xi) \) is a hypergeometric function with argument \( -\xi \), which has a branch cut at \( \xi \in (-\infty, -1) \) and is analytic elsewhere. As a consequence, the discontinuities in the range \( \xi \in (-1, 0) \) stem only from the logarithms in the expansions above, that is \( \text{Disc}_{\xi<0} \log \xi = 2\pi i \) and \( \text{Disc}_{\xi<0} \log^2 \xi = 4\pi i \log(-\xi) \). Thus we have

\[
\text{Disc}_{-1<\xi<0} \mathcal{F}_{\text{ope}}^{(0)}(\xi) = \pi i \sum_{n=0}^{\infty} \xi^{n+1} \langle a_n^{(-1)} \gamma_n^{(1)} \rangle g_{\text{ope}}(2n + 2; \xi), \tag{3.78}
\]

\[
\text{Disc}_{-1<\xi<0} \mathcal{F}_{\text{ope}}^{(1)}(\xi) = \pi i \sum_{n=0}^{\infty} \xi^{n+1} \left( \frac{1}{2} \langle a_n^{(-1)} \gamma_n^{(1)} \rangle \log(-\xi) + \langle a_n^{(-1)} \gamma_n^{(2)} \rangle + \langle a_n^{(0)} \gamma_n^{(1)} \rangle 
\right.
\]

\[
+ \langle a_n^{(-1)} \gamma_n^{(1)} \rangle \partial_\xi \right) g_{\text{ope}}(2n + 2; \xi). \tag{3.79}
\]

\(^\text{10}\)The derivatives are understood as \( \partial_x g_{\text{ope}}(2n + 2; \xi) = \partial_x g_{\text{ope}}(\Delta_n; \xi)|_{\epsilon \to 0} \).
and, for the double discontinuity of $F_{\text{ope}}^{(1)}(\xi)$,

$$
d\text{Disc} F_{\text{ope}}^{(1)}(\xi) \equiv \text{Disc}_{\xi>0} \text{Disc}_{-1<\xi<0} F_{\text{ope}}^{(1)}(\xi) = \pi^2 \sum_{n=0}^{\infty} \xi^{n+1} \langle a_n^{(-1)}(\gamma_n^{(1)})^2 \rangle_{\text{ope}}(2n+2; \xi). \tag{3.80}
$$

It is convenient to use these formulas to match the discontinuities of the bulk-channel expansion with the ones of the explicitly known expression (3.67), rather than working with the whole correlator for this matching.\textsuperscript{11} Note that $\text{Li}_2(-1/\xi)$ in (3.66) has a discontinuity at $\xi \in (-1, 0)$. Using the linear transformation \cite[(1.7)], \cite[(3.2)]

$$
\text{Li}_2(-1/\xi) = -\frac{\pi^2}{6} - \frac{1}{2} \log^2 \xi - \text{Li}_2(-\xi), \tag{3.81}
$$

we can express the discontinuity at $\xi \in (-1, 0)$ in terms of $\log^2 \xi$, since $\text{Li}_2(-\xi)$ on the right-hand side has its branch cut at $\xi \in (-\infty, -1)$.

The coefficients in the expansions (3.74)-(3.76) can be found by expanding around $\xi = 0$, which truncates the infinite sums. We begin by considering (3.74) for $F_{\text{ope}}^{(-1)}$ to deduce that

$$
\langle a_0^{(-1)} \rangle = 2(N + 8), \quad \langle a_n^{(-1)} \rangle = 4(N + 8), \tag{3.82}
$$

Next we use (3.78) to extract the anomalous dimensions from the discontinuity of $F_{\text{ope}}^{(0)}$:

$$
\text{Disc}_{-1<\xi<0} F_{\text{ope}}^{(0)}(\xi) = 12\pi i \xi(\xi - 1) \quad \Rightarrow \quad \frac{\langle a_n^{(-1)}(\gamma_n^{(1)}) \rangle}{\langle a_n^{(-1)} \rangle} = \frac{6n^2 - 1}{N + 8} , \quad n \geq 0, \tag{3.83}
$$

which is in agreement with the result \cite[(33)], \cite[(2.5)]

The first consistency check of our newly computed contribution $F_{\text{ope}}^{(1)}(\xi)$ is that its double discontinuity is given by (3.80) with the data (3.82) and (3.83). This is indeed the case, with

$$
\text{dDisc} F_{\text{ope}}^{(1)}(\xi) = 72\pi^2 \xi \frac{1 - \xi + 4\xi^2}{N + 8} \Rightarrow \frac{\langle a_n^{(-1)}(\gamma_n^{(1)})^2 \rangle}{\langle a_n^{(-1)} \rangle^2} = \left(\frac{6n^2 - 1}{N + 8}\right)^2 , \quad n \geq 0. \tag{3.84}
$$

That this gives the square of (3.83) also indicates that at this level no degeneracy is lifted and (3.83) gives indeed just $\gamma_n^{(1)}$, implying that we can advance to the next order without having to solve a mixing problem.

As a next step, we determine $\langle a_n^{(0)} \rangle$ from $F_{\text{ope}}^{(0)}$. Using (3.82) and (3.83) we can compute all the sums in (3.75) except the one containing $\langle a_n^{(0)} \rangle$ and obtain

$$
F_{\text{ope}}^{(0)}(\xi) = -\frac{\xi(12\xi^2 + N - 4)}{2(\xi + 1)} \log(\xi + 1) + \frac{\xi^{3/2}(N + 2 - 6\xi)}{(\xi + 1)} \tan^{-1}\left(\sqrt{\xi}\right)
$$

$$
+ 6(\xi - 1)\xi \log \xi + \sum_{n=1}^{\infty} \langle a_n^{(0)} \rangle \xi^{n+1} g_{\text{ope}}(2n+2; \xi), \tag{3.85}
$$

\textsuperscript{11}For further details about this use of discontinuities see [14].
where \( n = -1 \) is the contribution from the identity operator. Comparing this to our result (3.67) we identify

\[
\langle a_{-1}^{(0)} \rangle = \frac{N}{2}, \quad \langle a_{0}^{(0)} \rangle = -\frac{N^2 + 74N + 408}{2(N + 8)},
\]

\[
\langle a_{n \geq 1}^{(0)} \rangle = 24n - 2\frac{N^2 + 46N + 244}{N + 8} - (N + 8) \left( \frac{3}{n} + 4H_{n-1} \right),
\]

where \( H_n \) is the \( n \)-th harmonic number,

\[
H_n = \sum_{k=1}^{n} \frac{1}{k}.
\]

In order to extract \( \langle a_n^{(-1)} \gamma_n^{(2)} \rangle \) from \( \overline{F}_{\text{ope}}^{(1)} \) we use (3.79). The discontinuity of \( \overline{F}_{\text{ope}}^{(1)} \) in (3.67) is

\[
\text{Disc}_{-1<\xi<0} \overline{F}_{\text{ope}}^{(1)} = 36\pi i \xi \frac{1 - \xi + 4\xi^2}{N + 8} \log(-\xi) - 2\pi i \xi \frac{10N + 44 + (9N + 126)\xi + 72\xi^2}{N + 8} \log(\xi + 1) + 4\pi i \xi \frac{4N + 41 - (55N + 2)\xi}{N + 8}.
\]

(3.87)

We substitute the data (3.82), (3.83) and (3.86) into (3.79) and expand it in powers of \( \xi \). Comparing this with an analogous expansion of (3.87) order by order in \( \xi \) allows us to obtain

\[
\frac{\langle a_{0}^{(-1)} \gamma_{0}^{(2)} \rangle}{\langle a_{0}^{(-1)} \rangle} = \frac{(N + 2)(13N + 44)}{2(N + 8)^3},
\]

\[
\frac{\langle a_{n}^{(-1)} \gamma_{n}^{(2)} \rangle}{\langle a_{n}^{(-1)} \rangle} = -2 \frac{6n^2(N + 20) + 13N + 50}{(N + 8)^2} H_{n-1} + \frac{36n^4 - 3n^2(N + 44) - 13N - 50}{n(N + 8)^2} + \frac{n^2(N(11N + 314) + 1628) - 2(N(2N + 77) + 398)}{(N + 8)^3}, \quad n \geq 1.
\]

(3.88)

For \( n = 0, 1, 2 \) this agrees with the known anomalous dimensions for the operators \( \phi_i \phi^i \), \((\phi_i \phi^i)^2 \) [47] and \((\phi_i \phi^i)^3 \) [48]. We will see in the next section that for \( n > 2 \) our result (3.88) contains averaged values with contributions of multiple operators that are degenerate at lower orders in \( \epsilon \).

### 3.7 Comparison to known anomalous dimensions

At large \( N \), the \( O(N) \) model is described by a non-linear \( \sigma \)-model, based on the field \( \phi^i(x) \) and the auxiliary field \( \alpha(x) \), which has been intensively studied in [49–51]. The primary operators can be ordered into classes \((Y, p)\) by their irreducible \( O(N) \) representation \( Y \) and the number \( p \) of constituent fields \( \phi^i(x) \). These operators can be identified by the \( d \)-dependence of the conformal dimensions at large \( N \),

\[
\Delta_{p,q} = p \left( \frac{d}{2} - 1 \right) + q + O \left( \frac{1}{N} \right), \quad p, q \in \mathbb{N}.
\]

(3.89)
Each of these classes contains primary operators labelled by their conformal dimensions and spins. The bulk operators that appear in the two-point function computed above are singlets under $O(N)$, i.e. $Y = \emptyset$. Furthermore, their spin is zero. Since we worked in the $\epsilon$ expansion, the value of $p$ cannot be identified, however in order to form $O(N)$ singlets, the number of fields $\phi^i(x)$ has to be even. This means that the only operators that can appear in our two-point function are scalars from the classes

$$ (Y, p) = (\emptyset, 2k), \quad k \in \mathbb{N}. \tag{3.90} $$

The class $(\emptyset, 0)$ was analyzed in detail in [51]. The scalars in this class are non-degenerate and are given by powers of the auxiliary field. Their dimensions at large $N$ are given by [51, (5.7)],

$$ \Delta_{\alpha^{n+1}} = 2n + 2 - \frac{2^d \Gamma\left(\frac{d+1}{2}\right) \sin\left(\frac{\pi d}{2}\right)}{\pi^\frac{d}{2} \Gamma\left(\frac{d}{2} + 1\right)} (n + 1) \left( (n - 1)(d - 2) + \frac{n}{2}(d - 4)(d - 1) \right) \frac{1}{N} + O\left(\frac{1}{N^2}\right) $$

$$ = 2n + 2 + 6(n^2 - 1) \frac{\epsilon}{N} - \frac{1}{2} \left( 22n^2 + 9n - 13 \right) \frac{\epsilon^2}{N} + O(\epsilon^3) + O\left(\frac{1}{N^2}\right). \tag{3.91} $$

These dimensions match the large-$N$ limit of the anomalous dimensions (3.83) at order $O(\epsilon)$ for any $n$. However, at $O(\epsilon^2)$ the large-$N$ limit of (3.88) is matched only for $n = 0, 1, 2$.

In [48], the anomalous dimensions of the operators $(\phi^i \phi^j)^n$ have been computed in the $\epsilon$ expansion to order $O(\epsilon^2)$, which allows us to compare even beyond the large $N$ expansion. The result [48, (14)] is

$$ \Delta_{(\phi^i \phi^j)^{n+1}} = 2n + 2 + \frac{6(n^2 - 1)}{N + 8} \epsilon - \frac{n + 1}{(N + 8)^3} \left( n(34(n - 1)(N + 8) + 11N^2 + 92N + 212) \right. $$

$$ \left. - \frac{1}{2} (13N + 44)(N + 2) \right) \epsilon^2 + O(\epsilon^3). \tag{3.92} $$

This also matches (3.88) for $n = 0, 1, 2$ but not for higher values of $n$. That the averaged result (3.88) does not match the anomalous dimensions of these specific operators means that for $n \geq 3$ there are multiple operators that are degenerate at $O(\epsilon)$ but not at $O(\epsilon^2)$. In the large-$N$ classification this means that operators from the other classes $(\emptyset, 2k), k > 0$ have to contribute. For small values of $n$ there should be only a small number of degenerate operators and it would be interesting to disentangle this further by matching (3.88) to sums of anomalous dimensions for values of $n$ beyond 2.

## 4 Conclusion

The most important result of this work, summarized in the box on page 6, is the identification of a power $\zeta^{\hat{\Delta} - \lambda}$ as the BOE block for the layer susceptibility. In other words, each term in the power series for the layer susceptibility in terms of the variable $\zeta$ can be attributed to a single primary boundary operator. The powers determine the dimensions of these operators and the coefficients map to the BOE coefficients of the two-point function.
The perturbative calculation of the layer susceptibility is significantly simpler than that of the correlation function. As a consequence, a viable path to derive a two-point function is to calculate the layer susceptibility, identify the coefficients at powers of $\zeta$ and sum up the BOE for the two-point function. We performed these steps for the correlator $\langle \phi_i(x)\phi_i(x') \rangle$ in the $O(N)$ model at the extraordinary transition to order $O(\epsilon)$ in the $\epsilon$ expansion. We further expanded the resulting two-point function in the bulk OPE channel, obtaining an average of the bulk anomalous dimensions to order $O(\epsilon^2)$. This can be seen as a consistency check and matches the known anomalous dimensions of the operators $\phi_i\phi_i$, $(\phi_i\phi_i)^2$ and $(\phi_i\phi_i)^3$, implying that for these operators there is no mixing problem to solve at this order.

The extraordinary transition is especially well suited for a study in terms of the BOE, where the leading contributions come from only two operators. These are the displacement operator, which appears in the longitudinal correlator, and an operator of dimension $\Delta = d-1$ in the transverse correlator. Having the dimension of a conserved current, we expect the latter to be related to the breaking of the $O(N)$ symmetry at the extraordinary transition. In contrast, an infinite number of operators contribute to the OPE already at the leading order. For other examples like the ordinary or special transition, the bulk OPE data is known better than the BOE data. For this reason, an interesting question is whether there is some other physical quantity that is, like the layer susceptibility, equivalent to the two-point function but simplifies the form of the OPE.

It would be interesting to apply our approach to higher orders in $\epsilon$. At order $O(\epsilon^3)$ one needs to solve a mixing problem to derive the bulk spectrum of scalar operators. One could also calculate the layer susceptibility and hence the two-point correlation function in other theories. An immediate future direction would be to consider the $O(N)$ vector models at large $N$ using the non-linear $\sigma$-model. Other examples where similar constructions could be fruitful are the interface and defect CFTs. We hope to report on this in the future.

A Feynman-graph expansion for $m(z)$

The one-loop Feynman-graph expansion for the one-point function $\langle \phi^1(x) \rangle = m(z)$ (see (3.4), (3.23)-(3.24)) is given by\textsuperscript{12}

$$m(z) = \quad \quad 0 \quad + \quad \quad 0 = m_0(z) - \frac{u_0}{2} \quad - \quad 0 - \frac{u_0}{6} (N-1) \quad - \quad 0. \quad \quad \quad (A.1)$$

The one-loop graphs give the next-to-leading correction $m_1(z)$ to the mean-field profile $m_0(z)$,

$$m_0(z) = \sqrt{\frac{12}{u_0}} \frac{1}{z}. \quad \quad \quad (A.2)$$

The tadpoles in (A.1) are given by the $r \to 0$ limits of the free propagators (3.14),

$$\gamma_y = G_0^L (r=0; y, y) = \gamma_L y^{-2+\epsilon}, \quad \gamma_L = \frac{6 - \epsilon}{2 + \epsilon} \gamma_T; \quad (A.3)$$

$$\gamma_y = G_0^T (r=0; y, y) = \gamma_T y^{-2+\epsilon}, \quad \gamma_T = \frac{4 - \epsilon}{\epsilon} \gamma_D. \quad (A.4)$$

Here $\gamma_D$ is the constant factor in an analogous tadpole with the Dirichlet propagator, which is given by the two first terms of $g_0^L$ in (3.14)-(3.15):

$$\gamma_y = G_0^D (r=0; y, y) = \gamma_D y^{-2+\epsilon}, \quad \gamma_D = \frac{2^{-2+\epsilon}}{S_d(d-2)}. \quad (A.5)$$

Thus, for the one-loop Feynman integrals in (A.1) we have

$$\int_0^\infty dy \chi_0^L (z, y) G_0^L (r=0; y, y) m_0(y) = \sqrt{\frac{12}{u_0}} \frac{\gamma_L}{(1+\epsilon)(4-\epsilon)} z^{1+\epsilon} \quad (A.6)$$

$$\int_0^\infty dy \chi_0^T (z, y) G_0^T (r=0; y, y) m_0(y) = \sqrt{\frac{12}{u_0}} \frac{\gamma_T}{(1+\epsilon)(4-\epsilon)} z^{1+\epsilon}. \quad (A.7)$$

Inserting (A.6) and (A.7) into (A.1) we obtain

$$m_1(z) = -\frac{\sqrt{3u_0}}{(1+\epsilon)(4-\epsilon)} \left(\gamma_L + \frac{N-1}{3} \gamma_T \right) z^{-1+\epsilon} = \sqrt{\frac{3u_0}{S_d(d-2)}} \frac{2^{-2+\epsilon}}{\epsilon(1+\epsilon)} \left(\frac{6 - \epsilon}{2 + \epsilon} + \frac{N-1}{3} \right) z^{-1+\epsilon}. \quad (A.8)$$

Taking into account that $m_1(z)$ is proportional to $1/\epsilon$ we write

$$m(z) = \sqrt{\frac{12}{u_0}} \frac{1}{z} \left[1 + \frac{u_0}{\epsilon} c(\epsilon) z^\epsilon + O(u_0^2) \right]. \quad (A.9)$$

\textsuperscript{12}Formally the same graphical expansion has been used in [52, Sec. V] for the ordinary transition at $T < T_c$. For the case of our present interest, the extraordinary transition at $T = T_c$, see [34, p. 4668], and with $N = 1$ [33, p. 5843] and [18, App. A].
where \( c(\epsilon) \) is finite as \( \epsilon \to 0 \).

The pole term \( \sim 1/\epsilon \) in \( m_1(z) \) has to be removed by the renormalization of the bare coupling constant \( u_0 \) in \( m_0(z) \). In doing the vertex renormalization we follow \([4, 33]\). For the present case of the \( O(N) \) model the analogue of \([33, (3b)]\) is

\[
u_0 s_d = u_0 \epsilon \left[ 1 + \frac{N + 8}{3} \frac{u}{\epsilon} + O(u^2) \right], \quad s_d = (4\pi)^{-d/2}. \tag{A.10}\]

Here \( \mu \) is an arbitrary momentum scale which represents the (momentum) dimension of \( u_0 \) while the renormalized coupling constant \( u \) is dimensionless. The introduction of the scale \( \mu \) in \( (A.10) \) leads also to appearance of the dimensionless coordinate \( \mu z \). In order to simplify notation we shall omit \( \mu \) in the following. In terms of the expansion parameter \( u \) we have

\[
m(z) = \sqrt{s_d} \sqrt{\frac{12}{u}} \frac{1}{z} \left[ 1 - \frac{N + 8}{6} \frac{u}{\epsilon} + \frac{u}{s_d} \frac{c(\epsilon)}{\epsilon} \right] + O(u^2) \tag{A.11}\]

Now, expanding the combination \( c(\epsilon)z^\epsilon/s_d \) to first order in \( \epsilon \) we see that the pole terms cancel as they should. Further, using in \( (A.11) \) the fixed-point value \([4, (3.80)]\)

\[
u_0 = 3 \epsilon N + 8 \left[ 1 + 3 \frac{3N + 14}{(N + 8)^2} \epsilon + O(\epsilon^2) \right], \tag{A.12}\]

we obtain

\[
m(z) = 2\sqrt{s_d} \sqrt{\frac{N + 8}{\epsilon}} \frac{1}{z} \left[ 1 + \gamma E \epsilon + \epsilon \frac{\nu(N)}{2 N + 8} + O(\epsilon^2) \right] \tag{A.13}\]

where \( \nu(N) \) is

\[
u(N) = -\frac{N^2 + 31 N + 154}{N + 8}. \tag{A.14}\]

In \( (A.13) \) we have exponentiated the \( \ln z \) term. The power of \( z \) agrees with the general form \( m(z) \sim z^{-\Delta_\phi} \) where \( 1 - \epsilon/2 \) is just the free part \( \Delta_\phi^{(0)} \) of the scaling dimension of the field, \( \Delta_\phi = (d - 2)/2 + O(\epsilon^2) \). Noticing that \( s_d = 1/(16\pi^2)[1 + (\epsilon/2)\ln(4\pi) + O(\epsilon^2)] \) we obtain the \( \epsilon \) expansion

\[
m(z) = \frac{1}{\pi} \sqrt{\frac{N + 8}{\epsilon}} \left[ 1 + \frac{\gamma E + \ln \pi}{4} \epsilon + \frac{\epsilon}{2 N + 8} \frac{\nu(N)}{2 N + 8} + O(\epsilon^2) \right] (2z)^{-\Delta_\phi} = \mu_0 (2z)^{-\Delta_\phi}. \tag{A.15}\]

From this we can directly obtain the disconnected part \((3.68)\) of the two-point function in \((3.67)\).

**B Feynman integrals for the layer susceptibility**

In this appendix we calculate the Feynman integrals appearing in \((3.28)\) and \((3.29)\) except for \((c)\) and \((d)\) known from \([8]\). For completeness, we shall further transcribe the results for
these two graphs. We start with the Feynman integrals \( (b) \) and \( (b_T) \). With \( \chi_{0\,T}^{L} \) from (3.13) and \( m_0 \) and \( m_1 \) from (A.2), (A.8), their calculation is straightforward:

\[
0 \quad 1
\begin{array}{c}
(b) \\
\int_0^\infty dy \, \chi^{L}_0(z, y) \, m_0(y) m_1(y) \, \chi^{L}_0(y, z') \end{array} = \int_0^\infty dy \, \chi^{T}_0(z, y) \, m_0(y) m_1(y) \, \chi^{T}_0(y, z') \tag{B.1}
\]

\[
0 \quad 1
\begin{array}{c}
(b_T) \\
\int_0^\infty dy \, \chi^{T}_0(z, y) \, m_0(y) m_1(y) \, \chi^{T}_0(y, z') \end{array} = \int_0^\infty dy \, \chi^{L}_0(z, y) \, m_0(y) m_1(y) \, \chi^{L}_0(y, z') \tag{B.2}
\]

Here we defined the functions

\[
f_L(\zeta) = z'^{-1+\epsilon} \zeta^{-3} \int_0^\infty dy \, \frac{\min^3(z, y)}{\max^2(z, y)} \, y^{-2+\epsilon} \frac{\min^3(y, z')}{\max^2(y, z')} = \frac{\zeta^\epsilon}{5+\epsilon} + \frac{1-\zeta^\epsilon}{\epsilon} + \frac{1}{5-\epsilon} \tag{B.3}
\]

and

\[
f_T(\zeta) = z'^{-1+\epsilon} \zeta^{-2} \int_0^\infty dy \, \frac{\min^2(z, y)}{\max^2(z, y)} \, y^{-2+\epsilon} \frac{\min^2(y, z')}{\max^2(y, z')} = \frac{\zeta^\epsilon}{3+\epsilon} + \frac{1-\zeta^\epsilon}{\epsilon} + \frac{1}{3-\epsilon} \tag{B.4}
\]

with \( \zeta \) from (2.17). In terms of these functions, the Feynman integrals associated with the tadpole graphs are

\[
0 \quad 1
\begin{array}{c}
(c) \\
\int_0^\infty dy \, \chi^{L}_0(z, y) \, G^{L}_0(r=0; y, y) \, \chi^{L}_0(y, z') \end{array} = \int_0^\infty dy \, \chi^{L}_0(z, y) \, G^{T}_0(r=0; y, y) \, \chi^{L}_0(y, z') = \frac{1}{25} \gamma_L z'^{1+\epsilon} \zeta^3 f_L(\zeta) \tag{B.5}
\]

\[
0 \quad 1
\begin{array}{c}
(c_t) \\
\int_0^\infty dy \, \chi^{T}_0(z, y) \, G^{L}_0(r=0; y, y) \, \chi^{T}_0(y, z') \end{array} = \int_0^\infty dy \, \chi^{T}_0(z, y) \, G^{T}_0(r=0; y, y) \, \chi^{T}_0(y, z') = \frac{1}{25} \gamma_T z'^{1+\epsilon} \zeta^3 f_L(\zeta) \tag{B.5}
\]

\[
0 \quad 1
\begin{array}{c}
(c_T) \\
\int_0^\infty dy \, \chi^{T}_0(z, y) \, G^{T}_0(r=0; y, y) \, \chi^{T}_0(y, z') \end{array} = \int_0^\infty dy \, \chi^{T}_0(z, y) \, G^{T}_0(r=0; y, y) \, \chi^{T}_0(y, z') = \frac{1}{9} \gamma_L z'^{1+\epsilon} \zeta^2 f_T(\zeta) \tag{B.5}
\]

and

\[
0 \quad 1
\begin{array}{c}
(c_t') \\
\int_0^\infty dy \, \chi^{T}_0(z, y) \, G^{T}_0(r=0; y, y) \, \chi^{T}_0(y, z') \end{array} = \int_0^\infty dy \, \chi^{T}_0(z, y) \, G^{T}_0(r=0; y, y) \, \chi^{T}_0(y, z') = \frac{1}{9} \gamma_T z'^{1+\epsilon} \zeta^2 f_T(\zeta) \tag{B.5}
\]

In their evaluation we used the tadpoles \( G^{L}_0(r=0; y, y) \) and \( G^{T}_0(r=0; y, y) \) from (A.3), (A.4).
The Feynman integral \((d)\) has been calculated in \([8]\). It is given by

\[
(d) = \frac{3}{25u_0} \frac{2^{2+\epsilon}}{S_d(d-2)} \zeta^{1+\epsilon} \zeta^3 \left( \frac{\zeta^\epsilon K}{5+\epsilon} + \frac{L-\zeta^\epsilon K}{\epsilon} + \frac{L}{5-\epsilon} + H_d(\zeta) \right), \tag{B.6}
\]

where the constants \(K\) and \(L\) are

\[
K = \frac{(2-\epsilon)(72-\epsilon^2)}{6\epsilon(2+\epsilon)(4+\epsilon)(6+\epsilon)}, \quad L = \frac{(2-\epsilon)(4-\epsilon)(6-\epsilon)}{48\epsilon(2+\epsilon)}, \tag{B.7}
\]

and the function \(H_d(\zeta)\) is

\[
H_d(\zeta) = f_0(\zeta) + \frac{25}{5+\epsilon} f_1(\zeta) \left( (1-\zeta)^{3+\epsilon} + (1+\zeta)^{3+\epsilon} \right) + \frac{25}{5+\epsilon} f_2(\zeta) \left( (1-\zeta)^{3+\epsilon} - (1+\zeta)^{3+\epsilon} \right)
\]

with

\[
f_0(\zeta) = \frac{5(2-\epsilon)(7-\epsilon)}{48\epsilon(1-\epsilon^2)} - \frac{25(5-\epsilon)}{12(1-\epsilon^2)(2+\epsilon)(3+\epsilon)} + \frac{75(3-\epsilon)}{2\epsilon(1-\epsilon^2)(3+\epsilon)(4+\epsilon)(5+\epsilon)} \zeta^{-4}
\]

\[
+ \frac{50+5\epsilon^2}{300 \zeta^{-6}} \epsilon(1+\epsilon)(2+\epsilon)(3+\epsilon)(5+\epsilon)(6+\epsilon)(7+\epsilon), \tag{B.8}
\]

\[
f_1(\zeta) = -\frac{24(1-\epsilon)(4+\epsilon)(\zeta^{-2}+\zeta^{-6})}{4\epsilon(1-\epsilon^2)(2+\epsilon)(3+\epsilon)(4+\epsilon)(6+\epsilon)(7+\epsilon)} - \frac{432+282\epsilon+67\epsilon^2+2\epsilon^3+\epsilon^4}{48\epsilon(2+\epsilon)} \zeta^{-4}, \tag{B.9}
\]

\[
f_2(\zeta) = \frac{50+5\epsilon^2}{2\epsilon(1-\epsilon^2)(2+\epsilon)(4+\epsilon)(6+\epsilon)(7+\epsilon)}. \tag{B.10}
\]

We are left with the diagrams \((d')\) and \((d_T)\) which are the most complicated ones apart from \((d)\) due to the parallel integrations in inner loops. We begin with

\[
(d') = \int_0^\infty dy \int_0^\infty dy' \chi_0^T(z,y)m_0(y)B^T(y,y')m_0(y') \chi_0^T(y',z'), \tag{B.11}
\]

where we defined

\[
B^T(y,y') = \int d^{d-1}r \left[ G_0^T(r; y, y') \right]^2 \equiv \frac{2^\epsilon}{S_d(d-2)} b^T(y,y'). \tag{B.12}
\]

The function \(b^T(y,y')\) evaluates to

\[
b^T(y,y'|y < y') = \frac{1}{4(1+\epsilon)} \left( |y_{-}|^{1+\epsilon} + y_{+}^{1+\epsilon} + 2y_{-}^{1+\epsilon} - y_{+}^{1+\epsilon} \right) - \frac{1}{\epsilon(1+\epsilon)} \frac{|y_{-}|^{1+\epsilon} - y_{+}^{1+\epsilon}}{y y'} - \frac{1}{\epsilon(1+\epsilon)(3+\epsilon)} \left( \frac{|y_{-}|^{3+\epsilon} + y_{+}^{3+\epsilon}}{y^2 y'^2} - \frac{2}{1-\epsilon} \frac{1}{y^2} \left( 4y_{+}^{1+\epsilon} - (3+\epsilon)|y_{-}| + y_{+}^{1+\epsilon} \right) \right), \tag{B.13}
\]
where \( y_\pm = y \pm y' \). Since
\[
b^T(y, y'|y < y') = y^{-1+\epsilon} b^T(1, y'/y|y < y'),
\]
following [18] we do one of the two integrations in (B.11) without using the explicit form of the function \( b^T \). The integrals are elementary, however one needs to take into account the dependence of the susceptibilities (3.13) on relative magnitudes of their arguments. We fix \( z < z' \) which implies \( \zeta = \frac{z}{z'} < 1 \) as in (2.17). As a result we obtain
\[
0 \quad 0 \quad 0 \quad 0 \quad (d') = \frac{3}{25u_0} \frac{2^{2+\epsilon}}{S_d(d-2)} z'^{\epsilon+1} \zeta^3 Y_d'(\zeta), \tag{B.15}
\]
with
\[
Y_d'(\zeta) = \int_1^\infty dZ b^T(1, Z) Z^{-3} f_L\left(\frac{\zeta}{Z}\right) + \int_1^{1/\zeta} dZ b^T(1, Z) Z^{2-\epsilon} f_L(\zeta Z) + \zeta^{-5+\epsilon} \int_{1/\zeta}^\infty dZ b^T(1, Z) Z^{-3} f_L((\zeta Z)^{-1}). \tag{B.16}
\]
Here the first integral originates from the integration region \( y < y' \) where the substitution \( Z = \frac{y}{y'} \) was used. The second and third terms stem from \( y > y' \) with \( Z = \frac{y'}{y} \) and the integral was split into two parts at \( Z = \frac{1}{\zeta} \) to get terms with a fixed ordering of arguments of the susceptibilities. The functions \( f_L \) and \( f_T \) are again those of (B.3) and (B.4). The final integration over \( Z \) results in
\[
0 \quad 0 \quad 0 \quad 0 \quad (d') = \frac{9}{u_0} \frac{2^{3+\epsilon}}{S_d(d-2)} z'^{\epsilon+1} \zeta^3 \sum_{i=1}^4 g_i(\zeta), \tag{B.17}
\]
where
\[
\begin{align*}
g_1(\zeta) &= -(2+\epsilon) \frac{\zeta^{-4}}{12(-1+\epsilon)} - \frac{\zeta^{-2}}{72(1-\epsilon^2)(2+\epsilon)} + \frac{2-\epsilon}{120 \epsilon^2(1-\epsilon)(5-\epsilon)} - \frac{(24-\epsilon^2) \zeta^\epsilon}{180 \epsilon^2(2+\epsilon)(4+\epsilon)(5+\epsilon)}, \\
g_2(\zeta) &= \frac{3+\epsilon}{12(-1+\epsilon)} \left( \zeta^{-5} f_3(\zeta) + f_4(\zeta) \right), \\
g_3(\zeta) &= -\frac{(7+3\epsilon) \epsilon}{24(-1+\epsilon)} \left( \zeta^{-3} f_3(\zeta) + \zeta^{-2} f_4(\zeta) \right), \\
g_4(\zeta) &= \frac{10+\epsilon-\epsilon^2}{24 (-1+\epsilon)} \left( \zeta^{-1} f_3(\zeta) + \zeta^{-4} f_4(\zeta) \right),
\end{align*}
\]
and \( (a)_k = a(a+1)\ldots(a+k-1) \) are again the Pochhammer symbols.
The last Feynman integral to compute is

\[
\begin{array}{c}
0 \\
\begin{array}{c}
-+ \\
\end{array}
\end{array}
\quad \int_0^\infty dy \int_0^\infty dy' \chi_0^T(z, y) m_0(y) B^{LT}(y, y') \chi_0^T(y', z'),
\] 

(B.20)

where we defined

\[
B^{LT}(y, y') = \int d^{d-1} r G_0^L(r; y, y') G_0^T(r; y, y') = \frac{2^\epsilon}{S_d(d-2)} b^{LT}(y, y').
\] 

(B.21)

A straightforward calculation yields

\[
b^{LT}(y, y' | y < y') = |y_-|^{-1+\epsilon} - y_+^{-1+\epsilon} - 2 \frac{y_1^{1+\epsilon} + |y_-|^{1+\epsilon} + y_+^{1+\epsilon} + 3 \frac{y_1^{2+\epsilon} - |y_-|^2}{\epsilon (1+\epsilon)(2+\epsilon)y^2y'} + 6 \frac{y_1^{3+\epsilon} - |y_-|^{3+\epsilon}}{\epsilon (2+\epsilon)(3+\epsilon)y^3y'^2} - 6 \frac{|y_-|^{5+\epsilon} + y_1^{5+\epsilon}}{\epsilon (2+\epsilon)(5+\epsilon)y^3y'^2} - 12 \frac{y_1^{2+\epsilon}(|y_-|^2 - (3+\epsilon)y_- + y_1^2)}{\epsilon (1+\epsilon)(2+\epsilon)(3+\epsilon)(5+\epsilon)y^2y'^2}.
\]

The double integral in (B.20) can be done analogously to the one in (B.11). The first integration yields

\[
\begin{array}{c}
0 \\
\begin{array}{c}
-+ \\
\end{array}
\end{array}
\quad \frac{1}{3u_0} \frac{2^{2+\epsilon}}{S_d(d-2)} z^{1+\epsilon} \zeta^2 \tilde{Y}_{dT}(\zeta),
\] 

(B.22)

with

\[
\tilde{Y}_{dT}(\zeta) = \int_0^\infty dZ b^{LT}(1, Z) Z^{-2} f_T \left( \frac{\zeta}{Z} \right) + \int_0^{1/\zeta} dZ b^{LT}(1, Z) Z^{1-\epsilon} f_T(\zeta Z) + \zeta^{-3+\epsilon} \int_0^\infty dZ b^{LT}(1, Z) Z^{-2} f_T((\zeta Z)^{-1}).
\] 

(B.23)

The final integration over \( Z \) in (B.23) gives the result

\[
\begin{array}{c}
0 \\
\begin{array}{c}
-+ \\
\end{array}
\end{array}
\quad \frac{9}{u_0} \frac{2^{2+\epsilon}}{S_d(d-2)} z^{1+\epsilon} \zeta^2 \sum_{i=1}^4 q_i(\zeta),
\] 

(B.24)

with

\[
q_1(\zeta) = \frac{1}{(\epsilon)_6} \zeta^{-4} - \frac{3 - \epsilon}{3(-1 + \epsilon)_5} \zeta^{-2} + \frac{1 + (3 - \epsilon)\epsilon}{9\epsilon^2(1 - \epsilon^2)(2 + \epsilon)(3 - \epsilon)} - \frac{2(2 - \epsilon)}{9\epsilon^2(2 + \epsilon)(3 + \epsilon)(4 + \epsilon)} \zeta^\epsilon,
\]

\[
q_2(\zeta) = \frac{50 - 21\epsilon + \epsilon^2}{12(-1 + \epsilon)_7} (\zeta^{-3} f_3(\zeta) + f_4(\zeta)),
\] 

(B.25)

\[
q_3(\zeta) = \frac{40 - 11\epsilon + \epsilon^2}{4(-1 + \epsilon)_7} (\zeta^{-1} f_3(\zeta) + \zeta^{-2} f_4(\zeta)),
\]

\[
q_4(\zeta) = \frac{1 - \epsilon}{2(-1 + \epsilon)_7} (\zeta f_3(\zeta) + \zeta^{-4} f_4(\zeta)),
\]
where $f_3(\zeta)$ and $f_4(\zeta)$ are defined in (B.19). After some algebra, the results (B.17) and (B.24) can be brought to a form similar to (B.6).
