Abstract

We study the production processes $e^+ e^- \to \tilde{\chi}_i^\pm \tilde{\chi}_j^\mp$, $i, j = 1, 2$, and $e^+ e^- \to \tilde{\chi}_m^0 \tilde{\chi}_n^0$, $m, n = 1, \ldots, 4$, working out the advantages of polarizing both beams. For $e^+ e^- \to \tilde{\chi}_1^+ \tilde{\chi}_1^-$ with $\tilde{\chi}_1^\pm \to \tilde{\chi}_i^0 e^\mp \tilde{\nu}$ and $e^+ e^- \to \tilde{\chi}_1^0 \tilde{\chi}_2^0$ with $\tilde{\chi}_2^0 \to \tilde{\chi}_i^0 e^+ e^-$ we perform a detailed analysis, including the complete spin correlations between production and decay. We analyze the forward–backward asymmetry of the decay electron for various beam polarizations. We also study polarization asymmetries in $e^+ e^- \to \tilde{\chi}_1^0 \tilde{\chi}_2^0$. These asymmetries strongly constrain the gaugino parameter $M_1$ and the masses $m_{\tilde{\ell}_L}, m_{\tilde{\ell}_R}, m_{\tilde{\nu}}$ also if $m_{\tilde{\ell}, \tilde{\nu}} \geq \sqrt{s}/2$. We give numerical predictions for three scenarios for a linear collider with $\sqrt{s} = 500 – 1000$ GeV.

1 Introduction

The search for supersymmetric (SUSY) particles and the determination of their properties will be one of the main goals of a future $e^+e^-$ linear collider. Particularly interesting will be the experimental study of charginos and neutralinos, which are the quantum mechanical mixtures of the charged and neutral gauginos and higgsinos, the SUSY partners of the charged and neutral gauge and Higgs bosons. In the Minimal Supersymmetric Standard Model (MSSM) there are two charginos $\tilde{\chi}_i^\pm$, $i = 1, 2$, and four neutralinos $\tilde{\chi}_i^0$, $i = 1, \ldots, 4$. Usually the lightest neutralino $\tilde{\chi}_1^0$ is the lightest SUSY particle LSP. The masses and couplings of the charginos are determined by the SUSY parameters $M_2$, $\mu$ and $\tan \beta$. The neutralino properties depend in addition on the gaugino mass parameter $M_1$. An $e^+e^-$ linear collider, where charginos and neutralinos can be pair produced, will allow a precise determination of the SUSY parameters involved.

Previous papers mainly analyzed production cross sections and decay branching ratios in the MSSM (see, e.g. [1, 2] and references therein). Recently a method for determining the SUSY parameters $M_2$, $\mu$ and $\tan \beta$ by measuring suitable observables in chargino production $e^+e^- \rightarrow \tilde{\chi}_i^+\tilde{\chi}_j^-$ ($i, j = 1, 2$) has been proposed [3]. The gaugino mass parameter $M_1$ can in principle be determined from the neutralino mass spectrum [3, 4]. Models with an extended neutralino sector have been discussed in [5, 6]. A detailed study of the neutralino system is also helpful for examining the question whether the MSSM or another SUSY model is realized in nature.

In the present paper we study the production and decay of charginos and neutralinos with both the $e^-$ and the $e^+$ beam polarized. We show that suitably polarizing both beams has three advantages: One can gain higher cross sections and thereby reduce the experimental errors. By measuring suitable observables one can get additional information on the mixing components of charginos and neutralinos as well as on the masses of the exchanged $\tilde{\nu}_e$, $\tilde{e}_L$, $\tilde{e}_R$. Moreover, the background can be reduced by appropriately polarizing the beams.

In the calculation of the decay angular distributions one has to take into account the spin correlations between production and decay of the charginos and neutralinos. They are particularly important near threshold. The processes $e^+e^- \rightarrow \tilde{\chi}_i^+\tilde{\chi}_j^-$, $\tilde{\chi}_i^+ \rightarrow \tilde{\nu}_e^0\ell^+$ and $e^+e^- \rightarrow \tilde{\chi}_i^0\tilde{\chi}_j^0$, $\tilde{\chi}_i^0 \rightarrow \tilde{\nu}_e^0\ell^+$, including the full spin correlations, have been studied in [7, 8]. In [9, 10] we have given the complete analytical formulae for longitudinally $e^-$ and $e^+$ polarized beams in the laboratory system.

In our numerical analysis we will consider three scenarios, where $\tilde{\chi}_{1,2}^0$,
\( \tilde{\chi}_1^\pm \) are gaugino–like and which differ in \( \tan \beta \) and the selectron masses. We analyze the \( e^- \) and \( e^+ \) polarization dependence of all production sections accessible at a linear collider in the 500-1000 GeV range. In the case of \( \tilde{\chi}_1^+ \tilde{\chi}_1^- \) pair production and associated \( \tilde{\chi}_1^0 \tilde{\chi}_2^0 \) production we study the dependence of the cross section and the forward–backward asymmetry of the decay electron on the beam polarizations and on the masses of the exchanged \( \tilde{\nu}, \tilde{e}_L \) and \( \tilde{e}_R \).

We also relax the GUT relation between \( M_1 \) and \( M_2 \), \( M_1/M_2 = \frac{5}{3} \tan^2 \Theta_W \), and study the \( M_1 \) dependence of the forward-backward asymmetry of the decay electron and the polarization asymmetry.

2 Spin Correlations between Production and Decay

The helicity amplitudes for the production processes

\[
\begin{align*}
\text{e}^+\text{e}^- & \rightarrow \tilde{\chi}_i^+ \tilde{\chi}_j^-, \\
\text{e}^+\text{e}^- & \rightarrow \tilde{\chi}_i^0 \tilde{\chi}_j^0,
\end{align*}
\]

are denoted by \( T^{\lambda_i\lambda_j} \) and those for the decay processes

\[
\begin{align*}
\tilde{\chi}_i^+ & \rightarrow \tilde{\chi}_k^0 \ell^+ \nu, \\
\tilde{\chi}_i^0 & \rightarrow \tilde{\chi}_k^0 \ell^+ \ell^-,
\end{align*}
\]

by \( T_{D,\lambda_i} \) (and analogously \( T_{D,\lambda_j} \) for the decaying \( \tilde{\chi}_j^- \) and \( \tilde{\chi}_j^0 \)). The corresponding Feynman diagrams are given in Figs. 1a and b.

The amplitude squared of the combined process of production and decay is (summed over helicities):

\[
|T|^2 = |\Delta(\tilde{\chi}_i)|^2 |\Delta(\tilde{\chi}_j)|^2 \rho^{\lambda_i\lambda_j\lambda'_i\lambda'_j} \rho_{D,\lambda_i\lambda'_i} \rho_{D,\lambda_j\lambda'_j}.
\]

It is composed of the (unnormalized) spin density production matrix

\[
\rho^{\lambda_i\lambda_j\lambda'_i\lambda'_j} = T^{\lambda_i\lambda_j}_P T^{\lambda'_i\lambda'_j}_P,
\]

the decay matrices

\[
\rho_{D,\lambda_i\lambda'_i} = T_{D,\lambda_i} T^{\lambda'_i}_{D,\lambda'_i}, \quad \rho_{D,\lambda_j\lambda'_j} = T_{D,\lambda_j} T^{\lambda'_j}_{D,\lambda'_j},
\]

and the propagator

\[
\Delta(\tilde{\chi}_k) = 1/[p_k^2 - m_k^2 + im_k \Gamma_k].
\]
Here $p_k^2$, $\lambda_k$, $m_k$ and $\Gamma_k$ denote the four-momentum squared, helicity, mass and total width of $\tilde{\chi}_k$. For this propagator we use the narrow-width approximation.

The density matrices can be expanded in terms of the Pauli matrices $\sigma^a$:

\[
\rho^{\lambda_i \lambda_j \lambda'_{i'}} = (\delta_{\lambda_i \lambda'_{i'}} P(\tilde{\chi}_i \tilde{\chi}_j) + \delta_{\lambda_j \lambda'_{j'}} \sum_{a=1}^{3} \sigma^a_{\lambda_i \lambda'_{i'}} \Sigma^a_P(\tilde{\chi}_i) + \delta_{\lambda_i \lambda'_{j'}} \sum_{b=1}^{3} \sigma^b_{\lambda_j \lambda'_{j'}} \Sigma^b_P(\tilde{\chi}_j)),
\]

(9)

\[
\rho_{D,\lambda_i \lambda_i} = (\delta_{\lambda_i \lambda_i} D(\tilde{\chi}_i) + \sum_{a=1}^{3} \sigma^a_{\lambda_i \lambda_i} \Sigma^a_D(\tilde{\chi}_i)),
\]

(10)

\[
\rho_{D,\lambda_j \lambda_j} = (\delta_{\lambda_j \lambda_j} D(\tilde{\chi}_j) + \sum_{b=1}^{3} \sigma^b_{\lambda_j \lambda_j} \Sigma^b_D(\tilde{\chi}_j)).
\]

(11)

We have chosen the polarization vectors such that $\Sigma^1_P(\tilde{\chi}_{i,j})$ describes the transverse polarization in the production plane, $\Sigma^2_P(\tilde{\chi}_{i,j})$ denotes the polarization perpendicular to the production plane and $\Sigma^3_P(\tilde{\chi}_{i,j})$ describes the longitudinal polarization of the chargino or neutralino, respectively. $\Sigma^{ab}_P(\tilde{\chi}_i \tilde{\chi}_j)$ is due to correlations between the polarizations of both charginos or neutralinos, respectively. The complete analytical expressions for the production density matrix and for the decay matrices are given in [7, 9].

The amplitude squared $|T|^2$ of the combined process of production and decay, eq. (5), can be rewritten as:

\[
|T|^2 = 4|\Delta(\tilde{\chi}_i)|^2 |\Delta(\tilde{\chi}_j)|^2 \left(P(\tilde{\chi}_i \tilde{\chi}_j)D(\tilde{\chi}_i) D(\tilde{\chi}_j) + \sum_{a=1}^{3} \Sigma^a_P(\tilde{\chi}_i) \Sigma^a_D(\tilde{\chi}_i) D(\tilde{\chi}_j) + \sum_{b=1}^{3} \Sigma^b_P(\tilde{\chi}_j) \Sigma^b_D(\tilde{\chi}_j) D(\tilde{\chi}_i) + \sum_{a,b=1}^{3} \Sigma^{ab}_P(\tilde{\chi}_i \tilde{\chi}_j) \Sigma^{ab}_D(\tilde{\chi}_i) \Sigma^{ab}_D(\tilde{\chi}_j) \right).
\]

(12)

The differential cross section is then given by

\[
d\sigma_\epsilon = \frac{1}{2s} |T|^2 (2\pi)^4 \delta^4(p_1 + p_2 - \sum_i p_i) dlips(p_3 \ldots p_{10}),
\]

(13)

where $dlips(p_3, \ldots, p_{10})$ is the Lorentz invariant phase space element.

If one neglects all spin correlations between production and decay only the first term in (12) contributes. The second and third term in (12) describe
the spin correlations between the production and the decay process. The last term is due to spin–spin correlations between both decaying charginos or neutralinos.

3 Numerical Analysis and Discussion

In the following analysis we use the MSSM [11] as our general framework. The masses and couplings of neutralinos and charginos are determined by the parameters $M_1$, $M_2$, $\mu$, tan $\beta$, which can be chosen real if CP violation is neglected. Moreover, one usually makes use of the GUT relation

$$M_1 = \frac{5}{3} M_2 \tan^2 \Theta_W. \quad (14)$$

The explicit expressions for the neutralino and chargino mass mixing matrices can be found in [1] (note that in Refs. [1, 7] the notation $M'$ and $M$ for $M_1$ and $M_2$ was used).

In our analysis we study chargino and neutralino production and decays in three scenarios, which we denote by A1, A2 and B. The corresponding parameters are given in Table 1. In scenario A1 one has $\tan \beta = 3$ and the masses $m_{\tilde{e}_L} = 176$ GeV, $m_{\tilde{e}_R} = 132$ GeV, $m_{\varphi} = 161$ GeV [12]. In this scenario $\tilde{\chi}_1^0$ is $\tilde{B}$-like, $\tilde{\chi}_2^0$ is $\tilde{W}^3$-like, and $\tilde{\chi}_1^\pm$ is $\tilde{W}^\pm$-like and $\tilde{H}^\pm$-like. Scenario A2 differs from A1 only by the higher $\tilde{e}_L$ mass $m_{\tilde{e}_L} = 500$ GeV. In scenario B one has $\tan \beta = 30$ and $m_{\tilde{e}_L} = 217$ GeV, $m_{\tilde{e}_R} = 183$ GeV and $m_{\varphi} = 202$ GeV [12]. In this scenario $\tilde{\chi}_1^0$, $\tilde{\chi}_2^0$ and $\tilde{\chi}_1^\pm$ are also gaugino–like.

3.1 Beam Polarization Effects in Chargino Production

We study the dependence of the cross sections $\sigma(e^+e^- \rightarrow \tilde{\chi}_i^+ \tilde{\chi}_j^-)$, $i, j = 1, 2$, on the electron beam polarization $P_{e^-}$ and positron beam polarization $P_{e^+}$ (with $P_{e^\pm} = \{-1, 0, 1\}$ for \{left,un,right\} polarized) at $\sqrt{s} = m_{\tilde{\chi}_i^+} + m_{\tilde{\chi}_j^-} + 10$ GeV for scenarios A1 and B. We choose $\sqrt{s}$ not too far from threshold, because the spin correlations to be discussed below are largest near threshold [4]. As an abbreviation we write in the following just the final state $\tilde{\chi}_i^+ \tilde{\chi}_j^-$ for the process $e^+e^- \rightarrow \tilde{\chi}_i^+ \tilde{\chi}_j^-$. 

- $\tilde{\chi}_1^\pm \tilde{\chi}_1^-$ 
  **Scenario A1** (see Fig. 2a): Due to the $\tilde{\nu}_e$ exchange and the gaugino character of $\tilde{\chi}_1^\pm$, a left polarized electron beam and a right polarized positron beam lead to the largest cross section. For $P_{e^-} = -85\%$ and $P_{e^+} = +60\%$ we obtain 410 fb, which means that the cross section is
enhanced by a factor of about three with respect to unpolarized beams (Table 2).

Scenario B: One gets a similar dependence on the beam polarizations and the same enhancement factor as in scenario A1. With $P_{e^-} = -85\%$ and $P_{e^+} = +60\%$ a cross section of 709 fb is reached (Table 2).

- $\tilde{\chi}_1^\pm \tilde{\chi}_2^\mp$

Scenario A1 (see Fig. 2b): In this case $\gamma$ exchange does not contribute and $\tilde{\nu}_e$ exchange is suppressed due to the higgsino-like $\tilde{\chi}_2^-$. Therefore, right polarized electrons and left polarized positrons are favoured. Due to the different character of $\tilde{\chi}_1^+$ and $\tilde{\chi}_2^-$ the cross section is small and reaches only 6 fb with $P_{e^-} = +85\%$ and $P_{e^+} = -60\%$ (Table 2).

Scenario B (see Fig. 2d): In this case somewhat higher cross sections of about 10 fb can be reached with $P_{e^-} = +85\%$ and $P_{e^+} = -60\%$.

- $\tilde{\chi}_2^\mp \tilde{\chi}_2^\pm$

Scenario A1 (see Fig. 2c): As $\tilde{\chi}_2^\pm$ is higgsino-like $\tilde{\nu}_e$ exchange is negligible. The cross section is enhanced if the electrons are left and the positrons are right polarized, mainly due to the $\gamma - Z^0$ interference. For $P_{e^-} = -85\%$ and $P_{e^+} = +60\%$ it is enhanced by a factor 2.5 and reaches 113 fb.

Scenario B: One gets a similar dependence on the beam polarizations and the same enhancement factor as in scenario A1. With $P_{e^-} = -85\%$ and $P_{e^+} = +60\%$ a cross section of 194 fb is reached (Table 2).

A summary of our results for scenario A1 and B is given in Table 2.

Since $\tilde{\nu}_e$ exchange favours left polarized electron beams and right polarized positron beams, one expects for gaugino-like scenarios the following sequence of polarized cross sections $[10, 13]$ (for $|P_{e^-}| = 85\%$ and $|P_{e^+}| = 60\%)$:

$$\sigma^{-+} > \sigma^{-0} > \sigma^{00} > \sigma^{++} > \sigma^{+0} > \sigma^{+-}.$$  \hspace{1cm} (15)

Here ($-+$) etc. denotes the sign of the electron polarization $P_{e^-}$ and of the positron polarization $P_{e^+}$, respectively.

On the other hand, for pure higgsinos one would have due to $Z^0$ exchange

$$\sigma^{-+} > \sigma^{+-} > \sigma^{-0} > \sigma^{00} > \sigma^{+0} > \sigma^{++}.$$  \hspace{1cm} (16)

These orderings are also valid if the decays are included.

The relations $[15]$, $[13]$ are, however, modified by the $\gamma$ exchange contribution. Nevertheless, one can get additional information by using polarized
electron and positron beams, because the sequences of polarized cross sections for gaugino–like and higgsino–like scenarios are different. If only the electron beam is polarized, one would obtain in both scenarios the same sequence of polarized cross sections, namely $\sigma^{-0} > \sigma^{00} > \sigma^{+0}$.

In scenarios A1 and B we get the results in Table 2 for $|P_{e^-}| = 85\%$ and $|P_{e^+}| = 60\%$ at $\sqrt{s} = m_{\tilde{\chi}_i^\pm} + m_{\tilde{\chi}_j^\pm} + 10$ GeV. For $e^+e^- \rightarrow \tilde{\chi}_1^0\tilde{\chi}_1^0$ the relation is fulfilled. However, for $e^+e^- \rightarrow \tilde{\chi}_2^+\tilde{\chi}_2^-$ (higgsino–like $\tilde{\chi}_2^\pm$) the sequence is different from relation due to $\gamma$ exchange and in particular $\gamma Z^0$ interference.

Usually, one defines an effective polarization

$$P_{\text{eff}} = \frac{P_{e^-} - P_{e^+}}{1 - P_{e^-}P_{e^+}}.$$  

The error of the effective polarization can be reduced when both beams are polarized.

### 3.2 Beam Polarization Effects in Neutralino Production

In this subsection we study the dependence of the cross section $\sigma(e^+e^- \rightarrow \tilde{\chi}_i^0\tilde{\chi}_j^0)$, $i, j = 1, \ldots, 4$, on the longitudinal beam polarizations $P_{e^-}$ and $P_{e^+}$ at $\sqrt{s} = (m_{\tilde{\chi}_i^0} + m_{\tilde{\chi}_j^0}) + 30$ GeV, for scenario A1, A2 and B. In the following we again denote the production process $e^+e^- \rightarrow \tilde{\chi}_i^0\tilde{\chi}_j^0$ by its final state $\tilde{\chi}_i^0\tilde{\chi}_j^0$.

- $\tilde{\chi}_1^0\tilde{\chi}_2^0$
  
  **Scenario A1** (see Fig. 3a): Since $\tilde{\chi}_1^0$ is mostly $\tilde{B}$–like and $\tilde{\chi}_2^0$ is mostly $\tilde{W}^3$–like mainly $\tilde{e}_L$ and $\tilde{e}_R$ exchange in the t– and u– channel contribute. One gets the largest cross section for left polarized electrons and right polarized positrons. Due to the strong $\tilde{B}$ component of $\tilde{\chi}_1^0$ one gets a slight enhancement also for right polarized electrons and left polarized positrons. For $P_{e^-} = -85\%$ and $P_{e^+} = +60\%$ the cross section goes up to 56 fb, which is larger by a factor of 1.8 than for unpolarized beams.

  - **Scenario A2** (see Fig. 3b): Since $m_{\tilde{e}_L} \gg m_{\tilde{e}_R}$ $\tilde{e}_L$ exchange is suppressed leading to an enhancement for right polarized electrons and left polarized positrons. With $P_{e^-} = +85\%$ and $P_{e^+} = -60\%$ one reaches 35 fb, that is an enhancement by a factor 2.7 with respect to unpolarized beams.

  - **Scenario B** (see Fig. 3c): Due to the different couplings for large $\tan \beta$ the dependence on the beam polarizations slightly changes. For $P_{e^-} =$
−85% and $P_{e^-} = +60\%$ one has an enhancement factor of 2.4 with respect to the unpolarized case. The cross section reaches 50 fb.

- $\tilde{\chi}^0_2 \tilde{\chi}^0_2$
  
  Scenario A1 (see Fig. 3d): Owing to the $\tilde{W}^3$ nature of $\tilde{\chi}^0_2$, the cross section is governed by $\tilde{e}_L$ exchange. Hence the cross section is largest for left polarized electrons and right polarized positrons. It reaches 121 fb for $P_{e^-} = −85\%$ and $P_{e^+} = +60\%$, which gives an enhancement by a factor of 3 with respect to unpolarized beams.

  Scenario B: One gets the same enhancement factor compared to the unpolarized case as in scenario A1. Due to the smaller lepton-slepton-neutralino couplings the cross sections are about a factor two smaller. For $P_{e^-} = −85\%$ and $P_{e^+} = +60\%$ one gets 59 fb.

- $\tilde{\chi}^0_1 \tilde{\chi}^0_3$
  
  Scenario A1 (Fig. 4a): Since $\tilde{\chi}^0_1$ is $\tilde{B}$–like and $\tilde{\chi}^0_3$ is higgsino–like the cross sections are smaller than for $\tilde{\chi}^0_1 \tilde{\chi}^0_2$ production, reaching only 25 fb. Due to the large $\tilde{\chi}^0_1 \tilde{e}_R$ coupling one gets an enhancement by a factor of 2.7 for $P_{e^-} = +85\%$ and $P_{e^+} = −60\%$ compared with the unpolarized case.

  Scenario B: One gets a similar enhancement factor of about 2.8 as in scenario A1. Due to slightly larger $\tilde{\chi}^0_3 \tilde{e}_R$ coupling the cross section is 42 fb for $P_{e^-} = +85\%$ and $P_{e^+} = −60\%$.

- $\tilde{\chi}^0_2 \tilde{\chi}^0_3$
  
  Scenario A1 (see Fig. 4b): Since the $\tilde{\chi}^0_2$ has a strong $\tilde{W}^3$ component one gets the largest cross sections with left polarized electrons and right polarized positrons. With $P_{e^-} = −85\%$ and $P_{e^+} = +60\%$ the cross section is enhanced by a factor of 2.6 and reaches 41 fb.

  Scenario B: Due to slightly larger $\tilde{\chi}^0_3$ couplings than in scenario A1 one gets a cross section of 79 fb for $P_{e^-} = −85\%$ and $P_{e^+} = +60\%$.

Table 3 gives a survey of all cross sections $e^+e^− \rightarrow \tilde{\chi}^0_i \tilde{\chi}^0_j$ (including the invisible channel $e^+e^− \rightarrow \tilde{\chi}^0_1 \tilde{\chi}^0_1$) for different beam polarizations. Note the large cross sections for $e^+e^− \rightarrow \tilde{\chi}^0_3 \tilde{\chi}^0_4$ due to the large Z$^0$ couplings to the higgsino components. In summary the cross sections can be enhanced.
by a factor two to three by polarizing both beams. For pure gaugino–like neutralinos and $m_{\tilde{e}_L} \gg m_{\tilde{e}_R}$, for $P_{e^-} = +1$, $P_{e^+} = -1$ ($P_{e^-} = -1$, $P_{e^+} = +1$) the cross section could even be enlarged by a factor 4. For pure higgsino–like neutralinos and $P_{e^-} = +1$, $P_{e^+} = -1$ ($P_{e^-} = -1$, $P_{e^+} = +1$) the enhancement factor is 1.7 (2.3) [10, 14].

If the polarizations of both beams are varied, the relative size of the cross sections strongly depends on the mixing character of both neutralinos and on the selectron masses [10]. In particular, for $e^+ e^- \rightarrow \tilde{\chi}_i^0 \tilde{\chi}_j^0$ and if $\tilde{\chi}_i^0$ and $\tilde{\chi}_j^0$ are pure higgsinos, one obtains for $|P_{e^-}| = 85\%$ and $|P_{e^+}| = 60\%$ the sequence

$$\sigma^{-+} > \sigma^{+-} > \sigma^{-0} > \sigma^{00} > \sigma^{0+} > \sigma^{++}.$$ (18)

If $\tilde{\chi}_i^0$ and $\tilde{\chi}_j^0$ are pure gauginos, the order of the cross sections depends on the relative magnitude of the selectron masses $m_{\tilde{e}_L}$ and $m_{\tilde{e}_R}$. For $m_{\tilde{e}_L} \gg m_{\tilde{e}_R}$ only right selectron exchange contributes, and one obtains

$$\sigma^{++} > \sigma^{+0} > \sigma^{00} > \sigma^{0+} > \sigma^{-0} > \sigma^{-+},$$ (19)

whereas for $m_{\tilde{e}_R} \gg m_{\tilde{e}_L}$ (which may be realized in extended SUSY models, [8] and references therein), one gets:

$$\sigma^{-+} > \sigma^{-0} > \sigma^{00} > \sigma^{0-} > \sigma^{+0} > \sigma^{+-}.$$ (20)

A comparison of (18) and (20) shows that polarizing both beams allows one to distinguish between a higgsino–like scenario and a gaugino–like scenario with dominating $\tilde{e}_L$ exchange. This is not possible if only the electron beam is polarized.

From Table 3 one notices that for $e^+ e^- \rightarrow \tilde{\chi}_1^0 \tilde{\chi}_1^0$ one obtains the same ordering of the polarized cross sections in scenario A1 and B (with $\tilde{\chi}_1^0$ and $\tilde{\chi}_1^0$ higgsino–like) as in (18). Comparing the sequence of cross sections for $e^+ e^- \rightarrow \tilde{\chi}_1^0 \tilde{\chi}_2^0$ in scenario A2 (with $\tilde{\chi}_1^0$, $\tilde{\chi}_2^0$ gaugino–like) with (19), one observes the influence of $\tilde{e}_L$ exchange which is however suppressed due to the high mass $m_{\tilde{e}_L} = 500$ GeV.

### 3.3 Decoys Lepton Forward–Backward Asymmetries

We will discuss the forward–backward asymmetry of the lepton angular distribution $d\sigma_e / d\cos \Theta_e$ in the overall c.m.s. of the combined reactions

$$e^+ e^- \rightarrow \tilde{\chi}_1^+ \tilde{\chi}_1^-, \quad \tilde{\chi}_1^- \rightarrow \tilde{\chi}_1^0 e^- \bar{\nu}$$ (21)

and

$$e^+ e^- \rightarrow \tilde{\chi}_1^0 \tilde{\chi}_2^0, \quad \tilde{\chi}_2^0 \rightarrow \tilde{\chi}_1^0 e^+ e^-.$$ (22)
Here $\Theta_e$ denotes the angle between the electron beam and the decay electron $e^-$. The forward–backward asymmetry $A_{FB}$ of the decay electron is defined as

$$A_{FB} = \frac{\sigma_e(\cos \Theta_e > 0) - \sigma_e(\cos \Theta_e < 0)}{\sigma_e(\cos \Theta_e > 0) + \sigma_e(\cos \Theta_e < 0)},$$

(23)

where

$$\sigma_e = \sigma(e^+e^- \rightarrow \tilde{\chi}_1^+\tilde{\chi}_1^-) \times BR(\tilde{\chi}_1^- \rightarrow \tilde{\chi}_1^0e^−\tilde{\nu})$$

(24)

for chargino production and decay and

$$\sigma_e = \sigma(e^+e^- \rightarrow \tilde{\chi}_1^0\tilde{\chi}_2^0) \times BR(\tilde{\chi}_2^0 \rightarrow \tilde{\chi}_1^0e^+e^-)$$

(25)

for neutralino production and decay. Note that $d\sigma_e/d\cos \Theta_e$ and $A_{FB}$ are sensitive to spin correlations.

The observable $A_{FB}$, eq. (23), is very sensitive to the gaugino component of the chargino/neutralino and the mass of the exchanged sneutrino or slepton. It has the advantage of being independent of the parameters of the squark sector which enter in $\sigma_e$, eqs. (24), (25), via the leptonic branching ratio, which cancels in eq. (23).

### 3.3.1 $\sigma_e$ and $A_{FB}$ in Chargino Production and Decay

Obviously, if the chargino $\tilde{\chi}_1^\pm$ has a substantial gaugino component, the sneutrino exchange in the $t$–channel has a strong influence on the cross section and angular distribution of chargino production. In [15, 16] the possibility of determining the sneutrino mass $m_{\tilde{\nu}_e}$ from the angular distribution of the production process $e^+e^- \rightarrow \tilde{\chi}_1^+\tilde{\chi}_1^-$ was studied. In the following we study the $m_{\tilde{\nu}_e}$ dependence of the decay lepton forward–backward asymmetry $A_{FB}$, eq. (23), in $e^+e^- \rightarrow \tilde{\chi}_1^+\tilde{\chi}_1^-, \tilde{\chi}_1^- \rightarrow \tilde{\chi}_1^0e^−\tilde{\nu}_e [7, 13]$. As close to threshold this observable depends decisively on spin correlations, it is instructive to have a closer look on its $m_{\tilde{\nu}_e}$ dependence. $A_{FB}$ also depends on the slepton mass $m_{\tilde{\ell}_L}$, due to the $\tilde{\ell}_L$ exchange in the decay amplitude. Since $\tilde{\ell}_L$ and $\tilde{\nu}_e$ are members of the same $SU(2)_L$ doublet, their masses are connected by the relation [10, 17]

$$m_{\tilde{\ell}_L}^2 = m_{\tilde{\nu}_e}^2 - m_W^2 \cos 2\beta$$

(26)

with $m_W$ the mass of the $W^\pm$ boson. Relation (26) is fulfilled at tree level, and is only modified by radiative corrections.

We first show in Fig. 5 the cross section $\sigma_e$, eq.(24), as a function of $m_{\tilde{\nu}_e}$ at $\sqrt{s} = 2m_{\tilde{\chi}_1^\pm} + 10$ GeV, fixing $m_{\tilde{\ell}_L}$ by eq. (26). $\sigma_e$ exhibits a pronounced
minimum, which is due to the destructive interference between $Z$ exchange and $\tilde{\nu}_e$ exchange [4]. For $\sqrt{s}$ near threshold this minimum is approximately at $m_{\tilde{\nu}_e} \approx m_{\tilde{\chi}_1^\pm}$ and in the limit $\sqrt{s} \rightarrow 2m_{\tilde{\chi}_1^\pm}$ the minimum reaches exactly $m_{\tilde{\nu}_e} \rightarrow m_{\tilde{\chi}_1^\pm}$. Due to this minimum there is an ambiguity when one tries to determine $m_{\tilde{\nu}_e}$ by measuring $\sigma_e$. At higher $\sqrt{s}$ the minimum is shifted to higher values of $m_{\tilde{\nu}_e}$ [10, 13].

In Fig. 6a and b we show the contour lines of $A_{FB}$ as a function of $m_{\tilde{\nu}_e}$ and $m_{\tilde{\chi}_L}$ at $\sqrt{s} = 2m_{\tilde{\chi}_1^\pm} + 10$ GeV and $\sqrt{s} = 500$ GeV, respectively, for $P_{e^-} = -85\%$ and $P_{e^+} = +60\%$. In order to study separately the $m_{\tilde{\nu}_e}$ and $m_{\tilde{\chi}_L}$ dependence of $A_{FB}$ we have relaxed the mass relation eq. (26). Apart from $m_{\tilde{\nu}_e}$ and $m_{\tilde{\chi}_L}$ the parameters are as in scenario A1. The large asymmetry is mainly due to $\tilde{\nu}_e$ exchange in the crossed channel of the production. Close to threshold also the $\tilde{\ell}_L$ exchange in the decay $\tilde{\chi}_1^- \rightarrow \chi_1^0 e^- \tilde{\nu}_e$ plays an important role, see Fig. 6a. At energies far from threshold the charginos have a large energy, and the decay lepton has essentially the same direction as the chargino [18]. Therefore, the $\tilde{\ell}_L$ dependence is weaker [13], see Fig. 6b.

Due to the dominance of the $t$–channel contribution in scenario A1 the polarization dependence of the nominator and denominator in the ratio, eq. (23), almost cancels. Therefore $A_{FB}$ depends only weakly on the polarizations of the beams.

Turning now to the question how accurate the sneutrino mass $m_{\tilde{\nu}_e}$ can be determined from chargino pair production and decay, Figs. 6a and b show that there is an appreciable $m_{\tilde{\nu}_e}$ dependence of $A_{FB}$. We first consider the case $m_{\tilde{\nu}_e} \gtrsim \sqrt{s}/2$, where $\tilde{\nu}_e \tilde{\nu}_e$ pair production is kinematically not possible. We assume that the slepton mass $m_{\tilde{\ell}_L}$ and the other SUSY parameters are known with good precision. For definiteness, we take, $m_{\tilde{\ell}_L} = 200$ GeV, and the other SUSY parameters as in scenario A1.

At $\sqrt{s} = 500$ GeV, with a luminosity of $\mathcal{L} = 500$ fb$^{-1}$, $A_{FB}$ can be measured up to $< \pm 1\%$, if we take only the statistical error $\delta(A_{FB})$. This means that in the range 350 GeV $\lesssim m_{\tilde{\nu}_e} \lesssim$ 800 GeV an accuracy of about $|\delta m_{\tilde{\nu}_e}| < 10$ GeV may be achieved. The experimental errors of $m_{\tilde{\ell}_L}$ and the other SUSY parameters are neglected. The ambiguity at $\sqrt{s} = 500$ GeV (Fig. 6b) in the range 250 GeV $\lesssim m_{\tilde{\nu}_e} \lesssim$ 350 GeV can be resolved by measuring $A_{FB}$ at different c.m.s. energies. Similarly, at $\sqrt{s} = 2m_{\tilde{\chi}_1^\pm} + 10$ GeV (Fig. 6a), $A_{FB}$ is quite sensitive to $m_{\tilde{\nu}_e}$ in the range 135 GeV $\lesssim m_{\tilde{\nu}_e} \lesssim$ 350 GeV, where direct production is again not possible. If only the electron beam is polarized, $\delta(A_{FB})$ would be larger by about 20\% in the case considered. Moreover, for $P_{e^-} = -85\%$ and $P_{e^+} = +60\%$ we obtain $P_{eff} = 96\%$. If $P_{e^-}$ and $P_{e^+}$ have an error of $\pm 1\%$, the error of $P_{eff}$ would only be $\pm 0.83\%$. For a more
quantitative assessment of the accuracy of $m_{\tilde{\nu}_e}$ that can be expected from measuring the decay lepton forward–backward asymmetry in chargino production, Monte Carlo studies taking into account experimental cuts and detector simulation would be necessary. For instance a cut $-0.9 < \cos \Theta_e < 0.9$ would lead to about 10% smaller values of $\sigma_e$ and $A_{FB}$.

In case $m_{\tilde{\nu}_e} < \sqrt{s}/2$, $\tilde{\nu}_e \bar{\tilde{\nu}}_e$ pairs can be directly produced. If $m_{\tilde{\chi}^\pm_1} < m_{\tilde{\nu}_e}$, then the visible decay $\tilde{\nu}_e \rightarrow e^- \tilde{\chi}^+_1$ is kinematically allowed, and will presumably have a sufficiently high branching ratio. We do not treat this case here, because measuring the cross section of $e^+ e^- \rightarrow \tilde{\nu}_e \bar{\tilde{\nu}}_e$ at threshold will allow us to determine $m_{\tilde{\nu}_e}$ with good accuracy [19]. If $m_{\tilde{\nu}_e} < m_{\tilde{\chi}^\pm_1} < \sqrt{s}/2$, then $\tilde{\nu}_e$ has no visible decay with sufficiently high branching ratio. However, the two–body chargino decay $\tilde{\chi}^\pm_1 \rightarrow e^\pm (\rightarrow) \tilde{\nu}_e$ is possible. Measuring the endpoints of the energy spectrum of the decay leptons $e^+$ and $e^-$ will provide a very precise determination of the masses $m_{\tilde{\chi}^\pm_1}$ and $m_{\tilde{\nu}_e}$. The alternative method to determine $m_{\tilde{\nu}_e}$ by measuring the decay lepton forward–backward asymmetry $A_{FB}$ of chargino production will, in principle, also be possible. However, the accuracy of $m_{\tilde{\nu}_e}$ obtainable in this way is expected to be lower than that from the decay lepton energy spectrum.

### 3.3.2 $A_{FB}$ in Neutralino Production and Decay

Owing to the Majorana character of the neutralinos the angular distribution of the production process is symmetric under the exchange $\cos \Theta \leftrightarrow -\cos \Theta$, where $\Theta$ is the production angle of $\tilde{\chi}^0_j$ [21]. The angular distribution of the decay lepton $\ell^-$, however, depends on the polarization of $\tilde{\chi}^0_j$. Since the longitudinal polarization $\Sigma^3_P$ and the transverse polarization $\Sigma^1_P$ of $\tilde{\chi}^0_j$ are forward–backward antisymmetric, the lepton forward–backward asymmetry $A_{FB}$ of the decay lepton, eq. (23), may become quite large. We will plot $A_{FB}$ not too far from threshold because it decreases with $\sqrt{s}$ for fixed neutralino masses.

In Figs. 7a we show $A_{FB}$ of the decay electron for reaction (22) as a function of the beam polarizations for scenario A1 at $\sqrt{s} = (m_{\tilde{\chi}^0_1} + m_{\tilde{\chi}^0_2}) + 30$ GeV. As one can see, by appropriately polarizing both beams one gets a larger asymmetry. Note that in this scenario $A_{FB}$ is practically zero if both beams are unpolarized.

In Figs. 7b and c we show the contour lines of $A_{FB}$ as a function of $m_{\tilde{\nu}_e}$ and $m_{\tilde{\chi}^\pm}$ at $\sqrt{s} = m_{\tilde{\chi}^0_1} + m_{\tilde{\chi}^0_2} + 30$ GeV, for $P_{e^-} = -85\%$, $P_{e^+} = +60\%$ and $P_{e^-} = +85\%$, $P_{e^+} = -60\%$, respectively. The other parameters are as
in scenario A1. For \(m_{\tilde{e}_L} \approx m_{\tilde{e}_R}\) the asymmetry \(A_{FB}\) is very small for both polarizations considered, but can reach approximately \(\pm 23\%\) if \(m_{\tilde{e}_L} \neq m_{\tilde{e}_R}\). Measuring the lepton forward–backward asymmetry \(A_{FB}\) in addition to the total cross section will give constraints on the selectron masses \(m_{\tilde{e}_L}\) and \(m_{\tilde{e}_R}\).

In the following we will estimate the precision to be expected if one tries to constrain the selectron masses by the data of \(A_{FB}\) of reaction (22). We assume that the right selectron mass is known with good precision and, for definiteness, we take \(m_{\tilde{e}_R} = 240\) GeV. We further assume that the measurement of \(A_{FB}\) has given \(A_{FB} = -10\%\) at \(\sqrt{s} = m_{\tilde{\chi}^0_1} + m_{\tilde{\chi}^0_2} + 30\) GeV. For an integrated luminosity \(L = 500\) fb\(^{-1}\) the statistical error is expected to be \(\delta(A_{FB}) \approx \pm 3\%\). Fig. 7b shows that, for \(P_{e^-} = -85\%\) and \(P_{e^+} = +60\%\), \(m_{\tilde{e}_L}\) has to be either in the range 280 GeV < \(m_{\tilde{e}_L}\) < 320 GeV or in 410 GeV < \(m_{\tilde{e}_L}\) < 460 GeV. This example demonstrates that the mass of \(\tilde{e}_L\) can be constrained by measuring \(A_{FB}\) even if it is too heavy to be directly produced in \(e^+e^-\) annihilation. As a second example we assume that \(m_{\tilde{e}_R}\) is known to be \(m_{\tilde{e}_R} = 340\) GeV, and \(A_{FB} = +15\%\) has been measured. This constrains \(m_{\tilde{e}_L}\) to be either in the mass region 250 GeV < \(m_{\tilde{e}_L}\) < 300 GeV or in 450 GeV < \(m_{\tilde{e}_L}\) < 600 GeV.

As in the chargino case, if both beams are polarized the cross sections can be enhanced and therefore the statistical error of \(A_{FB}\) can be reduced. Moreover, also the error of the effective polarization \(\delta(P_{eff})\) can be reduced.

In [14] we also studied the \(\sqrt{s}\) dependence of the lepton forward–backward asymmetry \(A_{FB}\). For \(\sqrt{s} \gg (m_{\tilde{\chi}^0_1} + m_{\tilde{\chi}^0_2})\) the angular distribution of the decay lepton is essentially the same as that of the neutralino \(\tilde{\chi}^0_2\) and the Majorana character of the decaying neutralino \(\tilde{\chi}^0_2\) the lepton forward–backward asymmetry now practically vanishes.

### 3.3.3 \(M_1\) Dependence of \(\sigma_e\), \(A_{FB}\) and \(A_{pol}\) in Neutralino Production and Decay

As is well known, the neutralino masses as well as the \(Z^0\tilde{\chi}^0_1\tilde{\chi}^0_i\) couplings and the \(\tilde{\chi}^0_i\ell\ell\) couplings also depend on the gaugino mass parameter \(M_1\) [8, 14]. So far we have used the GUT relation (14) for the gaugino masses. In the following we will be more general and not use this relation [3, 4, 18, 21, 22]. We will discuss the \(M_1\) dependence of the cross section, the polarization asymmetry and the forward–backward asymmetry of the decay electron [3, 14] in the reaction \(e^+e^- \rightarrow \tilde{\chi}^0_1\tilde{\chi}^0_2\), \(\tilde{\chi}^0_2 \rightarrow \tilde{\chi}^0_1e^+e^-\). All other parameters are chosen as in scenario A1 except the mass of \(\tilde{e}_R\), which we
take $m_{\tilde{e}_R} = 161$ GeV.

Fig. 8a exhibits the $M_1$ dependence of $\sigma(e^+e^- \to \tilde{\chi}_1^0\tilde{\chi}_2^0) \times BR(\tilde{\chi}_2^0 \to e^+e^-\tilde{\chi}_1^0)$ at $\sqrt{s} = (m_{\tilde{\chi}_1^0} + m_{\tilde{\chi}_2^0}) + 30$ GeV for $m_{\tilde{e}_R} = 161$ GeV and $m_{\tilde{e}_L} = 176$ GeV in the region $40$ GeV $< M_1 < m_{\tilde{e}_R}$ for various beam polarizations [14]. We do not consider values $|M_1| > m_{\tilde{e}_R}$, where $m_{\tilde{\chi}_2^0} > m_{\tilde{\ell}_R}$, because then the two–body decay $\tilde{\chi}_2^0 \to \tilde{\ell}_R + \ell$ would be the dominant decay channel.

Fig. 8b shows the analogous curves for $m_{\tilde{e}_L} = 500$ GeV. One clearly sees from the curves for left polarized electrons and/or right polarized positrons that the $\tilde{e}_L$ exchange is strongly suppressed, and one obtains higher cross sections for right polarized $e^-$ beams.

We have also studied the $M_1$ dependence of the forward–backward asymmetry $A_{FB}$ of the decay electron, eq. (23), shown in Fig. 9a and b for $m_{\tilde{e}_L} = 176$ GeV and $m_{\tilde{e}_L} = 500$ GeV. One notices a significant variation with $M_1$ and a strong dependence on the beam polarizations. Comparing Fig. 9a and b, one observes that in the region $40$ GeV $< M_1 < 100$ GeV the forward–backward asymmetries of the decay electron are different. This is due to the suppression of $\tilde{e}_L$ exchange in Fig. 9b.

Another observable which has a characteristic $M_1$ dependence is the polarization asymmetry defined as

$$A_{pol} = \frac{\sigma_{AB} - \sigma_{CD}}{\sigma_{AB} + \sigma_{CD}} = \frac{\sigma_{e^- e^-} - \sigma_{e^+ e^+}}{\sigma_{e^- e^-} + \sigma_{e^+ e^+}},$$

(27)

where $A, C$ indicate two values of the polarization $P_{e^-}$, and $B, D$ two values of the polarization $P_{e^+}$.

In Fig. 10 we show $A_{pol}$ as a function of $M_1$ at $\sqrt{s} = m_{\tilde{\chi}_1^0} + m_{\tilde{\chi}_2^0} + 30$ GeV for different beam polarizations. Apart from $M_1$ we take the parameters and masses as in scenario A1. In the case of a small mass difference between $\tilde{e}_L$ and $\tilde{e}_R$, $M_1$ can be constrained by measuring $A_{pol}$ for different beam polarizations. For larger selectron mass differences the $M_1$ dependence of $A_{pol}$ is much weaker.

4 Conclusions

The objective of this paper has been twofold. Firstly, we have studied the advantage of having both the $e^-$ and the $e^+$ beam polarized. If the polarizations of $e^-$ and $e^+$ are varied, the cross sections depend significantly on the mixing character of the charginos and neutralinos and on the masses of $\tilde{\nu}_e$, $\tilde{e}_L$ and $\tilde{e}_R$. By an appropriate choice of polarizations one can obtain up to three times larger cross sections than in the unpolarized case. Secondly,
we have studied the forward–backward asymmetry of the decay electron in $e^+e^- \rightarrow \tilde{\chi}_1^+\tilde{\chi}_1^-$, $\tilde{\chi}_1^- \rightarrow \tilde{\chi}_1^0\tilde{\nu}_e$, and in $e^+e^- \rightarrow \tilde{\chi}_1^0\tilde{\chi}_2^0$, $\tilde{\chi}_2^- \rightarrow \tilde{\chi}_1^0e^+e^-$ taking into account the full spin correlations between production and decay. Measuring this asymmetry for various beam polarizations gives further constraints on the masses of $\tilde{\nu}_e$, $\tilde{e}_L$ and $\tilde{e}_R$, also if direct production of these particles is kinematically not possible. It also constrains the mixing properties of the charginos and neutralinos. We have also studied the dependence on the gaugino mass parameter $M_1$. For a determination of $M_1$ the use of polarized $e^+$ and $e^-$ beams would also be very useful.

Acknowledgments

We thank U. Martyn for many valuable discussions. Parts of the calculations have been performed on the QCM cluster at the University of Karlsruhe, supported by the Deutsche Forschungsgemeinschaft under contract number FOR 264/2-1. We are grateful to W. Porod and S. Hesselbach for providing the computer programs for neutralino and chargino total widths. This work was also supported by the German Federal Ministry for Research and Technology (BMBF) under contract number 05 7WZ91P (0), by the Deutsche Forschungsgemeinschaft under contract Fr 1064/4-1, and the ‘Fonds zur Förderung der wissenschaftlichen Forschung’ of Austria, Project No. P13139-PHY.

Table 3: Polarized cross sections $\sigma = \sigma(e^+e^- \to \hat{\chi}^{0} \chi^{0}_j)$/fb, i, j=1,..,4, at $\sqrt{\mathcal{s}} = m_{\chi_i} + m_{\chi_j} + 30$ GeV in scenarios A1, A2 and B, see Table 4, for unpolarized beams (00), only electron beam polarized ($-$), (00) with $P_e^- = \pm 85\%$ and both beams polarized with $P_{e^+} = \pm 85\%$, $P_{e^-} = \pm 60\%$.  

18
Figure 1a: Feynman diagrams for chargino production $e^+e^- \rightarrow \tilde{\chi}_i^\pm \tilde{\chi}_j^\mp$ and neutralino production $e^+e^- \rightarrow \tilde{\chi}_i^0 \tilde{\chi}_j^0$.

Figure 1b: Feynman diagrams for chargino decays $\tilde{\chi}_i^\pm \rightarrow \tilde{\chi}_k^0 \ell^\pm$ and neutralino decays $\tilde{\chi}_i^0 \rightarrow \tilde{\chi}_k^0 \ell^+ \ell^-$.
Figure 2: Contour lines of cross section $\sigma(e^+e^- \rightarrow \tilde{\chi}_1^+\tilde{\chi}_1^-)$ at $\sqrt{s} = m_{\tilde{\chi}_1^+} + m_{\tilde{\chi}_1^-} + 10$ GeV. The longitudinal beam polarization for electrons (positrons) is denoted by $P_{e^-}$ ($P_{e^+}$). The white region is for $|P_{e^-}| \leq 85\%$, $|P_{e^+}| \leq 60\%$ (dashed line if only the electron beam is polarized).
Figure 3: Contour lines of cross section $\sigma(e^+e^- \rightarrow \tilde{\chi}^0_1\tilde{\chi}^0_2)$ at $\sqrt{s} = m_{\tilde{\chi}_1^0} + m_{\tilde{\chi}_2^0} + 30$ GeV in scenario A1. The longitudinal beam polarization for electrons (positrons) is denoted by $P_{e^-}$ ($P_{e^+}$). The white region is for $|P_{e^-}| \leq 85\%$, $|P_{e^+}| \leq 60\%$ (dashed line if only the electron beam is polarized).
a) Scenario A1, $e^+e^- \rightarrow \tilde{\chi}_1^0 \tilde{\chi}_1^0$

**Figure 4:** Contour lines of cross section $\sigma(e^+e^- \rightarrow \tilde{\chi}_1^0 \tilde{\chi}_1^0)$ in fb at $\sqrt{s} = (m_{\tilde{\chi}_1^0} + m_{\tilde{\chi}_2^0}) + 30$ GeV in scenario A1. The longitudinal beam polarization for electrons (positrons) is denoted by $P_{e^-}$ ($P_{e^+}$). The white region is for $|P_{e^-}| < 85\%$, $|P_{e^+}| < 60\%$ (dashed–line if only electron beam polarized).

$\sigma_{e}$/fb

Figure 5: Cross section $\sigma_e = \sigma(e^+e^- \rightarrow \tilde{\chi}_1^0 \tilde{\chi}_1^0) \times BR(\tilde{\chi}_1^- \rightarrow \tilde{\chi}_1^0 e^- \bar{\nu}_e)$ in fb at $\sqrt{s} = 2m_{\tilde{\chi}_1^\pm} + 10$ GeV as function of $m_{\tilde{\nu}_e}$ for unpolarized beams (00), only the electron beam polarized $P_3^- = -85\% (-0)$ and both beams polarized $P_3^- = -85\%$, $P_3^+ = +60\%$ (-+). Other parameters as in scenario A1.

b) Scenario A1, $e^+e^- \rightarrow \tilde{\chi}_2^0 \tilde{\chi}_2^0$
Figure 6: Contour lines of the forward–backward asymmetry of the decay electron $A_{FB}/%$ of $e^+e^- \rightarrow \tilde{\chi}_1^+ \tilde{\chi}_1^-$, $\tilde{\chi}_1^- \rightarrow \tilde{\chi}_0^0 e^- \bar{\nu}$ at a) $\sqrt{s} = 2m_{\tilde{\chi}_1^\pm} + 10$ GeV and b) $\sqrt{s} = 500$ GeV, as a function of $m_{\tilde{\ell}_L}$ and $m_{\tilde{\nu}}$ for $P_{e^-} = -85\%$, $P_{e^+} = +60\%$, the other parameters as in scenario A1. The light covered region is dominated by the two–body decay $\tilde{\chi}_1^- \rightarrow \tilde{\ell}_L \bar{\nu}_e$ or $\tilde{\chi}_1^- \rightarrow \bar{\nu}_e e^-$. Outside the red coloured region direct production of $\tilde{\ell}_L$ or $\tilde{\nu}_e$ is not possible, $\sqrt{s}/2 > m_{\tilde{\ell}_L}, m_{\tilde{\nu}_e}$. 
Figure 7: Contour lines of the forward–backward asymmetry of the decay electron $A_{FB}/\%$ of $e^+e^- \rightarrow \tilde{\chi}_1^0\tilde{\chi}_2^0 \rightarrow \tilde{\chi}_1^0 e^+e^-$ at $\sqrt{s} = (m_{\tilde{\chi}_1^0} + m_{\tilde{\chi}_2^0}) + 30$ GeV in scenario A1 as a function of a) $P_{e^-}$ and $P_{e^+}$, b) $m_{\tilde{\chi}_L}$ and $m_{\tilde{\chi}_R}$ for $P_{e^-} = -85\%$, $P_{e^+} = +60\%$, and c) $m_{\tilde{\chi}_L}$ and $m_{\tilde{\chi}_R}$ for $P_{e^-} = +85\%$, $P_{e^+} = +60\%$. The light covered region is dominated by the two–body decay $\tilde{\chi}_2^0 \rightarrow \tilde{\chi}_{L,R}^0 e^-$. Outside the red coloured region direct production of $\tilde{\chi}_L$ or $\tilde{\chi}_R$ is not possible, $\sqrt{s}/2 > m_{\tilde{\chi}_{L,R}}$. 

a) $m_{\tilde{\chi}_L} = 176$ GeV, $m_{\tilde{\chi}_R} = 132$ GeV

b) $P_{e^-} = -85\%$, $P_{e^+} = +60\%$

c) $P_{e^-} = +85\%$, $P_{e^+} = -60\%$
Figure 8: Cross sections $\sigma_e$ at $\sqrt{s} = m_{\tilde{\chi}_1^0} + m_{\tilde{\chi}_2^0} + 30$ GeV as function of gaugino parameter $M_1$ for unpolarized beams (00), for only electron beam polarized $(-0)$, $(+0)$ with $P_{e^-} = \pm 85\%$ and for both beams polarized $(-+)$, $(+-)$ with $P_{e^-} = \mp 85\%$, $P_{e^+} = \pm 60\%$. The slepton masses are a) $m_{\tilde{\ell}_L} = 176$ GeV, $m_{\tilde{\ell}_R} = 161$ GeV, and b) $m_{\tilde{\ell}_L} = 500$ GeV, $m_{\tilde{\ell}_R} = 161$ GeV; the other SUSY parameters as in scenario A1.

Figure 9: Forward–backward asymmetries $A_{FB}$ of the decay electron of $e^+e^- \rightarrow \chi_1^0\chi_2^0$, $\chi_1^0 \rightarrow \chi_1^0 e^+e^-$ at $\sqrt{s} = m_{\tilde{\chi}_1^0} + m_{\tilde{\chi}_2^0} + 30$ GeV, as a function of the gaugino parameter $M_1$ for a) $m_{\tilde{\ell}_L} = 176$ GeV, $m_{\tilde{\ell}_R} = 161$ GeV and b) $m_{\tilde{\ell}_L} = 500$ GeV, $m_{\tilde{\ell}_R} = 161$ GeV for unpolarized beams (00), only electron beam polarized $(-0)$, $(+0)$ and both beams polarized $(-+)$, $(+-)$; the other SUSY parameters as in scenario A1.
Figure 10: Polarization asymmetries $A_{pol}$, eq. (27), of $e^+e^- \rightarrow \tilde{\chi}_1^0\tilde{\chi}_2^0$, $\tilde{\chi}_1^0 \rightarrow \tilde{\chi}_1^0 e^+e^-$ at $\sqrt{s} = m_{\tilde{\chi}_1^0} + m_{\tilde{\chi}_2^0} + 30$ GeV as a function of the gaugino parameter $M_1$ for $m_{\tilde{e}_L} = 176$ GeV, $m_{\tilde{e}_R} = 161$ GeV (dark) and $m_{\tilde{e}_L} = 500$ GeV, $m_{\tilde{e}_R} = 161$ GeV (light); the other SUSY parameters as in scenario A1. $(-+), (+-)$ corresponds to $A_{pol} = (\sigma_{e^+} - \sigma_{e^-})/(\sigma_{e^+} + \sigma_{e^-})$ and analogously for the other curves.
