Recent developments in string compactifications demonstrate obstructions to the simplest constructions of low energy cosmologies with positive vacuum energy. The existence of obstacles to creating scale-separated de Sitter solutions indicates a UV/IR puzzle for embedding cosmological vacua in a unitary theory of quantum gravity. Motivated by this puzzle, we propose an embedding of positive energy Friedmann-Lemaître-Robertson-Walker cosmology within string theory. Our proposal involves confining 4D gravity on a brane which mediates the decay from a nonsupersymmetric five-dimensional anti–de Sitter false vacuum to a true vacuum. In this way, it is natural for a 4D observer to experience an effective positive cosmological constant coupled to matter and radiation, avoiding the need for scale separation or a fundamental de Sitter vacuum.

DOI: 10.1103/PhysRevLett.121.261301

Introduction.—Since the discovery of dark energy, string theory has been faced with the challenge of reproducing a small positive vacuum energy. The dominant approach has been the reliance on a landscape of different vacua [1] equipped with a transition mechanism such that the anthropic principle selects our vacuum [2]. This approach became calculable in string theory with the construction of KKLT [3], in which one can achieve a landscape of scale-separated vacua, with both positive and negative cosmological constant (CC), by tuning flux numbers. However, there has been a recent debate regarding the correct application of supersymmetry-breaking and nonperturbative effects necessary in the construction of the landscape [4–12]. While the issues are not yet settled, some authors suggest that not a single rigorous string vacuum has been constructed, and further speculate that string theory abhors de Sitter space and any solution with positive vacuum energy will suffer from instabilities.

Given this lively debate, it is reasonable to consider the possibility that neither metastability nor scale separation are achieved in string theory in the way envisioned. It seems, therefore, that something completely different may be needed. In order to construct an alternative, we will take motivation from work that received considerable attention around the turn of the millennium just before the idea of the string landscape from work that received considerable attention around the turn of the millennium just before the idea of the string landscape...
solution of the Einstein equations, the stress-energy tensor on the shell needs to source a jump in extrinsic curvature. This results in a constant tension of the shell à la Israel-Lanczos-Sen (Here we have suppressed world-volume fields that are constrained to the brane, which would appear on the right-hand side. We will comment on their contribution below.) [20–22],

$$\sigma = \frac{3}{8\pi G_5} \left( \sqrt{k_+^2 + \frac{1}{a^2} \frac{\dot{a}^2}{a^2} - \sqrt{k_-^2 + \frac{1}{a^2} \frac{\dot{a}^2}{a^2}}} \right),$$  \hspace{1cm} (1)$$

where the dot denotes the derivative with respect to $\tau$. In Fig. 1 we plot the induced CC as a function of the tension. In general, the resulting Friedmann equation will be nonlinear in the shell tension. However, when the 5D CC’s $k_\pm$ are large compared to the 4D Hubble parameter, the tension of the shell approaches (from below) the extremal tension which results in a flat shell

$$\sigma_{\text{ext}} = 3(k_- - k_+)/8\pi G_5.$$  \hspace{1cm} (2)$$

Expanding Eq. (1) in $\varepsilon = 1 - \sigma/\sigma_{\text{ext}}$ gives the usual Friedmann equation plus small corrections:

$$\frac{\dot{a}^2}{a^2} = -\frac{1}{a^2} + \frac{8\pi G_4}{3} \Lambda_4 + O(\varepsilon^2),$$  \hspace{1cm} (3)$$

with the identifications

$$G_4 = 2k_-k_+G_5/(k_- - k_+) \quad \text{and} \quad \Lambda_4 = \sigma_{\text{ext}} - \sigma.$$  \hspace{1cm} (4)$$

This shows that in order to have an expanding (dS) bubble, the tension needs to be subextremal, i.e., $\sigma < \sigma_{\text{ext}}$. The bubble nucleates with $\dot{a} = 0$ with its radius set by the 4D CC. As a consequence, the universe starts out with a size comparable to the horizon scale, with the subsequent expansion further reducing the curvature.

The presence of mass in the bulk modifies the AdS$_5$ metric via $f(r) = 1 + k_\pm^2 r^2 - 4G_5 m_\pm/(\pi r^2)$, where $m_{\pm(\pm)}$ is the mass measured inside (outside) the bubble. Through the space-space component of the junction condition, one sees that matter in the bulk contributes a radiation term to the Friedmann equation

$$\frac{\ddot{a}^2}{a^2} = -\frac{1}{a^2} + \frac{8\pi G_4}{3} \left[ \Lambda_4 + \frac{3}{4\pi^2} \left( \frac{m_+}{k_+} - \frac{m_-}{k_-} \right) \frac{1}{a^4} \right],$$  \hspace{1cm} (5)$$

where we drop terms higher order in $\varepsilon$ and $m_\pm/k_\pm$. The time-time component of the junction condition (i.e., the second Friedmann equation) can be combined with the first Friedmann equation to reproduce the 4D continuity equation on the shell. From this perspective we can identify the gravitational backreaction of bulk matter as the source of an effective energy density with a radiation equation of state on the shell.

Adding matter is a bit more subtle. As we have just seen, 5D matter confined to the shell yields a $1/a^4$ contribution to the Friedmann equation. The way to get a matter contribution that dilutes with volume $1/a^3$ is to construct massive particles as strings ending on the shell. The metric (Black hole geometries sourced by uniform distribution of strings have been discussed in literature. See Ref. [23] for such a construction in flat spacetime and Ref. [24] for an analogous construction in AdS in a different context.) is then given by $m_\pm(r) = 0$ for $r < a$ and $m_\pm(r) = \eta r$ for $r > a$, where $\eta$ is the effective tension of the strings. This gives an effective 4D matter with density $\rho = \eta/a^3 k_\pm$ on the shell. As the shell climbs up the throat it eats the strings and the massive particles represented by the end points are supplied with the required potential energy to keep a constant rest mass.

If all of these massive particles annihilate into massless radiation on the shell, by 5D energy conservation, $m_+$ just outside of the shell would be equal to the total mass of the strings that vanished. In addition, $m_-$, evaluated on the shell, will increase dramatically to represent the mass that was captured by the shell. The 4D observer only feels the difference $(m_+ - m_-)$, which will be determined through 4D energy conservation. In this way, all processes on the shell world will be like shadows of processes taking place in 5D involving much larger energies.

One might wonder about the stability of the universe on top of the shell. An obvious decay channel would be another bubble of true vacuum nucleating on top of the shell as was considered in Ref. [25]. However, this decay channel seems to be absent, giving a strong indication in favor of the stability of these bubbles. We intend to analyze the issue of stability in detail in an upcoming work [26].

Finally, we estimate the number of degrees of freedom on the shellworld centered in $\text{AdS-Schwarzschild}$ by considering how thermal equilibrium is established. For an $\text{AdS-Schwarzschild}$ metric outside the bubble with $m = m_+$, the effective temperature just outside the shell as measured by a distant observer, at $r \gg 1/k_\pm$, scales as $T_+^4 \sim m_+ k_+^2/r^4$. In the interior of the bubble, all mass is in the form of a black hole with mass $m_-$ (not necessarily equal to $m_+$) with temperature $T_-^4 \sim m_- k_-^2/r^4$. For the shell to be in equilibrium we need $T_+ = T_- = T$, leading to $m_- k_-^2 = m_+ k_+^2$. Since $k_- > k_+$, we find that $m_- < m_+$,
indicating that the black hole has lost some mass due to the presence of the shell. Using these conditions, the energy density for radiation on the shell at $a = r$ can be estimated as $p \sim (m - L_+ - m - L_-)/a^4 = (L_+^3 - L_-^3)T^4/a^4$, implying that the number of degrees of freedom is proportional to $L_+^3 - L_-^3$. (The same scaling behavior can also be derived using AdS/CFT from the Weyl anomaly of the holographically renormalized stress-energy tensor on the shell [27–30]).

Shellworld gravity.—We now turn our attention to local gravitational physics on the 4D shell. We will show that while the massless graviton propagates in five dimensions, it has a zero mode in its KK reduction that mediates an effective gravitational theory at low energy. Thus, while scattering at high momenta will probe the radial direction, low energy physics will appear 4D on the brane.

For simplicity, we consider a bubble at late times, when curvature is negligible, in the Poincaré patch, written in domain-wall coordinates: $dx^2 = \tilde{a}(z) \eta_{\mu\nu} dx^\mu dx^\nu + dz^2$, with $\tilde{a}(z) = \exp(zk_+)$. In RS-like constructions, $\tilde{a}(z)$ is chosen to be $\exp(zk_-)\exp(-zk_+)$ for $z < z_{RS}$ and $\exp(zk_-)$ for $z > z_{RS}$ so that the warp factor falls off exponentially on both sides of the brane. When expressed in terms of Poincaré coordinates, this yields a volcano-shaped effective potential for the graviton modes (see the central region of Fig. 2).

In contrast, our setup consists of an inside and an outside and therefore the warp factor increases towards the boundary. This results in a potential as shown in the unshaded region of Fig. 2. For such configurations, the zero mode of the graviton is not normalizable due to divergence at the boundary of AdS [31]. If we place a cutoff brane near the boundary, the non-normalizable mode causes both branes to bend [32]. This effect can be interpreted as localized sources induced on the branes by the bulk modes. We identify these sources as the end points of the strings stretched between the branes. The strings result in a relation between these two sources which ensures continuity of the zero mode across the branes. One example of this setup is depicted in Fig. 2 where a RS brane at $\tilde{a}(z) = \tilde{a}_{RS}$ plays the role of a cutoff brane. (In principle, the RS brane can be placed arbitrarily close to the boundary.) The RS brane has $\mathbb{Z}_2$ symmetry across it, which gives a mirror shell. Our shell nucleates at $\tilde{a}_b \ll \tilde{a}_{RS}$ and expands with time to approach the RS brane.

Consider fluctuations to the metric of the form $g_{\mu\nu} \mapsto g_{\mu\nu} + h_{\mu\nu}$, where $h_{\mu\nu}$ is transverse and traceless. The radial component of $h_{\mu\nu}$ obeys a Schrödinger like equation of the form $[-\partial_w^2/2 + V(w)]\psi(w) = (\omega^2 - p^2)\psi(w)$, where we have changed coordinates from domain wall coordinate $z$ to the Poincaré coordinate $w$. The potential $V(w)$ is plotted in Fig. 2.

The zero mode of momentum space graviton propagators, $\chi$, with 3-momentum $p$, satisfy the equation $(-p^2/\tilde{a}^2 + \partial_w^2 - 4k^2)\chi_p(z, w) = 0$, [33] which has solutions $\chi_p(z, w) = A(p)I_2[p/(k\tilde{a})] + B(p)K_2[p/(k\tilde{a})]$, where $I_2$ and $K_2$ are Bessel functions. Variation of the extrinsic curvature across the shell gives an additional boundary condition $\chi_p'(p, \tilde{a}_b) - \chi_p'(p, \tilde{a}_b) - (\sigma/3)\chi_p(p, \tilde{a}_b) = \Sigma_b$, where prime denotes derivative with respect to $\tilde{a}$ and $\Sigma_b$ is a source on the shell. The presence of stretched strings results in a $\chi(z, p)$ proportional to $K_2$ near the cutoff. This gives

$$\chi_b = \frac{\Sigma_b \tilde{a}_b^2}{p^2 + O(p/\tilde{a}_b k_+)^3}, \quad (6)$$

where $G_4 = (2k_+ k_-)/(k_+ - k_-)$ is the 4D Newton’s constant induced on the shell by the bulk geometry. Thus, we have reproduced the correct $1/p^2$ interaction for Newtonian gravity at small $p$, including the correct constant of proportionality $G_4$ (4), providing a consistency check for our scenario. The tensor $\Sigma_b$ appearing in Eq. (6) consists of two parts $\Sigma_b = \Sigma_{b}^{brane} + \Sigma_{b}^{str}$, where the first term $\Sigma_{b}^{brane} := T_{\mu\nu} - Tg_{\mu\nu}/3$ contains the contribution from the world-volume fields confined to the shell with induced metric $g_{\mu\nu}$. This term gives a negative contribution to Eq. (6) just as it does in the Friedmann equation.

The other piece, $\Sigma_{b}^{str}$, arises from the bending effect of the strings on the shell. Viewing the effect of mass as a localized deformation imparted by the endpoint of the stretched string, the contribution from strings is of the form $\Sigma_{b}^{str} \sim -(\alpha_+ / k_+ - \alpha_- / k_-)$, where $\alpha_\pm$ is the energy carried by the strings. This follows from consistency with the Friedmann equation when one identifies $\alpha_\pm$ with $m_\pm$. Therefore $\Sigma_{b}^{str}$, yields a positive contribution to $\chi_b$ in (6). The above arguments imply that not only are the strings important for the existence of a nonvanishing zero mode, but also to ensure a well-defined propagator realizing localized gravitational effects on the shellworld.

These string sources in the bulk give an effective 5D geometry outside the bubble that mimics the CHR construction [34]. Gravitational collapse of the string endpoints in four dimensions results in an unstable black string solution in five dimensions. This is the source of a long-standing problem in satisfactorily realizing black holes in a braneworld scenario [35]. However, the 5D uplift of black shells proposed in Refs. [36,37] avoid the instability by
construction and may provide a way to realize black hole solutions on the shellworld. This is currently being investigated [26].

Construction in string theory.—To realize this scenario in string theory, we propose the decay of the nonsupersymmetric Romans vacuum [38] to the supersymmetric AdS$_5 \times S^5$ vacuum via the nucleation of a spherical $(p,q)$-5 brane. Reducing this picture to five dimensions, where the $(p,q)$-5 brane is an $S^5$, will result in an instance of the EFT with gravitational interactions described in the previous section. The Romans vacuum is given by the reduction of type IIB over a 5D Sasaki-Einstein manifold seen as a U(1) fibration over a $\mathbb{CP}^3$ base, in close analogy with the constructions in Ref. [39]. The vacuum results from a nontrivial relative stretching of the fiber to the base and is supported by three-form flux. This solution has been identified with the SU(3) $\times$ U(1) invariant critical point of 5D supergravity [40,41].

While the consistent truncation to 5D supergravity is perturbatively stable at the SU(3) $\times$ U(1) critical point [42,43], it is still possible that there are tachyonic modes that have been truncated out [44]. Because of the lack of supersymmetry the instability is likely and has been taken as a foregone conclusion [45]. However, it is also possible that one may remove the offending tachyonic modes by taking an orbifold. The orbifold of the Romans vacuum will decay into AdS$_5 \times S^5/\mathbb{Z}_k$, which is in general not supersymmetric and has a bubble of nothing nonperturbative instability [46]. However, bubbles of nothing nucleating within the true vacuum must remain inside the lightcone describing the braneworld trajectory and will therefore not affect our scenario.

In addition to the self-dual five-form flux present in the supersymmetric vacuum, the Romans vacuum has nonzero three-form flux $G_3 = F_3 + \tau H_3$, which breaks all supersymmetry and leads to the squashing of the $S^5$. The 10D metric is given by the product AdS$_5 \times M_5$, where $M_5$ is a specific fibration over $\mathbb{CP}^2$.

$$ds^2_{10} = \frac{L_5^2}{\rho^2} ds^2_{\text{AdS}} + \frac{d\rho^2}{1 + \rho^2/L_5^2} + L_5^2 (\rho dS^2_{\mathbb{CP}^2} + \nu^{-4} e_5^2),$$

where $L_{\text{AdS}}$ ($L_5$) parametrizes the AdS (KK) scale, $\nu$ controls the relative fiber to base stretching, and $e_5$ is a one-form satisfying $de_5 = J$, where $J$ is the Kähler form for the unit $\mathbb{CP}^2$.

The axion $C_{(0)}$ is set to zero, while the other fluxes read

$$F_{(5)} = \alpha_5 (1 + \nu) \text{vol}_5,$$

$$G_{(3)} = \alpha_3 F_{(3)} + \beta_3 H_{(3)} = dK = L_5 e^{3i\phi} K \wedge e_5,$$

where $K$ is a holomorphic two-form on $\mathbb{CP}^2$ and $\phi$ is the fiber coordinate. Solving the 10D field equations yields

$\text{SUSY: } L_{\text{AdS}} = L_5, \quad \nu = 1, \quad \alpha_5 = \frac{4}{g_s L_5}$,

$\$\text{SUSY: } L_{\text{AdS}} = \frac{211/10}{33/5} L_5, \quad \nu = \left(\frac{2}{3}\right)^{1/5}, \quad \alpha_5 = \frac{108^{1/5}}{g_s L_5}, \quad \beta_3 = g_3 \alpha_3 = \frac{34/5}{23/10} \frac{1}{L_5}. \quad (8)$

For the sake of comparison we will measure the curvature in the two vacua in 5D Planck units: $M_{\text{Pl}}^3 = L_5^3 \pi^2/(g_s^2 \langle 2 \rangle^2 \alpha^4)$. Furthermore, we are interested in decay via nucleation of 5-branes, which remove $G_{(3)}$ but leave $F_{(5)}$ untouched. The flux quantization condition for $F_{(5)}$ reads

$$\int_{M_5} F_{(5)} = (4\pi^2 \alpha')^2 N_5 = \alpha_5 L_5^3 \pi^2.$$  

Thus, holding $N_5$ fixed and using Planck units we have,

$$L_{\text{AdS}} = \left(\frac{N_5}{\pi}\right)^{2/3} M_{\text{Pl}}^{-1} \times \left\{ \begin{array}{ll} \text{SUSY}, & \text{10 dimensions: } V_{\text{SUSY}} \leq 9^{23/3} \lesssim 1, \quad (10) \end{array} \right.$$ 

indicating that the supersymmetric vacuum lies below the nonsupersymmetric vacuum.

In order for a nonperturbative decay channel to exist, the $(p,q)$-5 brane in the theory that realizes the desired flux shift should have a tension $\sigma < \sigma_{\text{ext}}$. Using Eq. (10) we can compute $\sigma_{\text{ext}}$ from Eq. (2),

$$\sigma_{\text{ext}} = M_{\text{Pl}}^4 \left(\frac{\pi}{N_5}\right)^{2/3} (6 - \frac{9}{2^{7/6}}). \quad (11)$$

While the precise embedding of the 5-branes which mediate this decay depends on the orbifold needed to ensure perturbative stability and will be left to future work, we are able to demonstrate the existence of such a decay channel by using supergravity to obtain the tension of the requisite 5-brane. We use the superpotential and potential derived in [41](see also Refs. [42,47]):

$$W(\rho, \chi) = \frac{1}{4\rho^2} \left[ \cosh(2\chi)(\rho^6 - 2) - (3\rho^6 + 2) \right],$$

$$V(W) = g^2 \left[ \frac{1}{8} \left( \frac{\partial W}{\partial \rho} \right)^2 + \frac{1}{48} \rho \frac{\partial W}{\partial \rho} - \frac{1}{3} |W|^2 \right]. \quad (12)$$

The maximally supersymmetric critical point is at $\rho = 1, \chi = 0$, and the Romans vacuum is located at $\rho = 1, \chi_\ast = \text{arc cosh}(2)/2$. However, one immediately notices that the hierarchy of the vacua is reversed with respect to Eq. (10), i.e., $V_{\text{SU(5)}}/V_{\text{SUSY}} = 9/8 > 1$. This is because
moving in the $\chi$ direction corresponds to a deformation of the internal manifold that does not preserve $N_5$. However, since the superpotential is linear in the fluxes, rescaling the superpotential such that the hierarchy (10) is recovered will also amount to holding the five-form flux fixed. Thus, we should use the superpotential of Eq. (12) at the supersymmetric critical point, and $\tilde{W} = 2^{-2/3}W$ at the critical point corresponding to the Romans vacuum.

To deduce the tension of the fundamental $(p, q)5$-brane that can mediate our decay, we use the fact that there should be a BPS brane that sources the $G_{(3)}$ flux, the tension of which will be given by the junction condition for an extremal brane (2) where $k_+$ and $k_-$ are associated to $V_+ = -g^2 W^2(1, \chi_+) / 3$ and $V_- = -g^2 W^2(1, 0) / 3$. Again, because the superpotential is linear in flux, and we have rescaled $\tilde{W}$ such that the difference relative to $W$ is entirely due to the change in three-form flux, using the superpotential such that the hierarchy (10) is recovered will also amount to holding the five-form flux fixed. Thus, we should use the superpotential of Eq. (12) at the supersymmetric critical point, and $\tilde{W} = 2^{-2/3}W$ at the critical point corresponding to the Romans vacuum.

Finally, in order to compare the tension of the BPS brane to the extremal tension (11), we note that the gauge coupling is fixed to $g = 2/L^2_{\text{AdS}}$ so that the potential reproduces $L_{\text{AdS}} = (4\pi g N_3)^{1/4} \sqrt{\alpha}$ at the supersymmetric critical point where $V_- = -3/L^2_{\text{AdS}}$. Thus, we find

$$\sigma_{\text{BPS}} = 3M_{\text{Pl}}^2 \frac{\alpha}{3} \left( |W(1, 0)| - |\tilde{W}(1, \chi_+)| \right)$$

$$= M_{\text{Pl}}^4 \left( \frac{\pi}{N_5} \right)^{2/3} \left( 6 - \frac{7}{2^{2/3}} \right).$$  \hspace{1cm} (13)

Comparing with Eq. (11) one finds $\sigma_{\text{BPS}} < \sigma_{\text{ext}}$ so that the fundamental brane that sources the correct charge can also facilitate the decay via a spherical bubble with finite Euclidean action. (Presence of the decay channel in this toy model does not guarantee that $\sigma$ can be tuned to near-extreemal values resulting in small 4D CC and linearized Friedmann equation.) The rescaling of $W$ that moves the brane tension away from the BPS value can also be understood as accounting for the backreaction of the moduli corresponding to the deformation of the $S^5$ in the nonsupersymmetric vacuum, which is not a priori captured by 5D supergravity. Note that this is a nontrivial check which posed an obstacle to embedding the canonical RS scenario in string theory [48]. A stringy realization of the setup is sketched in Fig. 3. Further study of the precise brane embedding in the orbifolded geometry remains an interesting topic for future research.
