**Abstract**

The present investigations were carried out with a view to know the extent of heterobeltiosis and standard heterosis in cowpea (*Vigna unguiculata* (L.) Walp.). Thirty hybrids were developed by adopting full diallel mating design. A set of thirty eight cowpea entries including six parents (NCK-15-9, NCK-15-10, NC-15-41, NC-15-42, NC-15-44, NC-15-45) thirty crosses and two check varieties, GC-3 and GDVC-2 evaluated at three locations viz. Navsari, Mangrol and Achhalia using randomized block design with three replications during *Kharif*-2017. The observations were recorded on parents and F$_1$’s for fifteen quantitative traits and one quality traits viz. Days to 50 per cent flowering, plant height (cm), primary branches per plant, pods per plant, pod length (cm), seeds per pod, green seed weight (g), green pod yield per plant (g), straw yield per plant (g), shelling percentage (per cent) and protein content (per cent). Significant heterobeltiosis and standard heterosis over GC-3 and GDVC-2 were observed for green pod yield per plant and grain yield per plant. The cross NC-15-45 X NC-15-41, NCK-15-10 X NC-15-45, and NC-15-45 X NCK-15-10 recorded high heterotic values for green pod yield per plant and grain yield per plant along with high *per se* performance.

**Introduction**

Cowpea [*Vigna unguiculata* (L.) Walp.] is diploid crop with chromosome number of (2n=22), belongs to family Fabaceae, one of the oldest source of human food, in form of green pods as well as grains has most likely been used as a crop. It is native of West Africa (Vavilov, 1951) but Steele (1976) suggested Ethiopia as the primary and Africa as the secondary centre of diversity. Among all the pulses, cowpea locally known as lobiya, chowla (chowli), southern pea or black eye pea, is an annual legume that is adopted to warm condition and cultivated in the tropics and sub-tropics for dry grains, green edible pods for vegetable as well as fodder. Development of cultivars with early maturity, acceptable grain as well as vegetable quality, resistance to some important diseases and pests have significantly increased the yield and cultivated area. The overall effect of plant breeding on genetic diversity has been a long standing concern in the evolutionary biology
of crop plants (Simmonds, 1962). Self-pollinating crop like cowpea, variability is often created through hybridization between carefully chosen parents. The scope of exploitation of hybrid vigour will depend on the direction and magnitude of heterosis, biological feasibilities and the type of gene action involved. The information of such estimates is essential to plan efficient breeding programme for the improvement of crop. Although, the hybrid vigour cannot be exploited commercially in highly self-pollinated crop like cowpea, the heterotic F₁'s can be used to isolate a higher frequency of productive derivatives in their later generations.

Materials and Methods

Thirty hybrids were developed by adopting full diallel mating design. The experimental material for the present investigation consisted of 38 entries including six parents(NCK-15-9, NCK-15-10, NC-15-41, NC-15-42, NC-15-44, and NC-15-45) and resultant 30 crosses (full diallel) along with GC-3 and GDVC-2 as checks. The seeds of these entries were obtained from Pulse Research Station, Navsari Agricultural University, Navsari. These parents were selected carefully on the basis of earlier reports as well as the observations recorded at the centre. For obtaining hybrid seeds, these six parents were sown at Main Pulse Research Station, NAU, Navsari during summer 2017. All possible single crosses (including reciprocals) were made to complete the 6 x 6 full diallel set. Hand emasculation and pollination methods were adopted. All the hybrids and self-seeds of parents were stored properly in seed packets for sowing in the kharif season 2017-18. The observations were recorded on parents and F₁’s for fifteen quantitative traits and one quality traits viz. Days to 50 per cent flowering, plant height (cm), primary branches per plant, pods per plant, pod length (cm), seeds per pod, green seed weight (g), green pod yield per plant (g), shelling percentage (per cent) and protein content (per cent). Heterosis expressed as per cent increase or decrease in the mean value of F₁ hybrid over mid parent (heterosis), better parent (heterobeltiosis) and over standard check (standard heterosis) was calculated for various characters over environments following procedure given by Fonseca and Patterson (1968).

Results and Discussion

Heterosis is of direct relevance for developing hybrids in cross-pollinated as well as in self-pollinated crops. But, exploitation of heterosis in cowpea has limited application because of practical difficulties for emasculation, pollination of flowers, difficulties of seed set and hybrid seed production in sufficient quantity. However, magnitude of heterosis provides information on the extent of genetic diversity of parents involved in a cross and helps to choose the parents in developing superior F₁’s so as to exploit the hybrid vigour. The nature and magnitude of heterosis can help in identifying superior cross combinations and their exploitation to get better transgressive segregants (Arunachalam, 1976). The knowledge of heterosis would also help in elimination of poor crosses in early generation of testing itself. Heterosis is a function of number of loci at which the parents carry different alleles and the magnitude and direction of the non-additive effects within or between those loci in hybrid combinations (Jinks, 1953).

Heterobeltiosis and standard heterosis of some important characters over all the three location and pooled basis is depicted in table 1 to 4. The spectrum of variation in heterobeltiosis and standard heterosis for all the characters and the number of crosses depicting heterosis in desirable directions is presented in table 5 and top ten crosses as per higher heterosis and highest per se performance are depicted in table 6.
**Table.1** Extent of heterobeltiosis and standard heterosis in per cent for days to 50 per cent flowering in different environments and pooled over environments in cowpea

*Significant at 5 per cent level and **Significant at 1 per cent level

Where,

DF- Days to 50 per cent flowering; PH- Plant height; PB- Primary branches per plant; PPP- pods per plant, PL- Pod length; SPP- seeds per pod; GSW- Green seed weight; GPY- Green pod yield per plant; SP- Shelling percentage; PRT- Protein content.
The number of heterotic crosses varied from character to character and the direction and magnitude of heterosis also varied from cross to cross for all the characters. Considerably high heterosis in certain hybrids and low in others revealed that nature of gene action varied with the genetic architecture of the parents. The range of heterobeltiosis and standard heterosis for different characters revealed that high heterosis was observed for primary, pods per plant, seeds per plant, green pod yield per plant. Medium level of heterosis was observed for days to 50% flowering, plant height, pod length, green seed weight and protein content. While low amount of heterosis were recorded for shelling ratio. The high magnitude of standard heterosis for branches per plant, pod s per plant was also reported earlier by Patil et al., (2005), Pal et al., (2007), Patil and Gosavi, (2007), Sharma, et al.,(2010), Kajale and Ravindrababu, (2012), Patel et al., (2013) and Pethe et al., (2017).

A perusal of present study revealed that crosses NC-15-45 X NC-15-41, NCK-15-10 X NC-15-45, and NC-15-45 X NCK-15-10 are top three hybrids for green pod yield per plant and these crosses also showed significant desirable heterosis for protein content. Thus from the present study it can be conclude that most of the hybrids exhibiting significant heterosis for different traits over better parent / standard check. Parents NC-15-45,NCK-15-10 and NC-15-41 provide the basic materials for breeding programme for further improvement in yield and yield contributing traits in cowpea. The crosses NC-15-45 X NC-15-41, NCK-15-10 X NC-15-45, and NC-15-45 X NCK-15-10 exhibited significant standard heterosis and heterobeltiosis for green pod yield per plant and other yield contributing traits. Thus these crosses may offer for the selection of transgressive segregant for vegetable purpose cowpea in subsequent generation. Owing to self-pollinated nature of cowpea, heterosis breeding may not be rewarding like in the case of a cross pollinated crops.
