Abstract

The Douglas–Rachford algorithm is a classical and very successful splitting method for finding the zeros of the sums of monotone operators. When the underlying operators are normal cone operators, the algorithm solves a convex feasibility problem. In this paper, we provide a detailed study of the Douglas–Rachford iterates and the corresponding shadow sequence when the sets are affine subspaces that do not necessarily intersect. We prove strong convergence of the shadows to the nearest generalized solution. Our results extend recent work from the consistent to the inconsistent case. Various examples are provided to illustrate the results.

Keywords: Affine subspace, Attouch–Théra duality, Douglas–Rachford splitting operator, firmly nonexpansive mapping, fixed point, generalized solution, linear convergence, maximally monotone operator, normal cone operator, normal problem, projection operator.
1 Introduction

Throughout this paper \( X \) is a real Hilbert space, with inner product \( \langle \cdot, \cdot \rangle \) and induced norm \( \| \cdot \| \). A (possibly) set-valued operator \( A : X \rightrightarrows X \) is \textit{monotone} if any two pairs \((x, u)\) and \((y, v)\) in the graph of \( A \) satisfy \( \langle x - y, u - v \rangle \geq 0 \), and is \textit{maximally monotone} if it is monotone and any proper enlargement of the graph of \( A \) (in terms of set inclusion) destroys the monotonicity of \( A \). Monotone operators play an important role in modern optimization and nonlinear analysis; see, e.g., the books [5], [9], [10], [12], [25], [26], [28], [29], and [30].

Let \( A : X \rightrightarrows X \) be maximally monotone and let \( \text{Id} : X \rightarrow X \) be the identity operator. The \textit{resolvent} of \( A \) is \( J_A := (\text{Id} + A)^{-1} \) and the \textit{reflected resolvent} is \( R_A := 2J_A - \text{Id} \). It is well-known that \( J_A \) is single-valued, maximally monotone and firmly nonexpansive.

The sum problem for two maximally monotone operators \( A \) and \( B \) is to find \( x \in X \) such that \( 0 \in Ax + Bx \). When \((A + B)^{-1}(0) \neq \emptyset \) one approach to solve the problem is the Douglas–Rachford splitting technique. Recall that the Douglas–Rachford splitting operator [21] for the ordered pair of operators \((A, B)\) is defined by

\[
T_{(A, B)} := \frac{1}{2} (\text{Id} + R_B R_A) = \text{Id} - J_A + J_B R_A.
\]

Let \( x_0 \in X \). When \((A + B)^{-1}(0) \neq \emptyset \) the “governing sequence” \((T_{(A, B)}^n x_0)_{n \in \mathbb{N}}\) produced by the Douglas–Rachford operator converges weakly to a point in \( \text{Fix} T_{(A, B)} \) (see [21]) and the “shadow sequence” \((J_A T_{(A, B)}^n x_0)_{n \in \mathbb{N}}\) converges weakly to a point \( (A + B)^{-1}0 \). For further information on the Douglas–Rachford algorithm, we refer the reader to [17], [21], [27], and also [5].

When \( A := N_U \) and \( B := N_V \) where \( U \) and \( V \) are nonempty closed convex subsets of \( X \), the sum problem is equivalent to the convex feasibility problem: Find \( x \in U \cap V \). In this case, using [5] Example 23.4,

\[
T := T_{(N_U, N_V)} = \text{Id} - P_U + P_V R_{U},
\]

where \( R_U = 2P_U - \text{Id} \). In the inconsistent case, when \( U \cap V = \emptyset \), the governing sequence is proved to satisfy that \( \| T^n x \| \rightarrow +\infty \) and the shadow sequence \((P_U T^n x)_{n \in \mathbb{N}}\) remains bounded with the weak cluster points being the best approximation pairs relative to \( U \) and \( V \) provided they exist (see [6]).

---

1 Fix \( T = \{ x \in X \mid x = T x \} \) is the set of fixed points of \( T \).

2 Throughout the paper we use \( N_C \) and \( P_C \) to denote the \textit{normal cone} and \textit{projector} associated with a nonempty closed convex subset \( C \) of \( X \), respectively.
Unlike the method of alternating projections, which employs the operator $P_V P_U$, the Douglas–Rachford method is not fully understood in the inconsistent case. Nonetheless, the Douglas-Rachford operator is used in [8] to define the “normal problem” when the original problem is possibly inconsistent. In this case the set of best approximation solutions relative to $U$ (which are also known as the normal solutions, see [8]) is $U \cap (v + V)$, where $v = P_{\text{ran}(\text{Id} - T)} 0$. It is natural to ask what can we learn about the algorithm in the highlight of the new concept of the normal problem.

The goal of this paper is to study the case when $U$ and $V$ are closed affine subspaces that do not necessarily intersect. The Douglas–Rachford method for two closed affine subspaces has recently shown to be very useful in many applications, for instance, the nonconvex sparse affine feasibility problem (see [18] and [19]) and basis pursuit problem (see [14]). Our results show that the shadow sequence will always converge strongly to a best approximation solution in $U \cap (v + V)$ and therefore we generalize the main results in [3]. This is remarkable because we do not have to have prior knowledge about the gap vector $v$; the shadow sequence is simply $(P_{U} T^n x_0)_{n \in \mathbb{N}}$. Our proofs critically rely on the well-developed results in the consistent case in [3] and the structure of the normal problem studied in [8].

We are now ready to briefly summarize our main results:

**R1** We compare the sequences $((-v) T^n x)_{n \in \mathbb{N}}$, $(T^n x - v)_{n \in \mathbb{N}}$ and $(T^n x + n v)_{n \in \mathbb{N}}$ when $T$ is an affine nonexpansive operator and $v := P_{\text{ran}(\text{Id} - T)} 0 \in \text{ran}(\text{Id} - T)$. We prove that the three sequences coincide (see Theorem 3.2). Surprisingly, when we drop the assumption of $T$ being affine, the sequences can be dramatically different (see Example 3.3).

**R2** We prove the strong convergence of the shadow sequence $(P_{U} T^n x_0)_{n \in \mathbb{N}}$ when $U$ and $V$ are affine subspaces that do not have to intersect (see Theorem 4.4). We identify the limit to be the best approximation solution; moreover, the rate of convergence is linear when $U + V$ is closed.

**R3** In view of **R2** it is tempting to conjecture that the shadow sequence $(J_A T^n x_0)_{n \in \mathbb{N}}$ in the inconsistent case (i.e., when $(A + B)^{-1} = \emptyset$) converges in a more general setting. We illustrate the somewhat surprising fact that if $A$ and $B$ are affine — but not normal cone — operators (see Example 4.8), the sequence $(J_A T^n x_0)_{n \in \mathbb{N}}$ can be unbounded. In fact, we can have $\|J_A T^n x_0\| \to +\infty$ even though the sum problem

---

3Let $w \in X$. We define the inner shift and outer shift of an operator $T$ by $w$ at $x \in X$ by $T_w x := T(x - w)$ and $wT x := -w + Tx$, respectively.
4Recall that $T$ is nonexpansive if $(\forall x \in X)(\forall y \in X) \| Tx - Ty \| \leq \| x - y \|.$
5In highlight of Fact 2.2 the vector $v$ is unique and well-defined.
has normal solutions\textsuperscript{5}. This illustrates that normal cone operators have additional structure that makes $\mathbb{R}^2$ possible.

Organization

The remainder of this paper is organized as follows. Section\textsuperscript{2} contains a collection of new results concerning nonexpansive and firmly nonexpansive operators whose fixed point sets could possibly be empty. Section\textsuperscript{3} focuses on affine nonexpansive operators and their corresponding inner and outer “normal” shifts. Various examples that illustrate our theory are provided. Section\textsuperscript{4} is devoted to present the main results. We prove strong convergence of the shadows of the Douglas-Rachford iterates of two (not necessarily intersecting) affine subspaces.

Notation

Let $C$ be a nonempty closed convex subset of $X$. The recession cone of $C$ is $\text{rec } C := \{x \in X \mid x + C \subseteq C\}$, the polar cone of $C$ is $C^\circ := \{u \in X \mid \sup \langle C, U \rangle \leq 0\}$ and the dual cone of $C$ is $C^{\circ\circ} = -C^\circ$. When $C$ is an affine subspace the linear space parallel to $C$ is $\text{par } C = C - C$. Otherwise, the notation we utilize is standard and follows, e.g., \textsuperscript{5} and \textsuperscript{24}.

2 Nonexpansive and firmly nonexpansive operators

In this section, we collect various results on (firmly) nonexpansive operators that will be useful later. Let $w \in X$. Recall that for a single-valued or set-valued operator $T$ we define the inner shift and outer shift by $w$ at $x \in X$ by

\begin{equation}
T_w x := T(x - w) \quad \text{and} \quad wT x := -w + Tx,
\end{equation}

respectively.

Lemma 2.1. Let $T : X \to X$ and let $w \in X$. Then the following hold:

(i) $\text{Fix}(T - w) = -w + \text{Fix}(w + T) = -w + \text{Fix}(-wT)$.

(ii) $w \in \text{ran}(\text{Id} - T) \iff \text{Fix}(w + T) \neq \emptyset \iff \text{Fix}(T - w) \neq \emptyset$.

\textsuperscript{6}The normal solutions are the counterpart of the best approximation solutions in the context of the normal problem \textsuperscript{8} when the operators are not normal cone operators (see Section\textsuperscript{4} for details).

\textsuperscript{5}The normal solutions are the counterpart of the best approximation solutions in the context of the normal problem \textsuperscript{8} when the operators are not normal cone operators (see Section\textsuperscript{4} for details).
(iii) \((\forall x \in X)(\forall n \in \mathbb{N}) \quad (T_nw)x = -w + (w + T)^nx + w) = -w + (-wT)^nx + w\).

Proof. (i): Let \(x \in X\). Then \(x \in \text{Fix}(T_nw) \iff x = T(x + w) \iff x + w = w + T(x + w) \iff x + w \in \text{Fix}(w + T) \iff x \in -w + \text{Fix}(w + T)\).

(ii) \(w \in \text{ran}(\text{Id} - T) \iff (\exists x \in X) \text{ such that } w = x - Tx \iff (\exists x \in X) \text{ such that } x = w + Tx \iff \text{Fix}(w + T) \neq \emptyset\). Now combine with (i).

(iii) We proceed by induction. The conclusion is clear when \(n = 0\). Now assume that for some \(n \in \mathbb{N}\) it holds that \((T_nw)x = -w + (w + T)^nx + w\). Then \((T_{n+1}w)x = T((T_nw)x + w) = T(-w + (w + T)^nx + w + w) = -w + w + T((w + T)^nx + w) = -w + (w + T)^{n+1}(x + w)\), as claimed. ■

We recall the following important fact.

**Fact 2.2 (Infimal displacement vector).** (See, e.g., [2], [11] and [22].) Let \(T : X \to X\) be nonexpansive. Then \(\text{ran}(\text{Id} - T)\) is convex; consequently, the infimal displacement vector

\[(4) \quad v := \text{P}_{\text{ran}(\text{Id} - T)}0\]

is the unique and well-defined element in \(\text{ran}(\text{Id} - T)\) such that \(\|v\| = \inf_{x \in X}\|x - Tx\|\).

Unless stated otherwise, throughout this paper we assume that

\[(5) \quad T \text{ is a nonexpansive operator on } X,\]

and that

\[(6) \quad v := \text{P}_{\text{ran}(\text{Id} - T)}0 \in \text{ran}(\text{Id} - T).\]

In view of (6) and Lemma 2.1(ii) we have

\[(7) \quad \text{Fix}(T_v) \neq \emptyset \quad \text{and} \quad \text{Fix}(v + T) \neq \emptyset.\]

We start with the following useful result.

**Lemma 2.3.** Let \(C\) be a nonempty closed convex subset of \(X\) and let \(c \in C\) satisfies that \(\|c\| = \|c\|_{\text{P}_C0}\). Then \(c = \text{P}_C0\).

**Proof.** See Appendix A. ■

**Proposition 2.4.** Let \(y_0 \in \text{Fix}(v + T)\). Then the following hold:

(i) \(y_0 - \mathbb{R}_+ v \subseteq \text{Fix}(v + T)\).
(ii) \( \text{Fix}(v + T) - \mathbb{R}_+ v = \text{Fix}(v + T) \).

(iii) \(-\mathbb{R}_+ v \subseteq \text{rec}(\text{Fix}(v + T)) \).

(iv) \((\forall n \in \mathbb{N}) \ T^n y_0 = y_0 - n v \).

(v) \([-\infty, 1] \cdot v + \text{Fix} T_{-v} \subseteq \text{Fix}(v + T) \). In particular it holds that \( \text{Fix}(T_{-v}) \subseteq \text{Fix}(v + T) \).

(vi) For every \( x \in X \), the sequence \((T^n x + n v)_{n \in \mathbb{N}} \) is Féjer monotone with respect to both \( \text{Fix}(v + T) \) and \( \text{Fix}(T_{-v}) \).

(vii) Suppose that \( x_0 \in \text{Fix} T_{-v} \) and set \((\forall n \in \mathbb{N}) x_n = T^n x_0 \). Then \( x_n = x_0 - n v \) and \((x_n)_{n \in \mathbb{N}} \) lies in \( \text{Fix}(T_{-v}) \).

**Proof.** (i) First we use induction to show that

\[(8) \quad (\forall n \in \mathbb{N}) \quad y_0 - n v \in \text{Fix}(v + T).\]

Clearly when \( n = 0 \) the base case holds true. Now suppose that for some \( n \in \mathbb{N} \) it holds that \( y_0 - n v \in \text{Fix}(v + T) \), i.e.,

\[(9) \quad y_0 - n v = v + T(y_0 - n v).\]

Using (6) and (9) we have

\[
\|v\| \leq \|(\text{Id} - T)(y_0 - (n + 1) v)\| = \|y_0 - (n + 1) v - T(y_0 - (n + 1) v)\|
\]

\[
= \|y_0 - n v - v - T(y_0 - (n + 1) v)\| = \|T(y_0 - n v) - T(y_0 - (n + 1) v)\| \leq \|v\|.
\]

Consequently all the inequalities above are equalities and we conclude that \( \|v\| = \|y_0 - (n + 1) v - T(y_0 - (n + 1) v)\| \). It follows from (6) and Lemma 2.3 that

\[(10) \quad y_0 - (n + 1) v - T(y_0 - (n + 1) v) = v.\]

That is, \( y_0 - (n + 1) v = v + T(y_0 - (n + 1) v) \), which proves (8). Now using [5 Corollary 4.15] we learn that \( \text{Fix}(v + T) \) is convex, which when combined with (8) yields (i).

(ii) On the one hand it follows from (i) that \( \text{Fix}(v + T) - \mathbb{R}_+ v \subseteq \text{Fix}(v + T) \). On the other hand \( \text{Fix}(v + T) = \text{Fix}(v + T) - 0 \cdot v \subseteq \text{Fix}(v + T) - \mathbb{R}_+ v \).

(iii) This follows directly from (ii).

(iv) We use induction. Clearly \( y_0 - 0 v = y_0 = T^0 y_0 \). Now suppose that for some \( n \in \mathbb{N} \) it holds \( T^n y_0 = y_0 - n v \). Using (i) we have \( T^{n+1} y_0 = T(y_0 - n v) = -v + y_0 - n v = y_0 - (n + 1) v \).
\(\text{(v)}\) Using Lemma 2.1(i) and (i) we have \(-\infty, 1]\cdot v + \operatorname{Fix} T_{-v} = v - \mathbb{R}_{+} v + \operatorname{Fix} T_{-v} = \operatorname{Fix}(v + T) - \mathbb{R}_{+} v = \operatorname{Fix}(v + T)\). In particular we have \(\operatorname{Fix} T_{-v} = 0 \cdot v + \operatorname{Fix} T_{-v} \subseteq \operatorname{Fix}(v + T)\).

\(\text{(vi)}\) Let \(x \in X\) and let \(y \in \operatorname{Fix}(v + T)\). Then using (iv) we have for every \(n \in \mathbb{N}\),

\[
\|T^{n+1}x + (n + 1) v - y\| = \|T^{n+1}x - (y - (n + 1) v)\| = \|T^{n+1}x - T^n y\| \leq \|T^n x - T^n y\| = \|T^n x - (y - n v)\| = \|T^n x + n v - y\|.
\]

The statement for \(\operatorname{Fix} T_{-v}\) follows from (v).

\(\text{(vii)}\) Combine (v) and (iv) to get that \(x_n = x_0 - n v\). Now by Lemma 2.1(i) \(x_0 + v \in \operatorname{Fix}(v + T)\). Using (i) we have \((\forall n \in \mathbb{N}) x_0 + v - n v \in \operatorname{Fix}(v + T)\) or equivalently by Lemma 2.1(i) \(x_0 - n v \in -v + \operatorname{Fix}(v + T) = \operatorname{Fix}(T_{-v})\). \(\blacksquare\)

The next example is readily verified.

**Example 2.5.** Let \(C\) be a nonempty closed convex subset of \(X\) and suppose that \(T = \operatorname{Id} - P_C\). Then \(T\) is firmly nonexpansive and \(v = P_C 0\). Let \(x \in X\). Then \(x \in \operatorname{Fix}(v + T) \iff P_Cx = v\), while \(x \in \operatorname{Fix} T_{-v} \iff P_C(x + v) = v\).

**Proposition 2.6.** Suppose that \(X = \mathbb{R}\), and that \(\operatorname{Fix} T = \emptyset\). Let \(x \in \mathbb{R}\) and set \((\forall n \in \mathbb{N}) y_n = T^n x + n v\). Then the following hold:

(i) \((y_n)_{n \in \mathbb{N}}\) converges.

(ii) \(\mathbb{R} \to \mathbb{R} : x \mapsto \lim_{n \to \infty} (T^n x + n v)\) is nonexpansive.

(iii) Suppose that \(T\) is firmly nonexpansive. Then \(\mathbb{R} \to \mathbb{R} : x \mapsto \lim_{n \to \infty} (T^n x + n v)\) is firmly nonexpansive.

**Proof.** (i) In view of Proposition 2.4(vi) the sequence \((y_n)_{n \in \mathbb{N}}\) is Féjer monotone with respect to \(\operatorname{Fix}(v + T)\). Now by Proposition 2.4(i) we know that \(\operatorname{Fix}(v + T)\) contains an unbounded interval. Since \(X = \mathbb{R}\) we conclude that \(\operatorname{int} \operatorname{Fix}(v + T) \neq \emptyset\). It follows from [5, Proposition 5.10] that \((y_n)_{n \in \mathbb{N}}\) converges.

(ii) Let \(y \in \mathbb{R}\). Then

\[
\lim_{n \to \infty} (T^n x + n v) - \lim_{n \to \infty} (T^n y + n v) = \lim_{n \to \infty} (T^n x + n v - T^n y - n v)
\]

\[
(11) \quad = \lim_{n \to \infty} |T^n x - T^n y| \leq \lim_{n \to \infty} |x - y| = |x - y|.
\]

\(\text{Recall that } T : X \to X \text{ is firmly nonexpansive if } (\forall x \in X)(\forall y \in X) \quad \|Tx - Ty\|^2 + \|(\operatorname{Id} - T)x - (\operatorname{Id} - T)y\|^2 \leq \|x - y\|^2.\)
It follows from [5] Proposition 4.2(iv) that an operator is firmly nonexpansive if and only if it is nonexpansive and monotone. Therefore, in view of (ii), we need to check monotonicity. Without loss of generality let \( y \in \mathbb{R} \) such that \( x \leq y \). Since \( T \) is firmly nonexpansive, hence monotone, one can verify that \((\forall n \in \mathbb{N}) \ T^n x \leq T^n y \) and therefore \((\forall n \in \mathbb{N}) \ T^n x + n v \leq T^n y + n v \). Now take the limit as \( n \to \infty \). ■

When \( X = \mathbb{R} \), it follows from Proposition 2.6(i) that the sequence \((T^n x + n v)_{n \in \mathbb{N}}\) converges. In view of Proposition 2.4(vi) the sequence \((T^n x + n v)_{n \in \mathbb{N}}\) is Féjer monotone with respect to \( \text{Fix}(v + T) \) which might suggest that the limit lies in \( \text{Fix}(v + T) \). We show in the following example that this is not true in general.

**Example 2.7.** Suppose that \( X = \mathbb{R} \) and that

\[
T : \mathbb{R} \to \mathbb{R} : x \mapsto \begin{cases} 
  x - \alpha, & \text{if } x \leq \alpha; \\
  0, & \text{if } \alpha < x \leq \beta; \\
  x - \beta, & \text{if } x > \beta,
\end{cases}
\]

where \( 0 < \alpha < \beta \). Then \( T \) is firmly nonexpansive but not affine, \( v = \alpha \), \( \text{Fix}(v + T) = [-\infty, \alpha] \), \( \text{Fix} T^{-} v = [-\infty, 0] \), and

\[
T^n + n v : \mathbb{R} \to \mathbb{R} : x \mapsto \begin{cases} 
  x, & \text{if } x \leq \alpha; \\
  \alpha, & \text{if } \alpha < x \leq \beta; \\
  x - n(\beta - \alpha), & \text{if } x > \beta \text{ and } n \leq \lfloor x/\beta \rfloor; \\
  \min \{ \alpha, x - \lfloor x/\beta \rfloor \beta \} + \alpha \lfloor x/\beta \rfloor, & \text{if } x > \beta \text{ and } n > \lfloor x/\beta \rfloor.
\end{cases}
\]

Consequently,

\[
\lim_{n \to \infty} (T^n + n v) : \mathbb{R} \to \mathbb{R} : x \mapsto \begin{cases} 
  x, & \text{if } x \leq \alpha; \\
  \alpha, & \text{if } \alpha < x \leq \beta; \\
  \min \{ \alpha, x - \lfloor x/\beta \rfloor \beta \} + \alpha \lfloor x/\beta \rfloor, & \text{if } x > \beta.
\end{cases}
\]

Therefore for every \( x_0 \in \mathbb{R} \) the sequence \((T^n x_0 + n v)_{n \in \mathbb{N}}\) is eventually constant. However, if the starting point \( x_0 \) lies in the interval \( \beta, \infty \), then \( \lim_{n \to \infty} T^n x_0 + n v = \min \{ \alpha, x - \lfloor x/\beta \rfloor \beta \} + \alpha \lfloor x/\beta \rfloor \notin \text{Fix}(v + T) \).

**Proof.** See Appendix B ■

### 3 Affine nonexpansive operators

In this section, we investigate properties of affine nonexpansive operators. This additional assumption allows for stronger results than those obtained in the previous section. We
recall the following fact.

Fact 3.1. (See \[5, Proposition 3.17\].) Let \( S \) be a nonempty subset of \( X \), and let \( y \in X \). Then
\[
(\forall x \in X) \quad P_{y+S}x = y + P_S(x - y).
\]

Theorem 3.2. Let \( L: X \to X \) be linear and nonexpansive, let \( b \in X \), and suppose that \( T: X \to X \): \( x \mapsto Lx + b \). Suppose also that \( v \in \text{ran}(\text{Id} - T) \), and let \( x \in X \). Then the following hold:

(i) \( v = P_{\text{Fix}\ L}(-b) \in \text{Fix}\ L = (\text{ran}(\text{Id} - L))^\perp \), and \( v \neq 0 \iff b \not\in \text{ran}(\text{Id} - L) \).

(ii) \( (\forall n \in \mathbb{N}) \quad T^n x = L^n x + \sum_{k=0}^{n-1} L^k b. \)

(iii) \( (\forall n \in \mathbb{N}) \quad T^n x + n v = L^n x + \sum_{k=0}^{n-1} L^k P_{\text{ran}(\text{Id} - L)} b. \)

(iv) \( (\forall n \in \mathbb{N}) \quad (T - v)^n x = T^n x + n v. \)

(v) \( (\forall n \in \mathbb{N}) \quad (T - v)^n x = (v + T)^n x. \)

(vi) \( \text{Fix } T - v = -v + \text{Fix } T - v = -v + \text{Fix}(v + T) = \text{Fix}(v + T). \)

(vii) \( \text{Fix}(T - v) = \text{Fix}(v + T) = \mathbb{R}v + \text{Fix}(v + T) = \mathbb{R}v + \text{Fix}(T - v). \) Consequently \( v \) lies in the lineality space\(^8\) of \( \text{Fix}(T - v) = \text{Fix}(v + T) \).

Proof. (i) Note that \( \text{ran}(\text{Id} - T) = \text{ran}(\text{Id} - L) - b \) and hence \( \text{ran}(\text{Id} - T) = \text{ran}(\text{Id} - L) - b \). Therefore, using Fact 3.1 we have \( v = P_{\text{ran}(\text{Id} - T)} 0 = P_{-b + \text{ran}(\text{Id} - L)} 0 = -b + P_{\text{ran}(\text{Id} - L)} (0 - (-b)) = -b + P_{\text{ran}(\text{Id} - L)} b. \) Using [5, Fact 2.18(iv)] and [2, Lemma 2.1], we learn that \( \text{ran}(\text{Id} - L)^\perp = \ker(\text{Id} - L^*) = \text{Fix } L^* = \text{Fix } L \), and hence
\[
v = (\text{Id} - P_{\text{ran}(\text{Id} - L)})(-b) = P_{(\text{ran}(\text{Id} - L))^\perp}(-b) = P_{\text{Fix } L}(-b).
\]

Note that \( v \neq 0 \iff b \not\in \text{ran}(\text{Id} - L) \).

(ii) We prove this by induction. When \( n = 0 \) the conclusion is obviously true. Now suppose that for some \( n \in \mathbb{N} \) it holds that
\[
T^n x = L^n x + \sum_{k=0}^{n-1} L^k b.
\]

Then \( T^{n+1} x = T(T^n x) = T(L^n x + \sum_{k=0}^{n-1} L^k b) = L(L^n x + \sum_{k=0}^{n-1} L^k b) + b = L^{n+1} x + \sum_{k=0}^{n} L^k b \), as claimed.

\[\text{---}\]

\(^8\)For the definition and a detailed discussion of the lineality space, we refer the reader to [23, page 65].
(iii) Note that \( b = P_{\text{ran}(\text{Id} - L)} b + P_{\text{Fix} L} b \). Using (i) and (ii) yields

\[
T^n x + n v = L^n x + \sum_{k=0}^{n-1} (L^k b + v) = L^n x + \sum_{k=0}^{n-1} (L^k b + L^k v)
\]

\[
= L^n x + \sum_{k=0}^{n-1} (L^k b - L^k P_{\text{Fix} L} b) = L^n x + \sum_{k=0}^{n-1} L^k (\text{Id} - P_{\text{Fix} L}) b
\]

\[
= L^n x + \sum_{k=0}^{n-1} L^k P_{\text{ran}(\text{Id} - L)} b.
\]

(iv) We prove this by induction. Note that by (i) \( v \in \text{Fix} L \), hence \( L v = v \). When \( n = 0 \) we have \((T_- v)^0 x = x = T^0 x + 0 \cdot v\). Now suppose that for some \( n \in \mathbb{N} \) it holds that \((T_- v)^n x = T^n x + n v\). Then \((T_- v)^{n+1} x = T_- v(T^n x + n v) = T(T^n x + n v + v) = L(T^n x) + L((n+1) v) + b = T^{n+1} x + (n+1) v\).

(v) We use induction again. The base case is obviously true. Now suppose that for some \( n \in \mathbb{N} \) it holds that \((v + T)^n x = T^n x + n v\). Then \((v + T)^{n+1} x = v + T(v + T)^n x = v + T(T^n x + n v) = v + L(T^n x + n v) + b = v + LT^n x + n v + b = LT^n x + b + (n + 1) v = T^{n+1} x + (n + 1) v\). Now combine with (iv).

(vi) Using (v) with \( n = 1 \) we have \(T_\cdot v = v + T\). Now apply Lemma 2.1 (i).

(vii) Using (vi) and the assumption that \( T \) is an affine operator, we have \( \text{Fix}(T_- v) = \text{Fix}(v + T) \) is an affine subspace. Now let \( y_0 \in \text{Fix}(T_- v) = \text{Fix}(v + T) \). Using Proposition 2.4 (i) we have \(-\mathbb{R}_+ v \subseteq \text{Fix}(v + T) - y_0 = \text{par Fix}(v + T) \) and therefore \( \mathbb{R} v \subseteq \text{par Fix}(v + T) \). Hence \( y_0 + \mathbb{R} v \subseteq \text{Fix}(v + T) \) which yields \( \text{Fix}(v + T) + \mathbb{R} v \subseteq \text{Fix}(v + T) \). Since the opposite inclusion is obviously true we conclude that (vii) holds.

Suppose \( T \) is nonexpansive but not affine. Theorem 3.2 might suggest that, for every \( x \in X \), the sequences \((T^n x + n v)_{n \in \mathbb{N}}, (T_- v x)_{n \in \mathbb{N}}\), and \((v + T)^n x)_{n \in \mathbb{N}}\) coincide, and consequently \((T^n x + n v)_{n \in \mathbb{N}}\) is a sequence of iterates of a nonexpansive operator. Interestingly, this is not the case as we illustrate now.

**Example 3.3.** Suppose that \( X = \mathbb{R} \) and let \( \beta > 0 \). Suppose that

\[
T : \mathbb{R} \to \mathbb{R} : x \mapsto \begin{cases} x - \beta, & x \leq \beta; \\ \alpha (x - \beta), & x > \beta, \end{cases}
\]

where \( 0 < \alpha < 1 \). Then \( \text{Fix} T = \emptyset \), \( v = \beta \), for every \( n \in \mathbb{N} \)

\[
(T_- v)^n : \mathbb{R} \to \mathbb{R} : x \mapsto \alpha^n \max \{x, 0\} + \min \{x, 0\},
\]

\[
(v + T)^n : \mathbb{R} \to \mathbb{R} : x \mapsto \alpha^n \max \{x - \beta, 0\} + \min \{x, \beta\},
\]

10
and

\[
T^n + n v : \mathbb{R} \to \mathbb{R} : x \mapsto \begin{cases} 
  x, & \text{if } x \leq \beta; \\
  \alpha^n x - \left(\frac{\alpha(1-\alpha^n)}{1-\alpha}\right) \beta + n \beta, & \text{if } x > \beta, n < q(x); \\
  \alpha q(x) x - \left(\frac{\alpha(1-\alpha q(x))}{1-\alpha}\right) \beta + q(x) \beta, & \text{if } x > \beta, n \geq q(x), 
\end{cases}
\]

where \( q(x) : \mathbb{R} \to \mathbb{N} : x \mapsto \left\lceil \log_\alpha \frac{\beta}{\alpha \beta + (1-\alpha) x} \right\rceil \). Consequently,

\[
(\forall x \in \mathbb{R}) \quad \lim_{n \to \infty} (T - v)^n x = \min \{x, 0\},
\]

\[
(\forall x \in \mathbb{R}) \quad \lim_{n \to \infty} (v + T)^n x = \min \{x, \beta\},
\]

and

\[
(\forall x \in \mathbb{R}) \quad \lim_{n \to \infty} (T^n x + n v) = \begin{cases} 
  x, & \text{if } x \leq \beta; \\
  \alpha q(x) x - \left(\frac{\alpha(1-\alpha q(x))}{1-\alpha}\right) \beta + q(x) \beta, & \text{if } x > \beta.
\end{cases}
\]

Moreover, there is no operator \( S : \mathbb{R} \to \mathbb{R} \) such that for every \( x \in \mathbb{R} \) and for every \( n \in \mathbb{N} \) we have \( S^n x = T^n x + n v \).

**Proof.** See Appendix C.

---

**Figure 1:** The solid curve represents \( \lim_{n \to \infty} (T - v)^n x \), the dashed dotted curve represents \( \lim_{n \to \infty} (v + T)^n x \), and the dashed curve represents \( \lim_{n \to \infty} T^n x + n v \), when \( \alpha = 0.5 \) and \( \beta = 1 \).
Figure 1 provides a plot of the functions defined by (22), (23) and (24) that illustrates that they are pairwise distinct.

4 The Douglas–Rachford operator for two affine subspaces

Unless otherwise stated we assume from now on that

\[ A \text{ and } B \text{ are maximally monotone operators on } X. \]

The Attouch–Théra dual pair of \((A, B)\) (see [1]) is the pair \((A, B)^* := (A^{-1}, B^{-\ominus})\), where

\[
A^{\ominus} := (-\text{Id}) \circ A \circ (-\text{Id}) \quad \text{and} \quad A^{-\ominus} := (A^{-1})^\ominus = (A^\ominus)^{-1}.
\]

We shall use

\[
Z := Z_{(A, B)} = (A + B)^{-1}(0) \quad \text{and} \quad K := K_{(A, B)} = (A^{-1} + B^{-\ominus})^{-1}(0),
\]

to denote the primal and dual solutions respectively (see e.g. [4]).

The normal problem associated with the ordered pair \((A, B)\) (see [8]) is to find \(x \in X\) such that

\[
0 \in vAx + Bv x = Ax - v + B(x - v),
\]

where

\[
v = P_{\text{ran}(\text{Id} - T)}^v,
\]

and \(T = T_{(A, B)}\) is defined by [1]. We recall (see [13, Lemma 2.6(iii)] and [4, Corollary 4.9]) that

\[
Z = J_A(\text{Fix } T) \quad \text{and} \quad K = (\text{Id} - J_A)(\text{Fix } T),
\]

and that \(T\) is self-dual (see [16, Lemma 3.6 on page 133] and [4, Corollary 4.3]), i.e.,

\[
T_{(A, B)} = T_{(A, B)^*} = T_{(A^{-1}, B^{-\ominus})}.
\]

The normal pair associated with the ordered pair \((A, B)\) is the pair \((vA, Bv)\) and the normal Douglas-Rachford operator is \(T_{(vA, Bv)}\). Using [8, Proposition 2.24] we have

\[
T_{(vA, Bv)} = T_{-v}.
\]

The set of normal solutions is \(Z_v := Z_{(vA, Bv)}\) and the set of dual normal solutions is \(K_v := K_{(vA, Bv)}\).
Lemma 4.1. The following hold:

(i) \( Z_v = J_{vA}(\text{Fix}(T-v)) = J_{-(v+A)}(\text{Fix}(T-v)) = J_{A}(\text{Fix}(T-v) + v) = J_{A}(\text{Fix}(v + T)). \)

(ii) \( K_v = (\text{Id} - J_{vA})(\text{Fix}(T-v)) = (\text{Id} - J_{-(v+A)})(\text{Fix}(T-v)). \)

(iii) \( K_v \neq \emptyset \iff Z_v \neq \emptyset \iff v \in \text{ran}(\text{Id} - T). \)

Proof. (i) Apply (29) to the normal pair \((vA, B_v)\) and use (31) and (3). Now apply [5, Proposition 23.15(ii)]. The last equality follows from Lemma 2.1(i). (ii) Apply (29) to the normal pair \((vA, B_v)\) then use (31) and [5, Proposition 23.15(iii)]. (iii) The first equivalence follows from applying [4, Proposition 2.4(v)] to the normal pair \((vA, B_v)\). Now combine Lemma 2.1(ii) and (i). □

In the following we assume that

(32) \( v = P_{\text{ran}(\text{Id} - T)}0 \in \text{ran}(\text{Id} - T), \)

that

(33) \( U \) and \( V \) are nonempty closed convex subsets of \( X \)

and that

(34) \( A = N_U \) and \( B = N_V. \)

Using [5 Example 23.4], (1) becomes

(35) \( T_{U,V} := T_{(N_U, N_V)} = \text{Id} - P_U + P_V R_U, \)

where \( R_U = 2P_U - \text{Id}. \) In this case (see [8 Proposition 3.16])

(36) \( v = P_{U-v}0, \)

or equivalently

(37) \( -v \in N_{U-v}(v). \)

The normal problem now is to find \( x \in X \) such that

(38) \( 0 \in N_U x - v + N_V(x - v). \)

Lemma 4.2. Let \( w \in X. \) Then the following hold:
(i) \( I_{-w + N_U} = I_{N_U}(\cdot + w) = P_U(\cdot + w) \).

(ii) \( I_{N_U}(\cdot - w) = w + J_{N_U}(\cdot - w) = w + P_U(\cdot - w) \).

(iii) \( N_V(\cdot - w) = N_{w + V} \).

(iv) Suppose that \( U \) is an affine subspace and that \( w \in (\text{par } U)^\perp \). Then \( \forall \alpha \in \mathbb{R} \) \( \forall x \in X \) \( P_U(x + \alpha w) = P_U x \).

Proof. [i] and [ii] See [5] Proposition 23.15(ii) and (iii) and Example 23.4]. [iii] One can easily verify that \( (\forall w \in X) \) we have \( i_V(\cdot - w) = i_{w + V} \). Therefore \( N_V(\cdot - w) = \partial_i V(\cdot - w) = \partial_{i_{w + V}} = N_{w + V} \). [iv] Let \( a \in U \). Then \( U = a + \text{par } U \). Using Fact 3.1 we have \( (\forall a \in \mathbb{R}) (\forall x \in X) \) \( P_U(x + a w) = P_{a + \text{par } U}(x + a w) = a + P_{\text{par } U} x = a + P_{\text{par } U}(x - a) + a P_{\text{par } U} w = a + P_{\text{par } U}(x - a) = P_{a + \text{par } U} x = P_U x \).

Proposition 4.3. Suppose that \( U \) and \( V \) are closed affine subspaces of \( X \) and that \( T = T_{U, V} \). Then the following hold:

(i) \( T \) is affine and \( T = \text{Id} - P_U - P_V + 2P_V P_U \).

(ii) \( v \in (\text{par } U)^\perp \cap (\text{par } V)^\perp \).

(iii) \( (\forall x \in X) (\forall \alpha \in \mathbb{R}) \) \( P_U x = P_U(x + \alpha v) \).

(iv) \( (\forall x \in X) (\forall \alpha \in \mathbb{R}) \) \( P_V x = P_V(x + \alpha v) \).

(v) \( T_{-v} = v + T = T_{N_U, N_V(-v)} = T_{U, V} \).

(vi) \( Z_V = U \cap (v + V) \).

(vii) \( K_V = (\text{par } U)^\perp \cap (\text{par } V)^\perp \).

(viii) Fix(\( T_{-v} \)) = Fix(v + T) = Z_V + K_V = (U \cap (v + V)) + ((\text{par } U)^\perp \cap (\text{par } V)^\perp).

Proof. [i] Note that \( I_A = P_U \) and \( I_B = P_V \) are affine (see e.g. [5] Corollary 3.20(ii)]). Using (35) we have \( T = \text{Id} - P_U + P_V (2P_U - \text{Id}) = \text{Id} - P_U + 2P_V P_U - P_V \). Since the class of affine operators is closed under addition, subtraction and composition we deduce that \( T \) is affine.

(ii) It follows from [6] Proposition 2.7 & Remark 2.8(ii)] that \( v \in (\text{rec } U)^\perp \cap (\text{rec } V)^\perp = (\text{par } U)^\perp \cap (\text{par } V)^\perp \), where the last equality follows from [5] Proposition 6.22 and Proposition 6.23(v)].

(iii) and (iv) Combine (ii) with Lemma 4.2(iv).
It follows from (iv) with $\alpha$ replaced by $-1$, and Lemma 4.2(ii) that $f_{N_V(-v)} = v + P_V(-v) = v + P_V$. Consequently, using Theorem 3.2(v) and (i) we have $T_{-v} = v + T = \text{Id} - P_U + v + P_V R_U = T_{N_{U,v}(-v)}$. Finally, Lemma 4.2(iii) implies that $T_{N_{U,v}(-v)} = T_{N_{U,v} + v} = T_{U,v} + T$. Consequently, using Theorem 3.2(v) and (1) we have

$$T_{-v} = v + T = \text{Id} - P_U + v + P_V R_U = T_{N_{U,v}(-v)}.$$  

Finally, Lemma 4.2(iii) implies that $T_{N_{U,v}(-v)} = T_{N_{U,v} + v} = T_{U,v} + T$.

(vi) See [8, Proposition 3.16].

(vii) Let $z \in U \cap (v + V) = Z_v$ and note that, as subdifferential operators, $N_U$ and $N_V$ are paramonotone (see, e.g., [20]) and so are the translated operators $-v + N_U$ and $N_V(-v)$. Therefore, in view of [4, Remark 5.4] and (ii) we have

$$K_v = (-v + N_U z) \cap (-N_V (z - v)) = (-v + (\text{par } U)') \cap (\text{par } V)'$$

(39)

(viii) Since $-v + N_U$ and $N_V(-v)$ are paramonotone, it follows from (v), (vii) and [4, Corollary 5.5] applied to the normal pair $(v, A, B_v)$ that $\text{Fix}(T_{-v}) = \text{Fix}(v + T) = Z_v + K_v$. Now combine with (vi) and (vii).

We are now ready for our main result. It illustrates that, even in the inconsistent case, the “shadow sequence” $(P_U T^n x)_{n \in \mathbb{N}}$ behaves extremely well because it converges to a normal solution without prior knowledge of the infimal displacement vector. The proof of Theorem 4.4 relies on the work leading up to this point as well as the convergence analysis of the consistent case in [3].

**Theorem 4.4 (Douglas-Rachford algorithm for two affine subspaces).** Let $x \in X$. Then $(\forall n \in \mathbb{N})$ we have

$$P_U T^n x = P_U(T^n x + n v) = P_U((T_{-v})^n x) = P_U T^n_{U,v + v} = J_{-v + N_U}((T_{-v})^n x),$$

and

$$P_U T^n x \to P_{Z_v} x = P_{U \cap (v + V)} x.$$  

Moreover, if $\text{par } U + \text{par } V$ is closed (as is always the case when $X$ is finite-dimensional) then the convergence is linear with rate being the cosine of the Friedrichs angle

$$c_F(\text{par } U, \text{par } V) := \sup_{\substack{u \in \text{par } U \cap W^\perp \cap \text{ball}(0;1) \\ v \in \text{par } V \cap W^\perp \cap \text{ball}(0;1)}} |\langle u, v \rangle| < 1,$$

(42)

where $W = \text{par } U \cap \text{par } V$ and $\text{ball}(0;1)$ is the closed unit ball.

---

9Recall that $x_n \to x$ linearly with rate $\gamma \in [0,1]$ if $(\gamma^{-n} \| x_n - x \|)_{n \in \mathbb{N}}$ is bounded.
Proof. Let $n \in \mathbb{N}$. Using 4.3(iii) with $(x, \alpha)$ replaced by $(T^n x, n)$ we learn that $P_U T^n x = P_U(T^n x + n v)$. Now combine with Theorem 3.2(iv) to get the second identity. The third identity follows from applying Proposition 4.3(v). Finally note that using the first identity, 4.3(iii) with $(x, \alpha)$ replaced by $((-v)^n x, 1)$ and Lemma 4.2(ii) we learn that $P_U T^n x = P_U((-v)^n x + v) = J_{-v + \text{ran}(T)}((-v)^n x)$. Now we prove (41). It follows from (32), Lemma 4.1(iii) and Proposition 4.3(vi) that $Z_v = U \cap (v+V) \neq \emptyset$. Now apply [3, Corollary 4.5].

Figure 2: Two nonintersecting affine subspaces $U$ (blue line) and $V$ (purple line) in $\mathbb{R}^3$. Shown are also the first few iterates of $(T^n x_0)_{n \in \mathbb{N}}$ (green points) and $(P_U T^n x_0)_{n \in \mathbb{N}}$ (red points).

Figure 2 shows a Geogebra snapshot [15] of the Douglas–Rachford iterates and its shadows for two nonintersecting nonparallel lines $U$ and $V$ in $\mathbb{R}^3$.

The following result is known (see e.g., [11, Corollary 1.5] and [2, Corollary 2.3]). We include a simple proof for completeness in Appendix D.

**Proposition 4.5.** Suppose that $T : X \to X$ be firmly nonexpansive, and that $v = P_{\text{ran}(\text{Id} - T)} 0 \in \text{ran}(\text{Id} - T)$. Then

\[(\forall x \in X) \quad T^n x - T^{n+1} x \to v.\]
Proposition 4.6 (When only one set is an affine subspace). Suppose that $U$ is an affine subspace of $X$, and that $T = T_{U,V}$. Then for every $x \in S$ we know that for every $x \in S$ then $P_{U}T^{n+1}x \to 0$.

Proof. Using [6, Remark 2.8(ii)] we have $v \in (\text{par } U)^{\perp}$. It follows from Lemma 4.2(iv) applied with $(x, a)$ replaced by $(T^{n+1}x, 1)$ and Proposition 4.5 that

$$\|P_{U}T^{n}x - P_{U}T^{n+1}x\| = \|P_{U}T^{n}x - P_{U}(T^{n+1}x + v)\| \leq \|T^{n}x - T^{n+1}x - v\| \to 0,$$

as claimed.

Example 4.7. (The dual shadows) Consider the case when $U$ and $V$ are affine subspaces of $X$ such that $U \cap V = \emptyset$. Set $\tilde{A} := N_{U}^{-1}$ and $\tilde{B} := N_{V}^{-\perp}$. Then $\tilde{A}^{-1} = N_{U}$, $\tilde{B}^{-\perp} = N_{V}$, and using (30) we have $T_{(\tilde{A}, \tilde{B})} = T_{(\tilde{A}^{-1}, \tilde{B}^{-\perp})} = T_{U,V}$. Moreover the inverse resolvent identity (see, e.g., [24, Lemma 12.14]) implies that $(\forall x \in X) J_{\tilde{A}}T^{n}x = (\text{Id} - P_{U})T^{n}x = T^{n}x - P_{U}T^{n}x$. Note that $K = U \cap V = \emptyset$, hence by (29) and (30) Fix $T_{(\tilde{A}, \tilde{B})} = \emptyset$. Using [22, Corollary 6(a)] we learn that for every $x \in X$ we have $\|T^{n}x\| \to \infty$. Moreover, in view of (32), using [6, Theorem 3.13(iii)] we know that for every $x \in X$ we have $(P_{U}T^{n}x)_{n \in \mathbb{N}}$ is a bounded sequence. Therefore, $\|J_{\tilde{A}}T^{n}x\| = \|T^{n}x - P_{U}T^{n}x\| \geq \|T^{n}x\| - \|P_{U}T^{n}x\| \to \infty$.

We conclude with the following example which shows that for two affine (but not normal cone) operators the shadows need not converge.

Example 4.8. Suppose that $X = \mathbb{R}^{2}$ and let $S : \mathbb{R}^{2} \to \mathbb{R}^{2} : (x_{1}, x_{2}) \mapsto (-x_{2}, x_{1})$, be the counter-clockwise rotator by $\pi/2$. Let $b \in \mathbb{R}^{2} \setminus \{(0,0)\}$. Suppose that $A := S$ and set $B := -S + b$. Then $\text{zer } A \neq \emptyset$, $\text{zer } B \neq \emptyset$ yet $\text{zer } (A + B) = \emptyset$. Moreover, $v = (\text{Id} + S)(b)$, the set of normal solutions $Z_{v} = \mathbb{R}^{2}$ and for every $x \in \mathbb{R}^{2}$ we have $\|J_{A}T^{n}x\| \to \infty$.

Proof. Let $x \in \mathbb{R}^{2}$ and note that $S$ and $-S$ are both linear, continuous, single-valued, monotone and $S^{2} = (-S)^{2} = -\text{Id}$. It follows from [8, Proposition 2.10] that $J_{A}x = J_{S}x = \frac{1}{2}(\text{Id} - S)x = \frac{1}{2}(x - Sx)$. Similarly using [5, Proposition 23.15(ii)] we can see that $J_{B}x = \frac{1}{2}(x - b + Sx - Sb)$. Therefore we have $R_{A}x = -Sx$ and $R_{B}x = -b + Sx - Sb$. Hence $R_{B}R_{A}x = S(-Sx) - Sb - b = -S^{2}x - Sb - b = x - Sb - b = x - (\text{Id} + S)b$. Consequently we have

$$\forall x \in \mathbb{R}^{2} \quad T^{n}x = \frac{1}{2}(\text{Id} + R_{B}R_{A})x = x - \frac{1}{2}(\text{Id} + S)b.$$

It follows from (45) that $\text{ran } (\text{Id} - T) = \{\frac{1}{2}(\text{Id} + S)b\}$, hence $v = \frac{1}{2}(\text{Id} + S)b$ and $T^{n}x \to -v$. Therefore, using Theorem 3.2(v) $\text{Fix } (v + T) = \text{Fix } (T_{-v}) = \mathbb{R}^{2}$. Moreover, using (29) and (31) applied to the normal pair $(\alpha A, \beta v)$ we learn that $Z_{v} = J_{A}(\text{Fix } (T_{-v})) = \mathbb{R}^{2}$. In view of Proposition 2.4(iii) we have $T^{n}x = x - n v$. Hence, using that $J_{A}$ is linear, we get $J_{A}T^{n}x = J_{A}(x - n v) = J_{A}x - nJ_{A}v$. Now $J_{A}v = \frac{1}{2}(\text{Id} - S)(\frac{1}{2}(\text{Id} + S)b) = \frac{1}{2}b \neq (0,0)$, which completes the proof.

Appendix A

Proof of Lemma 2.3. Using that $P_C$ is firmly nonexpansive we have

$$
\|c - P_C0\|^2 = \|P_Cc - P_C0\|^2 \leq \|c - 0\|^2 - \|(\text{Id} - P_C)c - (\text{Id} - P_C)0\|^2 = \|c\|^2 - \|c - P_Cc + P_C0\|^2 = \|c\|^2 - \|P_C0\|^2 = 0.
$$

\[
\square
\]

Appendix B

Proof of Example 2.7. Clearly

$$
(46) \quad \text{Id} - T = P_{[\alpha, \beta]} : \mathbb{R} \to \mathbb{R} : x \mapsto \begin{cases}
\alpha, & \text{if } x \leq \alpha; \\
(1 - n)\beta, & \text{if } \alpha < x \leq \beta; \\
x - n\beta, & \text{if } x > \beta.
\end{cases}
$$

Therefore, ran(\text{Id} - T) = [\alpha, \beta], and consequently $v = \alpha$. Moreover

$$
(47) \quad (\forall x \in \mathbb{R}) \quad x \geq Tx + \alpha \geq T^2x + 2\alpha \geq \cdots \geq T^nx + n\alpha \geq \cdots.
$$

It is clear from Example 2.5 that

$$
(48) \quad \text{Fix}(v + T) = [\beta - \infty, \alpha].
$$

The statement for Fix $T_{-v}$ then follows from combining (48) and Lemma 2.1(i). The convergence of the sequence follows from Example 2.5 or Proposition 2.6(i). Now we prove (13). We claim that

$$
(49) \quad T^n : \mathbb{R} \to \mathbb{R} : x \mapsto \begin{cases}
x - n\alpha, & \text{if } x \leq \alpha; \\
(1 - n)\alpha, & \text{if } \alpha < x \leq \beta; \\
x - n\beta, & \text{if } x > \beta \text{ and } n \leq \lfloor x/\beta \rfloor; \\
\min \{\alpha, x - \lfloor x/\beta \rfloor \beta \} + (\lfloor x/\beta \rfloor - n)\alpha, & \text{if } x > \beta \text{ and } n > \lfloor x/\beta \rfloor.
\end{cases}
$$

Using induction it is easy to verify the cases when $x \leq \alpha$ and when $\alpha < x \leq \beta$. Now we focus on the case when $x > \beta$. Set

$$
(50) \quad K := \lfloor x/\beta \rfloor \text{ and } r := x - K\beta,
$$

[30] E. Zeidler, *Nonlinear Functional Analysis and Its Applications I: Fixed Point Theorems*, Springer-Verlag, 1993.
and note that $x = K\beta + r$, $K \in \{1, 2, 3, \ldots\}$ and $0 \leq r < \beta$. In view of (47), if $n \in \{0, 1, 2, 3, \ldots, K\}$ we get $T^n x = x - n\beta = (K-n)\beta + r$. In particular,

$$T^K x = x - \lfloor x/\beta \rfloor \beta = r. \quad (51)$$

If $n > K$ we examine two cases. Case 1: $0 \leq r \leq \alpha$. It follows from (51) and (12) that $(\forall n \geq K) T^n x = r + (K-n)\alpha$. Case 2: $\alpha < r < \beta$. Note that $T^{K+1} x = 0$, therefore using (51) and (12) we have $(\forall n > K) T^n x = (K+1-n)\alpha = \alpha + (K-n)\alpha$, which proves (49).

Now (13) follows from (49) because $v = \alpha$. Letting $n \to \infty$ in (13) yields (14). Note that $\min\{\alpha, x - \lfloor \frac{x}{\beta} \rfloor \beta\} \geq 0$ and $\lfloor \frac{x}{\beta} \rfloor \geq 1$. By considering cases ($K = 1$ and $K \geq 1$), (14) implies that $\lim_{n \to \infty} (T^n x_0 + n \nu) = \min\{\alpha, x - \lfloor \frac{x}{\beta} \rfloor \beta\} + \lfloor \frac{x}{\beta} \rfloor \alpha > \alpha \not\in [-\infty, \alpha] = \text{Fix}(\nu+1)$.

\section*{Appendix C}

\textbf{Proof of Example 3.3} Considering cases, we easily check that

$$\text{Id} - T : \mathbb{R} \to \mathbb{R} : x \mapsto (1 - \alpha) \max \{x, \beta\} + \alpha \beta \geq \beta > 0. \quad (52)$$

Hence $\text{Fix} T = \emptyset$ and $\nu = \beta$ as claimed. Moreover, using (52) one can verify that

$$(\forall x \in X) \quad x \geq T x + \beta > \cdots > T^n x + n\beta \geq T^{n+1} x + (n+1)\beta \geq \cdots. \quad (53)$$

We also verify that

$$(\forall x \in \mathbb{R}) \quad T_{-\nu} : \mathbb{R} \to \mathbb{R} : x \mapsto \max \{x, 0\} \alpha + \min \{x, 0\}. \quad (54)$$

We now prove (19) by induction. Let $x \in \mathbb{R}$.

Clearly when $n = 0$ the base case holds true. Now suppose that for some $n \in \mathbb{N}$ (19) holds. If $x \leq 0$ then $(T_{-\nu})^n x = x \leq 0$, and therefore, (54) implies that $(T_{-\nu})^{n+1} x = T_{-\nu}((T_{-\nu})^n x) = T_{-\nu}x = x$. Similarly we have $x > 0 \Rightarrow \alpha^n x = (T_{-\nu})^n x > 0$, and consequently (54) implies that $(T_{-\nu})^{n+1} x = T_{-\nu}((T_{-\nu})^n x) = T_{-\nu}(\alpha^n x) = \alpha^{n+1} x$. The proof of (20) follows from combining (19) and Lemma 2.1(iii). Now we turn to (21). We consider two cases.

Case 1: $x \leq \beta$. It is obvious using the definition of $T$ that $(\forall n \in \mathbb{N}) T^n x = x - n\beta$.

Case 2: $x > \beta$. Let $n \in \mathbb{N}$ be such that $T^n x > \beta$. By (53) and (18) we have

$$T^{n+1} x = \alpha^{n+1} x - (\alpha^{n+1} + \alpha^n + \cdots + \alpha) \beta = \alpha^{n+1} x - \frac{\alpha(1 - \alpha^{n+1})}{1 - \alpha} \beta$$
\[
(55) \quad = \alpha^{n+1} \left( \frac{(1-\alpha)x + \alpha\beta}{1-\alpha} \right) - \frac{\alpha}{1-\alpha}\beta.
\]

In view of (53) there exists a unique integer, say, \(q(x)\) \(\in\{1,2,\ldots\}\) that satisfies \(T^{q(x)-1}x > \beta\) and \(T^{q(x)}x \leq \beta\). Since \(0 < \alpha < 1\), using (55) we have

\[
T^{q(x)}x \leq \beta \iff \alpha^{q(x)} \left( \frac{(1-\alpha)x + \alpha\beta}{1-\alpha} \right) \leq \frac{\beta}{1-\alpha} \iff \alpha^{q(x)} \left( (1-\alpha)x + \alpha\beta \right) \leq \beta
\]

Consequently, \(q(x) = \left\lfloor \log_{\alpha} \frac{\beta}{\alpha\beta + (1-\alpha)x} \right\rfloor\). At this point, since \(T^{q(x)}x \leq \beta\), we must have

\[(\forall n \geq q(x)) \quad T^n x = T^{q(x)} x - (n - q(x))\beta,\]

which proves (21). The formulae (22), (23) and (24) are direct consequences of (19), (20) and (21), respectively. To prove the last claim note that if \(S : \mathbb{R} \rightarrow \mathbb{R}\) is such that for every \(n \in \mathbb{N}\) we have \(S^n = T^n + n\beta\), then setting \(n = 1\) must yield

\[
(56) \quad S = \beta + T : \mathbb{R} \rightarrow \mathbb{R} : x \mapsto \begin{cases} x, & x \leq \beta; \\ \alpha (x-\beta) + \beta, & x > \beta. \end{cases}
\]

Now compare (20) and (21).

**Appendix D**

**Proof of Proposition 4.5** Let \(y_0 \in \text{Fix}(\beta + T)\) and note that Proposition 2.4(iv) implies that \((\forall n \in \mathbb{N}) \quad (\text{Id} - T)T^n y_0 = \beta\). Since \(T\) is firmly nonexpansive, it follows from Proposition 2.4(vi) and [5, Proposition 5.4(ii)] that

\[
\|T^n x - T^{n+1} x - \beta\|^2 = \| (\text{Id} - T)T^n x - (\text{Id} - T)T^n y_0 \|^2 \\
\leq \|T^n x - T^n y_0\|^2 - \|T^{n+1} x - T^{n+1} y_0\|^2 \\
= \|T^n x + n\beta - y_0\|^2 - \|T^{n+1} x + (n+1)\beta - y_0\|^2 \rightarrow 0.
\]
