Abstract

This work presents some results about Wick polynomials of a vector field renormalization in locally covariant algebraic quantum field theory in curved spacetime. General vector fields are pictured as sections of natural vector bundles over globally hyperbolic spacetimes and quantized through the known functorial machinery in terms of local $\ast$-algebras. These quantized fields may be defined on spacetimes with given classical background fields, also sections of natural vector bundles, in addition to the Lorentzian metric. The mass and the coupling constants are in particular viewed as background fields. Wick powers of the quantized vector field are axiomatically defined imposing in particular local covariance, scaling properties and smooth dependence on smooth perturbation of the background fields. A general classification theorem is established for finite renormalization terms (or counterterms) arising when comparing different solutions satisfying the defining axioms of Wick powers. The result is specialized to the case of general tensor fields. In particular, the case of a vector Klein-Gordon field and the case of a scalar field renormalized together with its derivatives are discussed as examples. In each case, a more precise statement about the structure of the counterterms is proved. The finite renormalization terms turn out to be finite-order polynomials tensorially and locally constructed with the backgrounds fields and their covariant derivatives whose coefficients are locally smooth functions of polynomial scalar invariants constructed from the so-called marginal subset of the background fields. The notion of local smooth dependence on polynomial scalar invariants is made precise in the text.

Our main technical tools are based on the Peetre-Slovák theorem characterizing differential operators and on the classification of smooth invariants on representations of reductive Lie groups.

1 Introduction

This work is a continuation of the work started in the previous article [KM16] by the first and last author. While we have aimed the current article to be self-contained, the reader may be referred to the previous article for the details of some proofs.

1.1 Wick polynomials

Wick polynomials and time-ordered products of Wick polynomial are the building blocks for perturbative renormalization of quantum fields, both in Minkowski spacetime and in curved spacetime, where the metric is considered as a given external classical field. Although of utmost physical relevance, e.g., the stress-energy tensor is a Wick polynomial and it plays a most important part in semiclassical quantum gravity (see [HP15, Sec.6.3] for some cosmological applications), these formal operators do not belong to the algebra of observables generated by the smoothly smeared field operators (operator-valued distributions). This is because they correspond to products of distributions at a given point and this notion is not well-defined in general. As an elementary example for the Klein-Gordon scalar field operator \( φ(x) \) on a spacetime \((M, g)\) viewed as formal integral kernel of a field operator represented on a Fock Hilbert space smeared with smooth compactly supported functions \( f \), namely \( φ(f) := \int_M φ(x)f(x)\sqrt{\det g} \, dx \), the simplest Wick power is a suitable interpretation of \( φ^2(x) = φ(x)φ(x) \). It stands for the integral kernel \( φ^2(f) = \int_M φ^2(x)f(x)\sqrt{\det g} \, dx \). However this interpretation is very difficult to support. For example, any naive attempt to define it (with \( \langle \cdot | \cdot \rangle \) the Fock inner product and \( Ψ \) any state in the appropriate domain) as the limit for \( n \to \infty \) of

\[
\int_{M×M} \langle Ψ|φ(x)φ(y)Ψ⟩f(x)δ_n(x,y)\sqrt{|\det g(x)|}\sqrt{|\det g(y)|} \, dy \, dx,
\]

where \( δ_n(x,y) \to δ(x,y) \) as \( n \to ∞ \), gives rise to divergences for any physically meaningful state \( Ψ \), such as the Fock vacuum in Minkowski spacetime. The popular and perhaps most effective procedure to eliminate the short-distance divergences consists of simply keep a regulated smearing function \( δ_n(x,y) \) and simply subtracting a suitable divergent function of \( n \) as \( n \to ∞ \), that is the regulator is removed. A much more elegant procedure (see [KM15] for a recent introductory account) consists of first restricting ourselves to a suitable class of physical states (Hadamard states). For any Hadamard state \( Φ \), the singularity structure of (more precisely the wavefront set of) \( \langle Φ|φ(x)φ(y)Φ⟩ \) is under sufficient control so that we can find a distribution \( G(x, y) \) that is independent of \( Φ \) (as long as it remains Hadamard) such that the difference \( \langle Φ|φ(x)φ(y)Φ⟩ - G(x, y) \) is regular enough to be smeared with some distributions and \( f(x)δ(x,y) \) in particular, with a test function \( f(x) \). Thus, we could formally define the Wick square by \( φ^2(x) := \lim_{n→∞} φ(x)φ(y) - G(x, y)1 \), and so on for higher Wick powers (this is known as the Hadamard parametrix regularization method [HW01, HW02, BF00]). In any case, even such a procedure do not lead to a unique definition. The constructed Wick powers (or also more generally time ordered products of Wick powers) may be still affected by (finite) ambiguities, popularly called finite-renormalization terms (or counterterms). Within the divergence subtraction paradigm their nature is obvious: depending on how the regularization is carried out, \( ∞ - ∞ \) could be any number.

A given Wick product \( φ^n(x) \), interpreted as a distributional kernel evaluated at \( x \), can always be be redefined by adding similar counterterms of lower order multiplied with coefficients depending on \( x \): \( φ^n(x) = \sum_{k<n} C_k(x)φ^k(x) \). The structure of these coefficients \( C_k \) can be fixed by imposing some further physical constraints.

A definite difference exists between flat and curved spacetime renormalization procedures defining Wick polynomials (we will not discuss time ordered products in this work). In Minkowski spacetime, Wick polynomials (though not time ordered products Wick polynomials) are completely fixed by the so called normal-ordering prescription which is feasible because there exist a unique Poincaré invariant reference state and all the manipulations are in fact performed in the Fock-Hilbert space, relying upon that vacuum state. The normal-ordering prescription is able to simultaneously get rid of ultraviolet divergences and fix all remaining finite renormalization ambiguities of Wick polynomials in Minkowski spacetime. From our viewpoint it
consists of removing the ultraviolet singularities and imposing that the expectation values of the obtained operators vanish on the unique Poincaré invariant state. Unfortunately no such preferred reference state exists in generic curved spacetime, though a viewpoint similar to the Minkowskian one may be adopted dealing with maximally symmetric spacetimes like de Sitter spacetime, where a natural and unique notion of symmetry-invariant vacuum is available (at least for massive fields [AF87]). In the absence of a sufficiently large group of Killing symmetries able to single out a physically privileged reference vacuum state, or for specific values of the parameters defining the quantum field (think of a Klein-Gordon field in Minkowski space time with $m^2 < 0$), the Minkowskian procedure cannot be adopted to completely fix the definition of Wick polynomial even if the normal ordering prescription is mathematically meaningful in the Fock space of every Gaussian (or quasi-free) state.

Still, a relic of the Minkowskian short-distance divergence remains in generic curved spacetime, encoded in the universal Hadamard short distance divergence of $n$-point functions, mathematically corresponding to a definite structure of the wavefront set of these distributions, in the language of microlocal analysis (e.g., see [KM15]). However removing this divergence is by no means sufficient to uniquely define Wick powers. Ambiguities remain and the best we can do is to reduce them to the smallest possible number of types and to classify them.

Let us briefly and heuristically describe how these ambiguities have been studied in previous works. In addition to the obvious requirement that any general procedure should give rise to the known result in Minkowski spacetime, the general strategy [HW01] is to avoid any specific choice from scratch: first of all, no preferred Hilbert space representation of operators is chosen and all the discussion takes place at the level of abstract $\ast$-algebras of operators $\phi_{(M,b)}(x)$, where $(M,b)$ denotes a spacetime endowed with a set of background fields, like the metric and the mass generally, both allowed to vary on $M$. Quantum states are algebraic states, namely positive normalized linear functionals over the said unital $\ast$-algebra of observables. The standard Hilbert space representation arises via the GNS theorem [KM15, Sec.5.1.3]. Next the notion of Wick polynomial is required to be consistent with the requirements of locality and covariance [BFV03]. In other words, Wick polynomials (and all other observables too) must be equivariant with respect to causal embeddings of different spacetimes (locality) and with respect to causal diffeomorphisms of a given yet arbitrary spacetime (covariance). This is not enough however to fix the Wick polynomials completely and, barring obvious technical requirements, further natural constraints must be added [HW01], like the behavior of Wick polynomials under rescaling of the metric and the other given background fields, which together allow a satisfactory classification of the remaining freedom in finite renormalizations. Unfortunately, one of the technical requirements from [HW01], so-called “analytic dependence on analytic metrics”, was long considered unnatural, despite its crucial role in the classification result.

An important refinement of these results was recently made (by some of the authors) for the real scalar field [KM16], where “analytic dependence” was replaced by the more natural “smooth dependence” of the Wick polynomial on smooth compactly localized perturbations of external fields. As a matter of fact one requires that smooth deformations of the background fields $b \mapsto b(s)$, where $s \in \mathbb{R}$, produces smooth fields $(x,s) \mapsto \phi^\eta_{(M,b(s))}(x)$, with a suitable precise interpretation of these mathematical objects. This smooth dependence requirement together with locality allowed us to replace all appeals to analyticity in the proof of the classification result by an appeal to the Peetre-Slovák theorem [Slo88]. This fundamental result in differential geometry states that a (possibly non-linear) map between spaces of smooth functions is a differential operator precisely when it is local (depends only on the germ of its argument) and maps smooth families of smooth functions to smooth families of smooth functions. The latter regularity condition is what inspired our “smooth dependence” requirement. This argument, applied in the case of the Klein-Gordon scalar field in [KM16], was used to show that
the renormalization coefficients $C_k(x)$ are locally given by differential operators applied to the background fields $b(x) = (g, m^2, \xi)$, which consist of the metric, the mass squared and the curvature coupling (cf. Section 6.1). The further requirements of locality, covariance and scaling finally restricts the functions $C_k(x)$ to be scalar polynomials in the mass $m^2$ and any other scalars covariantly built out of the Riemann tensor $R_{abcd}$ and its covariant derivatives, with the coefficients of these polynomials given by arbitrary smooth functions of the curvature coupling $\xi$. The difference between polynomial and smooth dependence on some of the parameters is explained by their different properties under scaling transformations. This classification result had reproduced the earlier results of [HW01], modulo their analytic dependence on $\xi$ vs. our smooth dependence on $\xi$, though with more natural hypotheses.

1.2 Structure of the work and main results

This work deals with the classification of Wick polynomials of a rather general locally covariant bosonic vector-valued quantum field, in the presence of rather general classical background fields. The constant parameters that usually defining a quantum field, like the mass and coupling constants, are included in among the classical background fields (and may be restricted to be constants). Fermionic fields (like the locally covariant Dirac field [Zah14]) are not handled by our analysis and will be discussed elsewhere.

Our main results are split in two. The first (Theorem 5.2) holds when both the dynamical and background fields are sections natural vector bundle over spacetime (natural here means that the bundle transforms in a well-defined way under diffeomorphisms, cf. [KMS93, Ch.IV]). It gives the structure of the general form of the finite renormalizations of Wick powers, which are parametrized by differential operators locally depending on the background fields, including the non-trivial relations between terms that renormalize Wick powers of different degrees. The simplest examples of natural tensor bundles are trivial bundles, tangent and cotangent bundles, as well as any direct sums and products thereof. But natural bundles also include more general examples like bundles of connection coefficients or even jet bundles themselves.

The second main result (Theorem 6.2) holds when we restrict the dynamical and background fields to be only tensor fields. It completely classifies the differential operators parametrizing the finite renormalizations of Wick powers to be covariantly constructed from the metric, the curvature, the background tensor fields and all of their covariant derivatives, and furthermore to have a certain polynomial structure of bounded degree.

The above results are the first complete and rigorous ones for non-scalar dynamical and background fields. To supplement our great generality, we illustrate our results with two physically relevant particular cases: the real vector Klein-Gordon field $A_a$, possibly with tensorial coupling to the curvature, and the $(\varphi, \nabla_a \varphi)$ pair consisting of the real scalar Klein-Gordon field and its spacetime derivative.

Similarly to [KM16], the more complex final classification theorem of Wick polynomials arises by assuming that the Wick products satisfy a certain list of axioms (Definition 3.4) including local covariance, scaling, smooth dependence on perturbations of background fields and commutation relations (kinematic completeness). The relevant commutation relations are quite general. Since no specific equations of motion are assumed, we only require that the commutator of two linear quantum fields is a $c$-number distribution satisfying a certain regularity condition (which is known to hold for usual causal propagator of a well-posed hyperbolic equation).

Except for some general remarks, we shall not discuss the existence of Wick products satisfying our set of axioms, same as in [KM16]. We expect that, at least for the Klein-Gordon field and related fields (e.g., its derivatives), a proof of existence may be obtained by a straightforward re-adaptation to the vector case field of the reasoning appearing in [HW01] and [HW02] for the
scalar field by taking advantage of the characterization of Hadamard states and parametrices for vector field presented in [SV01].

The paper is organized as follows, where we also list the main results of the work.

Section 2 introduces the general notations and the general geometric setup concerning vector bundles and their symmetric tensor powers, also jet bundles, as well as a brief discussion of the Peetre-Slovák theorem stated in a form useful for our purposes. This section also includes the definition and useful identities for the symmetrized product of sections of a vector bundle. The symmetrized product will be useful for giving index-free versions of various formulas in our results.

Section 3 is devoted to the introduction the concepts of natural vector bundles, background geometry, scaling and locally covariant net of algebras of quantum observables on a globally hyperbolic spacetime. The definitions will take advantage of elementary language of category theory and basic notions of operator algebras.

Section 4 deals with the precise notion of a general bosonic locally covariant quantum field, again with the help of notions from category theory. A precise notion of scaling degree is defined to be used later. The concept of c-number field is also presented.

Section 5 presents the general notion of a Wick power of a general bosonic local quantum field. The precise definition (Definition 5.2) lists all necessary physical requirements: behavior of Low Powers, Scaling, Kinematic Completeness, Commutator Expansion, and Smoothness. Based on these requirements, we prove our first main result in Theorem 5.2. It establishes that the difference of two different prescriptions for Wick powers with equal order can be expanded as a sum of lower order Wick powers whose coefficients are, by invoking the Peetre-Slovák theorem, tensor fields of suitable scaling degrees given by differential operators (of locally bounded order) locally depending on the background fields. It is difficult to say more about these differential operators without further assumptions.

Next, in Section 6, the last result is specialised to the case when both the dynamical and background fields are tensors. After some preparatory technical results, the central theorem of this paper (Theorem 6.2) is stated and proved. It precisely characterizes the form of the differential operator coefficients in the general finite renormalization formula of Theorem 5.2. As mentioned earlier, these coefficients must be linear combinations of tensor valued polynomials, covariantly constructed out of the curvature tensors, the background field tensors and all of their covariant derivatives. The number of independent terms and the degrees of these polynomials are a priori bounded, with the bound determined by the scaling dimension of the Wick power and the ranks of the tensors involved. The coefficients of these polynomials are locally (in a precise sense) smooth functions (no longer just polynomial) of finitely many polynomial scalars covariantly constructed out of the subset of the background fields. Crucially these finiteness results hold only when all background fields are admissible. Here a background tensor field is admissible if its physical scaling weight and its tensor rank satisfy an inequality (Definition 6.1). Those background fields that saturate the inequality are called marginal and only they are allowed to appear non-polynomially in the finite renormalization terms. In comparison with the treatment of the scalar field in [KM16], this classification demands much stronger results from the classical invariant theory of the general linear and (Lorentzian) orthogonal groups. The notion of local smooth dependence on a set of polynomial invariants (Definition C.6) was actually born out of the necessity of dealing with the complicated orbit structure for the action of the orthogonal group on background tensors.

1Similar terminology, marginal, relevant and irrelevant fields, appears also in the Wilsonian approach to the “renormalization group.” We emphasize that the similarity is only superficial, since both refer to some kind of scaling dimension. Note that the Wilsonian terminology refers to dynamical fields and only to physical scaling, while ours refers mostly to background fields and to a combination of physical and coordinate scalings.
The final part of Section 6 is devoted to two examples of physical relevance that illustrate the various aspects of our classification theorem: the vector Klein-Gordon field $A$ (Section 6.1) and the $(\varphi, \nabla_a \varphi)$ pair consisting of the scalar Klein-Gordon field and its spacetime derivative (Section 6.2).

The choice to deal with the KG field rather than the Proca one is due to a basic requirement we and previous works have imposed on Wick powers: they must be smooth functions of the mass around the zero value. The zero mass $m^2 \to 0$ limit is a very delicate issue for Proca field and gauge invariance should be taken into account. A recent paper on the subject is [SS17]. A short discussion on this point appears in Remark 13. Even the regularity for the KG (vector or scalar) field at zero mass is a delicate matter when Wick powers are constructed by the Hadamard parametrix regularization method, since the corresponding parametrix includes a term of the form $\ln m^2$. Remark 13 also contains a brief discussion on this technical problem.

Finally, three appendices collect technical results needed at various stages of the proof of Theorem 6.2. Appendix A contains results on (almost) homogeneous functions under scaling. Appendix B contains a convenient version of the Thomas Replacement Theorem, which roughly restricts any tensorial differential operator that is equivariant under diffeomorphisms to depend on the derivatives of the metric only through the Riemann curvature and its covariant derivatives. Appendix C collects fundamental results on smooth invariants of the (Lorentzian) orthogonal group acting on tensor representations. It should be noted that, even though Appendices B and C mostly collect results that are known, these results are rather scattered in the expert literature, and their proofs may be difficult to track down. Thus, for the convenience of the reader, we have aimed to provide complete proofs when they could be made reasonably elementary and concise.

2 Geometric setup

**Notations.** In the following, $VM \to M$ denotes a smooth real vector bundle over a manifold $M$ whose fibres $V_p$ are isomorphic to a given $\mathbb{R}^a$. We shall make use of the auxiliary tensor bundles $V^\otimes k M \to M$ and $V^* \otimes l M \to M$, which are bundles of tensor products of $k$ copies of the bundle $VM$ and $l$ copies of the dual bundle $V^* M$ respectively. In the following we also consider two special sub-bundles, namely those of the fully symmetrized contravariant and covariant tensor products, defined by

$$V^\otimes k M = S^k VM \subset V^\otimes k M,$$

$$V^* \otimes l M = MS^l V^* M \subset V^* \otimes l M$$

where we denoted with $\otimes$ the symmetric tensor product.

**Remark 1.** In the following we will consider bundles which are constructed as direct sum, i.e.,

$$VM = \bigoplus_{i=1}^N W_i M$$

for some vector bundles $W_i M \to M$. We stress that, in this case, using the distributivity of tensor product with respect to direct sum, we have

$$V^\otimes k M = \bigoplus_{|P|=k}^N \bigotimes_{i=1}^N W_i^{p_i} M,$$

$$S^k VM = \bigoplus_{|P|=k}^N \bigotimes_{i=1}^N S^{p_i} W_i M$$

where $P = (p_1, \ldots, p_N)$ is a multi-index and $|P| = p_1 + \cdots + p_N$. It is straightforward to write the analogous decomposition for $V^* \otimes l M$ and $S^l V^* M$. 

We will take advantage of the following spaces of smooth sections.

- $\mathcal{E}(X) := \Gamma(X)$ space of smooth sections of the bundle $X$;
- $\mathcal{D}(X)$ space of smooth and compactly supported sections of the bundle $X$;

where $X$ can be anyone of the introduced bundles. Obviously $\mathcal{E}(X) \supset \mathcal{D}(X)$.

**Remark 2.** In the sequel, we sometimes write tensors with indices, adopting the well-known abstract index notation [Wal84]. We use two types of indices: we use the notation with Greek indices for sections of a generic tensor bundle (for example, $v_{\mu_1 \ldots \mu_k}$ denotes a section of $V^{\otimes k}M$) and Latin indices for spacetime tensors, i.e., section of tensor products of $TM$ and $T^*M$ (for example $t_a^b \ldots ^k$ denotes a section of $T^{\otimes k}M$).

**Remark 3.** In the following, if the bundle $VM$ has the introduced direct sum structure, we will often take advantage of the identification: if $\mathcal{E}(VM) \ni f = \bigoplus_i f_i$ we identify $f_i \simeq \bigoplus_k \delta_i^k f_k$.

With this identification we can substitute the direct sum with a standard sum:

$$f = \sum_i f_i.$$

It is also convenient, for notational reason, to introduce the following contraction product between tensors. We recall [Pro07, Lem.9.1.1] that fully symmetric tensors are spanned by decomposable tensors of the form $f \otimes l$.

**Definition 2.1.** The $l$-contraction product of symmetric sections

$$\cdot_l : \mathcal{E}(S^lV^*M) \times \mathcal{E}(S^kVM) \rightarrow \mathcal{E}(S^{k-l}VM) \quad \text{with} \quad k \geq l,$$

is defined pointwise on decomposable tensors $g^{\otimes l} \in \mathcal{E}(S^lV^*M)$, $f^{\otimes k} \in \mathcal{E}(S^kVM)$ by

$$\left(g^{\otimes l} \cdot_l f^{\otimes k}\right) := \binom{k}{l} \langle g, f \rangle^l f^{\otimes k-l},$$

and extended by linearity.

**Proposition 2.1.** Let $k, l, s > 0$ be such that $l \leq k$ and $s \leq k - l$. For $h \in \mathcal{E}(S^sV^*M)$, $g \in \mathcal{E}(S^lV^*M)$ and $f \in \mathcal{E}(S^kVM)$ it holds

$$h \cdot_s (g \cdot_l f) = g \cdot_l (h \cdot_s f) \quad (2.1)$$

**Proof.** It is immediate using the definition. It is sufficient to prove the result for decomposable tensors and then use linearity to extend the proof to generic tensors. We consider $h^{\otimes s} \in \mathcal{E}(S^sV^*M)$, $g^{\otimes l} \in \mathcal{E}(S^lV^*M)$, $f^{\otimes k} \in \mathcal{E}(S^kVM)$. Thus

$$h^{\otimes s} \cdot_s \left(g^{\otimes l} \cdot_l f^{\otimes k}\right) = h^{\otimes s} \cdot_s \left(\binom{k}{l} \langle g, f \rangle^l f^{\otimes k-l}\right)$$

$$= \binom{k-l}{s} \binom{k}{l} \langle h, f \rangle^s \langle g, f \rangle^l f^{\otimes k-l-s}$$

$$= \binom{k}{s} \binom{k-s}{l} \langle h, f \rangle^s \langle g, f \rangle^l f^{\otimes k-l-s}$$

$$= g^{\otimes l} \cdot_l \left(h^{\otimes s} \cdot_s f^{\otimes k}\right).$$

\[\square\]
We now prove some technical results that will be useful in the subsequent part. In the following we often use the shorthand notation \( f^k := f \otimes f^{k-1} \).

**Proposition 2.2.** Let \( g \in \mathcal{E}(V^* M) \), \( f_i \in \mathcal{E}(V M) \) and \( p_i \geq 1 \) for \( i = 1, \ldots, N \). The following relations hold

(a) \( g \cdot \left( g^{l-1} \cdot f_i \right) = l g \cdot f^k \),

(b) \( g \cdot \left( f_1^{p_1} \otimes \cdots \otimes f_N^{p_N} \right) = \sum_{l=1}^{N} f_1^{p_1} \otimes \cdots \otimes (g \cdot f_i^{p_i}) \otimes \cdots \otimes f_N^{p_N} \),

(c) \( g^{l} \cdot \left( f_1^{p_1} \otimes \cdots \otimes f_N^{p_N} \right) = \sum_{|Q|=l} \left( \prod_{i=1}^{N} \frac{p_i}{q_i} \right) \left( g^{l} \cdot (f_1^{q_1} \otimes \cdots \otimes f_N^{q_N}) \right) f_1^{p_1-q_1} \otimes \cdots \otimes f_N^{p_N-q_N} \).

Moreover, if \( Q = (q_1, \ldots, q_N) \) and \( P = (p_1, \ldots, p_N) \) are multi-indices such that \( |Q| = |P| = l \), \( h^Q \in \mathcal{E} (\bigotimes_{i=1}^{N} S_{q_i} W_i M) \) and \( f \in \mathcal{E}(W_1 M) \), then

(d) \( h^Q \cdot \left( f_1^{p_1} \otimes \cdots \otimes f_N^{p_N} \right) = 0 \) if \( P \neq Q \).

**Proof.** Relation (a) follows immediately from the definition of contraction product. We prove relation (b). It is sufficient to prove the relation for the product \( f_1 \otimes f_2 \) and then the relation (b) follows immediately using the obtained result recursively. Defining \( f = f_1 + f_2 \) we obtain

\[
g \cdot f^2 = 2(g, f) \circ f = 2((g, f_1) + (g, f_2)) \circ (f_1 + f_2)
\]

\[
= g \cdot f_1^2 + 2(g, f_1) \circ f_2 + 2(g, f_2) \circ f_1 + g \cdot f_2^2
\]

\[
= g \cdot f_1^2 + 2(g \cdot f_1) \circ f_2 + 2(g \cdot f_2) \circ f_1 + g \cdot f_2^2
\]

but we also have

\[
g \cdot f^2 = g \cdot (f_1^2 + 2f_1 \circ f_2 + f_2^2) = g \cdot f_1^2 + 2g \cdot (f_1 \circ f_2) + g \cdot f_2^2
\]

and then

\[
g \cdot (f_1 \otimes f_2) = (g \cdot f_1) \otimes f_2 + f_1 \otimes (g \cdot f_2).
\]

We now prove relation (c). Applying recursively relation (a) and recalling that \( \cdot_1 \) acts as a derivation (relation (b)), we have, for \( q_i \leq p_i \),

\[
g^{l} \cdot \left( f_1^{p_1} \otimes \cdots \otimes f_N^{p_N} \right) = \frac{1}{l!} \sum_{l \text{-times}} \left( g \cdot \left( f_1^{p_1} \otimes \cdots \otimes f_N^{p_N} \right) \right)
\]

\[
= \frac{1}{l!} \sum_{|Q|=l} \left( \prod_{i=1}^{N} \frac{p_i}{q_i} \right) g^{l} \cdot \left( f_1^{p_1} \otimes \cdots \otimes f_N^{p_N} \right)
\]

\[
= \sum_{|Q|=l} \left( \prod_{i=1}^{N} \frac{p_i}{q_i} f_1^{p_i} \right) f_1^{p_1-q_1} \otimes \cdots \otimes f_N^{p_N-q_N}
\]

\[
= \sum_{|Q|=l} \left( \prod_{i=1}^{N} \frac{p_i}{q_i} \right) \left( g^{l} \cdot \left( f_1^{q_1} \otimes \cdots \otimes f_N^{q_N} \right) \right) f_1^{p_1-q_1} \otimes \cdots \otimes f_N^{p_N-q_N}
\]

8
where the last equality holds because, if \( f = \sum_i f_i \),

\[
g^l \cdot f^l = \left( \sum_i \langle g, f_i \rangle^l \right) = \sum_{|P| = l} \left( \begin{array}{l} l \end{array} \right) \prod_i \langle g, f_i \rangle_{P_i} = \sum_{|P| = l} \left( \begin{array}{l} l \end{array} \right) \prod_i g_{P_i} \cdot f_i^{P_i}
\]

but also

\[
g^l \cdot f^l = \sum_{|P| = l} \left( \begin{array}{l} l \end{array} \right) g^l \cdot f_l = \sum_{|P| = l} \left( \begin{array}{l} l \end{array} \right) \left( f^{P_1}_1 \circ \cdots \circ f^{P_N}_N \right) .
\]

Finally, we have to prove relation (d). Define \( h = \sum_i h_i \) and \( f = \sum_i f_i \) where \( h_i, f_i \in \mathcal{E}(W_i M) \). Then

\[
h^l \cdot f^l = \left( \sum_i \langle h_i, f_i \rangle^l \right) = \sum_{|P| = l} \left( \begin{array}{l} l \end{array} \right) \prod_i \langle h_i, f_i \rangle_{P_i} = \sum_{|P| = l} \sum_{|Q| = l} \delta_{PQ} \left( \begin{array}{l} l \end{array} \right) \prod_i \langle h_i, f_i \rangle_{P_i},
\]

but also

\[
h^l \cdot f^l = \sum_{|P| = l} \sum_{|Q| = l} \left( \begin{array}{l} l \end{array} \right) \left( h^{P_1}_1 \circ \cdots \circ h^{P_N}_N \right) \cdot f^{P_1}_1 \circ \cdots \circ f^{P_N}_N .
\]

Thus

\[
(h^{P_1}_1 \circ \cdots \circ h^{P_N}_N) \cdot f^{P_1}_1 \circ \cdots \circ f^{P_N}_N = 0, \quad \text{if } P \neq Q
\]

and, since \( h^P \) is a linear combination of \( h^{P_1}_1 \circ \cdots \circ h^{P_N}_N \), we have concluded the proof.

After the first part about notations, in this section we discuss some preliminary results: we briefly recall the notions of jet bundles, just to fix notations, and we present the Peetre-Slovák theorem, which is the most important result that we will use in the following.

If \( E \to M \) is a smooth bundle, unless otherwise specified, we henceforth denote the canonical projection by \( \pi_E : E \to M \), the standard fiber by \( E(\cdot) \) and \( \Gamma(E) \) indicates the set of the smooth sections of \( E \) (the smooth maps \( \psi : M \to E \) such that \( \pi_E(\psi(x)) = x \) for every \( x \in M \)).

### 2.1 Jet bundles

In the following we use extensively the notion of jets and jet bundles. Naively, given a bundle \( E \to M \) and a section \( f : M \to E \), the jet of \( f \) at a point \( p \in M \) collects the information about the coordinate derivatives of \( f \) at \( p \) up to some order. The collection of all jets then forms the jet bundle associated to \( E \) in particular \( E \) may be a bundle with base \( M \) and in this part we briefly recall some standard notions about jets and jet bundles [KMS93].

**Definition 2.2.** Consider a pair of smooth manifolds \( M, E \) and the class of smooth functions \( f : M \to E \), in particular \( E \) may be a bundle with base \( M \) and in this case the relevant set of functions \( f \) is that of smooth sections.

The **germ** of \( f \) at \( p \in M \) is the equivalence class \([f]_p\) of smooth functions (sections) \( M \to E \) that are equal to \( f \) on some neighbourhood of \( p \). The **r-jet** of \( f \) at \( p \in M \), denoted by \( j^r_p f \), is the equivalence class \([f]_{P}^r\) of smooth functions (sections) \( M \to E \) that have the same Taylor expansion at \( p \) to order \( r \) with respect to fixed local coordinate systems in \( M \) and \( E \) (this property being independent from the choice of the coordinate patch). When \( E \to M \) is a smooth bundle, \( J^r E \to M \) denotes the set of \( r \)-jets varying the point in the base, itself a smooth bundle. Finally, if \( \psi \in \Gamma(E) \) is a smooth section, the **r-jet extension** of \( \psi \), denoted with \( j^r \psi \in \Gamma(J^r E) \), is the section of \( J^r E \) which collects the \( r \)-jets of \( \psi \) over each point \( p \in M \).
A fiber \((J^rE)_p\) at \(p \in M\) is diffeomorphic to \(E_p \times \mathbb{R}^{s_r}\) where \(E_p\) is the fiber of \(E\) at \(p\) and \(s_r\) is the number of all (symmetrized) partial derivatives up to order \(r\) with respect to any local chart on the base around \(p\).

The notion of jet extension gives rise to the definition of **local adapted coordinates on jet bundles**.

**Definition 2.3.** Let \((x^a, v^i)\) be a local adapted coordinate chart on a bundle \(E \to M\), where \(x^a\) are local coordinates on an open domain \(U \subseteq M\) and \((x^a, v^i)\) are trivializing coordinates on the fibers over the open domain \(Z \subseteq E\) projecting onto \(U\). This charts extends to an adapted coordinates chart \((x^a, v^i_A)\) on the jet bundle \(J^rE\) defined as follows. Its domain is \(Z^r \subseteq J^rE\) is diffeomorphic to \(Z \times \mathbb{R}^{s_r}\). Moreover

\[
v^i_A(j^r\psi(p)) = \frac{\partial}{\partial x^{a_1}} \cdots \frac{\partial}{\partial x^{a_l}} v^i(j^r\psi(p))
\]

for any section \(\psi\) of the bundle \(E\) and where \(A = a_1 \cdots a_l\) is a multi-index of size \(|A| = l\) with \(l = 0, 1, \ldots, r\).

### 2.2 The Peetre-Slovák theorem

Let \(E \to M\) be a smooth bundle. We recall that the afore-mentioned \(r\)-jet extension of sections acts as a map \(j^r: \Gamma(E) \ni \psi \mapsto j^r\psi \in \Gamma(J^rE)\).

**Definition 2.4.** Let \(E \to M\) and \(F \to M\) be smooth bundles over the same base \(M\). Consider a map \(D: \Gamma(E) \to \Gamma(F)\).

1. \(D\) is a **differential operator of globally bounded order** if there exists an integer \(r \geq 0\), the order, and a smooth map

\[
d: J^rE \to F,
\]

which leaves fixed the base of the transformed point \((\pi_F \circ d = \pi_{J^rE})\) such that for any section \(\psi \in \Gamma(E)\) we have an associated section of the form

\[
D[\psi] = d \circ j^r\psi.
\]

2. \(D\) is a **differential operator of locally bounded order** if it satisfies a similar condition locally. Namely, if for every \(y \in M\) and every \(\psi_0 \in \Gamma(E)\), there exists

- a neighborhood \(U \subseteq M\) of \(y\) with compact closure;
- an integer \(r \geq 0\);
- an open neighborhood \(Z^r \subseteq J^r(E)\) of \(j^r\psi_0(U)\) projecting onto \(U\);
- a smooth function \(d: Z^r \to F\) which leaves fixed the base of the transformed point

such that

\[
D[\psi](x) = d \circ j^r\psi(x)
\]

for all \(x \in U\) and all \(\psi \in \Gamma(E)\) with \(j^r\psi(U) \subseteq Z^r\).

By elementary reasoning, the function \(d\) is actually uniquely determined by the operator \(D\), once the domain \(Z^r\) is fixed, since every point in \(Z^r\) lies on the graph of some \(j^r\psi\).

A differential operator \(D\) transforms sections \(\psi\) to sections \(D[\psi]\) with the constraint that the value \(D[\psi](x)\) of the transformed section attained at a point \(x \in M\) depends only on the value of the initial section \(\psi\) at the same point \(x\) together with the values of its \(M\)-derivatives at \(x\) up to
a certain order $k$, the jet $j^k_x \psi$ evaluated at the said $x$. A natural question is how to characterize these type of local transformations of sections among the whole class of maps $\Gamma(E) \to \Gamma(F)$. An answer is provided by some results known as the Peetre-Slovák theorem we state into two versions (there is a third more complete version we do not consider here [KMS93, Slo88]).

**Theorem 2.3** (Linear Peetre’s Theorem). Let $E \to M$ and $F \to M$ be vector bundles over the same base $M$ and $\Psi: \Gamma(E) \to \Gamma(F)$ a map such that $\Psi[\psi](x) \in F$ depends only on the germ of $\psi$ at $x$ for very $\psi \in \Gamma(E)$ and $x \in M$. If $\Psi$ is linear with respect to the natural vector space structures of $\Gamma(E)$ and $\Gamma(F)$, then $\Psi$ is a differential operator of locally bounded order.

In other words, if $\Psi$ is *linear*, even if the values $\Psi[\psi](x)$ potentially depends on the germ of $\psi$ around every considered $x \in M$, actually they only depend on the *jet* of $\psi$ at $x$ as it is proper of differential operators. This noticeable result for a function $\Psi: E \to F$, can be made stronger keeping the requirement of dependence on the germ but relaxing the linearity hypothesis (thus also dropping the vector space structure of the fibers of $E$ and $F$) and replacing linearity for a suitable *regularity* condition. This alternate condition demands regularity of $\Psi$ when it acts on certain smooth families of sections $\psi_s$ parametrized by $s \in \mathbb{R}^k$ we go to introduce with the help of an auxiliary bundle used to specify the joint-smoothness of these families. Given a smooth bundle $E \to M$ and the standard projection $\pi: \mathbb{R}^n \times M \ni (s, x) \mapsto x \in M$, we define an associated smooth bundle, called the **pullback bundle**, $p: \pi^*E \to \mathbb{R}^n \times M$ whose canonical fiber is isomorphic to that of $E$ and the base is $\mathbb{R}^n \times M$. As a set, $\pi^*E = \mathbb{R}^n \times E$ with canonical projection onto its base given by $p: \pi^*E \ni (s, e) \mapsto (s, \pi_E(e)) \in \mathbb{R}^n \times M$. The smooth differentiable structure of $\pi^*E$ is defined accordingly. The smooth projection $q: \pi^*E \ni (s, e) \mapsto e \in E$ restricts to fiber diffeomorphisms $q|_{p^{-1}(s, x)}: p^{-1}(s, x) \to \pi^{-1}_E(x)$. (This way the following diagram is commutative,

$$
\begin{array}{ccc}
\pi^*E & \xrightarrow{q} & E \\
\downarrow{p} & & \downarrow{\pi_E} \\
\mathbb{R}^n \times M & \xrightarrow{\pi} & M
\end{array}
$$

and can be used to abstractly define $\pi^*E$ taking advantage of a certain universal property of the triple $(\pi^*E, p, q)$.) It is now clear that a smooth section $\sigma \in \Gamma(\pi^*E)$ uniquely defines a $\mathbb{R}^n$-parametrized jointly-smooth family of sections $\{\psi_s\}_{s \in \mathbb{R}^n} \subseteq \Gamma(E)$, where $\psi_s(x) := q \circ \sigma(s, x)$ for $(s, x) \in \mathbb{R}^n \times M$. This observation justifies the following definition.

**Definition 2.5.** Given smooth bundle $E \to M$ and the associated pullback bundle $\pi^*E \to \mathbb{R}^n \times M$, $\sigma \in \Gamma(\pi^*E)$ is called smooth *$n$-dimensional family* of sections of $E$. If furthermore there exists a compact subset $K \subseteq M$ such that $\sigma(s, x) = \sigma(s', x)$ if $x \notin K$ and $s, s' \in \mathbb{R}^n$, then $\sigma$ is said to be a smooth *compactly supported* $n$-dimensional variation.

We are in a position to state the relevant definition about the necessary regularity required in the Peetre-Slovák Theorem [KMS93, Slo88].

**Definition 2.6.** Given smooth bundles $E \to M$ and $F \to M$, a map $\Psi: \Gamma(E) \to \Gamma(F)$ is **regular** if it maps smooth $n$-dimensional families of sections to smooth $n$-dimensional families of sections for every natural $n$. $\Psi$ is **weakly regular** (cf. [KM16, Apx.A]) if it maps smooth compactly supported $n$-dimensional variations to smoothly compactly supported $n$-dimensional variations for every natural $n$.

**Theorem 2.4** (Peetre-Slovák Theorem). Let $E \to M$ and $F \to M$ be smooth bundles over the same base $M$ and $\Psi: \Gamma(E) \to \Gamma(F)$ a map such that $\Psi[\psi](x) \in F$ depends only on the germ of $\psi$ at $x$ for every $\psi \in \Gamma(E)$ and $x \in M$. If $\Psi$ is weakly regular, then it is a differential operator of locally bounded order.
It is worth pointing out that there is an alternative version of the Peetre-Slovák theorem, which uses differentiability in the sense of Bastiani in place of our regularity hypothesis (see Theorem VII.3 of [BDLGR17], whose proof is a special case of the proofs given for the slightly more general Theorems VII.5,7). It is also argued in [BDLGR17] that these two hypotheses should in any case be equivalent, because $\Gamma(E)$ is a Fréchet space in the usual Whitney topology. This alternative version cannot immediately replace the version that we will need below, because weak regularity coincides with regularity only in the physically uninteresting case of compact $M$. However, there is no reason why Theorem VII.3 of [BDLGR17] could not be strengthened along the lines of Appendix A of [KM16], where we discussed strengthening the original Peetre-Slovák theorem from regularity to weak regularity. It remains an open question whether our version of weak regularity or such an alternative version based on Bastiani differentiability would be easier to verify in practice.

3 Algebras of quantum observables over spacetimes with background classical fields

Within this section we describe the general settings in which we study the renormalization of bosonic fields in curved spacetime. We consider a quantum field over a time-oriented globally-hyperbolic spacetime $(M, g)$ of dimension $n$. It is convenient to start from $M$ as a simple smooth manifold. In general, in addition to the quantum field, there are some classical assigned background fields on $M$. They influence the evolution of the quantum field, for example because they may be present in the equation of motion of the quantum field. The first necessary background field is the metric itself $g$, however further tensor or spinor fields may enter the theory. Background fields are described as sections $b$ of a suitable bundle $BM \to M$. Here, however, we do not assume a precise form for the fibers of $BM$ which will be completely fixed later. Since we are working with a locally covariant framework [BFV03], we have to deal with all bundles of (definite types of) background fields simultaneously and coherently for every globally-hyperbolic spacetime. To this end, we introduce all mathematical structures we need to appropriately describe background fields in a locally covariant framework equipped with other technical structures which will be useful later. We will take advantage of some elementary notions of the theory of categories.

3.1 Background geometries

A notion which will play a crucial technical role in our result is the action of the multiplicative group $\mathbb{R}^+$ as group of physical dilations. We state a general and abstract definition.

**Definition 3.1.** A bundle $E \to M$ is said to be dimensionful if it is equipped with a smooth action of the multiplicative group $\mathbb{R}^+ := (0, +\infty)$

$$\mathbb{R}^+ \times E \ni (\lambda, e) \mapsto e_{\lambda} \in E,$$

called *scaling*. It is assumed that every bundle diffeomorphism $E \ni e \mapsto e_{\lambda} \in E$ leaves fixed each fiber of $E$ (so that the $\lambda$-parametrized family of these restrictions to a given fiber defines a group representation of $\mathbb{R}^+$ in terms of fiber diffeomorphisms).

A dimensionful bundle is said to be dimensionless if the action is chosen to be everywhere trivial.

**Remark 4.** Every vector bundle or a cone sub-bundle of a vector bundle (a cone is a subset of a vector space that is invariant under multiplication by positive real numbers, e.g., the cone of
metrics of Lorentzian signature in the vector space of symmetric 2-tensors) can be viewed as
dimensional, since it can be equipped with a well-defined multiplication by scalars with some
fixed power $p \in \mathbb{R}$ on its fibers: $t \mapsto \lambda^p t$.

Next we pass to introduce some relevant categories which will be specialized later.

• $\mathfrak{Man}$ is a category of smooth manifolds. Here objects are connected smooth manifolds $M$
of fixed dimension $n$ and morphisms are smooth embeddings $\chi: M \to M'$.

• $\mathfrak{Bndl}$ is a category of dimensionful smooth bundles. Here objects $\pi_E: E \to M$ are smooth
bundles over a smooth base of fixed dimension $n$. Since a smooth bundle is locally trivializable,
its typical fiber is diffeomorphic to a fixed manifold $F$ with possibly some additional
structures (e.g., a vector space structure) compatible with the smooth structure. Morphisms
are smooth maps $\xi: E \to E'$ that are both

(i) **fiber preserving**: $\pi_{E'} \circ \xi = \chi \circ \pi_E$ for uniquely associated smooth maps $\chi_\xi: M \to M'$
and preserving the additional structure of the fiber if any,

(ii) **equivariant with respect to scaling**: $\xi(e)_{\lambda} = \xi(e)_{\lambda}$ for $\lambda \in \mathbb{R}^+$ and $e \in E$.

Remark 5. The definition applies also when a scaling action is not defined. In this case the
standard scaling action is assumed to be the trivial one, i.e., the bundles are supposed to be
dimensionless.

The interplay of a class of manifolds, which will be later interpreted as spacetimes, with cor-
responding bundles, which represent background classical fields (including the metric), and
implementing the ideas of local covariance is encapsulated in a certain type of functor [BFV03]
that we define below into a very general fashion. Later we specialize it to the case relevant to
our work.

**Definition 3.2.** A natural (dimensionful) bundle is a functor $H: \mathfrak{Man} \to \mathfrak{Bndl}$ such that, using
the notation $HM := H(M)$ for every $M \in \mathfrak{Man}$, a morphism $\chi: M \to M'$ has an associated
morphism $H_\chi: HM \to HM'$ with $\pi_{HM'} \circ H_\chi = \chi \circ \pi_{HM}$ and $H_\chi$ is a local diffeomorphism (a
diffeomorphism onto its image).

Given a morphism $\chi: M \to M'$ and exploiting the fact that $H_\chi$ is a local diffeomorphism, it is
possible to construct a **pullback action on sections** of the associated bundles

$$
\chi^*: \mathcal{E}(HM') \to \mathcal{E}(HM)
$$

which is completely defined by requiring that

$$
\chi^* h \cdot \chi = H_\chi \circ (\chi^* h) \quad \text{for } h \in \mathcal{E}(HM').
$$

(3.1)

Since the morphism $H_\chi$ is equivariant, the scaling commutes with the pull-back, i.e.,

$$
\chi^* (h_{\lambda}^\prime) = (\chi^* h_{\lambda}^\prime)_{\lambda} \quad \text{with } \lambda \in \mathbb{R}^+.
$$

Furthermore, exploiting the compactness of the support of the elements of $\mathcal{D}(HM)$, also a
natural push-forward map $\chi_*: \mathcal{D}(HM) \to \mathcal{D}(HM')$ arises immediately. It is defined as follows

$$
(\chi_* f)(p') = H_\chi|_{\chi^{-1}(p')} f(\chi^{-1}(p')) ,
$$

(3.2)

for $f \in \mathcal{D}(HM)$ and $p' \in \chi(M)$ and the right-hand side is extended to the zero function for
$p' \not\in \chi(M)$.
Finally, if $H, H': \text{Man} \to \mathfrak{Bndl}$ are natural bundles, the duals $H^*, H'^*$, the direct sum $H \oplus H'$ and tensor product $H \otimes H'$ also define natural bundles.

Dealing with a general framework of relativistic quantum field theory, a relevant natural bundle, denoted by $B: \text{Man} \to \mathfrak{Bndl}$, is

$$BM = S^2T^*M \bigoplus_{i=1}^N \left( T^{\otimes k_i}M \otimes T^{\otimes l_i}M \right) \quad (3.3)$$

where $S^2T^*M \subset S^2T^*M$ is the bundle of Lorentzian metrics over $M$ and some choice of tensor powers $k_i$ and $l_i$. We will later use $BM$ as the bundle of background fields for a model of quantum fields. Scalar fields in particular are admitted when $k_i = l_i = 0$. As previously observed, the bundles (3.3) are naturally dimensionful. The sections of these type of bundles represent the non-quantized fields of definite type assigned in every spacetime simultaneously and coherently. The metric is one of these given fields. Let us state a pair of precise definitions adding some further relevant details concerning the effective action of $\mathbb{R}^+$.

**Definition 3.3.** $B: \text{Man} \to \mathfrak{Bndl}$ is the natural bundle of the form (3.3), with fixed $k_i, l_i$.

A **background field** is a section $b: M \to BM$. A pair $(M, b)$ is a **background geometry**, provided the section $b = (g, t_1, \ldots, t_N)$ is such that $(M, g)$ is a time-oriented globally hyperbolic spacetime.

The action of $\mathbb{R}^+$ on the bundles of the form (3.3) is such that, for every background field,

$$(g, t_1, \ldots, t_N) \mapsto (\lambda^{-2}g, \lambda^{s_1}t_1, \ldots, \lambda^{s_N}t_N), \quad (g, t_1, \ldots, t_N) \in \mathcal{E}(BM) \quad \lambda \in \mathbb{R}^+, \quad (3.4)$$

for given reals $s_i$ independent from the section and $M$. Each such transformation is called **physical scaling** transformation.

**Definition 3.4.** Referring to the natural bundle $B: \text{Man} \to \mathfrak{Bndl}$ of the form (3.3), we define the following associated categories.

(a) $\mathfrak{BgtG}$ is the **category of background geometries**, having time-oriented background geometries as objects and morphisms given by smooth embeddings $\chi: M \to M'$ that preserve the background fields, $\chi^*b' = b$ on $M$, the time orientation, and causality (every causal curve between $\chi(p)$ and $\chi(q)$ in $M'$ is the $\chi$-image of a causal curve between $p$ and $q$ in $M$).

(b) $\mathfrak{BgtG}^+$ is the **category of oriented background geometries** having oriented and time-oriented background geometries as objects and morphisms as in $\mathfrak{BgtG}$, but also required to preserve the spacetime orientation.

**Remark 6.** The group of physical scaling transformations acts on the above categories as $(M, b) \mapsto (\lambda M, b, \chi)$, for any $\lambda \in \mathbb{R}^+$. By equivariance of the pullback of background fields, physical scalings actually act as functors, $\mathfrak{BgtG} \to \mathfrak{BgtG}$ and $\mathfrak{BgtG}^+ \to \mathfrak{BgtG}^+$ respectively.

**3.2 The net of local quantum observables**

The introduced formalism permits us to describe the **net algebras of local quantum observables** on our background geometries. We explicitly only deal with $\mathfrak{BgtG}$, but everything we say can be trivially re-adapted to $\mathfrak{BgtG}^+$.

**Definition 3.5.** A **net of algebras (of local quantum observables)** $\mathcal{W}$ is an assignment of a complex unital $*$-algebra $\mathcal{W}(M, b)$ to every background geometry $(M, b)$ in $\mathfrak{BgtG}$ together with an assignment of an injective unital $*$-algebra homomorphism $\iota_{\chi}: \mathcal{W}(M, b) \to \mathcal{W}(M', b')$ to every morphism in $\mathfrak{BgtG}$, respecting compositions and associating identities to identities.
other words $\mathcal{W}: \mathcal{BfgS} \to \mathcal{Alg}$ is a functor from the category of background geometries into the category of (complex) unital $\ast$-algebras whose morphisms are injective unital $\ast$-algebra homomorphisms. Further, we require that $\mathcal{W}$ respects (i) scaling and (ii) the time slice axiom, as described below.

(i) Physical scaling transformations $(M, b) \mapsto (M, b_\lambda)$ are represented in terms of $\ast$-algebra isomorphisms $\sigma_\lambda: \mathcal{W}(M, b) \to \mathcal{W}(M, b_\lambda)$ such that $\sigma_1 = \text{id}$ and $\sigma_\lambda \circ \sigma_\mu = \sigma_{\lambda \mu}$. Varying $(M, b)$, scaling transformations must commute with embeddings, i.e., they act as natural isomorphisms $\sigma_\lambda: \mathcal{W} \to \mathcal{W}_\lambda$ between the $\ast$-algebra valued functors $\mathcal{W}$ and $\mathcal{W}_\lambda$, the latter defined by $\mathcal{W}_\lambda(M, b) = \mathcal{W}(M, b_\lambda)$.

(ii) Given a morphism $\chi: M \to M'$ between the background geometries $(M, b)$ and $(M', b')$, if the image $\chi(M) \subseteq M'$ contains a Cauchy surface for $(M', g')$, then the induced $\ast$-homomorphism $\iota_\chi: \mathcal{W}(M, b) \to \mathcal{W}(M', b')$ is a $\ast$-isomorphism.

We refer to a similar functor $\mathcal{W}: \mathcal{BfgS}^+ \to \mathcal{Alg}$ with analogous properties as a net of algebras as well.

Remark 7.

(1) The unit of every algebra $\mathcal{W}(M, b)$ will be simply denoted by 1 in place of a cumbersome notation $1_{(M, b)}$.

(2) The scaling axiom is necessary because we will be required to compare local algebras defined on a given manifold which are identified by scaling transformations. These algebras must be viewed as distinct since their background fields are different. Therefore to compare them we need to assume that there is an isomorphism $\sigma_\lambda$ identifying them. In more physically minded presentations this structure is not discussed and the said identification is hidden in the formalism.

The time slice axiom has a consequence which will play a fundamental role in the sequel, in particular for the application of the Peetre-Slovák Theorem.

**Proposition 3.1.** Referring to Definition 3.5 consider $(M, b), (M, b') \in \mathcal{BfgS}$ (resp. $\mathcal{BfgS}^+$) such that $b = b'$ with identical temporal orientation outside a compact region $K \subseteq M$. There exists a unital $\ast$-algebra isomorphism

$$\tau: \mathcal{W}(M, b) \to \mathcal{W}(M, b')$$

such that $\tau|_{\mathcal{W}((N, b)|_N)}: \mathcal{W}(N, b|_N) \to \mathcal{W}(N, b'|_N)$ is the identity for every $(N, b|_N) \in \mathcal{BfgS}$ (resp. $\mathcal{BfgS}^+$) satisfying $N \cap J^+(M, b)(K) = \emptyset$.

**Proof.** The proof is based mainly on the time slice axiom (Definition 3.5). See [KM16, Sec.3] for more details.

\section{Quantum fields}

We have so far discussed all the mathematical structures we need to describe background fields and the abstract notion of a net of quantum observables. At this abstract level we may introduce the definition of quantum fields as special elements of the algebras of observables [BFV03].

**Definition 4.1.** Fix a net of local quantum observables $\mathcal{W}$ as in Definition 3.5 and a natural vector bundle $V$. A quantum $V$-field is an assignment $\Phi_{(M, b)}$ of an algebra-valued distribution

$$\Phi_{(M, b)}: \mathcal{D}(V^*M) \to \mathcal{W}(M, b)$$

to each background geometry $(M, b) \in \mathcal{BfgS}$.
The given definition does not yet assume any particular relation between $\Phi_{(M,b)}$ and $\Phi_{(M',b')}$ when $(M,b)$ and $(M',b')$ are connected by a morphism $\chi$ of $\mathfrak{Bfg}\mathfrak{G}$. A quantum field $\Phi$ is said to be \textit{locally covariant} when each pair of $\Phi_{(M,b)}$ and $\Phi_{(M',b')}$ is in fact connected according to a natural rule arising from the definition of a natural bundle, translating into the mathematical language the ideas of locality and general covariance.

**Definition 4.2.** A quantum $V$-field $\Phi$ (Definition 4.1) with respect to the net of local quantum observables $\mathcal{W}$ as in Definition 3.5 is said to be \textit{locally covariant} if it satisfies the following identity for each morphism $\chi : (M,b) \rightarrow (M',b')$ where $b = \chi^* b'$,

$$
t_{\chi}(\Phi_{(M,b)}(f)) = \Phi_{(M',b')}(\chi_* f), \quad \forall f \in \mathcal{D}(V^* M).
$$

where $\chi_*$ is the push-forward with respect to a natural bundle, as in (3.2).

**Remark 8.**

(1) It is usual to require that the field $\Phi$ has a definite \textit{scaling degree} $d_\Phi \in \mathbb{R}$ with respect to the action of physical scaling. However, when $\Phi$ has multiple components, different components of a $V$-field can be grouped together by their scaling degree, giving rise to the decomposition of the field bundle as in Remark 1. Then the role of the scaling degree is played by a globally diagonalizable endomorphism $d_\Phi : VM \rightarrow VM$, whose eigen-subspaces constitute the bundle decomposition $VM = \bigoplus_{i=1}^{n} W_i M$ and whose eigenvalues correspond to the weights of these field sub-bundles. Alternatively, once this field bundle decomposition is known, the endomorphism $d_\Phi$ can be identified with its eigenvalues $(d_{\Phi_1}, \ldots, d_{\Phi_n})$. Informally written, the relation between the scaling of background fields and $\Phi$ means that

$$
(g, t_1, \ldots, t_N) \mapsto (\lambda^{-2}g, \lambda^{e_1}t_1, \ldots, \lambda^{e_n}t_N) \quad \Rightarrow \quad \Phi \mapsto \lambda^{d_\Phi} \Phi, \quad (g, t) \in \Gamma(BM).
$$

To formulate a precise statement valid also for $V$-fields exploiting our formalism we need a precise scaling procedure based on the isomorphism $\sigma_\lambda$ introduced in Definition 3.5. If $\Phi$ is a quantum $V$-field, we can define the rescaled quantum $V$-field $S_\lambda \Phi$ as

$$
(S_\lambda \Phi)_{(M,b)}(f) = \sigma_\lambda^{-1}(\Phi_{(M,b)}(\lambda^n f)), \quad \lambda \in \mathbb{R}^+,
$$

where $n$ is the dimension of the spacetime $M$ and $\sigma_\lambda$ is the algebra isomorphism introduced in Definition 3.5. It should be clear here that both $\Phi_{(M,b)}$ and $(S_\lambda \Phi)_{(M,b)}$ are element of the same algebra $\mathcal{W}(M,b)$ due to the presence of $\sigma_\lambda^{-1}$ in the second case. The factor $\lambda^n$ just compensates the scaling of the volume form $dg \mapsto \lambda^{-n} dg$ when $g \mapsto \lambda^{-2}g$. A mathematically rigorous version of (4.2) is now

$$
(S_\lambda \Phi)_{(M,b)}(f) = \lambda^{d_\Phi} \Phi_{(M,b)}(f), \quad (M,b) \in \mathfrak{Bfg}\mathfrak{G}, \quad f \in \mathcal{D}(VM), \quad \lambda \in \mathbb{R}^+.
$$

(2) As usual, it is convenient to think of the algebra-valued distribution $\Phi$ as a formal point-like field $\Phi^\mu(x)$ smeared with a test function $f \in \mathcal{D}(V^* M)$. In the sequel, we will make extensive use of the case when $V$ is replaced by $S^k V$. Then we may write the formal point-like field $\Phi_{\mu_1 \cdots \mu_k}^\mu(x)$ smeared with a test section $f \in \mathcal{D}(S^k V^* M)$ as

$$
\Phi_{(M,b)}(f) = \int_M \Phi_{\mu_1 \cdots \mu_k}^\mu(x)f_{\mu_1 \cdots \mu_k}(x) \, dg(x),
$$

where $dg(x)$ is the volume form induced by the metric $g$ on $M$.

Similarly, if $C$ is any function that maps a background geometry $b$ to a distribution on a
certain space of test functions $C_{(M,b)}: \mathcal{D}(S^kVM) \to \mathbb{R}$, it is heuristically convenient to use the distributional notation
\[
C_{(M,b)}(f) := \int_M C[M,b]_{\mu_1 \cdots \mu_k}(x)f^{\mu_1 \cdots \mu_k}(x) \, dg(x), \quad f \in \mathcal{D}(S^kV^*M),
\]
where the formal $c$-number field $C[M,b]_{a_1 \cdots a_k}(x)$ may not be smooth. Such a function $C$ will be named a $c$-number $S^kV$-field. If the sections $C[M,b]$ are smooth for every $(M,b)$ (i.e., $C[M,b] \in \mathcal{E}(S^kV^*M)$), $C$ is said to be a smooth $c$-number $S^kV$-field. From now on we systematically identify $C_{(M,b)}(f)$ with the corresponding trivial element, a so called $c$-number, $C_{(M,b)}(f)$ of $\mathcal{W}(M,b)$. In this sense a $c$-number $S^kV$-field is a sub-case of a quantum $S^kV$-field and, for instance, the scaling action (4.3) applies to these particular quantum fields as well.

(3) If in addition $C$ satisfies the identity
\[
C_{(M,\chi^*b^\prime)}(f) = C_{(M',b^\prime)}(\chi^*f),
\]
for every background morphism $\chi: (M,b) \to (M',b')$ (so $b = \chi^*b'$) and every test section $f \in \mathcal{D}(S^kV^*M)$, then $C$ defines a locally covariant $c$-number $S^kV$-field.

Using the definitions of pull-back $\chi^* : \mathcal{E}(S^kV^*M') \to \mathcal{E}(S^kV^*M)$ and push forward $\chi_* : \mathcal{D}(S^kVM) \to \mathcal{D}(S^kVM')$, it is easy to prove that if $C$ is described by $C[M,b] \in \mathcal{E}(S^kV^*M)$ for every choice of $(M,b)$ by means of (4.4), then (4.5) is equivalent to
\[
C[M,\chi^*b^\prime](x) = (\chi^*C[M',b^\prime]) (x),
\]
for every background morphism $\chi: (M,b) \to (M',b')$ (with $b = \chi^*b'$) and $x \in M$.

5 Wick powers of quantum boson fields

In this section we want to study the renormalization of Wick powers of a generic quantum boson field. Before discussing this problem, we have to introduce a useful definition concerning the notion of physical scaling introduced in Section 3.1.

Physical scaling degree. Physical scaling will be used together with the notion of homogeneous and almost homogeneous scaling degree. Since these notions are quite abstract we can present them into a general inductive definition [KM16, Def.2.3].

Definition 5.1. Consider a linear representation $\rho: \mathbb{R}^+ \to GL(W)$ of the multiplicative group $\mathbb{R}^+$ on a vector space $W$ whose action is indicated by $W \ni F \mapsto F_\lambda := \rho(\lambda)F \in W$, for every $\lambda \in \mathbb{R}^+$.

(a) An element $F \in W$ is said to have homogeneous degree $k \in \mathbb{R}$ if
\[
F_\lambda = \lambda^k F, \quad \text{for all } \lambda \in \mathbb{R}^+.
\]

(b) An element $F \in W$ is said to have almost homogeneous degree $k \in \mathbb{R}$ and order $l \in \mathbb{N}$ if $l \geq 0$ is an integer such that (with the sum over $j$ is omitted when $l = 0$)
\[
F_\lambda = \lambda^k F + \lambda^k \sum_{j=1}^l (\log^j \lambda) G_j, \quad \text{for all } \lambda \in \mathbb{R}^+,
\]
and for some $G_j \in W$ depending on $F$, which have respectively almost homogeneous degree $k$ and order $l - j$. An element that is almost homogeneous of order $l = 0$ is homogeneous by definition.
Lemma 5.1. Referring to Definition 5.1, consider a pair of vector spaces \( W, W' \) endowed with corresponding representations of \( \mathbb{R}^+ \). Concerning (b) below, assume also that there is a product \( W \times W' \rightarrow V \) such that (i) \( V \) admits a representation of \( \mathbb{R}^+ \) and (ii) the map \( W \times W' \rightarrow V \) is equivariant: \( F_\lambda F'_\lambda = (FF')_\lambda \) for \( F \in W, F' \in W' \) and \( \lambda \in \mathbb{R}^+ \). The following facts hold.

(a) A linear combination of two elements \( F, F' \in W \) of almost homogeneous degree \( k \) and order \( l \) is of almost homogeneous degree \( k \) and order \( l \).

(b) A product of an element \( F \in W \) of almost homogeneous degree \( k \) and order \( l \), and an

\[ \text{element } F' \in W', \text{ of almost homogeneous degree } k' \text{ and order } l', \text{ has almost homogeneous degree } k + k' \text{ and order } l + l'. \]

General settings. Our general setting is the following:

1. We start with a bundle \( VM \) which is constructed as a direct sum of vector bundles

\[
VM = \bigoplus_{i=1}^{N} W_i M. \tag{5.1}
\]

2. We consider a locally covariant quantum \( V \)-field \( A_{(M,b)} : \mathcal{D}(VM) \rightarrow \mathcal{W}(M,b) \) and we characterize it as a quantum boson field in the following way. We assume that the commutator of two \( V \)-fields \( [A_{(M,b)}(f), A_{(M,b)}(g)] \) is a \( c \)-number, i.e.,

\[
[A_{(M,b)}(f), A_{(M,b)}(g)] = C_{(M,b)}(f \otimes g)1, \tag{5.2}
\]

where \( C_{(M,b)} \in \mathcal{D}'(VM \times VM) \) is a distribution with some suitable properties (e.g., for boson fields it vanishes for spacelike separated arguments). Thus, Schwartz' kernel theorem implies that a unique continuous linear map \( \Delta_{(M,b)} : \mathcal{D}(VM) \rightarrow \mathcal{D}'(VM) \) exists such that \( [\Delta_{(M,b)}(g)](f) = C_{(M,b)}(f \otimes g) \). We require moreover that \( \Delta_{(M,b)}(g) \) is regular in the sense that

\[
\Delta_{(M,b)} : \mathcal{D}(VM) \rightarrow \mathcal{E}'(V^* M), \tag{5.3}
\]

where we used the fact that \( \mathcal{E}'(V^* M) \subset \mathcal{D}'(VM) \). There are many ways to implement this requirement in practical cases, for example our assumption holds when the dynamics of the field \( A \) is ruled by any hyperbolic field equation in view of the theorem of propagation of singularities (in this case \( \Delta_{(M,b)} \) is simply the causal propagator, see Section 6.1 for an example). More generally it holds when some microlocal spectrum (cf. [KM15], [BF09, Ch.4]) hypothesis on the wavefront set of \( n \)-point functions is assumed with respect to relevant classes of states even in the absence of a field equation\(^2\).

If we use explicitly the decomposition (5.1) the map \( \Delta_{(M,b)} \) can be seen as a direct sum of maps

\[
\Delta_{(M,b)} = \bigoplus_{l=1}^{N} \sum_{j=1}^{N} \Delta_{(M,b)}^{ij},
\]

where \( \Delta_{(M,b)}^{ij} : \mathcal{D}(W_j M) \rightarrow \mathcal{E}'(W_j^* M) \).

\[^{2}(5.3) \text{ is valid when } WF(C_{(M,b)}) \neq (x,y,p_x,p_y) \text{ with either } p_x = 0 \text{ or } p_y = 0 \text{ and this is guaranteed as soon as some standard microlocal spectrum condition on } C_{(M,b)} \text{ is valid, in particular if } C_{(M,b)} \text{ is a bisolution of a hyperbolic field equation.}\]
3. Since we assumed a bundle constructed as in (5.1), the $V$-field $A_{(M,b)}$ can be written as a $N$-tuple of $W_i$-fields

$$A_{(M,b)} = ((A_1)_{(M,b)}, \ldots, (A_N)_{(M,b)}).$$

We assume that each $W_i$-field $(A_i)_{(M,b)}$ scales homogeneously under physical scaling with degree $d_{A_i} \in \mathbb{R}$, i.e.,

$$(S_\lambda A_i)_{(M,b)}(f) = \lambda^{d_{A_i}} (A_i)_{(M,b)}(f), \quad (M, b) \in \mathfrak{Btgs}, \quad f \in \mathcal{D}(W_i M), \quad \lambda \in \mathbb{R}^+. $$

We will say that the $V$-field $A_{(M,b)}$ scales homogeneously with degree $\mathbb{R}^N \ni d_A = (d_{A_1}, \ldots, d_{A_N})$ under physical scaling.

4. We then consider the Wick powers $A^k$ of $A$. These quantum fields $A^k$ have the physical interpretation of products of $k$ factors $A$ evaluated at the same point $x$. Formally, assuming a geometric background $(M, b)$ has been fixed,

$$A^k_{\mu_1 \ldots \mu_k} (x) = (A_{\mu_1} \cdots A_{\mu_k})(x).$$

It is worth stressing that these quantum fields are not elements of the sub unital $*$-algebra generated by 1 and elements $A(f)$ since these elements are associated with kernels formally evaluated at different points of spacetime, i.e., they are linear combinations of objects $A_{\mu_1}(x_1) \cdots A_{\mu_k}(x_k)$. Thus Wick powers need a specific definition which, as is well-known, involves some renormalization procedure.

Finally, we stress that, using the decomposition introduced in Remark 1, the Wick powers $A^k$ can be written as a sum

$$A^k(f) = \sum_{|P|=k} \binom{k}{P} A^k(f_{1}^{p_1} \circ \cdots \circ f_{N}^{p_N}) =: \sum_{|P|=k} \binom{k}{P} A^P(f_{1}^{p_1}, \ldots, f_{N}^{p_N}),$$

where $P = (p_1, \ldots, p_N)$ is a multi-index and $\binom{k}{P} = \frac{k!}{\prod_{i=1}^{N} p_i!}$. The last equality is intended as a definition.

We assume an axiomatic viewpoint stating five axioms regarding Wick powers. These axioms do not determine them, but determine the degrees of freedom due to the different possible choice of renormalization procedures and classify the finite renormalization counterterms. Regarding
the 5th requirement in the definition below, for clarity we recall the notion of a compactly supported variation from Definition 2.5. If \((M, b)\) is a background geometry, the jointly smooth function \(B = b_s(x)\) with \(s \in \mathbb{R}^m\) and \(x \in M\) defines a smooth \(m\)-dimensional \((m \geq 0\) integer) family of smooth compactly supported variations of \(b\) if \(b_s(x) = b(x)\) for \(x \in M\) and \(b_s(x) = b_{s'}(x)\) for \(s, s' \in \mathbb{R}^n\) and \(x \not\in K\) for a fixed compact \(K \subseteq M\) depending on the family. According to Proposition 3.1, we can identify each algebra \(\mathcal{W}(M, b_s)\) with \(\mathcal{W}(M, b)\) by means of the unital \(*\)-algebra isomorphism

\[
\tau_s : \mathcal{W}(M, b) \to \mathcal{W}(M, b_s),
\]

which reduces to the identity on every spacetime \((N, g_s|_N)\) if \(N \cap J^+_{(M, g)}(K) = \emptyset\).

**Definition 5.2 (Wick powers for general boson fields).** Consider a net of algebras \(\mathcal{W}\) on the category of background geometries \(\mathfrak{B}tg\mathfrak{G}\) (resp. \(\mathfrak{B}tg\mathfrak{G}^+\)) and a locally-covariant quantum \(V\)-field \(A\) (Definition 4.2) with \(A_{(M, b)} : \mathcal{D}(VM) \to \mathcal{W}(M, b)\) for every \((M, b) \in \mathfrak{B}tg\mathfrak{G}\) (resp. \(\mathfrak{B}tg\mathfrak{G}^+\)). A class of Wick powers \(\{A^k\}\) of \(A\), for \(k = 0, 1, 2, \ldots\) is a family of symmetric locally-covariant quantum \(S^k\)-fields (so that each \(k\) defines an assignment of algebra-valued distribution \(A^k_{(M, b)} : \mathcal{D}(S^kVM) \to \mathcal{W}(M, b)\) to every \((M, b) \in \mathfrak{B}tg\mathfrak{G}\) (resp. \(\mathfrak{B}tg\mathfrak{G}^+\)) respecting (4.1)) satisfying the following requirements.

1. **Low powers.** \(A^0 = 1\), the unit \(c\)-number field, \(A^1 = A\), the \(V\)-field.

2. **Scaling.** With respect to the decomposition (5.4), each component \(A^k_b\) of the Wick power \(A^k\) is almost homogeneous of degree \(\langle P, dA \rangle = p_1 dA_1 + \cdots p_N dA_N\), with respect to the action of physical scalings \(S_\lambda\) in (4.3); that is, there exists an integer \(l \geq 0\) and quantum \(k\)-tensor fields \(B_j\) such that

\[
S_\lambda A^P = \lambda^{\langle P, dA \rangle} A^P + \lambda^{\langle P, dA \rangle} \sum_{j=1}^l (\log \lambda)^j B_j,
\]

where each \(B_j\) is itself almost homogeneous of degree \(\langle P, dA \rangle\) and order \(l - j\). (Every degree is supposed to be independent from the choice of the background geometry.)

3. **Kinematic completeness.** For any \((M, b)\), an element \(a \in \mathcal{W}(M, b)\) satisfies

\[
[a, A_{(M, b)}(f)] = 0 \quad \text{for every } f \in \mathcal{D}(VM)
\]

iff \(a = \alpha 1\), with \(\alpha \in \mathbb{C}\) and 1 the unit element of the algebra.

4. **Commutator expansion.** Each Wick power \(A^k\) also satisfies the following properties\(^3\):

\[
\left[A^k_{(M, b)}(f), A_{(M, b)}(g)\right] = i A^{k-1}_{(M, b)}(\Delta_{(M, b)}(g) \cdot f), \quad f, g \in \mathcal{D}(S^kVM), \quad g \in \mathcal{D}(VM)
\]

where \(\Delta_{(M, b)} : \mathcal{D}(VM) \to \mathcal{E}(V^*M)\) is a given map.

5. **Smoothness.** If \((M, b) \in \mathfrak{B}tg\mathfrak{G}\) (resp. \(\mathfrak{B}tg\mathfrak{G}^+\)), we require that there exist a class of states \(S_{(M, b)}\) on \(\mathcal{W}(M, b)\) such that if \(\omega \in S_{(M, b)}\), the expectation values \(\omega \circ \tau_s^{-1} \left(A^k_{(M, b_s)}(f)\right)\) (with \(f \in \mathcal{D}(S^kVM)\)) can be written as

\[
\omega \circ \tau_s^{-1} \left(A^k_{(M, b_s)}(f)\right) = \int_M \omega_{\mu_1 \cdots \mu_k} (s, x) f^{\mu_1 \cdots \mu_k} (x) dg(x),
\]

\(^3\)We recall that there is a factor \(k\) hidden in the contraction product.
for some jointly smooth kernels $R^m \times M \ni (s, x) \mapsto \omega_{\mu_1 \cdots \mu_k}(s, x) \in \mathbb{R}$, for every smooth $m$-parameter family of compactly supported variations $b_s$ of $b$ on $M$ and $\tau_s: \mathcal{W}(M, b) \rightarrow \mathcal{W}(M, b_s)$ defined as in (5.5) and every integer $m \geq 0$.

6. **Hermiticity.** For all background geometry $(M, b)$ and $f \in \mathcal{D}(V^*M)$, we require that

$$A_{(M, b)}(f) = A_{(M, b)}(f)^*$$

where $*$ denotes the corresponding operation in the $*$-algebra $\mathcal{W}$.

**Remark 9.** While the first four axioms, and also the last one, are standard requirements, we would like to comment briefly the smoothness axiom. We require that any Wick powers has smooth expectation value both with respect to $x$, the coordinate on spacetime manifold, and $s$, the parameter that labels the variations of $b$. The smoothness with respect to $x$ reflect the physical idea that a renormalized observables is smooth since we have removed all singularity in the renormalization procedure. The joint smoothness in $(x, s)$ is a version of the parametrized microlocal spectrum condition that was introduced in [KM16, Def.3.5(iv)], as a substitute for the old analyticity condition of Hollands and Wald [HW01].

**Remark 10.** In components, i.e., with respect to equation (5.4), the commutator expansion axiom, for $j \in 1, \ldots, N$ and a multi-index $P$, becomes

$$\left[ A_1^{p_1} \cdots A_N^{p_N} \left( f_1^{p_1}, \cdots, f_N^{p_N} \right), A_j(g_j) \right] = i \sum_{l=1}^N A_1^{p_1} \cdots A_l^{p_l-1} \cdots A_N^{p_N} \left( f_1^{p_1}, \cdots, (\Delta^l(g_j) \cdot f_l^{p_l}), \cdots, f_N^{p_N} \right).$$

(5.7)

To show this, fixing a background geometry $(M, b)$, consider $g_j \in (W^*M)_j$ and $f = \sum_j f_l$ with $f_l \in W_lM$, where we have used the identification introduced in Remark 3, i.e.,

$$g_j = (0, \ldots, g_j, \ldots, 0), \quad f_j = (0, \ldots, f_j, \ldots, 0).$$

We recall that, by definition,

$$A_1^{p_1} \cdots A_N^{p_N} \left( f_1^{p_1}, \cdots, f_N^{p_N} \right) := A^k \left( f_1^{p_1} \circ \cdots \circ f_N^{p_N} \right),$$

then, using Proposition 2.2,

$$\left[ A_1^{p_1} \cdots A_N^{p_N} \left( f_1^{p_1}, \cdots, f_N^{p_N} \right), A_j(g_j) \right] = A^k \left( f_1^{p_1} \circ \cdots \circ f_N^{p_N} \right), \quad A(g_j)$$

$$= iA^{k-1} \left( \sum_{l=1}^N \Delta^l(g_j) \cdot f_l^{p_l} \circ \cdots \circ f_N^{p_N} \right)$$

$$= i \sum_{l=1}^N A^{k-1} \left( f_1^{p_1} \circ \cdots \circ (\Delta^l(g_j) \cdot f_l^{p_l}) \circ \cdots \circ f_N^{p_N} \right),$$

which by definition is equal to (5.7).
5.1 General renormalization formula for Wick products of a quantum boson field

If \{\tilde{A}^k\}_{k=1,2,\ldots} and \{A^k\}_{k=1,2,\ldots} are two families of Wick powers of the same quantum V-field A, our task is now to find a formula relating these two pairs of Wick powers relying on the fact that both classes satisfy the above set of general axioms. The following theorem is a generalization of [KM16, Lem.3.3]

**Theorem 5.2.** Let \{\tilde{A}^k\}_{k=1,2,\ldots} and \{A^k\}_{k=1,2,\ldots} be two families of Wick powers (Definition 5.2) of the same locally-covariant quantum V-field A (Definition 4.2) of homogeneous scaling degree \(d_A \in \mathbb{R}^N\). Then there exists a family of smooth locally-covariant c-number \(S^k\)V-fields \(\{C_k\}_{k=1,2,\ldots}\), where \(C_1 = 0\), such that, for every \(k = 1, 2, \ldots\),

\[
\tilde{A}^k_{(M,b)}(f) = A^k_{(M,b)}(f) + \sum_{l=0}^{k-1} A^l_{(M,b)} (C_{k-l}[M,b] \cdot \kappa - l f),
\]

(5.8)

where \((M,b) \in \mathfrak{B}\mathfrak{g}\mathfrak{S}\) (resp. \(\mathfrak{B}\mathfrak{g}\mathfrak{S}^+\)) and \(f \in \mathcal{D}(S^kV^*M)\). In components equation (5.8) turns out to be

\[
\tilde{A}^P_{(M,b)} (f_1^{p_1}, \ldots, f_N^{p_N}) = A^P_{(M,b)} (f_1^{p_1}, \ldots, f_N^{p_N})
\]

\[
+ \sum_{l=0}^{k-1} \sum_{|Q|=l} \left( \prod_{i=1}^N \frac{(p_i)}{(q_i)} \right) A^Q_{(M,b)} \left( \left( C^{P-Q}_{k-l}[M,b] \cdot \kappa - l f^{P-Q} \right) f_1^{p_1}, \ldots, f_N^{p_N} \right)
\]

(5.9)

where \(Q = (q_1, \ldots, q_N)\), \(P = (p_1, \ldots, p_N)\) are multi-indices and \(C_k = \sum_{|Q|=k} C^Q_k\).

Finally, for every fixed \(M \in \mathfrak{M}n\),

(i) the map

\[
\Gamma(BM) \ni b \mapsto C_k[M,b] \in \mathfrak{S}(S^kV^*M)
\]

is a differential operator of locally bounded order. Regarding components of the coefficients \(C^Q_k[M,b] \in \mathfrak{S}(\bigotimes_{i=1}^N S^{q_i}W^*_i M)\);

(ii) each \(C^Q_k[M,b]\) scales almost homogeneously of degree \((Q,d_A)\) under the physical scaling transformation on \(b\).

**Proof.** In the first part of the proof we write \(A(f)\) in place of \(A_{(M,b)}(f)\) and we adopt similar notations for the other involved fields, for the sake of notational simplicity. For all \(k\), the difference

\[
\tilde{A}^k(f) - A^k(f) = D_k(f), \quad f \in \mathcal{D}(S^kV^*M)
\]

defines, by construction, a symmetric locally-covariant quantum V-field of order \(k\), in particular is self-adjoint. Using Axiom 1 and the commutator expansion (5.6) in Axiom 4, it is easy to show that

\[
[D_k(f), A(g)] = iD_{k-1} (\Delta(g) \cdot f).
\]

(5.10)

\(D_k(f)\) is an element of the algebra \(W(M,b)\) and we go to prove that it can be expanded as a linear combination of elements of the form \(A^l\).

We proceed by induction in \(k\). The thesis holds for \(k = 1\) and \(C_1 = 0\) since, using again Axiom 1, \(D_1(f) = 0\) for all \(f \in \mathcal{D}(V^*M)\). Suppose now that (5.8) holds for \(k-1\) with respect to some functions \(C_i: \Gamma(BM) \rightarrow \mathfrak{S}(S^iV^*M), i = 1, 2, \ldots, k - 1\), that satisfy all the desired properties.
We intend to establish the validity of the thesis also for \( i = k \). Consider the Wick polynomial, for \( f \in \mathcal{D}(S^kVM) \),

\[
W_k(f) := \sum_{l=1}^{k-1} A^l(C_{k-l}[M, b] \cdot k-l f).
\]

We stress that the sections \( C_{k-1}[M, b], C_{k-2}[M, b], \ldots, C_1[M, b] \) appearing in the sum, by hypotheses are smooth and have all the desired properties stated in the theorem. Writing \( C_{k-1} \) in place of \( C_{k-1}[M, b] \), we have:

\[
[D_k(f) - W_k(f), A(g)] = iD_{k-1}(\Delta(g) \cdot f) - \sum_{l=1}^{k-1} \left[ A^l(C_{k-l} \cdot k-l f), A(g) \right]
\]

\[
= i \sum_{l=0}^{k-2} A^l(C_{k-1-l} \cdot k-1-l \Delta(g) \cdot f) - \sum_{l=1}^{k-1} iA^{l-1}(\Delta(g) \cdot f) \cdot C_{k-l} \cdot k-l f)
\]

\[
= i \sum_{l=1}^{k-1} A^{l-1}(C_{k-l} \cdot k-l \Delta(g) \cdot f) - A^{l-1}(\Delta(g) \cdot f) \cdot C_{k-l} \cdot k-l f) = 0,
\]

where we have used Proposition 2.1. Thus, we can conclude that \( [D_k(f) - W_k(f), A(g)] = 0 \) for any test function \( g \). Due to Axiom 3 we must therefore have

\[
D_k(f) - W_k(f) = C_k(f) 1,
\]

where \( C_k(f) \) is real and must define a locally-covariant \( c \)-number \( S^kV \)-field since it is a difference of that type of fields.

Next, we will appeal to the Peetre-Slovák theorem to characterize the dependence of \( C_k(f) \) on the background field \( b \). This theorem has two main hypotheses: \textit{locality} and \textit{weak regularity}, which we verify by the covariance and smoothness axioms, respectively. Let us consider any smooth variation of the background field \( b_s \), together with a corresponding family of distinguished states \( \omega^{(s)} = \omega \circ \tau_s^{-1} \). Then, the smoothness axiom implies that the left-hand side of

\[
\omega^{(s)}(D_{k[b,s]}(f) - W_{k[b,s]}(f)) = C_{k[b,s]}(f),
\]

is a distribution with smooth real kernel (it is real due to the \textit{hermiticity} axiom), meaning that so is \( C_{k[b,s]}(f) \), with \( C_{k[M, b_s]} \in \mathcal{D}(S^kVM) \) denoting its integral kernel for fixed \( s \). Moreover, the axiom also implies that \( C_{k[M, b_s]}(x) \) is jointly smooth in \( (x, s) \) and hence weakly regular. On the other hand, the covariance requirement implies that the dependence of \( C_k[M, b_s][x] \) at any point \( x \in M \) is local, for any fixed manifold \( M \). Namely, using smaller and smaller neighborhoods \( M' \ni x \) with \( M' \subseteq M \) viewed as background geometries on their own right (when equipped with the restriction of \( b \) to \( M' \)), covariance with respect to the inclusion embeddings \( \chi: M' \ni x' \rightarrow x' \in M \) implies that \( C_k[M, b_s][x] \) depends only on the germ of \( b \) at \( x \).

Thus the map \( C_k[M, \cdot] \) is local and weakly regular. The Peetre-Slovák theorem implies that \( \Gamma(BM) \ni b \mapsto C_k[M, b] \in \mathcal{D}(S^kVM) \) is a differential operator of locally bounded order. Summing up, we have proved that

\[
\tilde{A}^k(f) - A^k(f) = D_k(f) = W_k(f) + C_k(f) 1 = \sum_{l=0}^{k-1} A^l(C_{k-l} \cdot k-l f),
\]

where all coefficients \( C_l[M, b] \) from \( l = 0 \) to \( l = k \) have all properties stated in the thesis, but the scaling property which must be still established for \( C_k \) only. Choosing as test function
$f = f^P_1 \odot \cdots \odot f^P_N$ and using relation (e) and (d) from Proposition 2.2, we obtain immediately the formula (5.9).

Proceeding again by induction, thanks to the scaling property of $A^P$, $\tilde{A}^P$ and $(C^Q_k)_{l=1}^{k-1}$, $C^Q_k$ is a linear combination of products of terms with almost homogeneous degree that add up to $\langle Q, d_A \rangle$. Thus, by Lemma 5.1, $C^Q_k$ itself has almost homogeneous degree $\langle Q, d_A \rangle$, and thus

$$S_\lambda C^Q_k 1 = \lambda^{\langle Q, d_A \rangle} C^Q_k 1 + \lambda^{\langle Q, d_A \rangle} \sum_{j=1}^I (\log^j \lambda) B^Q_j,$$

where $S_\lambda$ is the action of physical scalings on fields here applied to a c-number field, with $B^Q_j$ some other quantum fields of almost homogeneous degree $\langle Q, d_A \rangle$. Using again the kinematic completeness of $A$, we find that $B^Q_j = F^Q_j 1$ are also c-number fields. Now, exploiting the definition of $S_\lambda$ as in (4.3), we find that $S_\lambda C^Q_k 1 = C^Q_k 1$, and similarly for the $F^Q_j$. Therefore, we find that for every $x \in M$,

$$C^Q_k [M, b_\lambda](x) = \lambda^{\langle Q, d_A \rangle} C_k [M, b](x) + \lambda^{\langle Q, d_A \rangle} \sum_{j=1}^I (\log^j \lambda) F^Q_j [M, b](x),$$

is an almost homogeneous element of degree $\langle Q, d_A \rangle$ of the vector space of maps $\Gamma(BM) \rightarrow \mathcal{E}(\otimes_{i=1}^N S^\otimes W^*_i M)$ under the action $F[M, b] \mapsto F[M, b_\lambda]$. The proof is concluded. \qed

We have finally obtained a general formula, (5.8), that classifies all finite renormalizations counterterms of Wick powers of a generic locally-covariant boson vector field $A$, where the coefficients $C_k [M, b]$ depends on the type of vector bundle $VM$ and the nature of background fields $b$ of the field $A$. For this reason, in order to study in detail these coefficients, we have to consider physically relevant models.

## 6 Tensor fields and renormalizations of their Wick powers

In this section we consider a class of physically relevant models and we study in detail the renormalization counterterms $C_k$ introduced in the last section. We choose as bundles

$$VM = \bigoplus_{i=1}^N T^* \otimes k_i M, \quad BM = \hat{S}^2 T^* M \oplus \bigoplus_{j=1}^K T^* \otimes l_j M$$

which means that we are considering as fields an $N$-tuple of tensor fields with different tensor ranks

$$A = (A_1, \ldots, A_N) \quad A_i : \mathcal{D}(T^* \otimes k_i M) \longrightarrow W(M, b)$$

and we will say that $A$ has tensor rank $k = (k_1, \ldots, k_N)$. As background fields we consider the metric $g$ together with other (covariant) tensor fields $t_j$ of rank $l_j$

$$(g, t_1, \ldots, t_K), \quad g \in \mathcal{E}(\hat{S}^2 T^* M), \quad t_j \in \mathcal{E}(T^* \otimes l_j M).$$

Regarding physical scaling, we assume the most general situation, i.e.,

$$A_i \rightarrow \lambda^{d_A_i} A_i, \quad (g, t_1, \ldots, t_K) \rightarrow \left( \lambda^{-2} g, \lambda^{s_1} t_1, \ldots, \lambda^{s_K} t_K \right) \quad \lambda \in \mathbb{R}^+$$

under physical scaling transformation, where $s_j \in \mathbb{R}$ for $j = 1, \ldots, K$. We require also another property of the background fields, encoded in the following
Definition 6.1. A background field $t_j$ is called \textbf{admissible} if its rank $l_j$ and its degree under physical scaling $s_j$ fulfill the following condition

$$l_j + s_j \geq 0.$$ 

If the above relation is an equality, then we also call $t_j$ \textbf{marginal}. By convention, let us order the background fields such that each $t_j$ for $j = 1, \ldots, K_0 \leq K$ is marginal and collectively denote them by $z = (t_1, \ldots, t_{K_0})$. To emphasize their distinction from other background fields, we will also use the notation $z_j = t_j$.

Remark 11. We have chosen all dynamical and background tensor fields to be purely covariant, \textit{i.e.}, to be sections of powers of the cotangent bundle $T^* M$. This choice is motivated purely by convenience and the desire not to complicate our notation even further. Our main results, Theorems 5.2 and 6.2, hold in easily adapted forms also for contravariant or mixed tensors, as well as for tensors of symmetric, antisymmetric, or any other symmetry type. One does have to note that, in the definition of \textit{admissible} and \textit{marginal} background fields (Definition 6.1), the tensor rank $l_j$ must be taken to be the number of covariant tensor indices minus the number of contravariant indices of $t_j$.

Before studying the exact form for the renormalization counterterms in this case, we need to recall some results.

Preparatory definitions and results. In this paragraph, we introduce various local coordinate systems on $BM$ and $J^r BM$ together with the description of a particular class of diffeomorphisms called \textit{coordinate scalings}.

Let $(x^a)$ be a local coordinate chart on the open set $U \subseteq M$ and let $(x^a, g_{ab}, \ldots, (t_j)_{a_1 \ldots a_l} \ldots)$ be the corresponding adapted local coordinates on $Z \subseteq BM$ where by definition $Z$ projects onto $U$ and, more strongly, each fiber $BM_x$ is completely included in $Z$ if $x \in U$.

• \textbf{Covariant coordinates}. According to Definition 2.3, the chart $(x^a)$ on $U$ induces corresponding adapted local coordinates on $J^r BM$ called \textit{covariant coordinates}

$$\left( x^a, g_{ab,A}, (t_j)_{a_1 \ldots a_l,A} \right) \quad \text{on the afore-mentioned domain } Z^r \subseteq J^r BM,$$

where only $n(n+1)/2$ metric components are considered because $g_{ab}$ is a symmetric tensor.

• \textbf{Contravariant coordinates}. Since Lorentzian metrics are non-degenerate, they admit an inverse denoted, using a standard notation, with $g^{ab}$. We correspondingly obtain induced coordinates $g^{ab}_A$ on jets of the inverse-metric bundle. Using the notation $g^{AB} = g^{a_1b_1} \ldots g^{a_l b_l}$, for $|A| = |B| = l$, we define the following functions:

$$g = |\det g_{ab}|, \quad g^{ab,A} = g^{AB}g_{B}^{ab}, \quad (t_j)^{a_1 \ldots a_l,A} = g^{AB}(t_j)_B^{a_1 \ldots a_l},$$

where we have chosen fully contravariant coordinates for tensor bundles. We have then obtained the set of local \textit{contravariant coordinates}

$$\left( x^a, g^{ab,A}, (t_j)^{a_1 \ldots a_l,A} \right) \quad \text{on } Z^r \subseteq J^r BM.$$

• \textbf{Rescaled contravariant coordinates}. We can obtain another coordinate set by a suitable rescaling of the previous one: we introduce a factor of the form $g^\alpha$, with $\alpha \in \mathbb{R}$, to rescale the coordinates (n is the dimension of M):

$$\left( x^a, g, g^{-\frac{1}{n}}g_{ab}, g^{\frac{1}{n} + \frac{1}{n} |A|} g_{ab,A}, g^{\frac{1}{n} + \frac{s_j}{n} + \frac{1}{n} |A|}(t_j)^{a_1 \ldots a_l,A} \right) \quad \text{on } Z^r \subseteq J^r BM.$$

It should be noticed that the functions $g$ and $g^{-\frac{1}{n}}g_{ab}$ are not functionally independent due to the identity $g^{-1} = |\det g^{ab}|$. So, to make an honest the coordinate system, we (implicitly) omit one of the components of $g^{-\frac{1}{n}}g_{ab}$ and replaced by $g$. The relevance of the rescaled contravariant coordinates consists of the fact since $s_j$ is the (physical) scaling degree of $t_j$ these coordinates without the coordinate $g$, 

$$
\left(x^a, g^{-\frac{1}{n}}g_{ab}, g\frac{1}{n+\frac{1}{n}|A|}g^{ab,A}, g\frac{1}{n+\frac{1}{n}|A|}(t_j)^{a_1...a_l,A}\right)
$$

are invariant under physical scaling.

- **Curvature coordinates.** Since we have a Lorentzian metric $g$, we can always define the Levi-Civita connection $\nabla$ and the Riemann tensor $R$. By well-known formulas, we can also regroup the second order jet coordinates of the metric into the components of the Christoffel symbols $\Gamma^a_{bc}$, and the components of the fully covariant Riemann tensor $\bar{R}_{abcd}$. An alternative way to regroup the components of the Riemann tensor is into the fully contravariant tensor $S$, with components

$$
S_{abcd} := g^{aa'}g^{bb'}\bar{R}_{a'}^{(c,d)}.
$$

We denote by $\Gamma^a_{bc,A}$ the components of the $\partial_A$ coordinate derivatives of $\Gamma^a_{bc}$, by $\bar{S}^{abcd,A}$ the components of the symmetrized contravariant $\nabla^A = \nabla^{(a_1}...\nabla^{a_l)}$ derivatives of $S$, with $(\bar{t}_j)^{a_1...a_l,A}$ the components of the symmetrized contravariant derivatives of $(t_j)^{a_1...a_l}$. It is possible to prove [AT94, AT96] that

$$
\left(x^a, g_{ab}, \Gamma^a_{(bc,A),}, \bar{S}^{abcd,A}, (\bar{t}_j)^{a_1...a_l,A}\right)
$$

defines a complete coordinate system on $Z^r \subseteq J^rBM$, which we call curvature coordinates.

- **Rescaled curvature coordinates.** Analogously to rescaled contravariant coordinates, we can rescale the curvature coordinates obtaining a new coordinate system

$$
\left(x^a, g, g^{-\frac{1}{n}}g_{ab}, \Gamma^a_{(bc,A)}, g^{\frac{1}{2}+\frac{1}{2}|A|}\bar{S}^{abcd,A}, g^{\frac{1}{2}+\frac{1}{2}|A|}(\bar{t}_j)^{a_1...a_l,A}\right).
$$

As before, removing $g$ form the set of rescaled curvature coordinates we find a set of coordinates which is fixed under physical scaling (since $s_j$ is the scaling degrees of $t_j$).

- We call a diffeomorphism $M \rightarrow M$ a coordinate scaling around of $p \in M$ if, in a neighborhood of $p$ whose closure is included in the domain $U \subseteq M$ of local coordinates $(x^a)$ centered at $p$ itself, it acts as

$$
x^a \mapsto \mu^{-1}x^a \quad (a = 1, \ldots, n)
$$

for some $\mu > 0$, and smoothly extends to the identity before reaching the boundary of $U$. More precisely, defining $t := -\ln \mu$, the class of coordinate scaling around $p$ is represented by the one-parameter group of diffeomorphisms $\{\phi_t\}_{t \in \mathbb{R}}$ of the whole $M$ leaving $p$ fixed generated by the globally defined vector field $V^a = -h x^a \frac{\partial}{\partial x^a}$, where $h \in C_0^\infty(M)$ vanishes before reaching the boundary of $U$ and attains the constant value 1 in a neighborhood of $p$. We stress that, unlike physical scaling, these transformation are induced by diffeomorphisms of $M$. 

26
Lemma 6.1. Consider an admissible background field $t_j$. Then all its rescaled coordinates have positive or null scaling weight under coordinate scaling. In particular the rescaled coordinates scale as

$$g^{1/2} + x/a |A| (t_j)^{a_1...a_j,A} \mapsto g^{1/2} + x/a |A| (t_j)^{a_1...a_j,A}$$

Proof. Under coordinate scaling we have the following rescaling

$$(\bar{t}_j)^{a_1...a_j,A} \mapsto \mu^{1/2} [\bar{t}_j]^{a_1...a_j,A}.$$  

Then the result follows immediately. \hfill \Box

We are finally ready to state and prove our main result, which generalizes Theorem 3.1 of [KM16].

Theorem 6.2. Let $\{A^k\}_{k=1,2,...}$ and $\{\bar{A}^k\}_{k=1,2,...}$ be two families of Wick powers (Definition 5.2) of the same locally-covariant quantum $V$-field $A$ of homogeneous scaling degree $d_A \in \mathbb{R}^N$ and tensor rank $k$ (same as in Theorem 5.2), where the natural vector bundle $V = \bigoplus_{i=1}^N W_i$ is the $N$-tuple introduced in (6.1). Assume also that all background fields $b$, sections of the bundle $BM$ (Definition 3.3), are admissible (Definition 6.1). Recall also from Theorem 5.2 the renormalization coefficients $C_k$, $k = 1, 2, ..., (k = 0)$ appearing in (5.8) when comparing two families of Wick powers of $A$. Finally, recall the notation $R_{abcd}$ for the Riemann tensor, $\nabla_a$ for the Levi-Civita connection of $g_{ab}$, and $e^{a_1...a_n}$ for the associated Levi-Civita tensor.

Then the following facts hold:

(a) If $Q = (q_1, \ldots, q_N)$ is a multi-index with $|Q| = k$ such that $\langle Q, d_A + k \rangle = \sum_{i=1}^N q_i (d_{A_i} + k_i) < 0$, then the corresponding component $C_k^Q$ of the renormalization coefficient $C_k$ vanishes.

(b) If $A$ is locally covariant with respect to the category $\mathfrak{BtgS}$ (Definition 3.4), then for every background geometry $(M, b)$, every $x \in M$ and each $k = 1, 2, \ldots$, the renormalization coefficients $C_k$ are given by differential operators of globally bounded order

$$C_k[M, b](x) = C_k \left( g^{ab}(x), R_{abcd}(x), \ldots, \nabla_{e_1} \cdots \nabla_{e_k} R_{abcd}(x), \ldots \right.$$  

$$\left. \ldots (t_j)^{a_1...a_j}(x), \ldots, \nabla_{e_1} \cdots \nabla_{e_r} (t_j)^{a_1...a_j}(x), \ldots \right),$$

where $C_k(\cdots)$ is a tensor field covariantly constructed from its arguments, whose structure is described in more detail below.

(c) If $A$ is locally covariant with respect to the category $\mathfrak{BtgS}^+$ (Definition 3.4), then for every background geometry $(M, b)$, every $x \in M$ and each $k = 1, 2, \ldots$, the renormalization coefficients $C_k$ are given by differential operators of globally bounded order

$$C_k[M, b](x) = C_k \left( g^{ab}(x), \varepsilon^{a_1...a_n}, R_{abcd}(x), \ldots, \nabla_{e_1} \cdots \nabla_{e_k} R_{abcd}(x), \ldots \right.$$  

$$\left. \ldots (t_j)^{a_1...a_j}(x), \ldots, \nabla_{e_1} \cdots \nabla_{e_r} (t_j)^{a_1...a_j}(x), \ldots \right),$$

where $C_k(\cdots)$ is a tensor field covariantly constructed from its arguments, whose structure is described in more detail below.
In both (b) and (c), by covariantly constructed we mean that the $C_k$ are equivariant functions of their tensorial arguments, at each $x \in M$, in the sense of Lemma C.8. That is, each $C_k(...)$ is a linear combination of finitely many covariantly constructed tensors that are polynomial in $g_{ab}$, $g^{ab}$ and the rest of the tensorial arguments, with scalar coefficients that are smooth functions depending locally (Definition C.6) on finitely many polynomial scalars covariantly constructed from the tensor fields $z$, which consist of those background tensors $t$, that are marginal according to Definition 6.1. Moreover, the functional form of the $C_k(...)$ does not depend on $(M, b)$.

Finally, each $C_k$ can be written as $C_k = \sum_{Q=0}^{d_k} C_k^Q$ with respect to the multiplet decomposition $V = \bigoplus_{i=1}^{N} W_i$, where $Q$ is a multi-index and where each $C_k^Q$ is homogeneous degree under physical scalings. More precisely, it scales as

$$C_k^Q \mapsto \lambda^{(Q,d_k)}C_k^Q,$$

when its arguments are rescaled according to

$$(t_j)_{a_1...a_j} \mapsto \lambda^s(t_j)_{a_1...a_j}, \quad g^{ab} \mapsto \lambda^2 g^{ab}, \quad \varepsilon^{a_1...a_n} \mapsto \lambda^n \varepsilon^{a_1...a_n}, \quad R_{abcd} \mapsto \lambda^{-2} R_{abcd}$$

(the covariant derivatives are fixed under rescaling). These scaling properties fix the upper bound on the differential and polynomial order of $C_k^Q$.

**Remark 12.** Before going on to the proof, how it resembles and differs from the proof of Theorem 3.1 of [KM16], which proved a similar result but only for scalar dynamical and background fields. Generally speaking, the structure of the two proofs are similar, which are broken down into roughly the same number of steps, roughly in the same sequence. In both cases, we start out by knowing that the renormalization coefficients $C_k[M, b]$ are differential operators of locally bounded order. Hence, each $C_k$ is given by a smooth function defined on the jet bundle $J^rBM$ of the background fields, at least when applied to sections $b$ whose jets fall into some open neighborhood in the jet bundle. The remaining steps gradually fix the structure of the $C_k$ more and more rigidly, while also expanding its domain of definition on $J^rBM$, ultimately extending it to the entire jet bundle and thus showing that it is of *globally bounded* differential order. The structure of $C_k$ is first restricted by appealing to its properties under physical scaling, using results from Appendix A. One immediate difference in the new proof is the need to keep track of different (both physical and coordinate) scaling weights for the different components of the $C_k$. Next, the structure of the $C_k$ is further restricted by its local covariance, meaning that it commutes with diffeomorphisms. The results from Appendix B, provide the necessary tools for that, which essentially consist of a strengthened version of the Thomas Replacement Theorem reported in [KM16, Prop.2.6]. Finally, local covariance is once again used to fix the final form of the $C_k$, by using the results of Appendix C, which essentially strengthen the classification of equivariant and isotropic tensors reported in [KM16, Prop.2.7,Lem.2.8]. These supporting results needed to be strengthened, compared to the ones used in [KM16], because of the transition from only scalar dynamical and background fields to tensorial ones. While, the results reported in Appendices B and C are not original, they are somewhat difficult to locate in the existing literature. Thus, when possible to do so in a reasonably concise and elementary manner, they are reported with proofs and references to more specialized literature.

**Proof.** We already know that, from the Peetre-Slovák theorem (see Section 2.2), the coefficients $C_k^Q$ define a differential operator

$$\Gamma(BM) \ni b \mapsto C_k^Q[M, b] \in \mathcal{E}\left(\bigotimes_{i=1}^{N} S^q T^* \otimes k_i M\right) \subseteq \Gamma\left(\bigotimes_{i=1}^{N} S^q T^* \otimes k_i M\right)$$

of locally bounded order as established in Theorem 5.2. The rest of the proof is broken down into five steps, which are described in more detail below.
1. Physical scaling. We now take advantage from almost homogeneity under physical scaling of the components of the coefficients $C_k^Q$ to find their functional form. Consider a Lorentzian manifold $M$ endowed with a metric $g_0$, as well as a point $y \in M$ and an open neighborhood of $U$ of $y$ with compact closure. We also assume that $g_0$ restricted to $U$ is flat. Consider also a coordinate system $(x^d)$ on $U$ centered at $y$. These coordinates induce adapted local coordinates on $Z^r \subseteq J^rBM$, which we write as

$$(x^a, g, g^{ab}, (t_1)^{a_1}, \ldots, (t_K)^{a_1\ldots a_K}).$$

Recall that the coordinates $(g, g^{ab})$ are functionally independent up to the identity $|\det g_{ab}| = g$. We already know that $b \mapsto C_k^Q[M, b](x)$ is a differential operator of locally bounded order, thus for $g_0, y$ and $U$ (defined as above), there exists an integer $r \geq 0$ such that $C_k^Q$ is a differential operator on $U$ of local order $r$ when acting on sections of $BM$ close to $b_0 := (g_0, t_j = 0)^4$. In other words, there exists a neighbourhood $Z_1^r \subseteq Z^r \subseteq J^rBM$ of $j^r_b b_0$, projecting onto $U$, and a function

$$F_k^Q: Z_1^r \rightarrow \left( \bigotimes_{i=1}^N S_k^a T^{\otimes k_i} M \right) (x^a, g, g^{ab}, (t_j)^{a_1}, \ldots) \mapsto F_k^Q \left( x^a, g, g^{ab}, (t_j)^{a_1}, \ldots \right),$$

such that

$$C_k^Q[M, b](x) = F_k^Q \left( j^r b(x) \right), \quad (6.2)$$

for any section $b \in \Gamma(BM|U)$ such that $j^r b(U) \subseteq Z_1^r$. Without loss of generality, but possibly shrinking the domain of $F_k$, we choose it in such a way that

$$Z_1^r \simeq U \times W_1^r \rightarrow (x^a) \left( g, g^{ab}, (t_j)^{a_1}, \ldots \right).$$

At the moment, we are very far from arguing that $Z_1^r = J^rBM$ especially because, using the Peetre-Slovák theorem we only know that the order of the differential operator $C_k$ is locally bounded and a finite global bound may not exist. During the proof we will gradually enlarge the domain $Z_1^r$ to eventually cover all of $J^rBM$ while maintaining the identity $(6.2)$. The differential order $r$ of $C_k^Q$ may increase in the process, but will remain finite. These extensions will be labeled by an increasing index $j$ in $Z_1^r$. Presently $j = 1$.

Theorem 5.2 implies that $C_k^Q$ and hence the function $F_k^Q$ scales almost homogeneously with degree $\langle Q, dA \rangle$ under physical scaling of the background fields. Thus, thanks to Lemma A.1 and Lemma A.2, there exists an integer $l > 0$ and function $B_j$ on $Z_1^r$, for $h = 0, \ldots, l$, such that

$$F_k^Q = g - \langle Q, dA \rangle \sum_{h=0}^l \log^h \left( g^{-\frac{1}{2n}} \right) B_h, \quad (6.3)$$

where each $B_h$ is invariant under the action of physical scaling. Therefore, adopting rescaled coordinates (which are invariant under physical scaling), $B_h$ cannot depend on $g$ and can be written as

$$B_h = B_h \left( x^d, g^{-\frac{1}{2n}} g_{ab}, g^{\frac{1}{2n} + \frac{1}{2} A} g^{ab}, \ldots, g^{\frac{1}{2n} + \frac{1}{2} A} (t_j)^{a_1}, \ldots \right).$$

\footnote{We stress that the flatness assumption on $g_0$ is not a strong requirement because the flat metric is only the section with respect to which we consider variations. At the moment we can consider only metrics in a neighbourhood of $g_0$ but we will gradually enlarge it to the whole set of Lorentzian metrics. A similar argument is also valid for all $t_j$, which at the moment have to be close to the sections $t_j = 0$.}
We now extend the domain $Z_1^r$ to a larger domain $Z_2^r \subseteq J^rBM$. We define $Z_3^r$ to be the smallest domain invariant under physical scaling and containing $Z_1^r$. That is, we can write it as

$$Z_3^r \simeq \mathbb{R}^+ \times U \times W_2^r$$

$$\downarrow \quad \downarrow \quad \downarrow$$

$$\left( g \right) \quad \left( x^a \right) \quad \left( g_{ab} \right) \left( \Gamma_{(bc,A)}^a \right) \left( g^{\frac{1}{2} + \frac{1}{2} |B| g_{ab} B, g^{\frac{1}{2} + \frac{1}{2} |A| (j)_{a_1 \cdots a_j} A} \right).$$

Up to now, we know that the identity (6.2) holds only when the germ of $b$ at $x \in M$ projects onto one of the jets in the domain $Z_1^r \subseteq J^rBM$, but the function $F_k^Q$, via formula (6.3), has a unique extension to $Z_2^r$ that scales almost homogeneously and agrees with $F_k^Q$ on $Z_1^r$. The identity (6.2) must remain valid also for germs at $x$ that projects onto $Z_2^r$ since any element of $b' \in Z_2^r$, using the action of physical scaling, can be brought back to $b \in Z_1^r$, i.e., $b' = b_\lambda$ for some $\lambda > 0$. Since $C_k^Q|M, b|$ scales almost homogeneously and is already defined on $Z_2^r$, we conclude that it must coincide there with the unique extension of $F_k^Q$.

2. Diffeomorphism covariance. We consider now the covariance properties of the coefficient $C_k^Q$ under diffeomorphisms. In the previous paragraph, we fixed a point $y \in M$ and a fixed background geometry $b_0$. But, since that choice was arbitrary, all the same results are also valid for any other choice of $y' \in M$, open neighborhood $U' \subseteq M$ of $y'$ and background geometry $b_0'$, so long as $b_0 = \chi^* b_0$ on $U'$, where $\chi: M \to M$ is some diffeomorphism such that $\chi(y') = y$. The Peetre-Slováik theorem gives us a differential operator of order $r'$ on a domain $Z_2^{r'} \subseteq J^{r'}BM$. The diffeomorphism covariance of $C_k^Q$ then implies that the order may be chosen the same, $r = r'$.

We now extend the domain $Z_2^r$ to a larger domain $Z_3^r \subseteq J^rBM$. We define $Z_3^r$ to be the smallest domain invariant under Diff($M$) and containing $Z_2^r$. Since the coefficient $C_k^Q$ is Diff($M$)-covariant, the function $F_k^Q$ is itself Diff($M$)-covariant on $Z_3^r$. The case of orientation preserving diffeomorphisms Diff($M$) is strictly analogous.

Now we can use Thomas replacement theorem (Theorem B.3) in order to eliminate the dependence of $F_k^Q$ on some of the coordinates on $Z_3^r$. We apply Theorem B.3 separately to the various functions $B_h$ appearing in (6.3), obtaining

$$g^{-\frac{Q,d_A}{2n}} B_h \left( x^a, g^{-\frac{1}{2} g_{ab}}, g^{\frac{1}{2} + \frac{1}{2} |A| g^{ab}, A}, g^{\frac{1}{2} + \frac{1}{2} |A| (j)_{a_1 \cdots a_j} A} \right)$$

$$= g^{-\frac{Q,d_A}{2n}} G_j \left( g^{-\frac{1}{2} g_{ab}}, g^{\frac{1}{2} + \frac{1}{2} |A| g_{ab} B, A}, g^{\frac{1}{2} + \frac{1}{2} |A| (j)_{a_1 \cdots a_j} A} \right),$$

where each $g^{-\frac{Q,d_A}{2n}} G_j$ is equivariant under the action of $GL(n)$ (respectively $GL^+(n)$). In particular, $G_j$ does not depend on the coordinates $(x^a)$ and $(\Gamma_{(bc,A)}^a)$. Since $Z_3^r$ is Diff($M$) invariant it has the structure:

$$Z_3^r \simeq U \times \mathbb{R}^n \times W_3^r$$

$$\downarrow \quad \downarrow \quad \downarrow$$

$$\left( x^a \right) \quad \left( g_{ab} \right) \left( \Gamma_{(bc,A)}^a \right) \left( g^{\frac{1}{2} + \frac{1}{2} |B| g_{ab} B, A}, g^{\frac{1}{2} + \frac{1}{2} |A| (j)_{a_1 \cdots a_j} A} \right).$$

The second factor describes the metrics at a fixed point $p \in U$ and coincides with the full set $L_n$ of non-degenerate bilinear forms on $\mathbb{R}^n$ with Lorentzian signature. This is because the fiber action of the subgroup of Diff($M$) which leaves $p$ fixed is the action of the whole $GL(n)$ which, in turn, acts transitively on $L_n$. $W_3^r$ contains at least the point with all components
Let's recall that $F$ is constructed with the tensor ranks $k$ and all remaining coordinates, here denoted by $q$. The components of the marginal background fields $(g, z)$ are smooth there. Therefore we have the Taylor expansions of the argument of the functions $G$ around $(g, z)$, here denoted by $q^i$, $i = 1, \ldots, m_q$, have positive weight ($d_i > 0$) under coordinate scalings. There are no coordinates with negative weight (Lemma 6.1).

We can rewrite the set of coordinates over $\mathbb{R}$ for any point in $\mathbb{R}^n$. Now we use the equivariance of the function $F_k^Q$ under the action of a subgroup of $GL(n)$ (respectively $GL^+(n)$), the subgroup of coordinate scaling.\(^5\) We can rewrite the set of coordinates over $\mathbb{R}$ for any point in $\mathbb{R}^n$. The same argument applies to $Diff^+(M)$ and $GL(n)^+$.  

3. Covariance under coordinate scaling. Now we use the equivariance of the function $F_k^Q$ under the action of a subgroup of $GL(n)$ (respectively $GL^+(n)$), the subgroup of coordinate scaling.\(^5\) We can rewrite the set of coordinates over $\mathbb{R}$ for any point in $\mathbb{R}^n$. The same argument applies to $Diff^+(M)$ and $GL(n)^+$.

\[ F_k^Q \left( g, g^{-\frac{1}{2}}g_{ab}, z^j, q^i \right) = \mu^{-(Q,k)} F_k^Q \left( \mu^{2n} g, g^{-\frac{1}{2}}g_{ab}, z^j, \mu^{d_i} q^i \right) \]

\[ = g^{-\frac{(Q,d_{k})}{2n}} \sum_{h=0}^{l-1} \mu^{-(Q,d_{k}+k)} \log^h \left( \mu^{-1} g^{-\frac{1}{2n}} \right) G_h \left( g^{-\frac{1}{2}}g_{ab}, z^j, \mu^{d_i} q^i \right) \tag{6.4} \]

for any point in $Z_5$ and any $\mu > 0$. As we mentioned in the previous part, the limit $(g^{-\frac{1}{2}}g_{ab}, z^j, 0)$ of the argument of the functions $G_h$ as $\mu \to 0$, belongs to the domain of the function $G_h$, which is smooth there. Therefore we have the Taylor expansions

\[ G_h \left( g^{-\frac{1}{2}}g_{ab}, z^j, q^i \right) = \sum_{|I|<N_q} G_{h,I} \left( g^{-\frac{1}{2}}g_{ab}, z^j \right) q^I + O \left( q^{N_q} \right) , \]

around $(g, g^{-\frac{1}{2}}g_{ab}, z^j, 0)$, where $I = i_1 \cdots i_{m_q}$ is a multi-index with respect to the coordinates $(q^i)$, the coefficients $G_{h,I}$ are smooth, and $N_q > 0$ is an integer such that

\[ \langle d, I \rangle = \sum_{j=1}^{m_q} d_j i_j > \langle Q, d_{k} + k \rangle \quad \text{for all } I \text{ such that } |I| \geq N_q. \]

\(^5\)This part of the proof is analogous to part 4. of the proof of Theorem 3.1 in [KM16]. Unfortunately, that earlier argument contained an error when eliminating logarithmic terms from $F_k$. This error has been corrected in the current argument, which should also be considered retroactively inserted into the proof given in [KM16].
This choice guarantees that each error term \( O(q^{N_s}) \) is mapped to \( O(\mu^{(Q.d_A+k)+1}) \) under the substitution \( q^i \mapsto \mu^d q^i \) as \( \mu \to 0 \). Thus we obtain

\[
F_k^Q \left( g, g^{-\frac{1}{2}} g_{ab}, z^j, q^i \right) = g^{-\frac{(Q.d_A)}{2n}} \sum_{h=0}^{l-1} \mu^{-\frac{(Q.d_A+k)}{2n}} \log^h \left( \mu^{-\frac{1}{2}} g^{-\frac{1}{2n}} \right) G_h \left( g^{-\frac{1}{2}} g_{ab}, z^j, \mu^d q^i \right)
\]

\[
= g^{-\frac{(Q.d_A)}{2n}} \sum_{h=0}^{l-1} \sum_{|l|<N_q} \mu^{(d,l)-\frac{(Q.d_A+k)}{2n}} \log^h \left( \mu^{-\frac{1}{2}} g^{-\frac{1}{2n}} \right) G_h,l \left( g^{-\frac{1}{2}} g_{ab}, z^j \right) q^l
\]

\[
+ \mu^{-\frac{(Q.d_A+k)}{2n}} O \left( \mu^{(Q.d_A+k)+1} \right). \quad (6.5)
\]

Now, if we take the limit \( \mu \to 0 \), the left-hand side of (6.5) does not change, being independent of \( \mu \), and in particular remains bounded. Hence, for equality to hold, any term on the right-hand side of (6.5) that independently goes to \( \infty \) as \( \mu \to 0 \) must vanish. That is, the coefficient of each \( \mu^p \log^q \mu \) term with \( p < 0 \) or \( p = 0, h > 0 \) must be zero. Actually taking the \( \mu \to 0 \) limit on the right-hand side of (6.5) we obtain the identity

\[
F_k^Q \left( g, g^{-\frac{1}{2}} g_{ab}, z^j, q^i \right) = \sum_{\langle d,I \rangle = (Q.d_A+k)} g^{-\frac{(Q.d_A)}{2n}} G_{0,l} \left( g^{-\frac{1}{2}} g_{ab}, z^j \right) q^l. \quad (6.6)
\]

All terms \( \langle d,I \rangle > (Q.d_A + k) \) were set to zero by the limit, which by consistency means that they had zero coefficients to begin with. Notice that this identity implies that the function \( F_k^Q \) scales homogeneously with degree \( \langle Q.d_A \rangle \) (that is, it has almost homogeneous order zero). This sum could conceivably be empty, if it happens that \( \langle Q.d_A + k \rangle < 0 \) (recall that \( d_i > 0 \)), which can only happen if some of the combinations \( d_A + k_i < 0 \). In that case, \( F_k^Q = 0 \) and the corresponding component \( C_k^Q \) of the renormalization coefficient \( C_k \) vanishes, which proves part (a) of the theorem.

We can now enlarge again the domain of the function \( F_k^Q \) along the fibers, where the identity (6.2) holds, from \( Z_h^r \) to \( Z_h^r \subseteq J_r BM \). The new domain is isomorphic to

\[
Z_h^r \simeq U \times L_n \times W_4 \times \mathbb{R}^\gamma \times \mathbb{R}^{m_q}
\]

\[
\Rightarrow \left( x^a \right) \left( g^{-\frac{1}{2}} g_{ab} \right) (z^j) \left( i_{(bc,A)}^r \right) \left( g^{\frac{1}{2} + \frac{|A|}{2} S_{ab(cd,A)}}, g^{\frac{1}{2} + \frac{|A|}{2} A(\bar{I}_j)^{a_1 \cdots a_j}, -A \rangle_{I_j + a_j, 2|A|>0} \right).
\]

The function \( F_k^Q \) extends uniquely to \( Z_h^r \) as a covariant function under coordinate scaling. Essentially we have enlarged the factor \( W_4^r \) to \( W_4 \times \mathbb{R}^{m_q} \). We can do that because all the \( (q^i) \) coordinates have positive weight under coordinate scaling, so that their domain can be extended to all of \( \mathbb{R}^{m_q} \). The range of the \( (z^j) \) coordinates is limited to \( W_4 \subset \mathbb{R}^{m_q} \) because these coordinates are invariant under coordinate scaling. Note that the dependence of \( F_k^Q \) on the \( \mathbb{R}^\delta \) factor in \( Z_h^r \) is polynomial and remember that \( F_k^Q \) does not depend on the factor \( U \times \mathbb{R}^\gamma \) (see previous part).

4. Global definition. It is now the moment to expand the domain \( Z_h^r \) to all \( J_r BM \), for an appropriate choice of \( r \). In (6.6), a generic \( q^i \) is of the form

\[
\prod_{|A|, |B| \leq 0} \left( S_{ab(cd,A)} \right)^{p_s, |A|} \left( \bar{I}_j \right)^{a_1 \cdots a_j \cdot B}^{p_{j, |B|}},
\]

32
where all the $p$-exponents are non-negative integer numbers and $p_{j,0} = 0$ if $l_j + s_j = 0$. The constraint \( \langle d, I \rangle = \langle Q, d_A + k \rangle \) in (6.6) can be written explicitly as
\[
\langle Q, d_A + k \rangle = \sum_{|A|,|B|} (2 + |A|)p_{s,|A|} + (s_j + l_j + |B|p_{j,|B|}).
\]

By the admissibility of the background fields (Definition 6.1), we have $s_j + l_j \geq 0$. Hence, the coefficients of the $p$-exponents are non-negative and grow linearly with $|A|$ and $|B|$. Thus, there exists a bound on the maximum values of $|A|, |B|$ with non-zero $p$-exponents. Let $r_k$ be the maximum number of derivatives of the curvature or background tensors for which the $p$-exponents are non-zero. Note that $r_k$ depends only on the structure of the bundle $BM$ and $k$, and not on the chosen domain $Z_4^r$. Then we can set $r = r_k$ in all the previous parts of the proof, i.e., we end up with a domain
\[
Z_4^{r_k} \subseteq J^{r_k}BM,
Z_4^{r_k} = U \times L_n \times W_4 \times \mathbb{R}^6.
\]

We can now extend one last time the domain $Z_4^{r_k}$ keeping the order of $F_k$ globally bounded. The factor $L_n$ is already maximal since it contains all Lorentzian metrics. At the beginning of the proof we chose as the initial domain $Z_4^r$ a neighbourhood of the point $j^r_y(g_0, t_j) = 0$ $\in J^{r_k}BM$. Recall that we later split the coordinates on $J^{r_k}BM$ into two groups, the $q$-coordinates, identified by positive scaling weights ($s_j + l_j > 0$), and the $z$-coordinates, identified by zero scaling weights ($s_j + l_j = 0$), the components of the marginal tensor fields $z$ (Definition 6.1). What was essential for the subsequent arguments was that, for each allowed value of the $z$-coordinates, $(z, q = 0)$ was also contained in $Z_4^r$, because $q \circ j^r_y(g_0, t_j) = 0$. However, the condition $z(y) = z \circ j^r_y(g_0, t_j) = 0$ did not play a significant role. Thus, the entire proof would work without any changes had we chosen different background fields $t_j$ such that still $q \circ j^r_y(g_0, t_j) = 0$, but $z(y) = z \circ j^r_y(g_0, t_j)$ assuming an arbitrary value. Then, having a priori fixed $r = r_k$, the functions $F_k$ on different $Z_4^r$ domains would necessarily agree on overlaps (since they are merely local expressions of the globally defined differential operator $C_k$) and the union of all the $Z_4^r$ domains would cover arbitrary values of the $z$-coordinates. Thus, having already performed the extension of the domain into the $q$-coordinates, we can set $W^4 = \mathbb{R}^{m_q}$ in $Z_4^r$. In other words we can set
\[
Z_4^r = Z_4^{r_k} = \pi^{-1}(U)
\]
for some open neighborhood $U \subset M$ of $y \in M$, where $\pi : J^{r_k}BM \rightarrow M$.

The union of all those open sets $U$, when $y$ varies in $M$, completely covers $M$. Thus, the corresponding domains $Z_4^r$ completely cover $J^{r_k}BM$. Thus, the globally defined differential operator $C_k$ is of globally bounded order at most $r_k$ and its components $C^Q_k : J^{r_k}BM \rightarrow \bigotimes_{i=1}^N S^kT^* \otimes k_iM$ have the form (6.2) when restricted to a domain of the form $Z_4^{r_k}$ with the functions $F_k^Q$ satisfying (6.6).

5. GL(n)-equivariance. In this last point, we intend to give a precise form of the function $F_k^Q$ exploiting their $GL(n)$-equivariance. From the previous discussion we know that the function $F_k^Q$ satisfying (6.2), is defined on the domain $Z_4^{r_k} \simeq U \times \mathbb{R}^7 \times Z_4$, but it depends only on the coordinates corresponding to the factor $Z_4 = L_n \times \mathbb{R}^{m_z} \times \mathbb{R}^{m_q}$. We also know the following:

1. the dependence is polynomial with respect to the standard coordinates on the $\mathbb{R}^{m_q}$ factor;
2. the coefficients $g^{−\frac{2(Q,d_A)}{2m}}G_{0,1}(g^{−\frac{1}{2}}g_{ab}, z^j)$ of these polynomials depend only on $L_n \times \mathbb{R}^{m_z}$.  

33
Each factor in $Z_4$ carries a tensor density representation of $GL(n)$ (resp. $GL^+(n)$) arising from the action of the subgroup of $\text{Diff}(M)$ (resp. $\text{Diff}^+(M)$) which leaves fixed a given point of $U$. More precisely, if $u \in GL(n)$:

1. on $L_n$, the action is given by $(u, g) \mapsto |\det u|^{-\frac{2}{n}} u \otimes g$;

2. on $\mathbb{R}^{m_z}$, which corresponds to the rescaled components $g_{\frac{j}{2n}}^{\frac{s_j}{n}(\tilde{t}_j)^{a_1\cdots a_j}}$, $j = 1, \ldots, K_0$, of the marginal background tensor fields $z = (t_1, \ldots, t_{K_0})$ (Definition 6.1), the action is given by $(u, t_j) \mapsto |\det u|^{\frac{j}{2n}} u \otimes t_j$;

3. on $\mathbb{R}^{m_q}$, which corresponds to the rescaled components $g_{\frac{j}{n} + \frac{s_j}{n} + \frac{|A|}{n}(\tilde{t}_j)^{a_1\cdots a_j}}, A$ for $l_j + s_j + 2|A| > 0$, and $g_{\frac{j}{2n} + \frac{|A|}{2n}}^{\frac{s_j}{n} + \frac{2}{n}|A|} S_{ab(cd,A)}$, for $|A| \geq 0$, also decomposes into a direct sum of corresponding tensor density representations

$$\mathbb{R}^{m_q} = \bigoplus_{\alpha} R_{\alpha},$$

where $R_{\alpha}$ carries a tensor density representation of rank $n_{\alpha}$;

4. the fibers of the bundle where the functions $F^Q_k: Z_4 \to \bigotimes_{i=1}^{N} S^n T^{a_i \cdots a_k} M$ take their values also carry a representation of $GL(n)$ (resp. $GL^+(n)$), which obviously decomposes into a direct sum of tensor density representations, which we will denote by

$$\mathcal{T} = \bigoplus_{\beta} \mathcal{T}_{\beta},$$

where $\mathcal{T}_{\beta}$ has rank $n_{\beta}$.

Note also that, the homogeneous polynomials $\mathcal{P}^\delta$ of degree $\delta$ on $\mathbb{R}^{m_q}$ carry the representation

$$(uP)(\rho) := P(u^{-1}\rho), \quad \text{for any } u \in GL(n), P \in \mathcal{P}^\delta, \rho \in \mathbb{R}^{m_q}.$$  

This representation on polynomials is made up of direct sums of symmetric tensor powers of $\mathbb{R}^{m_q}$ and hence itself also decomposes into a direct sum of tensor density representations

$$\mathcal{P}^\delta = \bigoplus_{\gamma} S^\delta_\gamma,$$

where $S^\delta_\gamma$ has rank $n_{\gamma}$.

From the above remarks, it is easy to see that the equivariance of the functions $F^Q_k$ (see Proposition C.1 for the relation between invariant and equivariant functions) and the linear independence of the monomials $q^I$ on $\mathbb{R}^{m_q}$ implies that the polynomial coefficients in (6.6) are themselves smooth equivariant maps

$$G_0: L_n \times \mathbb{R}^{m_z} \to \mathcal{T} \otimes \mathcal{P}^{(Q,k)} = \bigoplus_{\beta, \gamma} \mathcal{T}_{\beta} \otimes S^{(Q,k)}_{\gamma},$$

(6.8)

See [KM16], point 5. of the proof of the main Theorem 3.1, for a more detailed elaboration of this argument.

Now, since the components $(G_0)_{\beta, \gamma}$ are equivariant tensor densities (Definition C.3), we can invoke the classification Lemma C.8 to conclude that each $(G_0)_{\beta, \gamma}$ is, up to an overall power of $g = |\det g_{ab}|$, a tensor of appropriate rank built covariantly out of $g_{ab}, g_{\alpha b}, g^{a_1\cdots a_n}(g)$ and

34
the tensor components of $z$, $t_j^{a_1 \ldots a_j}$, for $j = 1, \ldots, K_0$. To be more precise, each $(G_0)_{\beta,\gamma}$ is a finite linear combination of $T_\beta \otimes S_\gamma^{(Q,k)}$ terms, each built from a tensor product of finitely many aforementioned ingredients (possibly repeating) followed by any number of index contractions or permutations, with coefficients being smooth functions of all possible polynomial scalar invariants covariantly constructed from the same ingredients,

$$(G_0)_{\beta,\gamma} = g^{a_1 \ldots a_n} \sum_m c_{\beta,\gamma}^m(g, g^{a_1 \ldots a_n}(g), \ldots, t_j^{a_1 \ldots a_j}, \ldots) F_{\beta,\gamma}^m(g, g^{a_1 \ldots a_n}(g), \ldots, t_j^{a_1 \ldots a_j}, \ldots).$$

Lemma C.8 also tells us that, in each case, there are only finitely many algebraically independent polynomial scalar invariants that the coefficients $c_{\beta,\gamma}^m$ depend on and there are only finitely many tensor valued polynomials $P_{\beta,\gamma}^m$ that are linearly independent up to a redefinition of the $c_{\beta,\gamma}^m$ coefficients. The dependence on $\varepsilon(g)$ is allowed only in the $GL(n)^+$ case. Also, note that for the contractions $G_0, I Q^I$ to remain equivariant, all the explicit appearances of powers of $g = |\det g_{ab}|$ must cancel.

Finally, combining the above conclusions with (6.6), we can say that

$$F_k^Q = F_k^Q \left( g_{ab}, g_{abc}^{e_1 \ldots e_k}(g), \ldots, (z_j)_{a_1 \ldots a_j}, \ldots; g^{ab}, g^{a_1 \ldots a_n}(g), \ldots, S_{abc,(d,A)}, \ldots, (t_j)_{a_1 \ldots a_j}, \ldots, \right),$$

where the dependence on the second group of arguments is purely polynomial, while the dependence on first group of arguments is smooth with respect to finite set of algebraically independent scalar polynomial invariants that can be formed from them by tensor products and contractions. Recall that we have used the notation $z_j = t_j$, for $j = 1, \ldots, K_0$, that is for those background tensor fields such that are marginal, satisfying $s_j + l_j = 0$. This completes the proof. □

After the proof of this very general model, we can move on to some more physically relevant models.

### 6.1 Vector Klein-Gordon field

We now consider a specific quantum vector field in order to investigate in detail the form of the coefficients $C_k$ in (5.8): we focus on the vector Klein-Gordon field. The classical configurations of the vector KG field over an oriented globally hyperbolic spacetime $(M, g)$ are smooth 1-forms, i.e., sections of the cotangent bundle $T^*M$, namely $A \in \mathcal{S}(T^*M)$. The vector KG equation, where we include also a coupling term with the curvature $R$, reads

$$-\Box_g A + m^2 A + \xi R A = 0$$

(6.10)

where $m^2$ and $\xi$ are here smooth real-valued functions on $M$ (they can be constant functions, but in general we admit that $m^2$ and $\xi$ can vary on the spacetime). When passing to the quantum formulation, the locally-covariant quantum vector KG field, indicated by the same symbol $A$, is defined as in Definition 4.2 with $k = 1$ and $VM = T^*M$. Moreover we have the following requirements.

(a) The net of local quantum observables $\mathcal{W}$ including the vector KG field is as in Definition 3.5 is fixed according to equation (6.10), which suggests that the natural bundle of background fields is the one completely defined by

$$BM = \mathcal{S}^2 T^*M \oplus \mathbb{R} \oplus \mathbb{R},$$

(6.11)

so that the sections $M \rightarrow BM$ are triples $b = (g, m^2, \xi)$. (The metric $g$ affects the theory because it enters $\Box_g$, $R$ (also derived) and even the Levi-Civita tensor $\varepsilon$ in case one deals with the category of background geometries $\mathfrak{B}_g \mathfrak{G}^+$ instead of $\mathfrak{B}_g \mathfrak{G}$).
(b) The natural vector bundle is completely fixed by requiring

\[ VM = T^*M \]

and the morphism \( V_\chi \), whose associated pushforward on test sections is exploited to define the notion of local covariance as in Definition 4.2, is nothing but the natural lift of the embeddings \( \chi: M \to M' \) to the corresponding tangent bundles.

(c) According to its mass dimension, the physical scaling degree of the vector KG field is \( d_A = (n - 4)/2 \) when \( g \mapsto \lambda^{-2}g, m^2 \mapsto \lambda^2m^2 \) and \( \xi \mapsto \xi \) according to (3.4). We recall that the presence of covariant derivatives does not change this rescaling behaviour as the coordinates are dimensionless.

(d) We stress that all background fields of this model are scalars of non-negative physical scaling weight and hence are admissible according to Definition 6.1.

Remark 13.

1. The quantum vector KG field, in addition to the requirements in Definition 4.2, it is also supposed to verify (6.10) in a distributional sense for every background geometry

\[
A_{(M,b)}\left( (-\Box_g + m^2 + \xi R)f \right) = 0 \quad \forall f \in \mathscr{D}(TM).
\]

Though this fact does not play any role in our work, it implies several relevant facts which are mentioned in the some of subsequent remarks. Moreover, exactly as does the Klein-Gordon equation for the scalar field, this equation of motion plays a crucial role in the construction of an explicit algebra of Wick polynomials [HW01].

2. It is well-known [BD15, Sec.3.3.1] that the KG operator \( P = -\Box + m^2 + \xi R \) is Green hyperbolic for every choices of the involved given smooth functions \((m^2)\) may attain non-positive values in particular) and thus the retarded and advanced Green operators of \( P \) exist. In particular the function \( \Delta_{(M,b)} \) discussed in (4) Remark 5.2 in this case is the causal propagator of the KG equation [BD15, Sec.3.3.1]. As a consequence of the standard properties of the causal propagator, we also have that \([A_{(M,b)}(f), A_{(M,b)}(g)] = 0\) when the supports of \( f \) and \( g \) are causally disjoint.

3. As is well-known, exactly as for the scalar field (e.g., see [BD15, Sec.3.3.1]), the statement of the time-slice axiom for the locally covariant vector field \( A \) can be sharpened, based on the properties of the causal propagator of equation of motion (6.12). Namely, if \( O \) is an open neighborhood of any Cauchy surface of \((M,g)\) and \( f \in \mathscr{D}(TM)\), then \( A_{(M,b)}(f) = A_{(M,b)}(h) \) for a suitable \( h \in \mathscr{D}(TM) \), depending on \( f \), whose support is contained in \( O \).

4. When defining the Wick products \( A^b_{(M,b)}(f) \), the class of states \( S_{(M,b)} \) appearing in the smoothness requirement in Definition 5.2 should be naturally interpreted as consisting of the extensions of Hadamard states [SV01] from the unital \( * \)-subalgebra \( W_{0,(M,b)} \subset W_{(M,b)} \) to the whole ambient algebra, where \( W_{0,(M,b)} \) is generated by 1 and products of elements \( A_{(M,b)}(f) \).

5. It is worth also stressing that the case \( m = 0 \), even if the spacetime is Minkowski one, does not correspond to the quantization of the electromagnetic field (within Lorenz-gauge choice). Indeed, we are dealing here with the algebraic approach and, in a given spacetime, the (Weyl) \( * \)-algebra of vector KG field is well defined for every choice of the function \( m^2 \) which may also attain negative values, because its definition only relies on the fact that the spacetime is globally hyperbolic and on the nature of the operator \( P = -\Box + m^2 + \xi R \) which is Green hyperbolic. The existence of Hadamard states playing a role in requirement 5 can be proved
with a standard deformation argument even in Minkowski spacetime for \( m^2 \leq 0 \) constantly: it is enough to smoothly change the function \( m^2 \) in the past of a Cauchy surface \( \Sigma \) until it becomes a constant function with value \( m_0^2 > 0 \) in the past a second Cauchy surface \( \Sigma' \) in the past of \( \Sigma \) in Minkowski spacetime. Next, in the past of \( \Sigma' \) one may construct the standard Poincaré-invariant vacuum for (constant) squared mass \( m_0^2 > 0 \) and spin-1 particles. This state can be viewed as a state over the algebra in the future of \( \Sigma \) when taking advantage of time slice axiom and it remains Hadamard in view of the known singularity propagation property of Hadamard states. Obviously, for the algebra of fields in the future of \( \Sigma \), the constructed state is not the Poincaré-invariant vacuum which cannot be defined if \( m^2 < 0 \) (constantly) and the problem with negative-norm states would immediately arise for \( m^2 = 0 \) (usually removed by means of the Gupta-Bleuler treatment which also lower to 2 the physical degrees of freedom of particles associated to the field from the 3 degrees of freedom of massive spin-1 particles).

This way also the \( m^2 \leq 0 \) theory in Minkowski spacetime admits Hadamard states, but none of them is a Poincaré-invariant vacuum. In other words, for \( m^2 = 0 \), our vector KG field field does not describe photons. In the algebraic approach, photons are described by including gauge invariance into the algebra of fields from scratch which is a more complicated procedure than the one we are discussing [Hol08, FR12]. Using some delicate adiabatic changes of mass procedures similar to the ones pointed out above it is however possible, at least for the scalar field, to transform vacua states into vacua states with different masses [DHP17, DD16, DG17].

(6) It is also worth commenting on the existence of prescriptions of Wick polynomials that are smooth in \( m^2 \), including at \( m^2 = 0 \). For that, it is important to recall the precise form of the smoothness axiom (Definition 5.2, Axiom 5) and that the main candidate for such a construction is point splitting regularized with a Hadamard parametrix. That is, in the simplest smoothness axiom (Definition 5.2, Axiom 5) and that the main candidate for such a construction is point splitting regularized with a Hadamard parametrix. That is, in the simplest case, including at \( m^2 = 0 \) in the past a second Cauchy surface \( \Sigma \) until it becomes a constant function with value \( m_0^2 > 0 \) in the past a second Cauchy surface \( \Sigma' \) in the past of \( \Sigma \) in Minkowski spacetime. Next, in the past of \( \Sigma' \) one may construct the standard Poincaré-invariant vacuum for (constant) squared mass \( m_0^2 > 0 \) and spin-1 particles. This state can be viewed as a state over the algebra in the future of \( \Sigma \) when taking advantage of time slice axiom and it remains Hadamard in view of the known singularity propagation property of Hadamard states. Obviously, for the algebra of fields in the future of \( \Sigma \), the constructed state is not the Poincaré-invariant vacuum which cannot be defined if \( m^2 < 0 \) (constantly) and the problem with negative-norm states would immediately arise for \( m^2 = 0 \) (usually removed by means of the Gupta-Bleuler treatment which also lower to 2 the physical degrees of freedom of particles associated to the field from the 3 degrees of freedom of massive spin-1 particles).
depend on the difference $m^2(s, x) - m_0^2$, establishing the wanted smoothness property. Though we do not have a demonstration of that, we outline a possible way to construct a proof in the next paragraph. (The above conclusions are implicit in the discussion of Section 5.2 of [HW02].)

To argue that the retarded propagator with mass $m^2(s, x)$ has smooth dependence on $m^2(s, x) - m_0^2$, when the difference has compact support, we will refer to some results from [DHP17].

More precisely, we can express the retarded propagator $\Delta^R_{m^2}$ in terms of the retarded propagator $\Delta^R_{m_0^2}$ and an operator $R_{m_0^2}$ (Lemma 3.10 in [DHP17]), where $R_{m_0^2} = [1 + \Delta^R_{m_0^2}(m^2 - m_0^2)]^{-1}$ (Proposition 3.8 in [DHP17]). This comes down to the perturbative expression, cf. Equation (43) in [DHP17],

$$
\Delta^R_{m^2} = \sum_{n \geq 0} \left[ -\Delta^R_{m_0^2}(m^2 - m_0^2) \right]^n \Delta^R_{m_0^2}.
$$

Lemma B.1 of [DHP17] uses the support properties of $\Delta^R_{m_0^2}$ to show that the above series, together with all of its functional derivatives with respect to the difference $m^2 - m_0^2$, converges when $m_0^2 = 0$ and the background spacetime is Minkowski. Though we do not have a proof and the issue should be investigated elsewhere, it seems plausible that the same proof generalizes to more general globally hyperbolic spacetimes.

With the concrete case of the vector KG field, Theorem 5.2 can be sharpened to give a more explicit expression for the renormalization coefficients $C_k$. In terms of algebra valued distributions, equation (5.8) can be rewritten as

$$
\widehat{A}_{[\Lambda, m_0]}(f) = A_{[\Lambda, m_0]}(f)
$$

with $C_k[M, \mathbf{b}]_{b_1 \cdots b_k}(x) \in (T^*_x)^{\otimes k}M$ fully symmetric. Using Theorem 6.2 we can immediately obtain a precise form of the symmetric covariant $k$-tensor fields $C_k[M, \mathbf{b}]$. For example, if we choose $n = 4$ and $k = 2$ we obtain for all $f \in \mathcal{D}(S^2TM)$

$$
\widehat{A}_{[\Lambda, m_0]}(f) = A_{[\Lambda, m_0]}(f)
$$

which can be written in terms of distributional fields, omitting explicit $x$-dependence for simplicity, as

$$
\widehat{A}_{[\Lambda, m_0]} = A_{[\Lambda, m_0]} + \left( y_1 \nabla^2 + y_2 \mathcal{R} + y_3 \mathcal{R} + y_4 \nabla \mathcal{R} + y_5 \nabla^2 \mathcal{R} + y_6 \nabla \mathcal{R} + y_7 \nabla \mathcal{R} \right) f
$$

where $y_j(x) := Y_j(\xi(x))$ and $Y_j$, for $j = 1, \ldots, 5$, are dimensionless smooth functions which do not depend on the chosen spacetime. Obviously, in concrete physical theories the final values of some background fields like $m^2$ and $\xi$ are taken to be everywhere constant. In this case all derivatives of these fields disappear. In particular

$$
\widehat{A}_{[\Lambda, m_0]} = A_{[\Lambda, m_0]} + \left( y_1 \nabla^2 + y_2 \mathcal{R} + y_3 \mathcal{R} \right) f
$$

where the $y_j$ := $Y_j(\xi)$ turn out to be true renormalization constants independent form the chosen spacetime.
6.1.1 Vector Klein-Gordon field with tensor curvature coupling

It is possible to complicate a bit the previous example by adding a non-trivial background field. We consider a tensorial coupling to the scalar curvature in the vector KG equation, i.e.,

$$- \Box g A_a + m^2 A_b + R^{[b} A_{a]} = 0. \quad (6.16)$$

Lowering the upper index of the coupling tensor, $\xi_{ab} = g_{ac} \xi_{c}^b$, we have a fully covariant background 2-tensor field. We will take $\xi_{ab}$ to be symmetric, both for simplicity and because only symmetric tensorial coefficients are compatible with the existence of a Lagrangian density for (6.16). Then, the bundle of background field is now completely defined by

$$BM = \hat{S}^2 T^* M \oplus \mathbb{R} \oplus \hat{S}^2 T^* M \quad (6.17)$$

and the sections $M \rightarrow BM$ are triples $b = (g, m^2, \xi)$. The background field $\xi$ is marginal\(^7\) since the tensor index $l_M = 2$ and the physical scaling weight $s_M = -2$, hence satisfying $l_M + s_M = 0$. Clearly, $\xi_{ab}$ is the only marginal background field. All other hypotheses remain invariant with respect to the previous example.

To apply our main Theorem 6.2, we first need to analyze the structure of the scalar polynomial invariants on the fibers of $S^2 T^* M$ under the action of $O(1, n-1)$ (or $SO(1, n-1)$) and the separability of closed orbits by these invariants. As is well known [Pro07, Sec.11.8], a generating set of the polynomial invariants is given by the contractions

$$\left( \tr \xi = \xi_a^a, \tr \xi^2 = \xi^{[b,c} \xi_{a]}^a, \ldots, \tr \xi^n = \xi^{[a_1,a_2} \cdots \xi_{a_n]} \right), \quad (6.18)$$

which, as indicated, can be interpreted as traces of successive powers of $\xi_{ab}^a$, interpreted as $n$-dimensional endomorphisms (or $n \times n$ matrices). All higher order contractions are algebraically dependent due to the Cayley-Hamilton identity. The result obtained in Theorem 6.2 applied to this case when, for example, we choose $n = 4$ and $k = 2$ gives, omitting the $x$-dependence for simplicity,

$$\bar{A}_a A_b = A_a A_b + (y_1 g_{ab} m^2 + y_2 g_{ab} R + y_3 R_{ab} + y_4 m^2 \xi_{ab} + y_5 \xi_{ab} R + B_\xi),$$

with all terms that vanish when the background fields are constant collected in

$$B_\xi = y_6 g_{ab} \Box \xi_a^b + y_7 \nabla (a \nabla b) \xi_c^a + y_8 g_{ab} \nabla c \xi_d^a \nabla d \xi_e^b + y_9 g_{cd} \nabla (a \xi_{cd} \nabla b) \xi_e^c + y_{10} \nabla (a \nabla b) \xi_{ed} + y_{11} \nabla (a \xi_{ed} \nabla b) \xi_{cd} + y_{12} g_{ab} (\Box \xi_{ed}) \xi_{cd} + y_{13} g_{ab} \nabla c \xi_{de} \nabla c \xi_{ed} + y_{14} \xi_{ab} \Box \xi_e^c + y_{15} \xi_{ab} \nabla c \xi_d^a \nabla d \xi_e^b + y_{16} \Box \xi_{ab} + y_{17} \xi_{ab} (\Box \xi_{cd}) \xi_{cd} + y_{18} \xi_{ab} \nabla c \xi_{de} \nabla c \xi_{de} + y_{19} \xi_{cd} \nabla (a \xi_{cd} \nabla b) \xi_e^c + y_{20} \xi_{cd} \nabla (a \xi_{ef} \nabla b) \xi_{cd} \xi_{ef},$$

where the $y_i$ are locally smooth functions our invariant scalars (6.18) in the sense of Definition C.6 and Proposition C.7.

Now, we analyse in detail the structure of the coefficients $y_i$. In general, illustrating the phenomenon discussed in Appendix C, our invariant polynomials do not separate the closed orbits of $O(1, n-1)$ (or $SO(1, n-1)$) acting on the fibers of $S^2 T^* M$. For instance, given an orthonormal basis $v_a^0, \ldots, v_a^n$ with $v^0$ timelike and the rest spacelike, the following symmetric tensors with distinct $\lambda_0, \ldots, \lambda_4$ cannot be distinguished by invariant polynomials

$$\xi = -\lambda_0 v_a^0 v_b^0 + \lambda_1 v_a^1 v_b^1 + \lambda_2 v_a^2 v_b^2 + \lambda_3 v_a^3 v_b^3 \quad \text{and} \quad \xi' = -\lambda_1 v_a^0 v_b^0 + \lambda_0 v_a^1 v_b^1 + \lambda_2 v_a^2 v_b^2 + \lambda_3 v_a^3 v_b^3,$$

\(^7\)In the Lagrangian density, the curvature coupling term becomes $R g^{a d} g^{b c} \xi_{a c} A_a A_d \sqrt{-g}$. 39
even though they belong to different orbits. The orbits are distinct because any linear transformation mapping $\xi$ to $\xi'$ must exchange the $\lambda_0$- and $\lambda_1$-eigenvectors, hence exchanging a spacelike vector with a timelike vector, which cannot be done by any element of $O(1,n-1)$. Other examples of this kind can be constructed by looking at the complete classification of the orbit types of symmetric 2-tensors [SKM+03, Sec.5.1]. On the other hand, invariant polynomials do distinguish the orbit of $\xi$ from the orbit of any other point in a sufficiently small neighborhood, because the case of distinct eigenvalues allows us to choose the eigenvectors smoothly under small variations, and small variations of timelike (spacelike) vectors remain timelike (spacelike). Thus, the subsets where invariant polynomials can locally distinguish orbits must be separated by a “barrier” (the $Z^0$ subset of Proposition C.7). Since any continuous path from $\xi$ to $\xi'$ must pass through some tensor with degenerate eigenvalues, we can take $Z^0$ to consist of all tensors with at least two equal eigenvalues. The open sets $Z_j$ of Proposition C.7 can then be identified with the connected components of $Z \setminus Z_0$, where $Z$ is a generic fiber of $S^2 T^* M$.

The reason why the set $Z^0 \subset Z$ and the partition $Z \setminus Z^0 = \bigcup_j Z_j$ is consistent with Proposition C.7 is that $Z^0$ is actually the zero-set of an invariant polynomial $p_0(\xi) = \text{disc}(\xi)$, known as the matrix discriminant. It is defined by requiring that, for diagonalizable tensors with eigenvalues $\lambda_i$, it takes the value

$$\text{disc}(\xi) = \prod_{i<j} (\lambda_i - \lambda_j)^2,$$

which can be shown to coincide with the polynomial $\text{disc}(\xi) = \det (\text{tr} \xi^{i+j-2})_{i,j=1}^{n}$ [Par02, Lem.1]. In the $n = 4$ case, it has the explicit form

$$\text{disc}(\xi) = \det \begin{pmatrix} \text{tr} \xi & \text{tr} \xi^2 & \text{tr} \xi^3 \\ \text{tr} \xi^2 & \text{tr} \xi^3 & \text{tr} \xi^4 \\ \text{tr} \xi^3 & \text{tr} \xi^4 & \text{tr} \xi^5 \end{pmatrix},$$

where we recall that $\text{tr} \xi^5, \text{tr} \xi^6$ are algebraically dependent on lower order contractions due to the Cayley-Hamilton identity. Thus, the coefficients $y_i$ are locally smooth functions (Definition C.6) of the scalar polynomials invariants (6.18), i.e.,

$$y_i(x) = [Y_i]_{S^2 T^* M} (\text{tr} \xi(x), \text{tr} \xi^2(x), \text{tr} \xi^3(x), \text{tr} \xi^4(x)),$$

for $i = 1, \ldots, 20$, with respect to the partition $Z \setminus Z^0 = \bigcup_j Z_j$ indicated above, with $Z$ a generic fiber of $S^2 T^* M$.

### 6.2 Scalar field with derivative

We now consider the renormalization of Wick powers of a scalar field with its first derivative. The classical configurations of the scalar KG field over an oriented globally hyperbolic spacetime $(M, g)$ are smooth real-valued functions, i.e., sections of the bundle $T^* \otimes 0 M = M \times \mathbb{R}$, namely $\varphi \in \mathcal{C}^\infty(T^* \otimes 0 M) = C^\infty(M)$. Similarly to the previous case we have the following equation of motion

$$- \Box_g \varphi + m^2 \varphi + \xi R \varphi = 0,$$

(6.19)

where $m^2$ and $\xi$ are smooth real-valued functions on $M$ (they can be constant functions, but in general we admit that $m^2$ and $\xi$ can vary on the spacetime). Since we want to consider renormalization of a scalar field with its first derivative, we construct the field $\Phi$ as the pair of fields

$$\Phi = (\varphi, \nabla_\mu \varphi).$$
When passing to the quantum formulation, the \textit{locally-covariant quantum field} \( \Phi \), indicated by the same symbol \( \Phi \), is defined as in Definition 4.2, with the following details.

(a) As in the previous case, the net of local quantum observables \( \mathcal{W} \) including the scalar field, as in Definition 3.5, is fixed according to equation (6.19), which suggests that the natural bundle of background fields is the one completely defined by

\[
BM = \hat{S}^2 T^* M \oplus (M \times \mathbb{R}) \oplus (M \times \mathbb{R}),
\]

so that the sections \( M \to BM \) are triples \( b = (g, m^2, \xi) \).

(b) The natural vector bundle is completely fixed by requiring

\[
VM = (M \times \mathbb{R}) \oplus TM
\]

and the morphism \( V_\chi \), whose associated pushforward on test sections is exploited to define the notion of local covariance as in Definition 4.2, is nothing but the natural lift of the embeddings \( \chi: M \to M' \) to the corresponding tangent bundles.

(c) According to its mass dimension\(^8\), the physical scaling degree of the field \( \Phi \) is

\[
d_\Phi = \left( \frac{n-2}{2}, \frac{n-2}{2} \right),
\]

when \( g \mapsto \lambda^{-2} g \), \( m^2 \mapsto \lambda^2 m^2 \) and \( \xi \mapsto \xi \) according to (3.4). We recall that the presence of covariant derivatives do not change this rescaling behaviour as the coordinates are dimensionless.

(d) We stress that all background fields of this model are scalars of non-negative physical scaling weight and hence are admissible according to Definition 6.1.

For this specific model, using Theorem 5.2 and Theorem 6.2, we can immediately obtain a renormalization formula and a precise form of the renormalization counterterms. For example, if we choose \( n = 4 \) and \( k = 2 \) we obtain, in terms algebra valued distributions and for brevity omitting the all dependence on the spacetime point \( x \),

\[
\begin{bmatrix}
\hat{\varphi}^2 \\
\varphi \nabla_a \varphi \\
\nabla (a \varphi \nabla_b) \varphi
\end{bmatrix}
= 
\begin{bmatrix}
\varphi^2 \\
\varphi \nabla_a \varphi \\

abla (a \varphi \nabla_b) \varphi
\end{bmatrix}
+ 
\begin{bmatrix}
\alpha_1 m^2 + \alpha_2 R + A_{\xi, m^2} \\
\beta_1 \nabla_a R + B_{\xi, m^2} \\
m_{ab} (\gamma_1 m^2 + \gamma_2 m^2 R + \gamma_3 R^2) + (\gamma_4 m^2 + \gamma_5 \Box) R_{ab} + C_{\xi, m^2}
\end{bmatrix}
\]

where all \( \alpha-, \beta-, \gamma- \)coeficients are smooth functions of \( \xi \) and

\[
A_{\xi, m^2} = \alpha_3 \nabla^2 \xi \nabla_a \xi + \alpha_4 \Box \xi,
\]

\[
B_{\xi, m^2} = \beta_2 \nabla_a m^2 + \beta_3 m^2 \nabla_a \xi + \beta_4 R \nabla_a \xi + \beta_5 R_{ab} \nabla^b \xi
\]

\[
C_{\xi, m^2} = \gamma_6 \nabla (a \xi \nabla_b) m^2 + \gamma_7 m^2 \nabla (a \xi \nabla_b) \xi + \gamma_8 R \nabla_a \xi \nabla_b \xi + \gamma_9 R_{ab} \nabla^c \xi \nabla_c \xi + \gamma_{10} R_{(a \xi (\nabla_b) \xi \nabla_c) \xi} + \gamma_{11} g_{ab} \nabla^c \xi \nabla_a \xi \xi + \gamma_{12} g_{ab} m^2 \nabla^c \xi \nabla_c \xi + \gamma_{13} g_{ab} R \nabla^c \xi \nabla_c \xi + \gamma_{14} g_{ab} R_{(a \xi (\nabla_b) \xi \nabla_c) \xi} + \gamma_{15} g_{ab} \nabla^c \xi \nabla_c \xi
\]

\[
+ \gamma_{16} g_{ab} m^2 + \gamma_{17} g_{ab} m^2 + \gamma_{18} \nabla (a \xi \nabla_b) \xi + \gamma_{19} R_{(a \xi (\nabla_b) \xi \nabla_c) \xi} + \gamma_{20} g_{ab} \nabla^c \xi \nabla_c \xi
\]

\[
+ \gamma_{21} g_{ab} m^2 + \gamma_{22} g_{ab} \nabla^c \xi \nabla_c \xi + \gamma_{23} g_{ab} \nabla^c \xi \nabla_c \xi + \gamma_{24} R_{(a \xi (\nabla_b) \xi \nabla_c) \xi} + \gamma_{25} \nabla (a \xi \nabla_b) \xi + \gamma_{26} \nabla (a \xi \nabla_b) \xi
\]

\[
+ \gamma_{27} g_{ab} \nabla^c \xi \nabla_c \xi + \gamma_{28} g_{ab} \nabla^c \xi \nabla_c \xi
\]

\(^8\)E.g., assuming that both the terms summed in the Lagrangian density of the scalar field \( m^2 \varphi^2 \sqrt{g} \) and \( \nabla^a \varphi \nabla_a \varphi \sqrt{g} \) are dimensionless in natural \( h = c = 1 \) units.
are terms which depend on covariant derivatives of $\xi$ and $m^2$. Thus, if we choose constant values for $m^2$ and $\xi$:

$$
\begin{bmatrix}
\Delta^2 \tilde{\phi} \\
\partial^a \Delta^2 \tilde{\phi} \\
\Delta(\partial^a \Delta^2 \tilde{\phi})
\end{bmatrix} = 
\begin{bmatrix}
\Delta^2 \phi \\
\partial^a \Delta^2 \phi \\
\Delta(\partial^a \Delta^2 \phi)
\end{bmatrix} + 
\begin{bmatrix}
\alpha_1 m^2 + \alpha_2 R \\
\beta_1 \partial^a R \\
\gamma_1(m^2)^2 + \gamma_2 m^2 R + \gamma_3 R^2 + (\gamma_4 m^2 + \gamma_5 \Box) R_{ab}
\end{bmatrix}.
$$

Also, if we wanted to maintain the Leibniz rule $\partial^a \Delta^2 \phi = 2 \phi \Delta^2 \partial^a \phi$ (cf. [HW05]), we would have to require $2 \beta_1 = \alpha_2$, with the further requirements $2 \beta_2 = \alpha_1$, $2 \beta_3 = \alpha'_1$, $2 \beta_4 = \alpha'_2$, $2 \beta_6 = \alpha'_3$, $2 \beta_7 = \alpha'_4$, $2 \beta_8 = 2 \alpha_3$ and $2 \beta_9 = \alpha_4$ (where $'$ denotes $\frac{d}{d\xi}$) for other coefficients in the case of non-constant $m^2$ and $\xi$.

**Remark 14.** Following the same ideas of this section, it is possible to renormalize a scalar field with derivatives of arbitrary order. If we construct the $(m+1)$-tuple

$$((\phi, \partial^a \phi, \partial^a \partial^b \phi, \ldots, \partial^a \cdots \partial^m \phi)),
$$

i.e., if we choose as bundle of dynamical fields

$$VM = \bigoplus_{i=0}^m T^{\otimes i} M,$$

we can use Theorem 5.2 and Theorem 6.2 as we did in this section to obtain a renormalization formula with all renormalization counterterms. With the same idea it is possible to renormalize any tensor fields with an arbitrary number of derivatives.

### 7 Conclusions

This paper has focused on the general notion of Wick powers for general boson fields within the formulation of locally covariant algebraic quantum field theory on globally hyperbolic curved spacetimes. For us, a general boson field is a section of an arbitrary natural vector bundle of the spacetime (where naturality implies a well defined transformation law under diffeomorphisms). Besides the metric, the spacetime is also allowed to carry arbitrary classical background fields (also sections of natural vector bundles). In particular we have viewed the mass and other parameters as such background fields.

We define Wick powers axiomatically (Definition 5.2). Our list of axioms simply generalizes the axioms that were used for the scalar field in [KM16], which in turn descend from those given in [HW01] (with the crucial difference that their “analytic dependence” axiom was replaced by our “smooth dependence” axiom). Our main results consist of a classification of all possible finite renormalizations of Wick powers, which refer to the ambiguities in their axiomatic definition. Our work provides the first rigorous and complete such classification for non-scalar fields. The are analogous to those given in [KM16], but become more complicated in the details, due to the higher degree of generality.

The first half of our main result (Theorem 5.2), by an application of the Peetre-Slovák theorem, reduces finite renormalizations of a $k$-th Wick power to a linear combination of Wick powers of lower order with coefficients $C_k$ that are differential operators locally depending on the background fields, of fixed physical scaling weight and transforming covariantly under diffeomorphisms. The second half of our main result (Theorem 6.2) is specialized to the case when both the dynamical and background fields are restricted to be tensors (e.g., the case of connection fields is not covered), by an application of a general version of the Thomas Replacement...
theorem (Appendix B) and some fundamental results from smooth classical invariant theory of the orthogonal group $O(1, n−1)$ or $SO(1, n−1)$ (Appendix C), reduces the $C_k$ to linear combinations of finitely many tensor polynomials covariantly constructed from the curvature, the background tensor field, and all of their covariant derivatives. This finiteness result crucially depends on an admissibility criterion for all the background fields (Definition 6.1), which relates the physical scaling weight of a background field with its tensor rank by an inequality. The structure of these tensor polynomials is controlled by their physical scaling weights. It is possible that for a given tensor type and scaling weight the list of such polynomials is empty, meaning that the corresponding component of $C_k$ vanishes. The strongest departure from the results of [KM16] is in the structure of the scalar coefficients in front of these polynomial terms. These coefficients are actually allowed to depend smoothly (not just polynomially) on the background fields, but in a very restricted way. Namely, they are allowed to locally be smooth functions only of a finite number of scalar polynomial invariants constructed covariantly from the subset of marginal background fields (those that saturate the admissibility inequality). The notion of local smooth dependence on these scalar invariants (cf. Definition C.6 and Proposition C.7) can be made precise only by looking at the structure of the orbits of the action of $O(1, n−1)$ or $SO(1, n−1)$ on the marginal background tensor fields. In the scalar Klein-Gordon case considered [KM16], the only marginal background field was the scalar curvature coupling $\xi$.

We illustrate our results in detail with two physically relevant examples, checking in particular that they satisfy all the admissibility hypotheses: the vector Klein-Gordon field $A_a$ (Section 6.1), possibly coupled to the curvature through a tensor background field $\xi_{ab}$ (Section 6.1.1), and the case of Klein Gordon scalar field $\varphi$ accompanied by its spacetime derivative $\nabla_a \varphi$ (Section 6.2).

Several open issues remain and certainly deserve investigation. First of all, a theorem of existence for Wick polynomials should be established. This should be possible with existing tools, since the standard Hadamard parametrix regularization method [HW02] should be suitable for vector fields too, as discussed in Section 6.1. The main problem is to check that our “smooth dependence” axiom is actually satisfied by this method. We have already made more detailed comments on this in Section 4 of [KM16]. As remarked at the end of Section 2.2, it might be practically easier to verify the “smooth dependence” axiom when expressed in terms of Bastiani differentiability [BDLGR17], rather than our weak regularity (Definition 2.6).

Second, the constructed formalism should be so enlarged, possibly adding or changing some axioms, to cover the more delicate case of the Proca field. Here the main problem is that the zero mass limit $m^2 \to 0$ is known not to be smooth (see [SS17] for a careful recent discussion), whereas one of our axioms for Wick powers requires regularity exactly at the zero value of the mass. Some related remarks about subtleties with regular mass dependence appear in Remark 13.

Third, our results should be generalized to more general kinds of bosonic fields (for instance non-tensorial fields like connections) and also to fermionic fields (for instance Dirac spinor fields). We believe that such extensions should be fairly straightforward by building on the ground work that we have already laid. Such extensions will be discussed in forthcoming work.

A different and much more difficult extension would regard the renormalization of time-ordered products of Wick powers, extending the existing results [HW01, HW02, HW05], which are again currently available only in the scalar case. All these issues will be investigated elsewhere.

Acknowledgments. The authors are grateful to Charles Torre for sharing with them the unpublished report [AT94], also to Klaus Fredenhagen and Nicola Pinamonti for raising and clarifying some issues in Remark 13(6), and also to Jan Slovák for discussions that were helpful for Appendix B. A Technical result on physical scaling

In this Appendix we report some results from [KM16, Sec.2.4] with some generalization in order to consider the case of a tensor valued function. We recall that in Section 6 we have defined the bundle of background fields as

$$BM = \hat{S}^2T^*M \oplus \bigoplus_{j=1}^{K} T^*\otimes l^j M$$  \hspace{1cm} (A.1)$$

and that the physical scaling transformation on the sections of $\Gamma(BM)$ is given by

$$BM \ni (p, g(p), t_j(p)) \mapsto (p, \lambda^{-2} g(p), \lambda^{s_j} t_j(p)) \in BM,$$

where $\lambda \in \mathbb{R}^+$ defines the scaling transformation.

This (globally defined) representation of the multiplicative group $\mathbb{R}^+$ can be written in local coordinates

$$x^a \mapsto x^a, \quad g_{ab} \mapsto \lambda^{-2} g_{ab}, \quad (t_j)_{a_1...a_l} \mapsto \lambda^{s_j} (t_j)_{a_1...a_l}.$$

This transformation lifts to a transformation of the jet bundle $J^r BM$. In local coordinates

$$x^a \mapsto x^a, \quad g_{ab,A} \mapsto \lambda^{-2} g_{ab,A}, \quad (t_j)_{a_1...a_l,A} \mapsto \lambda^{s_j} (t_j)_{a_1...a_l,A}.$$

With respect to the Definition 5.1, we are interested in the case $W = \mathcal{C}^{\infty}(J^r BM, S^k V^*M)$. Moreover, since we have to consider also smaller domains $Z^r \subseteq J^r BM$ (with $Z^r$ not invariant under physical scaling), it is more convenient to consider the infinitesimal version of these transformations, which are effected by the following vector field\footnote{We use the following notation}

$$e = -2g_{ab,A} \partial^{ab,A} + s_j (t_j)_{a_1...a_l,A} \partial^{a_1...a_l,A},$$

in the sense that the induced action on tensor functions on $J^r BM$ satisfies

$$\frac{d}{d\lambda} \bigg|_{\lambda=1} F_{\lambda} = \mathcal{L}_e F,$$  \hspace{1cm} (A.2)

where $\mathcal{L}_e$ is the Lie derivative, $F \in W$ and $F_{\lambda} \in W$ is the transformed under physical scaling of $F$. We stress that, since the physical scaling transformation is globally defined, the vector field $e$ is globally defined on $J^r BM$.

**Lemma A.1.** A smooth function $F : J^r BM \rightarrow S^k V^*M$ that has almost homogeneous degree $k$ and order $l$ when the action $F \rightarrow F_{\lambda}$ is the one induced by physical scaling transformations, satisfies

$$\mathcal{(L}_e - k)^{l+1} F = 0.$$
Integral curves of $e$

Level sets of $g$

**Proof.** If $F$ is an almost homogeneous function of degree $k$ and order $l$, using equation (A.2), we obtain

$$(\mathcal{L}_e - k)F = G^{l-1},$$

where $G^{l-1}$ is an almost homogeneous function of degree $k$ and order $l - 1$. If we repeat this operation $l$ we obtain an homogeneous function $G^{(0)}$ of degree $k$:

$$(\mathcal{L}_e - k)^l F = G^{(0)}.$$ Since, for all homogeneous function $B$, we have $(\mathcal{L}_e - k) B = 0$ the proof is concluded. \[\square\]

Thanks to this result, we can give an infinitesimal definition of homogeneous and almost homogeneous function. This definition is very useful since we have to consider functions defined on a subset $Z' \subseteq J'BM$ which is not invariant under physical scaling.

**Definition A.1.** A smooth function $F: Z' \subseteq J'BM \rightarrow S^k V^*M$, where $Z'$ is an open subset which may coincide with all of $J'BM$, is said to have **almost homogeneous degree** $k \in \mathbb{R}$ and order $l \in \mathbb{N}$ (with $l \geq 0$) under physical scalings if it satisfies the identity

$$(\mathcal{L}_e - k)^l F = 0.$$ If $l = 0$, $F$ is said to have **homogeneous degree** $k \in \mathbb{R}$.

In the contravariant coordinates $(x^a, g^{ab,A}, (t_j)^{a_1...a_l,A})$, defined in Section 6, finite and infinitesimal physical scalings take the form

$x^a \mapsto x^a$, $g \mapsto \lambda^{-2n} g$, $g^{ab,A} \mapsto \lambda^{2|A|}g^{ab,A}$, $(t_j)^{a_1...a_l,A} \mapsto \lambda^{s_j + 2|A|}(t_j)^{a_1...a_l,A}$

$e = (2 + 2|A|)g^{ab,A}\partial_{ab,A} + (s_j + 2|A|)(t_j)^{a_1...a_l,A}\partial_{a_1...a_l,A}$ (A.3)

where, as remarked previously, we use $g$ as coordinate in place of one of the $g^{ab}$. Since $e$ is everywhere non zero its integral curves form a foliation of $J'BM$ and hence of $Z'$. Moreover, since $\mathcal{L}_eg^{-\frac{1}{2n}} = g^{-\frac{1}{2n}}$, $g$ restricts to a global coordinate on each orbit of $e$ and then the level sets of $g$ form another foliation of $J'BM$, transverse to the integral curves of $e$. For this reason it is convenient to study the structure of almost homogeneous function in **rescaled** coordinates:

$$\left(x^a, g, g^{-\frac{1}{n}}g_{ab}, g_{ab}^{\frac{1}{n} + \frac{1}{n}|A|}g^{ab,A}, g_{ab}^{\frac{1}{n} + \frac{1}{n}|A|}(t_j)^{a_1...a_l,A}\right).$$
Note that each of these functions but \(g\) is invariant under physical scaling. In our notation, we mean that the coordinates \(g\) and \(g^{-1/n}g_{ab}\) are functionally independent only up to the identity \(g = |\det g_{ab}|\).

**Lemma A.2.** Suppose that \(Z^r \subseteq J^rBM\) is an open set equipped with either coordinates \((x^a, g_{ab}, A, (t_j)_{a_1 \cdots a_l}, A)\) or some other coordinate system introduced in Section 6, and \(F: Z^r \rightarrow S^kV^*M\) is a smooth function that has almost homogeneous degree \(k\) and order \(l\) with respect to physical scaling. Then there exist uniquely defined homogeneous of degree 0 functions \(B_j: Z^r \rightarrow S^kV^*M\), for \(j = 0, 1, \ldots, l\), such that

\[ F = g^{-\frac{k}{n}} \sum_{j=0}^l \log^j \left( g^{-\frac{1}{n}} \right) B_j. \]

In particular, using rescaled contravariant coordinates, each \(B_j\) can be taken independent of \(g\) and written in the form

\[ B_j = B_j \left( x^a, g^{-\frac{1}{n}}g_{ab}, g^{\frac{1}{2} + \frac{1}{n}|A|} g^{ab}, \frac{\frac{1}{n} + \frac{2k}{n} + \frac{1}{n}|A|(t_j)_{a_1 \cdots a_l}, A) \right). \]

**Proof.** The proof is the same as [KM16, Lem.2.4] (since it is based on the notion of Lie derivative). \(\square\)

**B Thomas replacement theorem**

In this section we state and give a mostly self-contained proof of a version of the Thomas Replacement Theorem B.3, which basically states that any non-linear differential operator that depends on a Lorentzian (or pseudo-Riemannian) metric and a finite number of any kind of other tensor fields while itself transforming as a tensor field under diffeomorphisms must be expressible as a function of the covariant derivatives of the Riemann curvature and the other tensor arguments. This is a rather old result, with versions of it going back to the work of Thomas [Tho34] and in some form even to earlier works of Christoffel [Chr69]. However, it has since then taken on a folk nature, making it difficult to find precise references that state the result in a form most convenient for our applications, give a complete proof, with modern notation and terminology, that is concise and without an overabundance of formalism. If one omits at least some of the above conditions, the result of Theorem B.3 can be found in [Sch54, §III.7], [KMS93, §§28.14,33.10], and [Slo92, Thm.3]. Thus, this section aims to be of convenience to the reader and to those who will need prove related but slightly different results, which could be useful when tensors are replaced by more general natural geometric objects (like connections or possibly higher order jets) or even spinors. Such results could be useful in investigating finite renormalizations of Wick polynomials of fields with these more general transformation properties. Our attempt at providing such a useful reference is not the first and similar material, motivated by the heat kernel approach to the Index Theorem, can be found in [Gil73, ABP73]. These references concentrate on differential forms covariantly constructed from the metric, so the final results we state here are somewhat more general.

Let \(BM \rightarrow M\) be a natural bundle of the form

\[ BM = (S^2T^* \oplus T^k \otimes T^{l_1} \oplus \cdots \oplus T^k \otimes T^{l_N})M, \]

where \(T^k \otimes T^l M\) is the bundle of \((k,l)\)-tensors. Consider the curvature coordinates introduced in Section 6 (which is a version of the system (25) from [KM16]) on \(J^rBM\), which we consider with a slight change of notation,

\[ (x^a, g_{ab}, \Gamma^a_{bC}, Q_{ab,C}, t_{b_1 \cdots b_l}^{a_1 \cdots a_k}, C, \cdots t_{b_1 \cdots b_l}^{a_1 \cdots a_k}, C). \]
where the multi-indices $C = c_1 \cdots c_{|C|}$ range through the sizes $|C| = 1, \ldots, r$. They have the symmetry properties $\Gamma_{bc}^a = \Gamma_{bc}^a$, $Q_{ab,C} = Q_{ab,C} = Q_{ab,C}$ and $Q_{a(b,C)} = 0$. The notational change is that we use the notation $Q_{ab,cdE}$ instead of $S_{ab,cdE}$ that was introduced in Section 6. The reason for the change is that the $Q$-notation is better adapted to some index manipulation of which we will make use below. The above coordinates are defined by the relations

$$\Gamma_{bc}^a \circ j^* g = \partial_{(D} \Gamma_{bc)}^a[g], \quad (B.3)$$

$$Q_{ab,cdE} \circ j^* g = \nabla_{(E} \bar{S}_{abcd}[g], \quad (B.4)$$

$$t_{a_1 \cdots a_{k_1} C}^{b_1 \cdots b_{k_2}} = \nabla_{(C)} t_{a_1 \cdots a_{k_1} C}^{b_1 \cdots b_{k_2}}, \quad (B.5)$$

with $|D| \geq 0$ and $|E| \geq 0$, where

$$\Gamma_{bc}^a[g] = \frac{1}{2} g^{ae}(\partial_b g_{ec} + \partial_e g_{bc} - \partial_c g_{be}) \quad (B.6)$$

are the usual Christoffel symbols and we recall that $\bar{S}_{abcd}[g] = R_{a(c|b|d)}[g]$, which of satisfies

$$S_{abcd}[g] = S_{cdab}[g] = S_{(ab)cd}[g] = S_{ab(cd)}[g] \quad \text{and} \quad S_{a(bcd)} = 0. \quad (B.7)$$

All coordinates, other than $(x^a, \Gamma_{bc}^a, \Gamma_{bc,A}^a)$, correspond to components of tensor densities (Definition C.2) transforming under $GL(n)$, where $GL(n)$ is interpreted as the quotient of $\text{Diff}_x(M)$, the subgroup of diffeomorphisms fixing the point $x \in M$, by the subgroup of diffeomorphisms with vanishing Jacobian at $x$.

**Remark 15.** In the context of the use of Young diagrams to describe irreducible representations of $GL(n)$ [Ful96], we can say the following. Given a point $x \in M$, we can choose a section $\beta: M \rightarrow BM$ such that $(g_{ab,C}) \circ j^* \beta(x)$ take on arbitrary values consistent with the symmetry type of the tensors $(g_{ab,C})$ has contravariant (2) Young type, while $Q_{ab,C}$ has contravariant $\left(|C|, 2\right)$ Young type written in the row-symmetric convention [Pen60, p.193].

Given the particular symmetrizations that we have applied in defining the coordinates $\Gamma_{bc}^a$ and $Q_{ab,cdE}$, it is not immediately obvious that the system (B.2) really is a local coordinate system on $J^rBM$. This result is stated in Lemma (B.1). Our main result for this result is [AT94], some of whose results are also reported in [AT96]. A version of the coordinates (B.2) was introduced in Equation (2.18) of [AT94]. The structural results presented below can also be found in the more recent and detailed [Jen15]. There are two non-trivial facts that need to be noted.

**Lemma B.1.** (a) The coordinates (B.2) actually constitute a complete coordinate system on $J^rBM$, as can be seen from the inversion formulas

$$\partial_c g_{ab} = 2g_{d(a} \Gamma_{bc)}^d, \quad (B.8)$$

$$\partial_C g_{ab} = 2g_{d(a} \Gamma_{bc)}^d - \frac{2(|C| - 1)}{|C| + 1} Q_{ab,C} + (L.o.t_{|C|-1} abC) \quad (|C| \geq 2). \quad (B.9)$$

(b) The total coordinate and covariant derivatives act as follows (superscripted symmetrizations are performed later):

$$\partial_c \Gamma_{ab}^c = 2g_{d(a} \Gamma_{bc)}^d, \quad (B.10)$$

$$\partial_b \Gamma_{ab}^c = \Gamma_{bc}^a + \frac{2}{|C| + 1} \frac{Q_{ab,C}}{|C| + 1} + L.o.t_{|C|-1} (g, \Gamma, Q)_{bC} \quad (|C| \geq 2), \quad (B.11)$$

$$\nabla_c Q_{ab,C} = Q_{ab,cC} + \frac{2}{|C| + 2} Q_{c(a,b)C} + \frac{|C|}{|C| + 2} Q_{(c_1c_2c_3 \cdots |C|)abc} + L.o.t_{|C|-1} (g, Q)_{c,abc} \quad (|C| \geq 2). \quad (B.12)$$

\(^{10}\)Although the technical report [AT94] is unpublished, its authors have kindly shared it with us.
In each case, l.o.t. depends on \( g_{ab} \) and its derivatives only up to order \( r \), and only via given coordinates when indicated.

**Proof.** The inversion formulas follow from equations (2.7) and (2.17) of [AT94].

The total derivative formulas follow directly\(^\dagger\) from the structure equations (2.19), (2.19) and (2.22) of [AT94].

\(^\dagger\)Unfortunately, the last term on the first line of (2.22) in [AT94] has the wrong index structure. It can be corrected by re-deriving the result from the proof of Theorem 2.6 in [AT94].
is a vector or affine bundle, we can identify $VAM \cong (A \oplus A)M$ and consider the Lie derivative as a section $\mathcal{L}_\xi \alpha : M \to AM$.

The infinitesimal version of the equivariance condition $(\chi_\xi^s)^* F = F \circ p'^r(\chi_\xi^s)^*$ for $F$ is then

$$\frac{d}{ds} \left[ (\chi_\xi^s)^* F - F \circ p'^r(\chi_\xi^s)^* \right] \circ \beta^r \circ \chi_\xi^s \bigg|_{s=0} = (F \circ \beta^r, \mathcal{L}_\xi (F \circ \beta^r)) - VF \circ (\beta^r, \mathcal{L}_\xi \beta^r) = 0, \quad (B.16)$$

for any section $\beta^r : M \to J^rBM$, and with $VF : VJ^rBM \to V(T^k \otimes T^s)$ is a bundle map given by the restriction of the tangent map of $F$, $TF : T(J^rBM) \to T(T^k \otimes T^sM)$ to the vertical tangent bundle $VJ^rBM \subset T(J^rBM)$.

For tensors, the Lie derivative has the following well-known form:

$$(\mathcal{L}_\xi t)_{b_1 \cdots b_k}^{a_1 \cdots a_k} = \xi^c \partial_c t_{b_1 \cdots b_k}^{a_1 \cdots a_k} - (\partial_a \xi^b) t_{b_1 \cdots b_k}^{a_1 \cdots a_k - \cdots - (\partial_a \xi^b) t_{b_1 \cdots b_k}^{a_1 \cdots a_k} + (\partial_b \xi^a) t_{b_1 \cdots b_k}^{a_1 \cdots a_k} + \cdots + (\partial_b \xi^a) t_{b_1 \cdots b_k}^{a_1 \cdots a_k}$$

(B.17)

$$\mathcal{L}_\xi \nabla = \xi^c \nabla_c$$

(B.18)

where $\nabla_c$ is the Levi-Civita connection defined by the metric $g_{ab}$ (though the same formula also holds with any symmetric connection). We have specifically chosen the curvature coordinates

$$(x^a, \Gamma^a_{bc}, Q_{ab,c}, t_{b_1 \cdots b_k}, \xi^a_{b_1 \cdots b_k} ) \quad (B.19)$$

on $J^rBM$ so that the coordinate components of the Lie derivative of a holonomic $r$-jet, say the extension $j^r \beta$ of a section $\beta : M \to BM$, are given by (Lemma B.1(b))

$$\Gamma^a_{b_c} \circ \mathcal{L}_\xi j^r \beta = \partial_c \xi^a + l.o.t_{|C| - 1, r + 1} (\xi^a, \Gamma, Q)_{b_c} \circ j^r \beta,$$  

(B.20)

$$g_{ab} \circ \mathcal{L}_\xi j^r \beta = (g_{ac} \nabla_c \xi^b + g_{bc} \nabla_a \xi^b) \circ j^r \beta,$$  

(B.21)

$$Q_{ab,c} \circ \mathcal{L}_\xi j^r \beta = 2 \nabla_{(a} \xi^{b')} Q_{b')c} \circ j^r \beta + |C| \nabla_{(c_1} \xi^{c')} Q_{ab,c'|c_2 \cdots |c(C)} \circ j^r \beta$$

$$+ \xi^c Q_{ab,c} \circ j^r \beta$$

$$= \left( 2 \nabla_{(a} \xi^{b')} Q_{b')c} + |C| \nabla_{(c_1} \xi^{c')} Q_{ab,c'|c_2 \cdots |c(C)} \right)$$

$$+ \xi^c Q_{ab,c} \circ j^r \beta + \frac{2 |C| + 2 \xi^c Q_{ab,c} + |C|}{|C| + 2} \xi^c Q_{ab,c} \circ j^r \beta$$

$$+ \xi^c l.o.t.(g, Q)_{b,c} \circ j^r \beta,$$  

(B.22)

$$t_{b_1 \cdots b_k}^{a_1 \cdots a_k} \circ \mathcal{L}_\xi j^r \beta = \xi^b \nabla_b t_{b_1 \cdots b_k}^{a_1 \cdots a_k} + \nabla_{b_1} \xi^{b_1} t_{b_1 \cdots b_k}^{a_1 \cdots a_k} + \cdots + \nabla_{b_k} \xi^{b_k} t_{b_1 \cdots b_k}^{a_1 \cdots a_k}$$

$$- \nabla_{a_1} \xi^{a_1} t_{b_1 \cdots b_k}^{a_1 \cdots a_k} - \cdots - \nabla_{a_k} \xi^{a_k} t_{b_1 \cdots b_k}^{a_1 \cdots a_k},$$  

(B.23)

where $l.o.t_{|C| - 1, r + 1} (\xi^a, \Gamma, Q)$ stands for terms that may only involve coordinates on $J^{r+1}BM$ and derivatives of $\xi^a$ up to order $|C| - 1$, while $l.o.t.(g, Q)$ does not depend on $\Gamma$ or $\xi$ and depends
equivariantly on the $g$ and $Q$ coordinates on $J^rBM$. Let us also introduce the following notation for the components of the vertical tangent map $VF$, with $(\beta^r, \dot{\beta}^r) : M \to VJ^rBM$:

$$
VF \circ (\beta^r, \dot{\beta}^r) = \left( F \circ \beta^r, (g_{ab} \circ \dot{\beta}^r)([\partial_g]^{ab}F) \circ \beta^r \right) = (1)_{b\in C} \left( [\partial_T]_{a}^{bc} F \circ \beta^r + (Q_{ab,C} \circ \dot{\beta}^r)([\partial_Q]^{abc}F) \circ \beta^r + \left( t_{b1 \cdots b_k,C} \circ \dot{\beta}^r \right)([\partial_t]_{a1 \cdots a_k}^{b1 \cdots b_k} F) \right).
$$

(B.24)

When $\dot{\beta}^r = L_{\xi} j^r\beta$, the compositions with $\dot{\beta}^r$ should be expanded using Equations (B.20), (B.21) and (B.22). What is important to note is that all the resulting terms, with the exception of those proportional to $(\dot{\partial_T})_{a}^{bc}(\cdot, \cdot)$, will be proportional to either $\xi^a$ or $\nabla_a \xi^b$.

On the other hand, translating the tensor Lie derivative to covariant derivatives, we have

$$
L_{\xi}(F \circ j^r\beta)^{a_1 \cdots a_k}_{b_1 \cdots b_l} = \xi^a \nabla_a (F_{b_1 \cdots b_k}^{a_1 \cdots a_k} \circ j^r\beta) = -\left( (\nabla_a \xi^a)_{b_1 \cdots b_k} F_{b_1 \cdots b_k}^{a_1 \cdots a_k} \circ j^r\beta - \cdots - (\nabla_a \xi^a_{a_k} F_{b_1 \cdots b_k}^{a_1 \cdots a_k} \circ j^r\beta \right) + (\nabla_{b1} \xi_{b1} F_{b_1 \cdots b_k}^{a_1 \cdots a_k} \circ j^r\beta + \cdots + (\nabla_{b1} \xi_{b1} F_{b_1 \cdots b_k}^{a_1 \cdots a_k} \circ j^r\beta.
$$

(B.25)

What is important to note is that each term is proportional to either $\xi^a$ or $\nabla_a \xi^b$. In principle, we could expand the $\xi^a \nabla_a (F_{b_1 \cdots b_k}^{a_1 \cdots a_k} \circ j^r\beta$ term further, by using the chain rule. However, the chain rule here cannot be written solely in terms of covariant derivatives and the explicit expression in coordinate derivatives leads to rather complicated formulas that will not be immediately necessary.

Then, choosing $\xi^a(x) = 0$ and $\nabla_a \xi^b(x) = 0$ (Lemma B.2), the infinitesimal equivariance condition (B.16), expanded using Equations (B.25) and (B.24), by eliminating all terms proportional to $\xi^a$ or $\nabla_a \xi^b$ reduces to

$$
(\partial_C \xi^a + 1.o.t_{C}|_{-1,r+1}(\xi; g, \Gamma, Q)_{a}) (\partial_T)^{a_1 \cdots a_k}_{b_1 \cdots b_l} F_{b_1 \cdots b_k}(x, g, Q, t) = 0,
$$

(B.26)

for arbitrary $j^{r+1}\beta$ at $x \in M$. Since $\partial_C \xi^a(x)$ can still be chosen arbitrarily, for $|C| \geq 2$, even with $\xi^a(0) = 0$ and $\nabla_a \xi^b(x) = 0$ (Lemma B.2), we find that $(\partial_T)^{a_1 \cdots a_k}_{b_1 \cdots b_l}(x, g, \Gamma, Q) = 0$ at any value of its arguments. In other words, we have part of the desired conclusion:

$$
F_{a_1 \cdots a_k}(x, g, \Gamma, Q, t) = H_{b_1 \cdots b_k}(x, g, Q, t),
$$

(B.27)

with $H : J^rBM \to T^k \otimes T^{sl}M$ still Diff($M$)-equivariant. It remains to show that $H$ is a $GL(n)$-equivariant function of its tensorial arguments at any $x \in M$ and that the dependence on $x^a$ is trivial.

Since the dependence on the $\Gamma$-coordinates is trivial, choosing $\xi^a(x) = 0$ and $\nabla_a \xi^b(x) = J^b_a \in GL(n)$ at some point $x \in M$, the infinitesimal equivariance condition (B.16), again expanded using Equations (B.25) and (B.24), simplifies to

$$
\begin{align*}
-J_{a_1}^{a_1} H_{b_1 \cdots b_l}^{a_1 \cdots a_k} - \cdots - J_{a_k}^{a_k} H_{b_1 \cdots b_l}^{a_1 \cdots a_k} + J_{b_1}^{b_1} H_{b_1 \cdots b_l}^{a_1 \cdots a_k} + \cdots + J_{b_1}^{b_1} H_{b_1 \cdots b_l}^{a_1 \cdots a_k} \\
= 2J_{[a_1}^{[a_2} (Q_{b_1}, C) [\partial_C J^{a_2}_{a_2]}_{b_1]}^{b_2]} + |C| J^{a_1}_{a_1} (Q_{ab,C}^{a_2 \cdots a_k} C) (\partial Q)^{b_1 \cdots b_l} H_{b_1 \cdots b_l}^{a_1 \cdots a_k} \\
+ g_{a_a} J^{a_1}_{a_1} + g_{a_b} J^{a_1}_{b_1} (\partial T)^{a_1 \cdots a_k}_{b_1 \cdots b_l} H_{b_1 \cdots b_l}^{a_1 \cdots a_k} \\
+ \left( J^{a_1}_{a_1} J_{b_1}^{a_1} t_{a_2 \cdots a_k}^{a_2 \cdots a_k} - J_{a_1}^{a_1} t_{b_1}^{a_1} \cdots b_l, C - \cdots - J_{a_1}^{a_1} t_{b_1}^{a_1} \cdots b_l, C \right) (\partial T)^{b_1 \cdots b_l} C H_{b_1 \cdots b_l}^{a_1 \cdots a_k},
\end{align*}
$$

(B.28)
where $H$ is seen as a function on the product of the tensor bundles of appropriate ranks and index structures. We were justified by cancelling the composition with $(x, g, Q, t) \circ j^r \beta$ because $\beta$ can be chosen so that these coordinate components have arbitrary values with respect to the corresponding tensor type. The resulting identity is precisely the infinitesimal version of the $GL(n)$-equivariance condition [KMS93, Slo88] of $H$ at $x \in M$, with $x$ arbitrary.

Finally, we need to show that $H_{b_1 \ldots b_l}^{a_1 \ldots a_k}(x, g, Q, t)$ is actually independent of $x^a$ in any adapted coordinate system on $J^r BM$ induced from coordinates $(x^a)$ on $M$. We apply the equivariance condition (B.16) to $H$ with an arbitrary choice of $\xi^a(x) \neq 0$ and $\partial_a \xi^b(x) = 0$ at some $x \in M$. In this case, according to (B.17), we can replace the action of $L_\xi$ on tensors at $x \in M$ by the derivative operator $\xi^a \partial_a^r$ in adapted coordinates induced by the coordinates $(x^a)$:

\[
(\xi^a \partial_a^r g_{ab} \circ j^r \beta)(\partial_g)^{ab} H_{b_1 \ldots b_l}^{a_1 \ldots a_k} \circ j^r \beta \\
+ (\xi^a \partial_a^r Q_{ab,C} \circ j^r \beta)(\partial_Q)^{abC} H_{b_1 \ldots b_l}^{a_1 \ldots a_k} \circ j^r \beta \\
+ (\xi^a \partial_a^r)^{a_1 \ldots a_k} (\partial_q)^{b_1 \ldots b_l,C} H_{b_1 \ldots b_l}^{a_1 \ldots a_k} \circ j^r \beta
= \xi^a \partial_a^r|_{g,Q,t=const} H_{b_1 \ldots b_l}^{a_1 \ldots a_k} \circ j^r \beta + (\xi^a \partial_a^r g_{ab} \circ j^r \beta)(\partial_g)^{ab} H_{b_1 \ldots b_l}^{a_1 \ldots a_k} \circ j^r \beta \\
+ (\xi^a \partial_a^r Q_{ab,C} \circ j^r \beta)(\partial_Q)^{abC} H_{b_1 \ldots b_l}^{a_1 \ldots a_k} \circ j^r \beta \\
+ (\xi^a \partial_a^r)^{a_1 \ldots a_k} (\partial_q)^{b_1 \ldots b_l,C} H_{b_1 \ldots b_l}^{a_1 \ldots a_k} \circ j^r \beta.
\]

(C.29)

Cancelling the common terms from both sides of the above identity, we obtain the condition

\[
\xi^a \partial_a^r|_{g,Q=const} H_{b_1 \ldots b_l}^{a_1 \ldots a_k} \circ j^r \beta = 0.
\]

(B.30)

Because the choices of $x \in M$, $\xi^a(x)$ and $j^r \beta(x)$ were all arbitrary, we can then conclude that $H_{b_1 \ldots b_l}^{a_1 \ldots a_k}(x, g, Q, t)$, in an arbitrary adapted coordinate system on $V^r_x \subset J^r BM$, for some function $G: V^r_x \subset J^r BM \to T^k \otimes T^q M$.

\[\square\]

C Invariant theory

The goal of this section is to state and prove the Equivariance Lemma C.8, which generalizes some results proven in [KM16, Sec.2.6]. This Lemma is used in the proof of our main Theorem 6.2 to characterize all smooth $GL(n)$-equivariant (resp. $GL^+(n)$-equivariant, if we restrict ourselves to transformations that preserve spacetime orientation) tensor-valued maps that depend on a Lorentzian metric and any number of tensorial arguments.

The main difference with the previous weaker [KM16, Lem.2.8] is the allowed dependence on other tensors besides the metric. As a result of this generalization, the final characterization is a bit more complicated. In particular, while any such equivariant map is still polynomial in the metric $g$, its inverse $g^{-1}$ and possibly the Levi-Civita tensor $\varepsilon(g)$, it may depend on the additional tensor arguments $z$ in two different ways. First, being tensor-valued, any such equivariant may will be polynomially and covariantly constructed from $g$, $g^{-1}$, $\varepsilon(g)$ and the tensor components of $z$, but the coefficients in these polynomial will be allowed to depend in an essentially arbitrary smooth way on invariant scalar polynomials built out of $g$, $g^{-1}$, $\varepsilon(g)$ and the tensor components of $z$.

The precise statements and proofs of these results depend on some fundamental notions and facts from classical invariant theory of the $GL(n)$ and $O(1, n-1)$ (resp. $GL^+(n)$ and $SO(1, n-1)$ in the oriented case) groups. Invariant theory, which studies invariants of linear representations of groups and other related topics, is a highly developed subject (we will only mention [Pro07] and [GW09] as an introduction to the literature), but the majority of the literature, especially at
the introductory level, focuses on polynomial invariants on representations of complex algebraic groups. Thus, it is not always easy to locate some (even classical) results in the context of real Lie groups and smooth (rather than polynomial) invariants. For the convenience of the reader, we summarize the relevant notions and results below and, when possible, try to provide reasonably concise and elementary proofs that are not easy to extract from the literature.

In the following we will use the one point space \( * \cong \mathbb{R}^0 \) with the trivial action of \( GL(n) \) of any of its subgroup thereon.

**Definition C.1.** Let \( X \) and \( Y \) be spaces carrying actions of the group \( G \), respectively \( \rho_u^{(X)} : X \to X \) and \( \rho_u^{(Y)} : Y \to Y \) for \( u \in G \), in terms of bijective maps resp. \( X \to X \) and \( Y \to Y \). A map \( f : X \to Y \) is said to be **equivariant** if it commutes with the action of \( G \):

\[
 f \circ \rho_u^{(X)} = \rho_u^{(Y)} \circ f, \quad \text{for every } u \in G.
\]

In the spacial case \( Y = \mathbb{R} \) carrying the trivial representation, an equivariant \( f : X \to \mathbb{R} \) is called a **(scalar) invariant**. We denote the space of all scalar invariants by \( S_X \). When \( X \) is a vector space, we denote the subspace of **(scalar) polynomial invariants** by \( P_X \subseteq S_X \). The subspace \( P_X^k \subset P_X \) consists of all homogeneous polynomials of degree \( k \).

With the above definitions, it is easy to establish a relation between scalar invariants and equivariant maps for linear group representations by the following obvious

**Proposition C.1.** Let \( X \) and \( Y \) be finite dimensional vector spaces with linear representations of the group \( G \), and denote by \( Y^* \) the dual linear of \( Y \) equipped with the contragredient representation of \( G \). If \( f : X \to Y \) is an equivariant map, then \( f^*(x,y^*) := y^* \cdot f(x) \) is a scalar invariant \( f^* : X \times Y^* \to \mathbb{R} \). If \( h : X \times Y^* \to \mathbb{R} \) is a scalar invariant, then \( \frac{\partial h}{\partial y^*} |_{y^*=0} : X \to Y \) is an equivariant map. Moreover, for any equivariant map \( f : X \to Y \), \( \frac{\partial h}{\partial y^*} |_{y^*=0} = f \).

**Definition C.2.** Let \( M_{n}^p \) be the space of \( p \)-multilinear forms on \( \mathbb{R}^n \) and consider the natural linear action of \( GL(n) \) thereon. Denote by \( M_{n}^p \) the dual of \( M_{n}^p \), with the contragredient \( GL(n) \) representation on it. Let \( T \) be a finite-dimensional real vector space carrying a representation of \( GL(n) \).

1. If \( T \), with respect to some linear embedding \( T \hookrightarrow M_{n}^p \otimes M_{n}^{q*} \), is invariant under the action of \( GL(n) \), and if (the representation carried by) \( T \) is the restriction of the action of \( GL(n) \) on \( M_{n}^p \otimes M_{n}^{q*} \), then \( T \) is called **tensor representation** of \( GL(n) \). We call \((p,q)\), the **(covariant, contravariant) tensor rank** of \( T \) and \( p+q \) the **total tensor rank of \( T \)**.

2. If \( T \) is as in 1., but the action of \( GL(n) \supseteq u \mapsto \rho(u) \) on \( T \) is given by a tensor representation up to a multiplication by \( |\det u|^p \), then \( T \) is called **tensor density representation** of \( GL(n) \). We call \( s \) the tensor **weight** of \( T \).

3. Denote by \( \eta \in M_{2}^2 \) is the standard Minkowski metric with signature \((-+\cdots+)\), and by \( \epsilon \in M_{n}^n \) the standard antisymmetric Levi-Civita tensor. The orthogonal subgroup \( O(1,n-1) \subset GL(n) \) (resp. \( SO(1,n-1) \subset GL^+(n) \)) is the stabilizer subgroup of \( \eta \) under the action on \( M_{2}^2 \). A tensor (density) representation of the orthogonal group is a restriction of a tensor density representation of the general linear group.

**Remark 16.** Clearly, since for any \( u \in O(1,n-1) \), \( |\det u| = 1 \) and \( (u^{-1})^T = \eta u \eta^{-1} \) in the fundamental representation, the restriction of any two tensor density representations of \( GL(n) \) to \( O(1,n-1) \) or \( SO(1,n-1) \) are linearly equivalent as long as their total tensor rank is the same. So it is sufficient to talk only about **tensor** (rather than **tensor density**) representations of these subgroups.
Remark 17. Below, some results about a group $G$ and its representations require as a hypothesis that $G$ be reductive. There are several different flavors of reductive groups (cf. [Pro07, Sec.7.3]), not all of them being equivalent, with different ones serving as natural hypotheses for different results. The general property that they share is that each representation from a certain class is completely reducible (i.e., no reducible but indecomposable representations may occur). For the sake of uniformity, we specialize all results stated below to linearly reductive groups, even if the original result could be stated under looser hypotheses. First, note that a real (complex) algebraic group is a subgroup of $GL(n; \mathbb{R})$ ($GL(n; \mathbb{C})$), for some $n$, that is also a real (complex) algebraic subvariety (it is defined by polynomial equations). A real (complex) linearly reductive group $G$ is a real (complex) algebraic group such that each real (complex) finite dimensional rational representation of $G$ is completely reducible. Here polynomial and rational mean with respect to the matrix elements of the embedding of $G$ into $GL(n; \mathbb{R})$ ($GL(n; \mathbb{C})$). Obviously, any real algebraic group gives rise to a complex algebraic group, its complexification, simply by extending the defining polynomial equations from $GL(n; \mathbb{R})$ to $GL(n; \mathbb{C})$. A priori, the property of being reductive is different for a real algebraic group and its complexification. Fortunately, we only need to appeal to such hypotheses for the real orthogonal groups $O(1, n-1) := O(1, n-1; \mathbb{R})$ and $SO(1, n-1) := SO(1, n-1; \mathbb{R})$, both of which are known to be linearly reductive, and so are their complexifications $O(1, n-1; \mathbb{C})$ and $SO(1, n-1; \mathbb{C})$ (see [Pro07, Sec.7.3.2], [RS90, Sec.5.2]). Unless explicitly mentioned, below we always refer to real groups and their representations on real vector spaces.

Definition C.3. Let $L_n \subset M^2_n$ denote the space of Lorentzian bilinear forms (non-degenerate, with signature $(-+\cdots+)$), and let it inherit the natural action of $GL(n)$ (resp. $GL^+(n)$). Let $Z = \bigoplus Z_i$ and $T = \bigoplus T_j$ be finite sums of tensor density representations of $GL(n)$ (resp. $GL^+(n)$). We will refer to a smooth equivariant map

$$
\tau: L_n \times Z \to T \quad \text{(C.1)}
$$

as a $GL(n)$-equivariant tensor density (resp. $GL^+(n)$-equivariant tensor densities). The space of $GL(n)$-equivariant tensor densities will be denoted by $\mathcal{E}_{Z,T}$. The space of $GL^+(n)$-equivariant tensor densities will be denoted by $\tilde{\mathcal{E}}_{Z,T}$. In the special case when $T = \mathbb{R}$ carries the trivial representation, we call $S_Z := \mathcal{E}_{Z,\mathbb{R}}$ (resp. $\tilde{S}_Z := \tilde{\mathcal{E}}_{Z,\mathbb{R}}$) the space of scalar invariants.

Definition C.4. Let $Z = \bigoplus Z_i$ and $T = \bigoplus T_j$ be finite sums of tensor representations of $O(1, n-1)$ (resp. $SO(1, n-1)$). We will refer to a smooth equivariant map

$$
\tau: Z \to T \quad \text{(C.2)}
$$

as the space of $O(1, n-1)$-isotropic tensors (resp. $SO(1, n-1)$-isotropic tensors). The space of $O(1, n-1)$-isotropic tensors will be denoted by $\mathcal{E}_{Z,T}$. The space of $SO(1, n-1)$-isotropic tensors will be denoted by $\tilde{I}_{Z,T}$.

The above definitions can be contrasted with the Definitions 2.6–7 of [KM16]. There, the simpler notion equivariant and isotropic tensors did not allow for dependence on the extra parameter space $Z$ and use the simpler notations $\mathcal{E}_T \cong \mathcal{E}_{*,T}$ and $I_T \cong I_{*T}$, where $* = \mathbb{R}^0$ is the 1-point space or equivalently the trivial vector space (with complete analogy in the oriented case).

Proposition C.2. With the notation of Definitions C.3 and C.4, the space of equivariant tensor densities $\mathcal{E}_{Z,T}$ (resp. $\tilde{\mathcal{E}}_{Z,T}$) is isomorphic to the space of isotropic tensors $I_{Z,T}$ (resp. $\tilde{I}_{Z,T}$).
Proof. Here we use the same logic as in [KM16, Lem.2.8], where it is spelled out a bit tersely. Let \( \eta \in L_n \cong GL(n)/O(1, n-1) \cong GL^+(n)/SO(1, n-1) \), where the orthogonal group is interpreted as the stabilizer subgroup of \( \eta \). The equivariance of \( \tau : L_n \times Z \to T \) implies that \( \tau(u \eta, uz) = u \tau(\eta, z) \), whenever \( u \in GL(n) \) and \( u \cdot \eta = \eta \), meaning that \( \tau(\eta, -) : Z \to T \) is \( O(1, n-1) \) (resp. \( SO(1, n-1) \)) equivariant. On the other hand, since any \( L_n \ni g = u_g \cdot \eta \) for some \( u_g \in GL(n) \), the knowledge of \( \tau(\eta, -) \) uniquely determines the equivariant extension \( \tau(g, z) := u_g \tau(\eta, u_g^{-1} z) \). Clearly, this correspondence is bijective. \( \square \)

For the fundamental representations of \( O(1, n-1) \) and \( SO(1, n-1) \), homogeneous polynomials, invariant linear functionals and isotropic tensors all have a very explicit description. We give this description below in several different versions, related as follows. Any polynomial on a vector space that is invariant under the action of a linear representation can be written as a sum of invariant homogeneous polynomials. Any invariant homogeneous polynomial of degree \( p \) is also naturally a linear functional on a \( p \)-fold symmetric tensor product of the original representation and vice versa. By duality, the adjoint of a linear functional on a \( p \)-fold tensor product representation defines an equivariant map from \( * \) to the dual of the \( p \)-fold tensor product representation.

**Proposition C.3.** Let \( M_n^p \) and \( \eta \) be as in Definition C.4, let \( V^p = (\mathbb{R}^n)^p \) be the space of \( (v_1, \ldots, v_p) \) of \( p \)-copies of vectors in the fundamental representation of \( O(1, n-1) \) (or \( SO(1, n-1) \)), and let \( T = \bigoplus_j T_j \) be a finite sum of tensor representations of ranks \( p_j \) of \( O(1, n-1) \) (or \( SO(1, n-1) \)).

1. Polynomials \( p(v_1, \ldots, v_p) \in \mathcal{P}_{V^p} \) invariant under the simultaneous action of \( O(1, n-1) \) on its arguments are generated by the contractions \( \eta_{ab} v^a_i v^b_j \), with \( i, j = 1, \ldots, p \).

Polynomials \( p(v_1, \ldots, v_p) \in \mathcal{P}_{V^p} \) invariant under the simultaneous action of \( SO(1, n-1) \) on its arguments are generated by the contractions \( \eta_{ab} v^a_i v^b_j \) and \( \epsilon_{a_1 \cdots a_p} v^a_{i_1} \cdots v^a_{i_p} \), with \( i, j, i_k = 1, \ldots, p \).

2. The isotropic tensors \( \tilde{T}_n^p \) are linear combinations of tensor products of copies of \( \eta_{ab} \) with arbitrarily permuted indices.

The isotropic tensors \( \tilde{T}_n^p \) are spanned by tensor products of \( \eta_{ab} \) and \( \epsilon_{a_1 \cdots a_n} \) with arbitrarily permuted indices.

3. All \( O(1, n-1) \)-invariant linear functionals on \( M_n^p \) are spanned by arbitrary complete contractions of a tensor \( t_{a_1 \cdots a_p} \in M_n^p \) with copies of \( \eta_{ab} \), in an arbitrary order of indices.

All \( SO(1, n-1) \)-invariant linear functionals on \( M_n^p \) are spanned by arbitrary complete contractions of a tensor \( t_{a_1 \cdots a_p} \in M_n^p \) with copies of \( \eta_{ab} \) and \( \epsilon_{a_1 \cdots a_n} \), in an arbitrary order of indices.

4. All degree \( k \) homogeneous polynomial scalar \( O(1, n-1) \)-invariants \( p(t) \in \mathcal{P}_T^k \) on \( T \) are spanned by complete contractions of tensor products

\[
(t_{j_1})_{a_1^1 \cdots a_{p_{j_1}}} \cdots (t_{j_k})_{a_1^k \cdots a_{p_{j_k}}} \qquad (C.3)
\]

with copies of \( \eta_{ab} \), when \( t = \bigoplus_j t_j \).

All degree \( k \) homogeneous polynomial scalar \( SO(1, n-1) \)-invariants \( p(t) \in \mathcal{P}_T^k \) on \( T \) are spanned by complete contractions of tensor products \((C.3)\) with copies of \( \eta_{ab} \) and \( \epsilon_{a_1 \cdots a_n} \).

This proposition sometimes goes under the name of the joint tensor version of the First Fundamental Theorem (FFT) of invariant theory of \( O(1, n-1) \) (respectively \( SO(1, n-1) \)). While this specific version is well-known folklore, it is difficult to find with a concise statement and
proof, especially for part 3. Thus, we briefly sketch a proof below, summarizing the arguments from [Pro07, Sec.11.2.1] and [Pro07, Sec.11.6.8].

**Proof.** Parts 2–4 basically follow from part 1, so we first discuss these implications and then discuss a proof of part 1.

2. Note that the scaling transformations \((v_1, \ldots, v_i, \ldots, v_p) \mapsto (v_1, \ldots, \lambda v_i, \ldots, v_p)\) for \(\lambda \in \mathbb{R}\), with \(i = 1, \ldots, p\), commute with the action of the group on \(V^p\). Hence, any invariant polynomial on \(V^p\) decomposes into a sum of invariant polynomials with fixed homogeneous degrees in each of the vector arguments \(v_1, \ldots, v_p\). Since we can put \(M^p_n\) in bijection with polynomials on \(V^p\) which are homogeneous of degree 1 in each vector argument, the desired claims about \(I_{p,n}\) and \(I_{p,n}^*\) immediately follow.

3. Part 3 follows directly from part 2 by duality, since \(\eta\) defines a non-degenerate inner product on \(M^P_n\) by pairwise contraction of indices.

4. Since the decomposition \(T = \bigoplus_j T_j\) is into tensor representations, we have the equivariant embeddings \(T_j \to M^P_n\). As in the proof of part 2, the group representation on \(T\) commutes with separately multiplying each \(T_j\) by a scalar. Hence, degree \(k\) homogeneous polynomials, which are in bijection with the symmetric tensor power \(S^k T^*\), decompose into

\[
\bigoplus_{\sum_j q_j = k} \bigotimes_j S^{q_j} T_j^*
\]

and invariant polynomials respect this decomposition. Thus, to characterize all invariant polynomials in \(T\), it is sufficient to characterize invariant linear functionals on spaces of the form \(\bigotimes_j S^{q_j} T_j\), each of which come with equivariant embeddings into \(M^P_n\) with \(P = \sum_j q_j p_j\). The pullback along this embedding is a surjective equivariant map \((M^P_n)^* \to \bigotimes_j S^{q_j} T_j^*\). Now, invoking the fact that both \(O(1, n-1)\) and \(SO(1, n-1)\) are linearly reductive groups (Remark 17), both \((M^P_n)^*\) and \(\bigotimes_j S^{q_j} T_j^*\) decompose into direct sums of irreducible representations (for either group). The equivariance of the pullback map means that it diagonalizes with respect to the decomposition of the two spaces into isotypic components (maximal subspaces consisting of copies of a single irreducible representation) and its surjectivity means that it remains surjective on each isotypic component. The subspace invariant under the action of the group is simply one of the isotypic components (corresponding to the trivial representation) and hence every invariant linear functional on \(\bigotimes_j S^{q_j} T_j\) comes from pulling back an invariant linear functional from \(M^P_n\). Finally, the result of part 3 implies the desired structure of invariant polynomials on \(T\).

1. To prove part 1, we first reduce \(p\) to \(p = n\). Then, we proceed by induction on \(n\). We will use several times the following elementary fact: if both the variables \(y^i\) and a polynomial \(p(x; y) = \sum_I p_I(x) y^I\) are invariant under a group action, then the individual coefficients \(p_I(x)\) are also individually invariant. Another useful elementary fact is that two polynomials that agree on a non-empty open set agree everywhere.

First, assume that the desired conclusion holds for \(V^n\). If \(p < n\), then the desired conclusion follows from identifying invariant polynomials \(p(v_1, \ldots, v_p)\) with invariant polynomials \(p_I(v_1, \ldots, v_p, \ldots, v_n)\) that are constant with respect to the \(v_{p+1}, \ldots, v_n\) arguments. Considering an invariant polynomial \(p(v_1, \ldots, v_p)\) with \(p > n\), we can restrict it to the open subset of \(V^p\) where the first \(v_1, \ldots, v_n\) vectors are linearly independent. Then, for \(i > n\), we can write \(v_i = \sum_{j=1}^n w_j^i v_j\), where the \(w_j^i\) are invariant scalars. In fact, the \(w_j^i\) can be explicitly written as
polynomials in the contractions $\eta_{ab} v^a_j v^b_k$ and $(\det_{1 \leq j,k \leq n} \eta_{ab} v^a_j v^b_k)^{-1}$. Hence,

$$p(v_1, \ldots, v_n, v_{n+1}, \ldots, v_p) = p\left(v_1, \ldots, v_n; \sum_j w_{n+1}^j v_j, \ldots, \sum_j w_p^j v_j\right)$$

$$= p_1(v_1, \ldots, v_n; w_1^j)$$

$$= p_2\left(\eta_{ab} v^a_j v^b_k, \epsilon_{a_1 \cdots a_n} v_1^{a_1} \cdots v_n^{a_n}; w_1^j\right),$$

where $p_1$ is also polynomial in its arguments and $p_2$ is another polynomial that exists by applying to the $w$-coefficients of $p_1$ our earlier hypothesis that the desired conclusion holds for $V^n$. The contractions in the arguments of $p_2$ up to the semicolon involve only the vectors $v_1, \ldots, v_n$. Plugging in the explicit rational expressions for the $w_j^i$ into the arguments of $p_2$, since the result equals the polynomial $p$, all the denominators must cancel and we end up with an identity

$$p(v_1, \ldots, v_p) = p_3(\eta_{ab} v^a_j v^b_k, \epsilon_{a_1 \cdots a_n} v_1^{a_1} \cdots v_n^{a_n}),$$

where now the contractions may involve any of the $v_1, \ldots, v_p$ vectors, which holds for some polynomial $p$ on an open subset of $V^p$ and hence everywhere. Of course, the contractions with $\epsilon$ appear only in the case of $SO(1, n-1)$.

Next, assume the inductive hypothesis that the desired conclusion holds for $O(1, n'-1)$ and $SO(1, n'-1)$ for all $0 < n' < n$, with the $n' = 1$ case being trivial. Consider an invariant polynomial $p(v_1, \ldots, v_n)$, which we can restrict to the open subset of $V^n$ where arguments are linearly independent and the first $v_1, \ldots, v_{n-1}$ vectors span a hyperplane with a $\eta$-spacelike oriented unit normal vector $v$. Then, we can always write

$$v_n = \lambda v + w^1 v_1 + \cdots + w^{n-1} v_{n-1},$$

where the $w^i$ are invariant scalars. In fact, the $w^i$ can be explicitly written as polynomials in $\eta_{ab}(v_i)^a(v_n)^b$ and $(\eta_{ab}(v_i)^a(v_n)^b)^{-1}$. Hence,

$$p(v_1, \ldots, v_n) = p(v_1, \ldots, v_{n-1}, \lambda v + w^1 v_1 + \cdots + w^{n-1} v_{n-1})$$

$$= \sum_k p_{1,k}(v_1, \ldots, v_{n-1}; w^i) \lambda^k,$$

for some polynomials $p_{1,k}$. Consider for now only the invariance of $p$ under the subgroup of $SO(1, n-1)$ that fixes the spacelike vector $v$ up to a sign, which corresponds to $\lambda \mapsto \pm \lambda$ (the negative sign only accompanies those transformations that change the orientation of the hyperplane orthogonal to $v$). Let us identify this orthogonal hyperplane with $\mathbb{R}^{n'}$, where $n' = n - 1$ and let the $\eta'$ and $\epsilon'$ denote the restrictions of $\eta$ and $\epsilon$ to the hyperplane. The above mentioned subgroup can hence be identified with $O(1, n'-1)$ acting on $\mathbb{R}^{n'}$ and preserving $\eta'$. The invariance of $p$, together with the identification of $v_1, \ldots, v_{n-1}$ with vectors in $\mathbb{R}^{n'}$, implies that the $w$-coefficients of the $p_{1,k}$ are invariant under $O(1, n'-1)$ for even $k$ and invariant under $SO(1, n'-1)$ for odd $k$, and more specifically the odd $k$ coefficients are also odd under the change of orientation of $\mathbb{R}^{n'}$. It is now helpful to note that $\lambda^2$ can be written as a polynomial in $\eta_{ab}(v_i)^a(v_j)^b$ (including $i, j = n$) and $w^i$, while

$$\epsilon'_{a_1 \cdots a_{n-1}} v_1^{a_1} \cdots v_{n-1}^{a_{n-1}} \lambda = \epsilon_{a_1 \cdots a_n} v_1^{a_1} \cdots v_{n-1}^{a_{n-1}} v_n^{a_n}.$$ 

Thus, for even $k$, we have

$$p_{1,k}(v_1, \ldots, v_{n-1}; w^i) \lambda^k = p_{2,k}(\eta_{ab} v^a_j v^b_k; w^i)(\lambda^2)^{k/2}$$

$$= p_{3,k}(\eta_{ab} v^a_j v^b_k; w^i),$$
for some polynomials $p_{2,k}$, with $i,j \leq n - 1$ in its arguments before the semicolon, and $p_{3,k}$, with $i,j \leq n$ in its arguments before the semicolon. For odd $k$, we have
\[
p_{1,k}(v_1, \ldots, v_{n-1}; w') = p_{2,k}(\eta_{ab}v^a_j v^b_i; w')\epsilon_{a_1 \cdots a_{n-1}}v_1^{a_1} \cdots v_{n-1}^{a_{n-1}}\lambda(\lambda^2)^{(k-1)/2}
= p_{3,k}(\eta_{ab}v^a_j v^b_i; w')\epsilon_{a_1 \cdots a_n}v_1^{a_1} \cdots v_n^{a_n},
\]
for some polynomials $p_{2,k}$, with $i,j \leq n - 1$ in its arguments before the semicolon, and $p_{3,k}$, with $i,j \leq n$ in its arguments before the semicolon. Note that higher powers of $\epsilon'$ never needed to be considered because of the usual identity relating tensor powers of $\epsilon'$ with permutations of products of $\eta'$. Plugging in the explicit rational expressions for the $w'$ into the arguments of $p_{3,k}$, since the result equals the polynomial $p$, all the denominators must cancel and we end up with an identity
\[
p(v_1, \ldots, v_n) = p_4(\eta_{ab}v^a_j v^b_k, \epsilon_{a_1 \cdots a_n}v_1^{a_1} \cdots v_n^{a_n}),
\]
for some polynomial $p_4$, where now the contractions may involve any of the $v_1, \ldots, v_p$ vectors. It is important to note that, up until now, the above identity has only been established for $v_1, \ldots, v_{n-1}$ orthogonal to a given spacelike unit vector $v$. Fortunately, once we note that there always exists a transformation in $SO(1,n-1)$ that will transform any set of $n - 1$ vectors orthogonal to another unit spacelike vector $v'$ into a set of $n - 1$ vectors orthogonal to a given $v$, the invariance of both the original polynomial $p$ and the individual invariance of each argument of the polynomial $p_4$ implies that the above identity between $p$ and $p_4$ holds for any $v$. So the above identity between $p$ and $p_4$ holds on an open subset of $V^n$ and hence everywhere. Of course, the contractions with $\epsilon$ appear only in the case of $SO(1,n-1)$.

This concludes the proof. \qed

Remark 18. In the inductive step of the above proof, we reduced the problem from $O(1,n-1)$ to $O(1,n-2)$, by restricting to a subspace orthogonal to a spacelike vector, relying crucially also on the transitive action of $O(1,n-1)$ on the open subset of spacelike vectors. Clearly, the inductive step could have also used a timelike vector instead, without interfering with these crucial properties. It should also be clear that the same argument would work directly in the case of any $O(p,q)$, with reductions to either $O(p,q-1)$ or $O(p-1,q)$ both being possible inductive steps.

Before stating and proving our Equivariance Lemma C.8, we need the following fundamental results from invariant theory.

**Proposition C.4** (Hilbert [Pro07, Sec.14.1], [Mic08, §7.2]). Let $G$ be a linearly reductive group with a rational representation on a finite dimensional vector space $Z$. Then the algebra of polynomial scalar $G$-invariants on $Z$ is finitely generated.

**Definition C.5.** Let $G$ be a linearly reductive group with a rational representation on a finite dimensional vector space $Z$ and let $p_i \in C^\infty(Z)$, $i = 1, \ldots, N_Z$, be a generating set for the algebra of polynomial scalar $G$-invariants (Proposition C.4). A smooth function $\sigma \in C^\infty(Z)$ is said to be **stably $G$-invariant** if it is constant along each joint level set of the invariant polynomials $p_i$, $i = 1, \ldots, N_Z$.

Clearly, any function that is stably $G$-invariant is also $G$-invariant, but the converse is not always true. Also, it is easy to see that the definition is independent of the choice of the generating polynomials $p_i$. The stability in this definition is meant with respect to complexification, since upon replacing $G$ with its complexification the orbits become larger, while the invariant polynomials remain the same, in a way that invariant polynomials do completely separate all closed orbits, which erases the difference between $G$-invariant and stably $G$-invariant functions.
In Section 6.1.1, we discuss the action of $O(1,n-1)$ on the subspace of symmetric forms in $M_n^2$ (in this case, the action coincides with that of $SO(1,n-1)$). There, we give an explicit list of a generating set of scalar invariant polynomials and also discuss the structure of the orbits. That case also gives an explicit example of the difference between $G$-invariant and stably $G$-invariant functions, because invariant polynomials do not separate closed orbits on symmetric bilinear forms.

The following results seem to be close to the state of the art in characterizing the smooth scalar invariants that apply to our cases of interest. Unfortunately, we actually require a somewhat strengthened version of these results (though see also [Sto08] for more recent work), which we state below in Proposition C.7, but whose proof we do not discuss (Remark 19).

**Proposition C.5** (Luna [Lun76], [Mic08, §7.14] [KMS93, §26.3]). Let $G$ be a linearly reductive group with a rational representation on a finite dimensional vector space $Z$ and let $p_i \in P_Z$, $i = 1, \ldots, N_Z$, be a generating set for the algebra of polynomial scalar $G$-invariants (Proposition C.4). Then a smooth stably $G$-invariant function $\sigma \in C^\infty(Z)$ can always be written as $\sigma = \Sigma(p_1, \ldots, p_{N_Z})$ where $\Sigma$ is a smooth function of its arguments.

Though, as indicated above, the statement of Luna’s theorem can be found in several references, as far as we know, a proof is available only in the original reference [Lun76], written in French. However, the more recent result on the structure of invariants of finite $C^k$ differentiability [Rum98] does use a proof that is logically similar to Luna’s.

**Proposition C.6** (Richardson [Ric73, Thms.2,3,4,1]). Let $G$ be a linearly reductive group with a linearly reductive complexification and a rational representation of on a finite dimensional vector space $Z$. Let $p_i \in C^\infty(Z)$, $i = 1, \ldots, N_Z$, be homogeneous polynomials generating the algebra of polynomial scalar $G$-invariants on $Z$ (Proposition C.4). Then, there is a $p_0 = P(p_1, \ldots, p_{N_Z})$ polynomial in its arguments and, with $Z^0 = p_0^{-1}(0)$, a partition $Z \setminus Z^0 = \bigcup Z_j$ into finite union of disjoint connected open subsets $(Z_j)$ where each $Z_j$ is stable under the action of $G$ and, for each $j$ and for any two points $z_1, z_2 \in Z_j$ the stabilizer subgroups $G_{z_1}, G_{z_2} \subseteq G$ are conjugate in $G$.

The following definition is rather technical, but is necessary to precisely capture the difference between the behavior of smooth invariants and polynomial invariants (or analytic, or even stable smooth invariants).

**Definition C.6.** Let $Z$ be a finite dimensional vector space, $p_i \in C^\infty(Z)$, $i = 1, \ldots, N_Z$, be a set of homogeneous polynomials on $Z$, and $p_0 = P(p_1, \ldots, p_{N_Z})$ a polynomial in its arguments. With $Z^0 = p_0^{-1}(0)$, consider a partition $Z \setminus Z^0 = \bigcup_{j=1}^{r_Z} Z_j$ into pairwise disjoint open sets $Z_j$, for some $r_Z < \infty$. We say that a function $\sigma \in C^\infty(Z)$ is locally a smooth function of the polynomials $p_i$ with respect to the partition $(Z_j)$ if there exist $\Sigma_j \in C^\infty(\mathbb{R}^{N_Z})$, $j = 1, \ldots, r_Z$, such that $\sigma = \Sigma_j(p_1, \ldots, p_{N_Z})$ on $Z_j$. We say that $\sigma$ is a function of the $p_i$ (globally) if we can choose $\Sigma_j = \Sigma_i$, for $i, j = 1, \ldots, r_Z$. We write $\sigma = [\Sigma]_{ZZ}(p_1, \ldots, p_{N_Z})$.

**Proposition C.7** (extended Luna-Richardson). Let $G$ be a linearly reductive group with a linearly reductive complexification and a rational representation on a finite dimensional vector space $Z$. Also, let $p_i \in P_Z$, $i = 1, \ldots, N_Z$, be homogeneous polynomials generating the algebra of polynomial scalar $G$-invariants on $Z$ (Proposition C.4). Then, there exists a $p_0 = P(p_1, \ldots, p_{N_Z})$ polynomial in its arguments and, with $Z^0 = p_0^{-1}(0)$, a partition $Z \setminus Z^0 = \bigcup_{j=1}^{r_Z} Z_j$ into pairwise disjoint open $G$-invariant sets, such that any $G$-invariant function $\sigma \in C^\infty(Z)$ is locally a smooth function $\sigma = [\Sigma]_{ZZ}(p_1, \ldots, p_{N_Z})$ of the polynomials $p_i$ with respect to the partition $(Z_j)$ (Definition C.6).
Remark 19. The proof of Proposition C.7 follows from combining the details of the proofs of Propositions C.5 and C.6, which can be found in the original references [Lun76] and [Ric73] respectively. Discussing a complete proof goes beyond the scope of the current work and will be discussed elsewhere.

Combining the results presented so far allows us to finally formulate the main Equivariance Lemma that is needed in the proof of our main Theorem 6.2.

Lemma C.8 (Equivariance). Consider finite sums of tensor density representations $Z = \bigoplus_j Z_j$ and $T = \bigoplus_j T_j$ of $GL(n)$ (resp. $GL^+(n)$), and its natural action on $L_n$. Recall also (Definitions C.3, C.4) the notion of invariant scalars ($\mathcal{S}_Z, \tilde{\mathcal{S}}_Z \subset C^\infty(L_n \times Z)$), equivariant tensors ($\mathcal{E}_{Z,T}, \tilde{\mathcal{E}}_{Z,T} \subset C^\infty(L_n \times Z; T)$) and isotropic tensors ($\mathcal{I}_{Z,T}, \tilde{\mathcal{I}}_{Z,T} \subset C^\infty(Z; T)$), as well as their characterizations (Propositions C.1, C.2 and C.3)

1. There exist diagonalizable intertwiners $s_Z: Z \to Z$ and $s_T: T \to T$ such that $(u, z) \mapsto |\det u|^{-s_Z} (u \cdot z)$ and $(u, t) \mapsto |\det u|^{-s_T} (u \cdot t)$, for $u \in GL(n)$, $z \in Z$ and $t \in T$, define tensor representations (i.e., with density weight zero) on $Z$ and $T$. Denoting these tensor representations by $Z'$ and $T'$, we have $\mathcal{E}_{Z,T} \cong \mathcal{E}_{Z',T'}$ (resp. $\mathcal{E}_{Z,T} \cong \mathcal{E}_{Z',T'}$).

2. When $Z$ carries a tensor representation and $p \in \mathcal{S}_Z$ (resp. $\tilde{\mathcal{S}}_Z$) such that $p(g, z)$ is polynomial in $z$, then $p$ is a covariantly constructed scalar that is polynomial in the tensor components of $g$, $g^{-1}$ and $z$ (resp. of $g$, $g^{-1}$, $\varepsilon(g)$ and $z$).

3. There is a finite number of invariant $p_i \in \mathcal{S}_Z$ (resp. $\tilde{\mathcal{S}}_Z$), $i = 1, \ldots, N_Z$, such that each $p_i(g, z)$ is a homogeneous polynomial in $z$ and each $\sigma \in \mathcal{S}_Z$ (resp. $\tilde{\mathcal{S}}_Z$) is locally a smooth function $\sigma = \sum_{p_i \in \mathcal{S}_Z(p_1, \ldots, p_{N_Z})}$ of the invariant polynomials $p_i$, $i = 1, \ldots, N_Z$, as in Proposition C.7.

4. There is a finite number of equivariant tensors $q_j \in \mathcal{E}_{Z,T}$ (resp. $\tilde{\mathcal{E}}_{Z,T}$), $j = 1, \ldots, N_{Z,T}$, whose components are homogeneous polynomials on $Z$, such that each $\tau \in \mathcal{I}_{Z,T}$ (resp. $\tilde{\mathcal{E}}_{Z,T}$) is of the form $\tau = \sum_{j=1}^{N_{Z,T}} \sigma^j q_j$ with $\sigma^j \in \mathcal{S}_Z$ (resp. $\tilde{\mathcal{S}}_Z$).

Proof. After we establish point 1, we can without loss of generality assume that $Z$ and $T$ consist of direct sums of only tensor representations.

1. By hypotheses, both $Z$ and $T$ reduce to a sum of tensor density representations. This means that there exist diagonalizable intertwiners $s_Z: Z \to Z$ and $s_T: T \to T$ such that $(u, z) \mapsto |\det u|^{-s_Z} (u \cdot z)$ and $(u, t) \mapsto |\det u|^{-s_T} (u \cdot t)$, for $u \in GL(n)$, $z \in Z$ and $t \in T$, define tensor representations on $Z$ and $T$. Let us refer to the corresponding representations as $Z'$ and $T'$. If $\tau: L_n \times Z \to T$ is an equivariant map with respect to the tensor density representations on $Z$ and $T$, then

$$
\tau'(g, z') = |\det g|^{-s_T} \tau(g, |\det g|^{s_Z} z')
$$

(C.4)
defines an equivariant map $\tau': L_n \times Z' \to T'$ with respect to the corresponding tensor representations. Clearly, this operation can be reversed.

2. Recall that, in our notation, $\mathcal{S}_Z \cong \mathcal{E}_{Z,\mathbb{R}}$ (resp. $\tilde{\mathcal{S}}_Z \cong \tilde{\mathcal{E}}_{Z,\mathbb{R}}$) where $\mathbb{R}$ carries the trivial representation. Then, by Proposition C.2, we have the isomorphism $\mathcal{S}_Z = \mathcal{I}_{Z,\mathbb{R}}$ (resp. $\tilde{\mathcal{S}}_Z = \tilde{\mathcal{I}}_{Z,\mathbb{R}}$). Under this isomorphism, an invariant $p(g, z)$ is polynomial in $z$ iff the corresponding $p_\eta(z) = p(g = \eta, z)$ is polynomial. Moreover, by the classification Proposition C.3, any such polynomial $p_\eta(z)$ consists of a complete contraction of products of the tensor components of $z$ with copies of $\eta$ (and also $\varepsilon$ in the oriented case). Recalling the details of the restriction of tensor representations to the orthogonal subgroup (Remark 16), the invariant extension $p(g, z)$ of $p_\eta(z)$ clearly constitutes the same complete contraction of products of the tensor components.
of \( z \), but with every occurrence of \( \eta \) replaced by either \( g_{ab} \) (when contracting two contravariant indices), \( g^{ab} \) (when contracting two covariant indices) or \( \delta^a_b \) (when contracting a covariant and a contravariant index). Respectively, a contraction with \( \varepsilon \) is replaced by a contraction with \( \varepsilon(g) \) with its indices appropriately raised or lowered by \( g \). Thus, we arrive at the desired conclusion about the polynomiality of \( p(g, z) \) in \( g \), \( g^{-1} \) (and resp. \( \varepsilon(g) \)).

3. Recall the isomorphism \( S_Z \cong I_Z, \mathbb{R} \) (resp. \( \tilde{S}_Z \cong \tilde{I}_Z, \mathbb{R} \)) from point 2. Then, the desired conclusion follows from Proposition C.7, noting that \( O(1, n-1) \) (resp. \( SO(1, n-1) \)) is a linearly reductive Lie group (and so is its complexification, cf. Remark 17) and any tensor representation (Definition C.2) is obviously rational. The finiteness of the number of generating invariant polynomials \( p_i \) ultimately follows from Hilbert’s theorem (Proposition C.4), which can obviously be chosen to be homogeneous.

4. It follows from Proposition C.1 that any equivariant \( \tau \in \mathcal{E}_{Z,T} \) (resp. \( \tilde{\mathcal{E}}_{Z,T} \)), can be written as a gradient \( \tau(g, z) = \frac{\partial}{\partial t^*} \sigma(g, z, t^*)\big|_{t^*=0} \) for some invariant \( \sigma \in S_{Z \times T^*} \) (resp. \( \tilde{S}_{Z \times T^*} \)) that is linear in the \( t^* \) arguments. On the other hand, point 3 implies that

\[
\sigma = [\Sigma]_{Z \times T^*}(p_1, \ldots, p_{N_Z}, Q_1, \ldots, Q_{N_{Z,T}})
\]

is locally a smooth function of the invariants polynomial on \( Z \times T^* \), split into the \( p_i \) that do not depend on the \( T^* \), and the \( Q_i \) that depend on the \( T^* \) only linearly. By combining the chain rule with the notion of local dependence on polynomials (Definition C.6), we get

\[
\tau(g, z) = \frac{\partial}{\partial t^*}[\Sigma]_{Z}(p_1, \ldots, p_{N_Z}, Q_1, \ldots, Q_{N_Z})\big|_{t^*=0} = \sum_{j=1}^{N_{Z,T}} \left[ \frac{\partial}{\partial Q_j} \Sigma \right](p_1, \ldots, p_{N_Z}, Q_1, \ldots, Q_{N_Z})\big|_{Q_j=0} \frac{\partial Q_j}{\partial t^*}\big|_{t^*=0}
\]

\[
= \sum_{j=1}^{N_{Z,T}} \sigma^j(g, z) q_j(g, z),
\]

with the obvious definitions for \( \sigma^j \) and \( q_j \). This concludes the proof.
