COMPATIBILITY BETWEEN SATAKE AND BERNSTEIN-TYPE
ISOMORPHISMS IN CHARACTERISTIC p

RACHEL OLLIVIER

Abstract. We study the center of the pro-p Iwahori-Hecke ring \( \tilde{H}_Z \) of a connected split p-adic reductive group \( G \). For \( k \) an algebraically closed field with characteristic \( p \), we prove that the center of the \( k \)-algebra \( \tilde{H}_Z \otimes_Z k \) contains an affine semigroup algebra which is naturally isomorphic to the Hecke \( k \)-algebra \( H(G, \rho) \) attached to an irreducible smooth \( k \)-representation \( \rho \) of a given hyperspecial maximal compact subgroup of \( G \). This isomorphism is obtained using the inverse Satake isomorphism defined in \([25]\).

We apply this to classify the simple supersingular \( \tilde{H}_Z \otimes_Z k \)-modules, study the supersingular block in the category of finite length \( \tilde{H}_Z \otimes_Z k \)-modules, and relate the latter to supersingular representations of \( G \).

1. Introduction

The Iwahori-Hecke ring of a split $p$-adic reductive group $G$ is the convolution ring of $\mathbb{Z}$-valued functions with compact support in $I\backslash G/I$ where $I$ denotes an Iwahori subgroup of $G$. It is isomorphic to the quotient of the extended braid group ring associated to $G$ by quadratic relations in the standard generators. If one replaces $I$ by its pro-$p$ Sylow subgroup $\tilde{I}$, then one obtains the pro-$p$ Iwahori-Hecke ring $\tilde{H}_\mathbb{Z}$. In this article we study the center of $\tilde{H}_\mathbb{Z}$. We are motivated by the smooth representation theory of $G$ over an algebraically closed field $k$ with characteristic $p$ and subsequently will be interested in the $k$-algebra $\tilde{H}_k := \tilde{H}_\mathbb{Z} \otimes \mathbb{Z} k$. We construct an isomorphism of $k$-algebras between a subring of the center of $\tilde{H}_k$ and (generalizations of) spherical Hecke $k$-algebras by means of the inverse mod $p$ Satake isomorphism defined in [25]. This result is the compatibility between Bernstein and Satake isomorphisms referred to in the title of this article. We then explore some consequences of this compatibility. In particular, we study and relate the notions of supersingularity for Hecke modules and $k$-representations of $G$.

1.1. Framework and results. Let $\mathfrak{F}$ be a nonarchimedean locally compact field with residue characteristic $p$ and $k$ an algebraic closure of the residue field. We choose a uniformizer $\varpi$. Let $G := G(\mathfrak{F})$ be the group of $\mathfrak{F}$-rational points of a connected reductive group $G$ over $\mathfrak{F}$ which we assume to be $\mathfrak{F}$-split. In the semisimple building $\mathcal{X}$ of $G$, we choose and fix a chamber $C$ which amounts to choosing an Iwahori subgroup $I$ in $G$, and we denote by $\tilde{I}$ the pro-$p$ Sylow subgroup of $I$. The choice of $C$ is unique up to conjugacy by an element of $G$. We consider the associated pro-$p$ Iwahori-Hecke ring $\tilde{H}_\mathbb{Z} := \mathbb{Z}[\tilde{I}\backslash G/\tilde{I}]$ of $\mathbb{Z}$-valued functions with compact support in $\tilde{I}\backslash G/\tilde{I}$ under convolution.

Since $G$ is split, $C$ has at least one hyperspecial vertex $x_0$ and we denote by $K$ the associated maximal compact subgroup of $G$. Fix a maximal $\mathfrak{F}$-split torus $T$ in $G$ such that the corresponding apartment $\mathcal{A}$ in $\mathcal{X}$ contains $C$. The set $X_*(T)$ of cocharacters of $T$ is naturally equipped with an action of the finite Weyl group $\mathfrak{W}$. The choice of $x_0$ and of $C$ induces a natural choice of a
positive Weyl chamber of $\mathcal{A}$ that is to say of a semigroup $X_+^+(T)$ of dominant cocharacters of $T$.

1.1.1. The complex case. The structure of the spherical algebra $\mathbb{C}[K\backslash G/K]$ of complex functions compactly supported on $K\backslash G/K$ is understood thanks to the classical Satake isomorphism ([27], see also [13], [14])

$$s : \mathbb{C}[K\backslash G/K] \xrightarrow{\sim} (\mathbb{C}[X^+(T)])^w.$$  

On the other hand, the complex Iwahori-Hecke algebra $H_C := \mathbb{C}[I\backslash G/I]$ of complex functions compactly supported on $I\backslash G/I$ contains a large commutative subalgebra $A_C$ defined as the image of the Bernstein map $\theta : \mathbb{C}[X^+(T)] \hookrightarrow H_C$ which depends on the choice of the dominant Weyl chamber (see [23, 3.2]). The algebra $H_C$ is free of finite rank over $A_C$ and its center $Z(H_C)$ is contained in $A_C$. Furthermore, the map $\theta$ yields an isomorphism

$$b : (\mathbb{C}[X^+(T)])^w \xrightarrow{\sim} Z(H_C).$$

This was proved by Bernstein ([23, 3.5], see also [14, Theorem 2.3]). By [10, Corollary 3.1] and [14, Proposition 10.1], the Bernstein isomorphism $b$ is compatible with $s$ in the sense that the composition $(e_K \ast .)b$ is an inverse for $s$, where $(e_K \ast .)$ denotes the convolution by the characteristic function of $K$.

1.1.2. Bernstein and Satake isomorphisms in characteristic $p$. After defining an integral version of the complex Bernstein map, Vignéras gave in [33] a basis for the center of $\tilde{H}_Z$ and proved that $\tilde{H}_Z$ is noetherian and finitely generated over its center. In the first section of this article, we define a subring $Z^0(\tilde{H}_Z)$ of the center of $\tilde{H}_Z$ over which $\tilde{H}_Z$ is still finitely generated. In Proposition 2.8 we prove that $Z^0(\tilde{H}_Z)$ is not affected by the choice of another apartment containing $C$ and of another hyperspecial vertex of $C$ as long as it is conjugate to $x_0$. In particular, if $G$ is of adjoint type or $G = GL_n$, then $Z^0(\tilde{H}_Z)$ depends only on the choice of the uniformizer $\varpi$.

The natural image of $Z^0(\tilde{H}_Z)$ in $\tilde{H}_k = \tilde{H}_Z \otimes_\mathbb{Z} k$ is denoted by $Z^0(\tilde{H}_k)$ and we prove that it has a structure of affine semigroup algebra. More precisely, we have an isomorphism of $k$-algebras (Proposition 2.10)

$$k[X^+_+(T)] \xrightarrow{\sim} Z^0(\tilde{H}_k) \subseteq \tilde{H}_k.$$  

By the main theorem in [17] (and in [25]), this makes $Z^0(\tilde{H}_k)$ isomorphic to the algebra $\mathcal{H}(G, \rho)$ of any irreducible smooth $k$-representation $\rho$ of $K$. Note that when $\rho$ is the $k$-valued trivial representation $1_K$ of $K$, ones retrieves the convolution algebra $k[K\backslash G/K] = \mathcal{H}(G, 1_K)$.

In [25], we constructed an isomorphism

$$\mathcal{T} : k[X^+_+(T)] \xrightarrow{\sim} \mathcal{H}(G, \rho).$$
In the current article, we prove the following theorem.

**Theorem 1.1 (Theorem 4.3).** We have a commutative diagram of isomorphisms of $k$-algebras

\[
\begin{array}{ccc}
k[X^+_*(T)] & \xrightarrow{(1.1)} & Z^\circ(\tilde{H}_k) \\
\| & & \downarrow \\
k[X^+_*(T)] & \xrightarrow{\mathcal{T}} & H(G, \rho)
\end{array}
\]

where the vertical arrow on the right hand side is the natural morphism of $k$-algebras (4.3) described in Section 4.

The isomorphism $\mathcal{T}$ was constructed in [25] by means of generalized integral Bernstein maps, as are the subring $Z^\circ(\tilde{H}_k)$ and the map (1.1) in the current article. By analogy with the complex case, we can see the map (1.1) as an isomorphism à la Bernstein in characteristic $p$. The above commutative diagram can then be interpreted as a statement of compatibility between Satake and Bernstein isomorphisms in characteristic $p$. Note that under the hypothesis that the derived subgroup of $G$ is simply connected, it is proved in [25] that $\mathcal{T}$ is the inverse of the mod $p$ Satake isomorphism defined by Herzig in [17]. (The extra hypothesis on $G$ is probably not necessary).

If we worked with the Iwahori-Hecke algebra $k[I\backslash G/I]$, the analog of $Z^\circ(\tilde{H}_k)$ would actually be the whole center of $k[I\backslash G/I]$. We prove:

**Theorem (Theorem 2.14).** The center of the Iwahori-Hecke $k$-algebra $k[I\backslash G/I]$ is isomorphic to $k[X^+_*(T)]$.

1.1.3. **Generalized integral Bernstein maps.** One ingredient of the construction of $\mathcal{T}$ in [25] and of the proof of Theorem 1.1 is the definition of $\mathbb{Z}$-linear injective maps

\[\mathcal{B}^\sigma_F : \mathbb{Z}[\tilde{X}_*(T)] \to \tilde{H}_Z\]

defined on the group ring of the (extended) cocharacters $\tilde{X}_*(T)$, and which are multiplicative when restricted to the semigroup ring of any chosen Weyl chamber of $\tilde{X}_*(T)$ (see 1.2.5 for the definition of $\tilde{X}_*(T)$). The image of $\mathcal{B}^\sigma_F$ happens to be a commutative subring of $\tilde{H}_Z$ which we denote by $\mathcal{A}^\sigma_F$. The parameter $\sigma$ is a sign and $F$ is a standard facet, meaning a facet of $C$ containing $x_0$ in its closure. The choice of $F$ corresponds to the choice of a Weyl chamber in $\mathcal{A}$: for example if $F = C$ (resp. $x_0$), then the corresponding Weyl chamber is the dominant (resp. antidominant) one.

The maps $\mathcal{B}^\sigma_F$ are called *integral Bernstein maps* because they are generalizations of the Bernstein map $\theta$ mentioned in 1.1.1. In the complex case, it is customary to consider either $\theta$ which is constructed using the dominant chamber, or $\theta^-$ which is constructed using the antidominant
chamber (see the discussion in the introduction of [15] for example). By a result by Bernstein ([22]), a basis for the center of $H_C$ is given by the central Bernstein functions

$$\sum_{\lambda' \in O} \theta(\lambda')$$

where $O$ ranges over the $\mathfrak{W}$-orbits in $X_*(T)$. We refer to [14] for the geometric interpretation of these functions. It is natural to ask whether using $\theta^-$ instead of $\theta$ in the previous formula yields the same central element in $H_C$. The answer is yes (see [15, 2.2.2]). The proof is based on [22, Corollary 8.8] and relies on the combinatorics of the Kazhdan-Lusztig polynomials. Note that there is no theory of Kazhdan-Lusztig polynomials for the complex pro-$p$ Iwahori-Hecke algebra.

Integral (and pro-$p$) versions of $\theta$ and $\theta^-$ for the ring $\tilde{H}_\mathbb{Z}$ were defined in [33]. In our language they correspond respectively to $\mathcal{B}^+_C = \mathcal{B}^{-}_{x_0}$ and $\mathcal{B}^+_C = \mathcal{B}^{-}_{x_0}$. It is also proved in [33] that a $\mathbb{Z}$-basis for the center of $\tilde{H}_\mathbb{Z}$ is given by

$$(1.4) \quad \sum_{\lambda' \in O} \mathcal{B}^+_C(\lambda')$$

where $O$ ranges over the $\mathfrak{W}$-orbits in $\tilde{X}_*(T)$. It is now natural to ask whether the element (1.4) is the same if a/ we use $-$ instead of $+$, and if more generally, b/ we use any standard facet $F$ instead of $C$, and any sign $\sigma$. We prove:

**Lemma (Lemma 3.4).** The element

$$\sum_{\lambda' \in O} \mathcal{B}^\sigma_F(\lambda')$$

in $\tilde{H}_\mathbb{Z}$ does not depend on the choice of the standard facet $F$ and of the sign $\sigma$.

To prove the lemma, we first answer positively Question a/ above; we then study and exploit the behavior of the integral Bernstein maps upon a process of parabolic induction. In passing we also consider Question a/ in the $k$-algebra $\tilde{H}_k$ in the case when $G$ is semisimple, and we suggest a link between such questions and the duality for finite length $\tilde{H}_k$-modules defined in [26] (see Proposition 3.3).

1.1.4. In Section 5, we define and study a natural topology on $\tilde{H}_k$ which depends only on the conjugacy class of $x_0$. It is the $\mathfrak{I}$-adic topology where $\mathfrak{I}$ is a natural monomial ideal of the affine semigroup algebra $Z^{\circ}(\tilde{H}_k)$.

We define the supersingular block of the category of finite length $\tilde{H}_k$-modules to be the full subcategory of the modules that are continuous for the $\mathfrak{I}$-adic topology on $\tilde{H}_k$ (Proposition-Definition 5.10). A finite length $\tilde{H}_k$-module then turns out to be in the supersingular block if and only if all its irreducible constituents are supersingular in the sense of [33].
In the case when the root system of $G$ is irreducible, we establish the following results. We classify the simple supersingular $\tilde{H}_k$-modules (Theorem 5.14 and subsequent Corollary). (For example, when $G$ is semisimple simply connected, the simple supersingular modules all have dimension 1.) We prove in passing that even if the ideal $\mathcal{I}$ does depend on the choices made, the supersingular block is independent of all the choices.

Theorem 5.14 extends [33, Theorem 5]-[24, Theorem 7.3] that dealt with the case of $GL_n$ and relied on explicit minimal expressions for certain Bernstein functions associated to the minuscule coweights. The results of [33] and [24] together proved a “numerical Langlands correspondence for Hecke modules” of $GL_n(\mathfrak{F})$: there is a bijection between the finite set of all simple $n$-dimensional supersingular $\tilde{H}_k$-modules and the finite set of all irreducible $n$-dimensional smooth $k$-representations of the absolute Galois group of $\mathfrak{F}$, where the action of the uniformizer $\varpi$ on the Hecke modules and the determinant of the Frobenius on the Galois representations are fixed. Recently, Grosse-Klönne constructed a functor from the category of finite length $\tilde{H}_k$-modules for $GL_n(Q_p)$ to the category of étale $(\varphi, \Gamma)$-modules. This functor induces a bijection between the two finite sets above, turning the “numerical” correspondence into a natural and explicit correspondence in the case of $GL_n(Q_p)$. In fact, Grosse-Klönne constructs such a functor (with values in a category of modified étale $(\varphi, \Gamma)$-modules) in the case of a general split group over $Q_p$. In the case of $SL_n(\mathfrak{F})$, Koziol has defined packets of simple supersingular $\tilde{H}_k$-modules and built a bijection between the set of packets and a certain set of projective $k$-representations of the absolute Galois group of $\mathfrak{F}$; if $\mathfrak{F} = Q_p$, this bijection is proved to be compatible with Grosse-Klönne’s functor and therefore with the explicit Langlands-type correspondence for Hecke modules of $GL_n(Q_p)$. This result ([21]) is a first step towards a mod $p$ principle of functoriality for Hecke modules.

The current article provides, in the case of a general split group, a classification of the objects that one wants to apply Grosse-Klönne’s functor to, in order to investigate the possibility of a Langlands-type correspondence for Hecke modules in general.

1.1.5. In 5.6 we consider an admissible irreducible smooth $k$-representation $\pi$ of $G$. In the case where the derived subgroup of $G$ is simply connected, we use the fact that (1.2) is the inverse of the mod $p$ Satake isomorphism to prove that if $\pi$ is supersingular, then

$$\pi \text{ is a quotient of } \text{ind}_{\mathcal{I}}^{G1}/\mathcal{I}\text{ind}_{\mathcal{I}}^{G1}. \tag{1.5}$$

The condition (1.5) is equivalent to saying that $\pi^{\mathcal{I}}$ contains an irreducible supersingular $\tilde{H}_k$-module.

When $G = GL_n(\mathfrak{F})$ and $\mathfrak{F}$ is a finite extension of $Q_p$, we use the classification of the non-supersingular representations obtained in [18], the work on generalized special representations
in [11], and our Lemma 3.4, to prove that the condition (1.5) is in fact a characterization of the supersingular representations (Theorem 5.27).

Finally, we comment in 5.6 on the generalization of this characterization to the case of a split group (with simply connected derived subgroup), and on the independence of the characterization of the choices made.

We raise the question of the possibility of a direct proof of this characterization that does not use the classification of the nonsupersingular representations.

1.2. Notation and preliminaries. We choose the valuation \( \text{val}_\mathfrak{f} \) on \( \mathfrak{f} \) normalized by \( \text{val}_\mathfrak{f}(\infty) = 1 \) where \( \infty \) is the chosen uniformizer. The ring of integers of \( \mathfrak{f} \) is denoted by \( \mathcal{O} \) and its residue field by \( \mathbb{F}_q \) where \( q \) is a power of the prime number \( p \). Recall that \( k \) denotes an algebraic closure of \( \mathbb{F}_q \). Let \( G_{x_0} \) and \( G_C \) denote the Bruhat-Tits group schemes over \( \mathcal{O} \) whose \( \mathcal{O} \)-valued points are \( K \) and \( I \) respectively. Their reductions over the residue field \( \mathbb{F}_q \) are \( G_{x_0} \) and \( G_C \). Note that \( G = G_{x_0}(\mathfrak{f}) = G_C(\mathfrak{f}) \). By [31, 3.4.2, 3.7 and 3.8], \( G_{x_0} \) is connected reductive and \( \mathbb{F}_q \)-split. Therefore we have \( G^0_C(\mathcal{O}) = G_C(\mathcal{O}) = I \) and \( G^0_{x_0}(\mathcal{O}) = G_{x_0}(\mathcal{O}) = K \). Denote by \( K_1 \) the pro-unipotent radical of \( K \). The quotient \( K/K_1 \) is isomorphic to \( G_{x_0}(\mathbb{F}_q) \). The Iwahori subgroup \( I \) is the preimage in \( K \) of the \( \mathbb{F}_q \)-rational points of a Borel subgroup \( \mathcal{B} \) with Levi decomposition \( \mathcal{B} = T \mathcal{N} \). The pro-\( p \) Iwahori subgroup \( \bar{I} \) is the preimage in \( I \) of \( \mathcal{N}(\mathbb{F}_q) \). The preimage of \( \mathcal{T}(\mathbb{F}_q) \) is the maximal compact subgroup \( T^0 \) of \( T \). Note that \( T^0/T^1 = I/\bar{I} = \mathcal{T}(\mathbb{F}_q) \) where \( T^1 := T^0 \cap \bar{I} \).

1.2.1. Affine root datum. To the choice of \( T \) is attached the root datum \( (\Phi, X^*(T), \hat{\Phi}, X_*(T)) \). This root system is reduced because the group \( G \) is \( \mathfrak{f} \)-split. We denote by \( \mathcal{W} \) the finite Weyl group \( N_G(T)/T \), quotient by \( T \) of the normalizer of \( T \). Recall that \( \mathcal{A} \) denotes the apartment of the semisimple building attached to \( T \) ([31] and [29, I.1], and we follow the notations of [25, 2.2]). We denote by \( \langle \cdot, \cdot \rangle \) the perfect pairing \( X_*(T) \times X^*(T) \to \mathbb{Z} \). We will call coweights the elements in \( X_*(T) \). We identify \( X_*(T) \) with the subgroup \( T/T^0 \) of the extended Weyl group \( W = N_G(T)/T^0 \) as in [31, I.1] and [29, I.1]: to an element \( g \in T \) corresponds a vector \( \nu(g) \in \mathbb{R} \otimes \mathbb{Z} \) \( X_*(T) \) defined by

\[
\langle \nu(g), \chi \rangle = -\text{val}_\mathfrak{f}(\chi(g)) \quad \text{for any } \chi \in X^*(T).
\]

and \( \nu \) induces the required isomorphism \( T/T^0 \cong X_*(T) \). The group \( T/T^0 \) acts by translation on \( \mathcal{A} \) via \( \nu \). The actions of \( \mathcal{W} \) and \( T/T^0 \) combine into an action of \( W \) on \( \mathcal{A} \) as recalled in [29, page 102]. Since \( x_0 \) is a special vertex of the building, \( W \) is isomorphic to the semidirect product \( \mathcal{W} \rtimes X_*(T) \) where we see \( \mathcal{W} \) as the fixator in \( W \) of any point lifting \( x_0 \) in the extended apartment ([31, 1.9]). A coweight \( \lambda \) will sometimes be denoted by \( e^\lambda \) to underline that we see it as an element in \( W \), meaning as a translation on \( \mathcal{A} \).
Denote by $\Phi_{aff}$ the set of affine roots. The choice of the chamber $C$ implies in particular the choice of the positive affine roots $\Phi^+_{aff}$ taking nonnegative values on $C$. The choice of $x_0$ as an origin of $A$ implies that we identify the affine roots taking value zero at $x_0$ with $\Phi$. We set $\Phi^+ := \Phi^+_{aff} \cap \Phi$ and $\Phi^- = -\Phi^+$. The affine roots can be described the following way:

$$\Phi_{aff} = \Phi \times \mathbb{Z} = \Phi^+_{aff} \coprod \Phi^-_{aff}$$

where

$$\Phi^+_{aff} := \{(\alpha, r), \alpha \in \Phi, r > 0\} \cup \{(\alpha, 0), \alpha \in \Phi^+\}.$$

Let $\Pi$ be the basis for $\Phi^+$: it is the set of simple roots. The finite Weyl group $W$ is a Coxeter system with generating set $S := \{s_\alpha, \alpha \in \Pi\}$ where $s_\alpha$ denotes the (simple) reflection at the hyperplane $(., \alpha) = 0$. Denote by $\preceq$ the partial ordering on $X^+_W(T)$ associated to $\Pi$. Let $\Pi_m$ be the set of roots in $\Phi$ that are minimal elements for $\preceq$. Define the set of simple affine roots by $\Pi_{aff} := \{(\alpha, 0), \alpha \in \Pi\} \cup \{(\alpha, 1), \alpha \in \Pi_m\}$. Identifying $\alpha$ with $(\alpha, 0)$, we consider $\Pi$ a subset of $\Pi_{aff}$. For $A \in \Pi_{aff}$, denote by $s_A$ the following associated reflection: $s_A = s_\alpha$ if $A = (\alpha, 0)$ and $s_A = s_\alpha e^\alpha$ if $A = (\alpha, 1)$. The action of $W$ on the coweights induces an action on the set of affine roots: $W$ acts on $\Phi_{aff}$ by $\omega^A : (\alpha, r) \mapsto (w_\alpha, r - (\lambda, \alpha))$ where we denote by $(w, \alpha) \mapsto w_\alpha$ the natural action of $W$ on $\Phi$. The length on the Coxeter system $(W, S)$ extends to $W$ in such a way that the length $\ell(w)$ of $w \in W$ is the number of affine roots $A \in \Phi^+_{aff}$ such that $w(A) \in \Phi^-_{aff}$.

It satisfies the following formula, for $A \in \Pi_{aff}$ and $w \in W$:

\begin{equation}
\ell(w s_A) = \begin{cases} 
\ell(w) + 1 & \text{if } w(A) \in \Phi^+_{aff}, \\
\ell(w) - 1 & \text{if } w(A) \in \Phi^-_{aff}.
\end{cases}
\end{equation}

The affine Weyl group is defined as the subgroup $W_{aff}$ of $W$ generated by $S_{aff} := \{s_A, A \in \Pi_{aff}\}$. The length function $\ell$ restricted to $W_{aff}$ coincides with the length function of the Coxeter system $(W_{aff}, S_{aff})$ ([4, V.3.2 Thm 1(i)]). Recall ([23, 1.5]) that $W_{aff}$ is a normal subgroup of $W$: the set $\Omega$ of elements with length zero is an abelian subgroup of $W$ and $W$ is the semidirect product $W = \Omega \rtimes W_{aff}$. The length $\ell$ is constant on the double cosets of $W$ mod $\Omega$. In particular $\Omega$ normalizes $S_{aff}$.

The extended Weyl group $W$ is equipped with a partial order $\preceq$ that extends the Bruhat order on $W_{aff}$. By definition, given $w = \omega w_{aff}$, $w = \omega' w'_{aff} \in \Omega \rtimes W_{aff}$, we have $w \preceq w'$ if $\omega = \omega'$ and $w_{aff} \preceq w'_{aff}$ in the Bruhat order on $W_{aff}$ (see for example [14, 2.1]).

We fix a lift $\hat{w} \in N_G(T)$ for any $w \in W$. By Bruhat decomposition, $G$ is the disjoint union of all $I \hat{w} I$ for $w \in W$.

1.2.2. Orientation character. The stabilizer of the chamber $C$ in $W$ is $\Omega$. We define as in [26, 3.1] the orientation character $\epsilon_C : \Omega \to \{\pm 1\}$ of $C$ by setting $\epsilon_C(\omega) = +1$, resp. $-1$, if $\omega$ preserves, resp. reverses, a given orientation of $C$. Since $W/W_{aff} = \Omega$ we can see $\epsilon_C$ as a character of $W$. 

trivial on $W_{\text{aff}}$. By definition of the Bruhat order on $W$, we have $\epsilon_C(w) = \epsilon_C(w')$ for $w, w' \in W$ satisfying $w \leq w'$.

On the other hand, the extended Weyl group acts by affine isometries on the Euclidean space $\mathcal{A}$. We therefore have a determinant map $\det : W \to \{\pm 1\}$ which is trivial on $X_*(T)$. An orientation of $C$ is a choice of a cyclic ordering of its set of vertices (in the geometric realization of $\mathcal{A}$). Therefore, $\det(\omega)$ is the signature of the permutation of the vertices of $C$ induced by $\omega \in \Omega$ and $\det(\omega) = \epsilon_C(\omega)$.

**Lemma 1.2.**

i. For $w \in W_{\text{aff}}$, we have $\det(w) = (-1)^{\ell(w)}$.

ii. For $\lambda \in X_*(T)$, we have $\epsilon_C(w) = (-1)^{\ell(e^\lambda)}$ for any $w \in W$ such that $w \leq e^\lambda$.

**Proof.** The first point comes from the fact that $\det(s) = -1$ for $s \in S_{\text{aff}}$. For the second one, by definition of the Bruhat order, it is enough to prove that $\epsilon_C(e^\lambda) = (-1)^{\ell(e^\lambda)}$ for $\lambda \in X_*(T)$. Decompose $e^\lambda = \omega w_{\text{aff}}$ with $w \in W_{\text{aff}}$ and $\omega \in \Omega$. Recall that $\omega$ has length zero. Since $\epsilon_C$ is trivial on $W_{\text{aff}}$, we have $\epsilon_C(e^\lambda) = \epsilon_C(\omega) = \det(\omega)$. Since $\det(e^\lambda) = 1$ we have $\det(\omega) = \det(w_{\text{aff}}) = (-1)^{\ell(w_{\text{aff}})} = (-1)^{\ell(e^\lambda)}$.

\[\square\]

1.2.3. **Distinguished cosets representatives.**

**Proposition 1.3.**

i. The set $\mathcal{D}$ of all elements $d \in W$ satisfying $d^{-1}(\Phi^+) \subset \Phi^+_{\text{aff}}$ is a system of representatives of the right cosets $\mathcal{M}\backslash W$. It satisfies

\begin{equation}
\ell(wd) = \ell(w) + \ell(d) \text{ for any } w \in \mathcal{M} \text{ and } d \in \mathcal{D}.
\end{equation}

In particular, $d$ is the unique element with minimal length in $\mathcal{M}d$.

ii. An element $d \in \mathcal{D}$ can be written uniquely $d = e^\lambda w$ with $\lambda \in X^+_*(T)$ and $w \in \mathcal{M}$. We then have $\ell(e^\lambda) = \ell(d) + \ell(w^{-1}) = \ell(d) + \ell(w)$.

iii. For $s \in S_{\text{aff}}$ and $d \in \mathcal{D}$, we are in one of the following situations:

- $\ell(ds) = \ell(d) - 1$ in which case $ds \in \mathcal{D}$.
- $\ell(ds) = \ell(d) + 1$ in which case either $ds \in \mathcal{D}$ or $ds \in \mathcal{M}d$.

**Proof.** This proposition is proved in [24, Lemma 2.6, Prop. 2.7] in the case of $G = \text{GL}_n(\mathfrak{F})$. It is checked in [26, Prop. 4.6] that it remains valid for a general split reductive group (see also [25, Prop. 2.2] for ii), except for point iii when $s \in S_{\text{aff}} - S$. We check here that the argument goes through. Let $s \in S_{\text{aff}}$ and $A$ the corresponding affine root. Let $d \in \mathcal{D}$ and suppose that $ds \notin \mathcal{D}$, then there is $\beta \in \Pi$ such that $(ds)^{-1}\beta \in \Phi^-_{\text{aff}}$ while $d^{-1}\beta \in \Phi^+_{\text{aff}}$. It implies that $d^{-1}\beta = A$ which in particular ensures that $dA \in \Phi^+_{\text{aff}}$ and therefore $\ell(ds) = \ell(d) + 1$. Furthermore, $dsd^{-1} = s_{dA} = s_\beta \in \mathcal{M}$.

\[\square\]
There is an action of the group $G$ on the semisimple building $\mathcal{X}$ recalled in [29, p. 104] that extends the action of $N_G(T)$ on the standard apartment. For $F$ a standard facet, we denote by $\mathcal{P}^\dagger_F$ the stabilizer of $F$ in $G$.

**Proposition 1.4.**

i. The Iwahori subgroup $I$ acts transitively on the apartments of $\mathcal{X}$ containing $C$.

ii. The stabilizer $\mathcal{P}^\dagger_{x_0}$ of $x_0$ acts transitively on the chambers of $\mathcal{X}$ containing $x_0$ in their closure.

iii. A $G$-conjugate of $x_0$ in the closure of $C$ is a $\mathcal{P}^\dagger_C$-conjugate of $x_0$.

**Proof.** Point i is [6, 4.6.28]. For ii, we first consider $C'$ a chamber of $\mathcal{A}$ containing $x_0$ in its closure. The group $W$ acting transitively on the chambers of $\mathcal{A}$, there is $d \in D$ and $w_0 \in \mathcal{W}$ such that $C' = w_0dC$ and $C$ contains $d^{-1}x_0$ in its closure. By [26, Proposition 4.13 i.], it implies that $d^{-1}C = C$ and therefore $C' = w_0C$ or, when considering the action of $G$ on the building, $C' = \hat{w}_0C$ where $\hat{w}_0 \in K \cap N_G(T)$ denotes a lift for $w_0$. Now let $C''$ be a chamber of $\mathcal{X}$ containing $x_0$ in its closure. By [5, Corollaire 2.2.6], there is $k \in \mathcal{P}^\dagger_{x_0}$ such that $kC''$ is in $\mathcal{A}$. Applying the previous observation, $C''$ is a $\mathcal{P}^\dagger_{x_0}$-conjugate of $C$. Lastly, let $g_0x_0$ (with $g \in G$) be a conjugate of $x_0$ in the closure of $C$. By ii, the chamber $g^{-1}C$ is of the form $kC$ for $k \in \mathcal{P}^\dagger_{x_0}$ which implies that $gk \in \mathcal{P}^\dagger_C$ and $gx_0$ is a $\mathcal{P}^\dagger_C$-conjugate of $x_0$. □

**Remark 1.5.** By [26, Lemma 4.9], $\mathcal{P}^\dagger_C$ is the disjoint union of all $I\hat{\omega}I = \hat{\omega}I$ for $\omega \in \Omega$. Therefore, a $G$-conjugate of $x_0$ in the closure of $C$ is a $\mathcal{P}^\dagger_C \cap N_G(T)$-conjugate of $x_0$.

1.2.4. **Weyl chambers.** The set of dominant coweights $X^+_\ast(T)$ is the set of all $\lambda \in X_\ast(T)$ such that $\langle \lambda, \alpha \rangle \geq 0$ for all $\alpha \in \Phi^+$. It is called the dominant chamber. Its opposite is the antidominant chamber. A coweight $\lambda$ such that $\langle \lambda, \alpha \rangle > 0$ for all $\alpha \in \Phi^+$ is called strongly dominant. By [7, Lemma 6.14], strongly dominant elements do exist.

We call a facet $F$ of $\mathcal{A}$ standard if it is a facet of $C$ containing $x_0$ in its closure. Attached to a standard facet $F$ is the subset $\Phi_F$ of all roots in $\Phi$ taking value zero on $F$ and the subgroup $\mathcal{W}_F$ of $\mathcal{W}$ generated by the simple reflections stabilizing $F$. Let $\Phi_F^+ := \Phi^+ \cap \Phi_F$ and $\Phi_F^- := \Phi^- \cap \Phi_F$. Define the following Weyl chamber in $X_\ast(T)$ as in [25, 4.1.1]:

$$\mathcal{C}^+(F) = \{ \lambda \in X_\ast(T) \text{ such that } \langle \lambda, \alpha \rangle \geq 0 \text{ for all } \alpha \in (\Phi^+ - \Phi_F^+) \cup \Phi_F^- \}$$

and its opposite $\mathcal{C}^-(F) = -\mathcal{C}^+(F)$. They are respectively the images of the dominant and antidominant chambers by the longest element $w_F$ in $\mathcal{W}_F$.

By Gordan’s Lemma ([20, p. 7]), a Weyl chamber is finitely generated as a semigroup.
1.2.5. We follow the notations of [25, 2.2.2, 2.2.3]. Recall that $T^1$ is the pro-$p$ Sylow subgroup of $T^0$. We denote by $\hat{W}$ the quotient of $N_G(T)$ by $T^1$ and obtain the exact sequence

$$0 \rightarrow T^0/T^1 \rightarrow \hat{W} \rightarrow W \rightarrow 0.$$ 

The group $\hat{W}$ parametrizes the double cosets of $G$ modulo $\tilde{I}$. We fix a lift $\hat{w} \in N_G(T)$ for any $w \in \hat{W}$ and denote by $\tau_w$ the characteristic function of the double coset $\tilde{I}\hat{w}\tilde{I}$. The set of all $(\tau_w)_{w \in \hat{W}}$ is a $\mathbb{Z}$-basis for $\hat{H}_Z$ which was defined in the introduction to be the convolution ring of $\mathbb{Z}$-valued functions with compact support in $\tilde{I}\backslash G/\tilde{I}$. For $g \in G$, we will also use the notation $\tau_g$ for the characteristic function of the double coset $\tilde{I}g\tilde{I}$.

For $Y$ a subset of $W$, we denote by $\bar{Y}$ its preimage in $\hat{W}$. In particular, we have the preimage $\hat{X}_*(T)$ of $X_*(T)$. As well as those of $X_*(T)$, its elements will be denoted by $\lambda$ or $e^\lambda$ and called coweights. For $\alpha \in \Phi$, we inflate the function $\langle ., \alpha \rangle$ defined on $X_*(T)$ to $\hat{X}_*(T)$. We still call dominant coweights the elements in the preimage $\hat{X}_*(T)$ of $X_*(T)$.

Remark 1.6. We have the decomposition of $\hat{W}$ as a semidirect product $\hat{W} = \hat{W} \rtimes X_*(T)$ where $\hat{W}$ denotes the preimage of $\mathfrak{W}$ in $\hat{W}$.
1.2.7. Pro-p Hecke rings. The product in the generic pro-p Iwahori-Hecke ring $\tilde{H}_Z$ is described in [33, Theorem 1]. It is given by quadratic relations and braid relations. Stating the quadratic relations in $\tilde{H}_Z$ requires some more notations. We are only going to use them in $\tilde{H}_k$ where they have a simpler form, and we postpone their description to 1.2.8. We recall here the braid relations:

\[(1.11) \tau_{ww'} = \tau_w \tau_{w'} \quad \text{for } w, w' \in \tilde{W} \text{ satisfying } \ell(ww') = \ell(w) + \ell(w').\]

The functions in $\tilde{H}_Z$ with support in the subgroup of $G$ generated by all parahoric subgroups form a subring $\tilde{H}_Z^{aff}$ called the affine subring. It has $\mathbb{Z}$-basis the set of all $\tau_w$ for $w$ in the preimage $\tilde{W}^{aff}$ of $W^{aff}$ in $\tilde{W}$ (see for example [26, 4.5]). It is generated by all $\tau_s$ for $s$ in the preimage $\tilde{S}^{aff}$ of $S^{aff}$ and all $\tau_t$ for $t \in T^0/T^1$.

There is an involutive automorphism defined on $\tilde{H}_Z \otimes \mathbb{Z}[q^{\pm 1/2}]$ by ([33, Corollary 2]):

\[(1.12) \iota: \tau_w \mapsto \frac{1}{(-q)^{\ell(w)}} \tau_w^{-1}.\]

and it actually yields an involution on $\tilde{H}_Z$. Inflating the character $\epsilon_C : W \to \{\pm 1\}$ defined in 1.2.2 to a character of $\tilde{W}$, we define the following $\mathbb{Z}$-linear involution $\nu_C$ of $\tilde{H}_Z$ by:

\[\nu_C(\tau_w) = \epsilon_C(w) \tau_w \quad \text{for any } w \in \tilde{W}.\]

It is the identity on the affine subring $\tilde{H}_Z^{aff}$. We will consider the following $\mathbb{Z}$-linear involution on $\tilde{H}_Z$:

\[(1.13) \tau_C = \iota \circ \nu_C.\]

Remark 1.7. The involution $\iota$ fixes all $\tau_w$ for $w \in \tilde{W}$ with length zero. The involution $\tau_C$ fixes all $\tau_{e^\lambda}$ for $\lambda \in \check{X}^*(T)$ with length zero.

1.2.8. Let $R$ be a ring with unit $1_R$, containing an inverse for $(q1_R - 1)$ and a primitive $(q-1)^{th}$ root of $1_R$. The group of characters of $T^0/T^1 = \overline{T}(\mathbb{F}_q)$ with values in $R^\times$ is isomorphic to the group of characters of $\overline{T}(\mathbb{F}_q)$ with values in $\mathbb{F}_q^\times$ which we denote by $\overline{T}(\mathbb{F}_q)$. To $\xi \in \overline{T}(\mathbb{F}_q)$ we attach the idempotent element $\epsilon_\xi \in \tilde{H}_R$ as in [33] (definition recalled in [25, 2.4.3]). For $t \in T^0$ we have $\epsilon_\xi t_\tau = \tau_\tau \epsilon_\xi = \xi(t) \epsilon_\xi$. The idempotent elements $\epsilon_\xi$, $\xi \in \overline{T}(\mathbb{F}_q)$, are pairwise orthogonal and their sum is the identity in $\tilde{H}_Z \otimes \mathbb{Z} R$.

For $A \in \Pi^{aff}$, choose the lift $n_A \in G$ for $s_A$ defined after fixing an épingle for $G$ as in [33, 1.2]. We refer to [25, 2.2.5] for the definition of the associated subgroup $T_A$ of $T^0$ which identifies with a subgroup of $T^0/T^1$.

For $\xi \in \overline{T}(\mathbb{F}_q)$, we have in $\tilde{H}_Z \otimes \mathbb{Z} R$: \
\begin{equation}
\begin{cases}
\text{if } \xi \text{ is trivial on } T_A, \text{ then } \epsilon_\xi \tau_{n_A}^2 = \epsilon_\xi ((q1_R - 1) \tau_{n_A} + q1_R) \\
\text{otherwise } \epsilon_\xi \tau_{n_A}^2 \in qR^x \epsilon_\xi.
\end{cases}
\end{equation}

The field $k$ is an example of ring $R$ as above. In $\tilde{H}_k$ we have:

\begin{equation}
\begin{cases}
\text{if } \xi \text{ is trivial on } T_A, \text{ then } \epsilon_\xi \tau_{n_A}^2 = -\epsilon_\xi \tau_{n_A} \\
\text{otherwise } \epsilon_\xi \tau_{n_A}^2 = 0.
\end{cases}
\end{equation}

Remark 1.8. In $\tilde{H}_k$ we have $\tau_{n_A}(\tau_{n_A}) = 0$ for all $A \in S_{aff}$. Furthermore, $t(\tau_{n_A}) + \tau_{n_A}$ lies in the subalgebra of $\tilde{H}_k$ generated by all $\tau_t$, $t \in T^0/T^1$, or equivalently by all $\epsilon_\xi$, $\xi \in \mathfrak{T} (\mathbb{F}_q)$. This can be seen using for example [25, Remark 2.10], which also implies the following:

if $\xi$ is trivial on $T_A$, then $t(\epsilon_\xi \tau_{n_A}) = \epsilon_\xi t(\tau_{n_A}) = -\epsilon_\xi (\tau_{n_A} + 1)$

if $\xi$ is not trivial on $T_A$, then $t(\epsilon_\xi \tau_{n_A}) = -\epsilon_\xi \tau_{n_A}$.

1.2.9. **Parametrization of the weights.** The functions in $\tilde{H}_Z$ with support in $K$ form a subring $\tilde{H}_Z$. It has $\mathbb{Z}$-basis the set of all $\tau_w$ for $w \in \tilde{W}$. Denote by $\tilde{H}_k$ the $k$-algebra $\tilde{H}_Z \otimes_{\mathbb{Z}} k$. The simple modules of $\tilde{H}_k$ are one dimensional [30, (2.11)].

An irreducible smooth $k$-representation $\rho$ of $K$ will be called a weight. By [9, Corollary 7.5] the weights are in one-to-one correspondence with the characters of $\tilde{H}_k$ via $\rho \mapsto \rho^\dagger$. To a character $\chi : \tilde{H}_k \rightarrow k$ is attached the morphism $\tilde{\chi} : T^0/T^1 \rightarrow k^\times$ such that $\tilde{\chi}(t) = \chi(\tau_t)$ for all $t \in T^0/T^1$ and the set $\Pi_\chi$ of all simple roots $\alpha \in \Pi$ such that $\tilde{\chi}$ is trivial on $T_\alpha$. We then have $\chi(\tau_{s_\alpha}) = 0$ for all $\alpha \in \Pi - \Pi_\chi$, where $s_\alpha \in \tilde{W}$ is any lift for $s_\alpha \in W$. We denote by $\Pi_\chi$ the subset of all $\alpha \in \Pi_\chi$ such that $\chi(\tau_{s_\alpha}) = 0$. The character $\chi$ is determined by the data of $\tilde{\chi}$ and $\Pi_\chi$ (see also [25, 3.4]).

Remark 1.9. Choosing a standard facet $F$ is equivalent to choosing the subset $\Pi_F$ of $\Pi$ of the simple roots taking value zero on $F$. The standard facet corresponding to $\Pi_\chi$ in the previous discussion will be denoted by $F_\chi$.

2. **On the center of the pro-$p$ Iwahori-Hecke algebra in characteristic $p$**

2.1. **Commutative subrings of the pro-$p$ Iwahori-Hecke ring.** Let $\sigma$ be a sign and $F$ a standard facet.

2.1.1. As in [25, 4.1.1], we introduce the multiplicative injective map

$$\Theta_F^\sigma : \tilde{X}_*(T) \rightarrow \tilde{H}_Z \otimes_{\mathbb{Z}} q^{\pm 1/2}$$

and the elements $B_F^\sigma(\lambda) := q^{\ell(\epsilon_\lambda)/2} \Theta_F^\sigma(\lambda)$ for all $\lambda \in \tilde{X}_*(T)$. Recall that $B_F^\sigma(\lambda) = \tau_{e\lambda}$ if $\lambda \in C^\sigma (F)$. The map $B_F^\sigma$ does not respect the product in general, but it is multiplicative when
restricted to any Weyl chamber (see [25, Remark 4.3]). For any coweight \( \lambda \in \tilde{X}_\ast(T) \), the element \( B_P^\sigma(\lambda) \) lies in \( \tilde{H}_Z \) (see Lemma 2.3 below). Furthermore combining Lemmas 1.2ii., 2.3 and [25, Lemma 4.4]:

\[
\langle 2.1 \rangle
\]

\[ t_C(B_P^+(\lambda)) = B_P^-(\lambda). \]

Extend \( \Theta_P^\sigma \) linearly to an injective morphism of \( \mathbb{Z}[q^{\pm 1/2}] \)-algebras \( \mathbb{Z}[q^{\pm 1/2}][\tilde{X}_\ast(T)] \rightarrow \tilde{H}_Z \otimes_{\mathbb{Z}} \mathbb{Z}[q^{\pm 1/2}] \). We consider the commutative subring \( A_P^\sigma := \tilde{H}_Z \cap \text{Im}(\Theta_P^\sigma) \). By [25, Prop. 4.5], it is a free \( \mathbb{Z} \)-module with basis the set of all \( B_P^\sigma(\lambda) \) for \( \lambda \in \tilde{X}_\ast(T) \). Since the Weyl chambers (in \( \tilde{X}_\ast(T) \)) are finitely generated semigroups, \( A_P^\sigma \) is finitely generated as a ring.

**Remark 2.1.** Note that \( B_C^\sigma = B_C^- \) (resp. \( B_C^- = B_C^+ \)) coincides with the integral Bernstein map \( E^+ \) (resp. \( E \)) introduced in [33] and \( A_C^\sigma \) (resp. \( A_C^- \)) with the commutative ring denoted by \( A^{+,1}(\sigma) \) (resp. \( A^{1}(\sigma) \)) in [33, Theorem 2].

Identify \( X_\ast(T) \) with its image in \( \tilde{X}_\ast(T) \) via (1.9). We denote by \( (A_P^\sigma)^\circ \) the intersection

\[
(A_P^\sigma)^\circ := \tilde{H}_Z \cap \Theta_P^\sigma(\mathbb{Z}[X_\ast(T)]) \subseteq A_P^\sigma.
\]

A \( \mathbb{Z} \)-basis for \( (A_P^\sigma)^\circ \) is given by all \( B_P^\sigma(\lambda) \) for \( \lambda \in X_\ast(T) \). It is finitely generated as a ring.

**Proposition 2.2.** The commutative \( \mathbb{Z} \)-algebra \( A_P^\sigma \) is isomorphic to the tensor product of the \( \mathbb{Z} \)-algebras \( \mathbb{Z}[T^0/T^1] \) and \( (A_P^\sigma)^\circ \). In particular, \( (A_P^\sigma)^\circ \) is a direct summand of \( A_P^\sigma \) as a \( \mathbb{Z} \)-module.

**Proof.** Since the exact sequence (1.10) splits, \( A_P^\sigma \) is a free \( (A_P^\sigma)^\circ \)-module with basis the set of all \( \tau_t \) for \( t \in T^0/T^1 \). Recall indeed that \( B_P^\sigma(\lambda + t) = B_P^\sigma(\lambda)\tau_t = \tau_t B_P^\sigma(\lambda) \) for all \( \lambda \in \tilde{X}_\ast(T) \) and \( t \in T^0/T^1 \).

\[
2.1.2. \quad \text{The following is a direct consequence of the lemma proved in [14, §5] and adapted to the pro-}p \text{ Iwahori-Hecke algebra in [33, Lemma 13] (see also [32, 1.2 and 1.5]).}
\]

**Lemma 2.3.** Let \( F \) be a standard facet and \( \sigma \) a sign. For any \( \lambda \in \tilde{X}_\ast(T) \), we have

\[
B_P^\sigma(\lambda) = \tau_\lambda + \sum_{w \prec e} a_w \tau_w
\]

where \( (a_w)_w \) is a family of elements in \( \mathbb{Z} \) (depending on \( \sigma, F \) and \( \lambda \)) indexed by the set of \( w \in \tilde{W} \) such that \( w < e^\lambda \). For those \( w \), we have in particular \( \ell(w) < \ell(e^\lambda) \).

2.1.3. In this paragraph, we suppose that the root system of \( G \) is irreducible. It implies in particular that there is a unique element in \( \Pi_n \). It can be written \(-\alpha_0 \in \Phi^+ \) is the highest root: we have \( \beta \preceq \alpha_0 \) for all \( \beta \in \Phi \) ([4, VI. n°1.8]). For any standard facet \( F \neq x_0 \), we have \( \alpha_0 \notin \Phi_F \). Denote by \( s_0 \in S_{aff} \) the simple reflection associated to \(-\alpha_0, 1 \in \Pi_{aff} \) and \( n_0 := n(-\alpha_0, 1) \in G \) the lift for \( s_0 \) as chosen in 1.2.8.
Lemma 2.4. Suppose that $F \neq x_0$ and let $\lambda \in \tilde{X}_s^+(T)$ such that $\ell(e^\lambda) \neq 0$. We have
\[ B_F^+(\lambda) \in \tau_{\alpha_0} \tilde{H}. \]

Proof. It suffices to check the claim for $\lambda \in X_s^+(T)$. Let $\mu, \nu \in X_s(T)$ such that $\lambda = \mu - \nu$ and $w_F \mu, w_F \nu \in X_s^+(T)$ where we recall that $w_F$ denotes the longest element in $\mathfrak{W}_F$. Note that $w_F \alpha_0 \in \Phi^+$ because $F \neq x_0$. Furthermore, $\langle \lambda, \alpha_0 \rangle \geq 1$ because there is $\beta \in \Pi$ such that $\langle \lambda, \beta \rangle \geq 1$ and $\beta \leq \alpha_0$.

We have $e^\nu(-\alpha_0, 1) = (-\alpha_0, 1 + \langle \nu, \alpha_0 \rangle) = (-\alpha_0, 1 + \langle w_F \nu, w_F \alpha_0 \rangle) \in \Phi^+_aff$. Therefore $\ell(e^\nu n_0) = \ell(e^\nu) + 1$ and $\tau_{e^\nu n_0} = \tau_{e^\nu n_0}$ in $\tilde{H}$. On the other hand $e^{-\lambda}(-\alpha_0, 1) = (-\alpha_0, 1 - \langle \lambda, \alpha_0 \rangle) \in \Phi^-aff$ and therefore $\ell(n_0 e^\lambda) = \ell(e^\lambda) - 1$.

We perform the computations in $\tilde{H} \otimes \mathbb{Z}[q^{1/2}]$ where by definition, $B_F^+(\lambda) = q^{\ell(\lambda) - \ell(e^\mu) + 1} \tau_{e^\nu}^{-1} \tau_{e^\mu}$. By the previous remarks
\[ B_F^+(\lambda) = \tau_{n_0} q^{\ell(n_0 e^\lambda) + 1} \tau_{e^\nu}^{-1} \tau_{e^\mu}, \]
which, by the lemma evoked in 2.1.2, lies in $\tau_{n_0} \tilde{H}$.

\[ \square \]

2.2. On the center of the pro-$p$ Iwahori-Hecke ring.

2.2.1. The ring $\tilde{H}$ is finitely generated as a module over its center $Z(\tilde{H}) = (A_C^+)^{\mathfrak{W}}$ and the latter has $\mathbb{Z}$-basis the set of all
\[ \sum_{\lambda \in \mathcal{O}} B_C^+(\lambda') \]
where $\mathcal{O}$ ranges over the $\mathfrak{W}$-orbits in $X_s(T)$. Moreover, $Z(\tilde{H})$ is a finitely generated $\mathbb{Z}$-algebra.

Those results are proved in [33, Theorem 4] (note that the hypothesis of irreducibility of the root system of $G$ in [33] is not necessary for the statements about the center). One can also find a proof in [28].

2.2.2. We denote by $Z^0(\tilde{H})$ the intersection of $(A_C^+)^{\mathfrak{W}}$ with $Z(\tilde{H})$. We have $Z^0(\tilde{H}) = ((A_C^+)^{\mathfrak{W}})^{\mathfrak{W}}$. It has $\mathbb{Z}$-basis the set of all
\[ z_{\lambda} := \sum_{\lambda' \in \mathcal{O}(\lambda)} B_C^+(\lambda') \text{ for } \lambda \in X_s^+(T) \]
where we denote by $\mathcal{O}(\lambda)$ the $\mathfrak{W}$-orbit of $\lambda$.

Proposition 2.5.

i. The left (resp. right) $(A_C^+)^{\mathfrak{W}}$-module $\tilde{H}$ is finitely generated.
ii. As a $Z^0(\tilde{H})$-module, $\tilde{H}$ is finitely generated.
iii. \( Z^\circ(\tilde{H}_Z) \) is a finitely generated \( \mathbb{Z} \)-algebra.

iv. As \( \mathbb{Z} \)-modules, \( Z(\tilde{H}_Z), A_+^\circ, Z^\circ(\tilde{H}_Z) \) and \((A_+^\circ)^\circ\) are direct summands of \( \tilde{H}_Z \).

Proof. Using Proposition 2.2 and [33, Theorems 3 and 4] which state that \( \tilde{H}_Z \) is finitely generated over \( A_+^\circ \) (see Remark 2.1), we see that \( \tilde{H}_Z \) is finitely generated over \((A_+^\circ)^\circ\). Statements ii. and iii. follow from [3, \S 1 n. 9 Thm 2] because \( Z^\circ(\tilde{H}_Z) \) is the ring of \( \mathcal{M} \)-invariants of \((A_+^\circ)^\circ\) and \( \mathbb{Z} \) is noetherian. For iv., we first remark that the \( \mathbb{Z} \)-module \( Z(\tilde{H}_Z) \) (resp. \( Z^\circ(\tilde{H}_Z) \)) is a direct summand of \( A_+^\circ \) (resp. \((A_+^\circ)^\circ\)) since \( Z(\tilde{H}_Z) = (A_+^\circ)^{\mathcal{M}} \) (resp. \( Z^\circ(\tilde{H}_Z) = ((A_+^\circ)^\circ)^{\mathcal{M}} \)). The \( \mathbb{Z} \)-module \((A_+^\circ)^\circ\) is a direct summand of \( A_+^\circ \) by Proposition 2.2. It remains to show that \( A_+^\circ \) is a direct summand of \( \tilde{H}_Z \) which can be done by considering the integral Bernstein basis for the whole Hecke ring \( \tilde{H}_Z \) introduced in [33]. We recall it later in 5.1 and finish the proof of iv. in Remark 5.1.

\[ \square \]

2.2.3. Given a ring \( R \) with unit \( 1_R \), we denote by \( \tilde{H}_R \) the \( R \)-algebra \( \tilde{H}_Z \otimes \mathbb{Z} R \): we identify \( q \) with its image in \( R \). By Proposition 2.5iv., the \( R \)-algebra \( Z(\tilde{H}_Z) \otimes \mathbb{Z} R \) (resp. \( A_+^\circ \otimes \mathbb{Z} R \), \((A_+^\circ)^\circ \otimes \mathbb{Z} R \) and \( Z^\circ(\tilde{H}_Z) \otimes \mathbb{Z} R \)) identifies with a subalgebra of \( \tilde{H}_R \) which we denote by \( Z(\tilde{H}_R) \) (resp. \((A_+^\circ)_R\), \((A_+^\circ)^\circ_R\) and \( Z^\circ(\tilde{H}_R) \)). By the work of [28], \( Z(\tilde{H}_R) \) is not only contained in but equal to the center of \( \tilde{H}_R \).

Remark 2.6. Proposition 2.5 remains valid with \( x_0 \) instead of \( C \) (use the involution \( \iota_C \) and (2.1)). We introduce the subalgebras \((A_{x_0}^\circ)_R\) and \((A_{x_0}^\circ)^\circ_R\) of \( \tilde{H}_R \) with the obvious definitions.

For \( \lambda \in \check{X}_+(T) \) (resp. \( w \in \check{W} \)), we still denote by \( \mathcal{P}^\circ_F(\lambda) \) (resp. \( \tau_w \)) its natural image \( \mathcal{P}^\circ_F(\lambda) \otimes 1 \) (resp. \( \tau_w \otimes 1 \)) in \( \tilde{H}_R \). An \( R \)-basis for \( Z^\circ(\tilde{H}_R) \) is given by the set of all \( z_\lambda \) for \( \lambda \in X_+^\circ(T) \), where again we identify the element \( z_\lambda \) with its image in \( \tilde{H}_R \).

From Proposition 2.5 we deduce:

**Proposition 2.7.** Let \( R \) be a field. A morphism of \( R \)-algebras \( Z^\circ(\tilde{H}_R) \to R \) can be extended to a morphism of \( R \)-algebras \( Z(\tilde{H}_R) \to R \).

2.2.4. In the process of constructing \( Z^\circ(\tilde{H}_Z) \), we first fixed a hyperspecial vertex \( x_0 \) of \( C \) and then an apartment \( \mathcal{A} \) containing \( C \).

**Proposition 2.8.** The ring \( Z^\circ(\tilde{H}_Z) \) is not affected by

- the choice of another apartment \( \mathcal{A}' \) containing \( C \).
- the choice of another vertex \( x_0' \) of \( C \) provided it is \( G \)-conjugate to \( x_0 \).

Proof. Let \( g \) in the stabilizer \( \mathcal{P}^\dagger_C \) of \( C \) in \( G \). Let \( T' := gTg^{-1} \) and \( x_0' = gx_0g^{-1} \). The apartment \( \mathcal{A}' \) corresponding to \( T' \) contains \( C \) and \( x_0' \) is a hyperspecial vertex of \( C \). Starting from \( T' \) and \( x_0' \) we proceed to the construction of the corresponding commutative subring \( Z^\circ(\tilde{H}_Z)' \) of the center.
of $\tilde{\mathcal{H}}_\mathbb{Z}$. Since $g \in P^\dagger_C$, we have $IgI = \tilde{\mathcal{W}} \tilde{\mathcal{W}} = \tilde{\mathcal{W}} \tilde{\mathcal{W}}$ for some $\omega \in \tilde{\Omega}$. Since this element $\omega$ has length zero, for $\lambda \in X_*(T)$ the characteristic function of $Ig\lambda(g^{-1}I \tilde{\mathcal{W}} \tilde{\mathcal{W}}$ is equal to the product $\tau_g \tau_{\lambda(g^{-1})} \tau_g^{-1}$. Therefore, the restriction to $X_*(T)$ of the new map $(P^+_C)'$ corresponding to the choice of $x_0'$ and $T'$ is defined by

$$X_*(T') \longrightarrow \tilde{\mathcal{H}}_\mathbb{Z}, \lambda \mapsto \tau_g B^+(g^{-1}\lambda g) \tau_g^{-1}. $$

The element $z'_\lambda \in Z^0(\tilde{\mathcal{H}}_\mathbb{Z})'$ corresponding to the choice of $\lambda \in X^+_*(T') = gX^+_*(T)g^{-1}$ is therefore $\tau_g z_{g^{-1}\lambda g} \tau_g^{-1} = z_\lambda$. We have proved that $Z^0(\tilde{\mathcal{H}}_\mathbb{Z})' = Z^0(\tilde{\mathcal{H}}_\mathbb{Z})$.

By Proposition 1.4i and Remark 1.5

- changing $\mathcal{A}$ into another apartment $\mathcal{A}'$ containing $C$ and
- changing $x_0$ into another vertex $x_0'$ of $C$ which is $G$-conjugate to $x_0$

can be made independently of each other by conjugating by an element of $I$ and of $P^\dagger_C \cap N_G(T)$ respectively. We have checked that these changes do not affect $Z^0(\tilde{\mathcal{H}}_\mathbb{Z})$.

If $G$ is of adjoint type or $G = \text{GL}_n$, then all hyperspecial vertices are conjugate ([31, 2.5]):

**Corollary 2.9.** If $G$ is of adjoint type or $G = \text{GL}_n$, then $Z^0(\tilde{\mathcal{H}}_\mathbb{Z})$ depends only on the choice of the uniformizer $\varpi$.

**2.3. An affine semigroup algebra in the center of the pro-$p$ Iwahori-Hecke algebra in characteristic $p$.** We will use the following observation several times in this paragraph. Let $F$ be a standard facet and $\sigma$ a sign. For $\mu_1, \mu_2 \in X_*(T)$, we have in $\tilde{\mathcal{H}}_k$:

$$B^\sigma_F(\mu_1) B^\sigma_F(\mu_2) = \begin{cases} B^\sigma_F(\mu_1 + \mu_2) & \text{if } \mu_1 \text{ and } \mu_2 \text{ lie in a common Weyl chamber} \\ 0 & \text{otherwise.} \end{cases} $$

In $\tilde{\mathcal{H}}_\mathbb{Z} \otimes \mathbb{Z}[q^{\pm 1/2}]$ we have indeed $B^\sigma_F(\mu_1) B^\sigma_F(\mu_2) = q^{(\ell(\mu_1) + \ell(\mu_2) - \ell(\mu_1 + \mu_2))/2} B^\sigma_F(\mu_1 + \mu_2)$. If $\mu_1$ and $\mu_2$ lie in a common Weyl chamber, then $\ell(\mu_1) + \ell(\mu_2) - \ell(\mu_1 + \mu_2)$ is zero; otherwise, there is $\alpha \in \Pi$ satisfying $\langle \mu_1, \alpha \rangle \langle \mu_2, \alpha \rangle < 0$ which implies that this quantity is $\geq 2$. This gives the required equality in $\tilde{\mathcal{H}}_k$.

**2.3.1. The structure of $Z^0(\tilde{\mathcal{H}}_k)$.**

**Proposition 2.10.** The map

$$k[X^+_*(T)] \longrightarrow Z^0(\tilde{\mathcal{H}}_k)$$

is an isomorphism of $k$-algebras.

$$\lambda \mapsto z_\lambda$$
Proof. We already know that (2.5) maps a $k$-basis for $k[X^+_s(T)]$ onto a $k$-basis for $Z^o(\hat{H}_k)$. We have to check that it respects the product. Let $\lambda_1, \lambda_2 \in X^+_s(T)$ with respective $\mathfrak{W}$-orbits $O(\lambda_1)$ and $O(\lambda_2)$. We consider the product

$$z_{\lambda_1}z_{\lambda_2} = \sum_{\mu_1 \in O(\lambda_1), \mu_2 \in O(\lambda_2)} B^\sigma_F(\mu_1)B^\sigma_F(\mu_2) \in \hat{H}_k.$$ 

A Weyl chamber in $X^+_s(T)$ is a $\mathfrak{W}$-conjugate of $X^+_s(T)$. Given a Weyl chamber and a coweight (in $X^+_s(T)$), there is a unique $\mathfrak{W}$-conjugate of the coweight in the chosen Weyl chamber. The map $(\mu_1, \mu_2) \mapsto \mu_1 + \mu_2$ yields a bijection between the set of all $(\mu_1, \mu_2) \in O(\lambda_1) \times O(\lambda_2)$ such that $\mu_1$ and $\mu_2$ lie in the same Weyl chamber and the $\mathfrak{W}$-orbit $O(\lambda_1 + \lambda_2)$ of $\lambda_1 + \lambda_2$: it is indeed surjective and one checks that the two sets in question have the same size because, $\lambda_1$ and $\lambda_2$ being both dominant, the stabilizer in $\mathfrak{W}$ of $\lambda_1 + \lambda_2$ is the intersection of the stabilizers of $\lambda_1$ and of $\lambda_2$. Together with (2.4), this proves that $z_{\lambda_1 + \lambda_2} = z_{\lambda_1}z_{\lambda_2}$. □

For a different proof of this proposition, see the remark after Theorem 4.3.

2.3.2. Since $X^+_s(T)$ is a free abelian group (of rank $\dim(T)$), the $k$-algebra $k[X^+_s(T)]$ is isomorphic to an algebra of Laurent polynomials and has a trivial nilradical. By Gordan’s Lemma, $X^+_s(T)$ is finitely generated as a semigroup. So $k[X^+_s(T)]$ is a finitely generated $k$-algebra and its Jacobson radical coincides with its nilradical. The Jacobson radical of $Z^o(\hat{H}_k)$ is therefore trivial.

**Proposition 2.11.** The Jacobson radical of $Z(\hat{H}_k)$ is trivial.

**Proof.** Since $Z(\hat{H}_k)$ is a finitely generated $k$-algebra contained in $(A^+_C)_k$, it is enough to prove that the nilradical of $(A^+_C)_k$ is trivial. Using the notations of 1.2.8, it is enough to prove that, for any $\xi \in \mathbf{T}(\mathbb{F}_q)$, the nilradical of the $k$-algebra $\epsilon_\xi(A^+_C)_k$ with unit $\epsilon_\xi$ is trivial. By Proposition 2.2, the latter algebra is isomorphic to $(A^+_C)_k$. It is therefore enough to prove that the nilradical of $(A^+_C)_k$ is trivial.

By definition (see the convention in 2.2.3), the image of the $k$-linear injective map

$$\mathcal{B}^+_C : k[X^+_s(T)] \longrightarrow \hat{H}_k$$

coincides with $(A^+_C)_k$.

**Fact i.** Let $\lambda_0 \in X^+_s(T)$ be a strongly dominant coweight. The ideal of $(A^+_C)_k$ generated by $\mathcal{B}^+_C(\lambda_0)$ does not contain any nontrivial nilpotent element.

An element $a \in (A^+_C)_k$ is a $k$-linear combination of elements $\mathcal{B}^+_C(\lambda)$ for $\lambda \in X^+_s(T)$ and we say that $\lambda \in X^+_s(T)$ is in the support of $a$ if the coefficient of $\mathcal{B}^+_C(\lambda)$ is nonzero. Suppose that $a$ is nilpotent and nontrivial. After conjugating by an element of $\mathfrak{W}$, we can suppose that there is an element of $X^+_s(T)$ in the support of $a$. Then let $\lambda_0 \in X^+_s(T)$ be strongly dominant.
The element $aB_C^+(\lambda_0)$ is nilpotent and by (2.4) it is nontrivial. By Fact i, we have a contradiction.

**Proof of the fact:** The restriction of $B_C^+$ to $k[X_+^+(T)]$ induces an isomorphism of $k$-algebras $k[X_+^+(T)] \cong B_C^+(k[X_+^+(T)])$. By (2.4), the ideal $\mathfrak{A}$ of $(A_C^\circ)^\circ$ generated by $B_C^+(\lambda_0)$ coincides with the ideal of $B_C^+(k[X_+^+(T)])$ generated by $B_C^+(\lambda_0)$. Since the $k$-algebra $k[X_+^+(T)]$ does not contain any nontrivial nilpotent element, neither does $\mathfrak{A}$.

Since $k$ is algebraically closed, we have:

**Corollary 2.12.** Let $z \in Z(\tilde{H}_k)$. If $\zeta(z) = 0$ for all characters $\zeta : Z(\tilde{H}_k) \to k$, then $z = 0$.

2.3.3. The center of the Iwahori-Hecke algebra in characteristic $p$. Let $R$ be a ring containing an inverse for $(q_1 - 1)$ and a primitive $(q - 1)^{th}$ root of $1_R$. We can apply the observations of 1.2.8 and consider the algebra

$$\tilde{H}_R(\xi) := \epsilon_\xi \tilde{H}_R \epsilon_\xi.$$ 

It can be seen as the algebra $\mathcal{H}(G, I, \xi^{-1})$ of $G$-endomorphisms of the representation $\epsilon_\xi \text{ind}_I^G 1_R$ which is isomorphic to the compact induction $\text{ind}_I^G \xi^{-1}$ of $\xi^{-1}$ seen as a $R$-character of $I$ trivial on $\tilde{I}$: denote by $1_{I, \xi^{-1}} \in \text{ind}_I^G \xi^{-1}$ the unique function with support in $I$ and value $1_R$ at $1_C$, then the map

$$\tilde{H}_R(\xi) \to \mathcal{H}(G, I, \xi^{-1}), \ h \mapsto [1_{I, \xi^{-1}} \mapsto 1_{I, \xi^{-1}} h]$$

(2.6)

gives the identification. In particular, when $\xi = 1$ is the trivial character, then the algebra $\tilde{H}_R(1)$ identifies with the usual Iwahori-Hecke algebra $H_R = R[I \backslash G/I]$ with coefficients in $R$.

**Remark 2.13.** Let $\xi \in \hat{T}(F_q)$. We have inclusions

$$\epsilon_\xi Z(\tilde{H}_R) \subseteq \epsilon_\xi Z(\tilde{H}_R) \subseteq Z(\tilde{H}_R(\xi))$$

where the latter space is the center of $\tilde{H}_R(\xi)$. The inclusion $\epsilon_\xi Z(\tilde{H}_R(\xi)) \subseteq Z(\tilde{H}_R(\epsilon_\xi))$ is strict in general. For example if $G = \text{GL}_2(\mathfrak{F})$, $R = k$, and $\xi$ is not fixed by the non trivial element of $W$, then $\tilde{H}_k(\xi)$ is commutative with a $k$-basis indexed by the elements in $X_+(T)$ and contains zero divisors ([2, Proposition 13]) while the $k$-algebra $\epsilon_\xi Z(\tilde{H}_k)$ is isomorphic to $k[X_+^+(T)]$.

If $\xi = 1$ however, these inclusions are equalities: one easily checks by direct comparison of the basis elements (2.2) and (2.3) that the first inclusion is an equality. The second one comes from the fact that $\epsilon_1$ is a central idempotent in $\tilde{H}_R$. In particular we have:

**Theorem 2.14.** The center of the Iwahori-Hecke $k$-algebra $k[\tilde{I} \backslash G/I]$ is isomorphic to $k[X_+^+(T)]$. 

Proof. The map
\[ k[X^*_+(T)] \to \epsilon_1 Z(\tilde{H}_k) \]
\[ \lambda \mapsto \epsilon_1 z_\lambda \]
is surjective by the previous discussion. It is easily checked to be injective using Lemma 2.3 (compare with [32, (1.6.5)]). \[\Box\]

3. THE CENTRAL BERNSTEIN FUNCTIONS IN THE PRO-$p$ IWAHORI-HECKE RING

Let $O$ be a $\mathcal{W}$-orbit in $\tilde{X}_s(T)$. We call the central element of $\tilde{H}_Z$ (2.2)
\[ z_O := \sum_{\lambda' \in O} B_C^+(\lambda') \]
the associated central Bernstein function.

3.1. THE SUPPORT OF THE CENTRAL BERNSTEIN FUNCTIONS. For $h \in \tilde{H}_Z$, the set of all $w \in \tilde{W}$ such that $h(\tilde{w}) \neq 0$ is called the support of $h$. For $O$ a $\mathcal{W}$-orbit in $\tilde{X}_s(T)$ we denote by $\ell_O$ the common length of all the coweights in $O$.

Lemma 3.1. Let $O$ be a $\mathcal{W}$-orbit in $\tilde{X}_s(T)$. The support of $z_O$ (resp. $\iota_C(z_O)$) contains the set of all $e^\mu$ for $\mu \in O$: more precisely, the coefficient of $\tau_\mu$ in the decomposition of $z_O$ (resp. $\iota_C(z_O)$) is equal to 1. Any other element in the support of $z_O$ (resp. $\iota_C(z_O)$) has length $< \ell_O$.

Proof. This is a consequence of Lemma 2.3 (and of (2.1)). \[\Box\]

Proposition 3.2. The involution $\iota_C$ fixes the elements in the center $Z(\tilde{H}_Z)$ of $\tilde{H}_Z$.
In particular, for $O$ a $\mathcal{W}$-orbit in $\tilde{X}_s(T)$, the element $\sum_{\lambda' \in O} B_C^+(\lambda') \in \tilde{H}_Z$ does not depend on the sign $\sigma$.

Proof. We prove that $\iota_C$ fixes $z_O$ by induction on $\ell_O$.

If $\ell_O = 0$, then conclude using Remark 1.7. Let $O$ a $\mathcal{W}$-orbit in $\tilde{X}_s(T)$ such that $\ell_O > 0$. The element $\iota_C(z_O)$ is central in $\tilde{H}_Z$. Recall that a $Z$-basis for $Z(\tilde{H}_Z)$ is given by the central Bernstein functions $z_O$ where $O$ ranges over the $\mathcal{W}$-orbits in $\tilde{X}_s(T)$. Lemma 3.1 implies that $\iota_C(z_O)$ decomposes as a sum
\[ \iota_C(z_O) = z_O + \sum_{O'} a_{O'} z_{O'} \]
where $O'$ ranges over a finite set of $\mathcal{W}$-orbits in $\tilde{X}_s(T)$ such that $\ell_{O'} < \ell_O$ and $a_{O'} \in \mathbb{Z}$. By induction and applying the involution $\iota_C$ we get
\[ z_O = \iota_C(z_O) + \sum_{O'} a_{O'} z_{O'} \]
and 2(t(z_\mathcal{O}) - z_\mathcal{O})) = 0. Since \tilde{H}_\mathbb{Z} has no \mathbb{Z}\text{-torsion}, t(z_\mathcal{O}) = z_\mathcal{O}. The second statement follows from (2.1).

\[ \Box \]

When G is semisimple, the projection in \tilde{H}_k of the equality proved in Proposition 3.2 can be obtained independently using the duality for finite length \tilde{H}_k-modules defined in [26]:

**Proposition 3.3.** Suppose that G is semisimple. The element \( \sum_{\lambda' \in \mathcal{O}} B^\sigma_C(\lambda') \in \tilde{H}_k \) is fixed by the involution \( t_C \) and therefore does not depend on the sign \( \sigma \).

**Proof.** Suppose that G is semisimple. Let \( \mathcal{O} \) be a \mathcal{W}\text{-orbit in } \tilde{X}_*(T). We want to prove, without using Proposition 3.2, that in \tilde{H}_k we have \( z_\mathcal{O} = t_C(z_\mathcal{O}) \).

Let \( \zeta : Z(\tilde{H}_k) \to k \) a character and \( M = \tilde{H}_k \otimes_{Z(\tilde{H}_k)} \zeta \) the induced \tilde{H}_k-module. It is finite dimensional over \( k \) and therefore, by [26, Corollary 6.12] we have an isomorphism of right \tilde{H}_k-modules

\[ \text{Ext}^d_{\tilde{H}_k}(M, \tilde{H}_k) = \text{Hom}_k(t_C^* M, k) \]

where \( d \) is the semisimple rank of G and \( t_C^* M \) denotes the left \tilde{H}_k-module \( M \) with action twisted by the involution \( t_C \) defined by (1.13). The category of left \tilde{H}_k-modules is naturally a \( Z(\tilde{H}_k) \)-linear category and therefore, for \( X \) and \( Y \) two given left \tilde{H}_k-modules, \( \text{Ext}^d_{\tilde{H}_k}(X, Y) \) inherits a structure of central \( Z(\tilde{H}_k) \)-bimodule. Hence, the right \tilde{H}_k-module \( \text{Ext}^d_{\tilde{H}_k}(M, \tilde{H}_k) \) has a central character equal to \( \zeta \). On the other hand, \( \text{Hom}_k(t_C^* M, k) \) has \( \zeta \circ t_C \) as a central character. Therefore, \( \zeta(z_\mathcal{O}) = \zeta \circ t_C(z_\mathcal{O}) \). By Corollary 2.12, we have the required equality \( z_\mathcal{O} = t_C(z_\mathcal{O}) \). \( \Box \)

3.2. **Independence lemma.** The following lemma will be proved in 3.3.3.

**Lemma 3.4.** For \( \mathcal{O} \) a \mathcal{W}\text{-orbit in } \tilde{X}_*(T), the element

\[ \sum_{\lambda \in \mathcal{O}} B^\sigma_F(\lambda) \]

in \( \tilde{H}_\mathbb{Z} \) does not depend on the choice of the standard facet \( F \) and of the sign \( \sigma \).

**Corollary 3.5.** The center of \( \tilde{H}_\mathbb{Z} \) is contained in the intersection of all the commutative rings \( A^\sigma_F \) for \( F \) a standard facet and \( \sigma \) a sign.

3.3. **Inducing the generalized integral Bernstein functions.** We study the behavior of the integral Bernstein maps upon parabolic induction and subsequently prove Lemma 3.4.
3.3.1. Let $F$ be a standard facet, $\Pi_F$ the associated set of simple roots and $P_F$ the corresponding standard parabolic subgroup with Levi decomposition $P_F = M_F N_F$. The root datum attached to the choice of the split torus $T$ in $M_F$ is $(\Phi_F, X^*(T), \Phi_F, X_*(T))$ (notations in 1.2.4). The extended Weyl group of $M_F$ is $W_F = (N_G(T) \cap M_F)/T^0$. It is isomorphic to the semidirect product $\mathfrak{W}_F \rtimes X_*(T)$ where $\mathfrak{W}_F$ is the finite Weyl group $(N_G(T) \cap M_F)/T$ (also defined in 1.2.4). We denote by $\ell_F$ its length function and by $\preceq$ the Bruhat order on $W_F$.

Set $\tilde{W}_F = (N_G(T) \cap M_F)/T^1$. It is a subgroup of $\tilde{W}$, the double cosets of $M_F$ modulo its pro-$p$ Iwahori subgroup $\tilde{I} \cap M_F$ are indexed by the elements in $\tilde{W}_F$. For $w \in W_F$, we denote by $\tau_w^{F}$ the characteristic function of the double coset containing the lift $\hat{w}$ for $w$ (which lies in $N_G(T) \cap M_F$). The set of all $(\tau_w^{F})_{w \in W_F}$ is a basis for the pro-$p$ Iwahori-Hecke ring $\tilde{H}_Z(M_F)$ of $\mathbb{Z}$-valued functions with compact support in $(\tilde{I} \cap M_F)/\tilde{I} \cap M_F$. The ring $\tilde{H}_Z(M_F)$ does not inject in $\tilde{H}_Z$ in general.

An element in $w \in W_F$ is called $F$-positive if $w^{-1}(\Phi^+ - \Phi^+_F) \subset \Phi^+_\text{aff}$. For example for $\lambda \in X_*(T)$, the element $e^\lambda$ is $F$-positive if and only if $\langle \lambda, \alpha \rangle \geq 0$ for all $\alpha \in \Phi^+ - \Phi^+_F$. In this case, we will say that the coweight $\lambda$ itself is $F$-positive. If furthermore $\langle \lambda, \alpha \rangle > 0$ for $\alpha \in \Phi^+ - \Phi^+_F$ and $\langle \lambda, \alpha \rangle = 0$ for $\alpha \in \Phi^+_F$, then it is called strongly $F$-positive. The $F$-positive coweights are the $\mathfrak{W}_F$-conjugates of the dominant coweights. The $C$-positive (resp. strongly $C$-positive) coweights are the dominant (resp. strongly dominant) coweights. An element in $W_F$ is $F$-positive if and only if it belongs to $e^\lambda \mathfrak{W}_F$ for some $F$-positive coweight $\lambda \in X_*(T)$. If $\mu$ and $\nu \in X_*(T)$ are $F$-positive coweights such that $\mu - \nu$ is also $F$-positive, then we have the equality (see [25, 1.2] for example)

$$\ell(e^{\mu-\nu}) + \ell(e^\nu) - \ell(e^\mu) = \ell_F(e^{\mu-\nu}) + \ell_F(e^\nu) - \ell_F(e^\mu)$$

An element in $\tilde{W}_F$ will be called $F$-positive if its projection in $W_F$ is $F$-positive.

The subspace of $\tilde{H}_Z(M_F)$ generated over $\mathbb{Z}$ by all $\tau_w^{F}$ for $F$-positive $w \in \tilde{W}_F$ is denoted by $\tilde{H}_Z(M_F)^+$. It is in fact a ring and there is an injection of rings

$$j_F^+ : \tilde{H}_Z(M_F)^+ \hookrightarrow \tilde{H}_Z \quad \tau_w^{F} \quad \mapsto \quad \tau_w$$

which extends to an injection of $\mathbb{Z}[q^{\pm 1/2}]$-algebras

$$j_F : \tilde{H}_Z(M_F) \otimes_{\mathbb{Z}} \mathbb{Z}[q^{\pm 1/2}] \rightarrow \tilde{H}_Z \otimes_{\mathbb{Z}} \mathbb{Z}[q^{\pm 1/2}].$$

This is a classical result for complex Hecke algebras ([7, (6.12)]). The argument is valid over $\mathbb{Z}[q^{\pm 1/2}]$.

Remark 3.6. An element $w \in \tilde{W}_F$ is called $F$-negative (resp. strongly $F$-negative) if $w^{-1}$ is $F$-positive (resp. strongly $F$-positive) and as before, $\tilde{H}_Z(M_F)$ contains as a subring the space
\(\tilde{H}_Z(M_F)^-\) generated over \(\mathbb{Z}\) by all \(\tau_w^F\) for \(F\)-negative \(w \in \tilde{W}_F\). There is an injection of rings
\[ j_F^- : \tilde{H}_Z(M_F)^- \longrightarrow \tilde{H}_Z, \tau_w^F \longmapsto \tau_w. \]

**Fact ii.** Let \(v \in W_F\) such that \(v \leq e^\lambda\) for \(\lambda \in X_+(T)\) a \(F\)-positive coweight. Then \(v\) is \(F\)-positive.

**Proof.** Suppose first that \(\lambda\) is dominant. Then the claim is \([25, \text{Lemma } 2.9.\text{ii}]\). In general, \(\lambda\) is a \(\mathfrak{W}_F\)-conjugate of a dominant coweight \(\lambda_0\): there is \(u \in \mathfrak{W}_F\) such that \(e^\lambda = ue^{\lambda_0}u^{-1}\). We argue by induction on \(\ell_F(u)\). Let \(s\) be a simple reflection in \(\mathfrak{W}_F\) such that \(\ell_F(su) = \ell_F(u) - 1\). By the properties of Bruhat order (see \([14, \text{Lemma } 4.3]\) for example), one of \(v, vs, sv, svu\) is \(\leq se^\lambda s\) and by induction this element is \(F\)-positive, which implies that \(v\) is \(F\)-positive.

\(\square\)

3.3.2. Let \(F' \subseteq \overline{C}\) be another facet containing \(x_0\) in its closure such that \(F \subseteq F'\). It implies that \(\Phi_{F'} \subseteq \Phi_F\) and \(\Phi_F^+ \subseteq \Phi_{F'}^+\). Let \(F\Theta_{F'}^+\) be the map constructed as in 2.1 with respect to the root data attached to \(M_F\):
\[ F\Theta_{F'}^+ : \mathbb{Z}[q^{\pm 1/2}][\tilde{X}_+(T)] \longrightarrow \tilde{H}_Z(M_F) \otimes_{\mathbb{Z}} \mathbb{Z}[q^{\pm 1/2}]. \]
The corresponding \(\mathbb{Z}\)-linear integral map is denoted by \(F\mathcal{B}_{F'}^+ : \mathbb{Z}[\tilde{X}_+(T)] \longrightarrow \tilde{H}_Z(M_F)\) and defined by \(F\mathcal{B}_{F'}^+(\lambda) = q^{\ell_F(e^\lambda)/2} F\Theta_{F'}^+(\lambda)\) for all \(\lambda \in \tilde{X}_+(T)\). It satisfies \(F\mathcal{B}_{F'}^+(\lambda) = \tau_{e^\lambda}^F\) if \(\langle \lambda, \alpha \rangle \geq 0\) for all \(\alpha \in (\Phi_F^+ - \Phi_{F'}^+) \cup \Phi_{F'}^+\).

**Remark 3.7.** If \(F = x_0\) then \(x_0\mathcal{B}_{F'}^+ = \mathcal{B}_{F'}^+\).

**Lemma 3.8.** Let \(\lambda \in \tilde{X}_+(T)\) be an \(F\)-positive coweight. Then \(F\mathcal{B}_{F'}^+(\lambda)\) lies in \(\tilde{H}_Z(M_F)^+\) and
\[ (3.2) \quad j_F^+(F\mathcal{B}_{F'}^+(\lambda)) = \mathcal{B}_{F'}^+(\lambda). \]

**Proof.** Decompose \(\lambda = \mu - \nu\) with \(\mu, \nu \in \mathfrak{z}^+(F')\). Then in \(\tilde{H}_Z(M_F) \otimes_{\mathbb{Z}} \mathbb{Z}[q^{\pm 1/2}]\) we have \(F\mathcal{B}_{F'}^+(\lambda) = q^{(\ell_F(e^\mu) + \ell_F(e^\nu) - \ell_F(e^\mu))/2} \tau_{e^\mu}^F(\tau_{e^\nu}^F)^{-1}\). By Lemma 2.3 applied to the pro-\(p\) Iwahori-Hecke algebra \(\tilde{H}_Z(M_F)\), it decomposes in \(\tilde{H}_Z(M_F)\) into a linear combination of \(\tau_{w}^F\) for \(w \in \tilde{W}_F\) where the projection \(w\) of \(\tilde{w}\) in \(W_F\) satisfies \(w \leq e^\lambda\). Fact ii ensures that those \(w\) (and \(\tilde{w}\)) are \(F\)-positive. Now, \(j_F\) respects the product and
\[ j_F^+(F\mathcal{B}_{F'}^+(\lambda)) = j_F(F\mathcal{B}_{F'}^+(\lambda)) = q^{(\ell_F(e^\mu) + \ell_F(e^\nu) - \ell_F(e^\mu))/2} \tau_{e^\mu}^F(\tau_{e^\nu}^F)^{-1} \]
because \(\mu\) and \(\nu\) are in particular \(F\)-positive. Apply (3.1) to conclude.

\(\square\)
3.3.3. We prove Lemma 3.4. Let $\mathcal{O}$ be a $\mathfrak{W}$-orbit in $\check{X}_s(T)$. Since $\mathcal{B}_{x_0}^+ = \mathcal{B}_{C}^-$ and using (2.1), it is enough to prove

$$\sum_{\lambda \in \mathcal{O}} \mathcal{B}_F^+(\lambda) = \sum_{\lambda \in \mathcal{O}} \mathcal{B}_C^+(\lambda).$$

for any standard facet $F$. If $F = x_0$ then the result is given by Proposition 3.2. Let $F$ be a standard facet such that $F \neq x_0$.

1/ Let $\mu \in \check{X}_s(T)$ be a $F$-positive coweight with $\mathfrak{W}_F$-orbit $\mathcal{O}_{F}$. We have the following identity

$$\sum_{\mu' \in \mathcal{O}_F} \mathcal{B}_F^+(\mu') = \sum_{\mu' \in \mathcal{O}_F} j_F^+ (F \mathcal{B}_F^+(\mu')) = \sum_{\mu' \in \mathcal{O}_F} \mathcal{B}_C^+(\mu')$$

where the first and third equalities come from (3.2) and the second one from Proposition 3.2 applied to $M_F$.

2/ Choose $\nu$ a strongly $F$-positive coweight such that $\lambda + \nu$ is $F$-positive for all $\lambda \in \mathcal{O}$. Decompose the $\mathfrak{W}$-orbit $\mathcal{O}$ into the disjoint union of $\mathfrak{W}_F$-orbits $\mathcal{O}_i^F$ for $i \in \{1, .., r\}$. Since $\nu$ lies in both $\check{X}_s(T)$ and $\mathcal{C}^+(F)$, we have $\mathcal{B}_F^+(-\nu) = \mathcal{B}_C^+(-\nu) = \iota_C(\tau_{e^{-\nu}})$.

Let $i \in \{1, ..., r\}$ and $\lambda \in \mathcal{O}_i^F$. We have $\mathbb{H}_Z \otimes Z[q^{\pm 1/2}]$

$$\mathcal{B}_F^+(\lambda) = q^{\ell(e^\lambda) - \ell(e^{\lambda+\nu}) - \ell(e^\nu)} \mathcal{B}_F^+(\lambda + \nu) \mathcal{B}_C^+(-\nu).$$

Note that $\ell(e^\lambda) - \ell(e^{\lambda+\nu}) - \ell(e^\nu)$ does not depend on $\lambda \in \mathcal{O}_{i}^F$: since $\langle \lambda, \alpha \rangle = 0$ for all $\alpha \in \Phi_+^F$, this quantity is equal to $\sum_{\alpha \in \Phi_+^F} |\langle \lambda, \alpha \rangle| - |\langle \lambda + \nu, \alpha \rangle| - |\langle \nu, \alpha \rangle|$ which does not depend on the choice of $\lambda \in \mathcal{O}_{i}^F$ because $\Phi_+^F - \Phi_+^F$ is invariant under the action of $\mathfrak{W}_F$. Therefore, if we pick a representative $\lambda_i \in \mathcal{O}_{i}^F$, we have

$$\sum_{\lambda \in \mathcal{O}_{i}^F} \mathcal{B}_F^+(\lambda) = \sum_{\lambda \in \mathcal{O}_{i}^F} \mathcal{B}_F^+(\lambda + \nu) \mathcal{B}_C^+(-\nu).$$

by 1/ applied to the $\mathfrak{W}_F$-orbit of $\lambda + \nu$

$$= \sum_{\lambda \in \mathcal{O}_{i}^F} \mathcal{B}_C^+(\lambda)$$

which proves that $\sum_{\lambda \in \mathcal{O}} \mathcal{B}_F^+(\lambda) = \sum_{\lambda \in \mathcal{O}} \mathcal{B}_C^+(\lambda)$.
In this section all the algebras have coefficients in $k$.

Let $(\rho, V)$ be a weight and $v$ a chosen nonzero $\tilde{I}$-fixed vector. Let $\chi : \tilde{\mathcal{H}}_k \to k$ be the associated character and $F_\chi$ the corresponding standard facet (Remark 1.9). We consider the compact induction $\text{ind}^G_K \rho$ and its $k$-algebra of $G$-endomorphisms $\mathcal{H}(G, \rho)$. The $\tilde{I}$-invariant subspace $(\text{ind}^G_K \rho)^{\tilde{I}}$ is naturally a right $\tilde{H}_k$-module. Let $1_{K,v} \in \text{ind}^G_K \rho$ be the ($\tilde{I}$-invariant) function with support $K$ and value $v$ at 1. The map

$$\mathcal{Z}(\tilde{\mathcal{H}}_k) \to \text{Hom}_{\tilde{\mathcal{H}}_k}((\text{ind}^G_K \rho)^{\tilde{I}}, (\text{ind}^G_K \rho)^{\tilde{I}}) \quad z \mapsto [f \mapsto fz]$$

(4.1)

defines a morphism of $k$-algebras. On the other hand, by [25, Corollary 3.14], passing to $\tilde{I}$-invariants yields an isomorphism of $k$-algebras

$$\mathcal{H}(G, \rho) = \text{Hom}_G(\text{ind}^G_K \rho, \text{ind}^G_K \rho) \sim \text{Hom}_{\tilde{\mathcal{H}}_k}((\text{ind}^G_K \rho)^{\tilde{I}}, (\text{ind}^G_K \rho)^{\tilde{I}}).$$

(4.2)

Composing (4.1) with the inverse of (4.2) therefore gives a morphism of $k$-algebras $\mathcal{Z}(\tilde{\mathcal{H}}_k) \to \mathcal{H}(G, \rho)$ and we consider its restriction to $\mathcal{Z}(\tilde{\mathcal{H}}_k)$:

$$\mathcal{Z}(\tilde{\mathcal{H}}_k) \to \mathcal{H}(G, \rho) \quad z \mapsto [1_{K,v} \mapsto 1_{K,v} z].$$

(4.3)

For $\lambda \in X^+_T$, we denote by $\mathcal{T}_\lambda \in \mathcal{H}(G, \rho)$ the image by (4.3) of the central Bernstein function $z_\lambda$ defined by (2.3).

On the other hand, recall that we have the isomorphism of $k$-algebras ([25, Theorem 4.11])

$$\mathcal{T} : k[X^+_T] \sim \mathcal{H}(G, \rho)$$

(4.4)

where $\mathcal{T}_\lambda$ for $\lambda \in X^+_T$ is defined by

$$\mathcal{T}_\lambda : 1_{K,v} \mapsto 1_{K,v} \mathcal{B}_{F_\chi}^+(\lambda).$$

(4.5)

**Proposition 4.1.** We have $\mathcal{T}_\lambda = \mathcal{T}_\lambda$ for all $\lambda \in X^+_T$.

**Proof.** It is enough to check that these operators coincide on $1_{K,v}$. If $\lambda$ has length zero, then $\mathcal{B}_{F_\chi}^+(\lambda) = z_\lambda = \tau_e \lambda$ and the claim is true. Otherwise $\lambda$ has length $> 0$ and recall that $\mathcal{O}(\lambda)$ denotes the $\mathfrak{m}$-orbit of $\lambda$.

a/ Let $\lambda' \in \mathcal{O}(\lambda)$ and suppose that $\lambda' \neq \lambda$. By (4.4), we have $\mathcal{B}_{F_\chi}^+(\lambda') \mathcal{B}_{F_\chi}^+(\lambda) = \mathcal{B}_{F_\chi}^+(\lambda) \mathcal{B}_{F_\chi}^+(\lambda') = 0$ in $\tilde{\mathcal{H}}_k$. It implies that $\mathcal{T}_\lambda(1_{K,v} \mathcal{B}_{F_\chi}^+(\lambda')) = 0$ and therefore that $1_{K,v} \mathcal{B}_{F_\chi}^+(\lambda') = 0$ by [18, Corollary 6.5] that claims that $\text{ind}^G_K \rho$ is a torsion-free $\mathcal{H}(G, \rho)$-module.
b/ By Lemma 3.4, we have

\[ T'(1_{K,v}) = 1_{K,v}B_\psi^+(\lambda) + \sum_{\lambda' \in O(\lambda), \lambda' \neq \lambda} 1_{K,v}B_\psi^+(\lambda') \]

\[ = T_\lambda(1_{K,v}) + \sum_{\lambda' \in O(\lambda), \lambda' \neq \lambda} 1_{K,v}B_\psi^+(\lambda') \]

\[ = T_\lambda(1_{K,v}) \quad \text{by } \text{a/}. \]

\[ \Box \]

**Remark 4.2.** By [25, Lemma 3.6], the map

\[ \chi \otimes \tilde{\mathbb{H}}_k \cong (\text{ind}_{\mathbb{G}}^G \rho)^I \]

\[ 1 \otimes 1 \mapsto 1_{K,v} \]

induces an \( \tilde{\mathbb{H}}_k \)-equivariant isomorphism. Proposition 4.1 combined with (4.6) proves that for \( \lambda \in X^+(T) \), the right actions of \( z_\lambda \) and of \( B_\psi^+(\lambda) \) on \( 1 \otimes 1 \in \chi \otimes \tilde{\mathbb{H}}_k \) coincide. This remark will be important for the classification of the simple supersingular \( \tilde{\mathbb{H}}_k \)-modules in 5.4.

Proposition 4.1 implies:

**Theorem 4.3.** The diagram

\[ k[X^+(T)] \xrightarrow{(2.5)} Z^\circ(\tilde{\mathbb{H}}_k) \]

\[ \quad \bigg| \bigg| \bigg| \]

\[ k[X^+(T)] \xrightarrow{T} \mathcal{H}(G, \rho) \]

is a commutative diagram of isomorphisms of \( k \)-algebras.

Remark that we have not used the fact that (2.5) is multiplicative. We proved this fact beforehand in Proposition 2.10 but it can also be seen as a consequence of the commutativity of the diagram.

5. **Supersingularity**

We turn to the study of the \( \tilde{\mathbb{H}}_k \)-modules with finite length. We consider right modules unless otherwise specified. Recall that \( k \) is algebraically closed with characteristic \( p \).

5.1. **A basis for the pro-\( p \) Iwahori-Hecke ring.** We recall the \( \mathbb{Z} \)-basis for \( \tilde{\mathbb{H}}_\mathbb{Z} \) defined in [33]. It is indexed by \( w \in \tilde{\mathbb{W}} \) and is denoted by \( (E_w)_{w \in \tilde{\mathbb{W}}} \) in [33]. We will call it \( (B_{\mathbb{Z}^0}(w))_{w \in \tilde{\mathbb{W}}} \) because it coincides on \( \tilde{X}_s(T) \) with the definition introduced in 2.1 (see also Remark 2.1). Recall that we have a decomposition of \( \tilde{\mathbb{W}} \) as the semidirect product:

\[ \tilde{\mathbb{W}} = X_s(T) \rtimes \tilde{\mathbb{W}}. \]
Proposition 5.4. For $w_0 \in \tilde{\mathfrak{m}}$ set $\mathcal{B}^+_{x_0}(w_0) = \tau_{w_0}$ and for $w = e^\lambda w_0 \in X_*(T) \times \tilde{\mathfrak{m}}$, define in $\tilde{H}_Z \otimes \mathbb{Z}[q^{\pm 1/2}]$:

$$\mathcal{B}^+_{x_0}(w) = q^{(\ell(w) - \ell(w_0))/2} \mathcal{B}^+_{x_0}(\lambda) \mathcal{B}^+_{x_0}(w_0) = q^{(\ell(w) - \ell(w_0))/2} \Theta_{x_0}(\lambda) \tau_{w_0}. $$

By [33, Theorem 2 and Proposition 8], this element lies in $\tilde{H}_Z$ and the set of all $(\mathcal{B}^+_{x_0}(w))_{w \in \tilde{\mathfrak{m}}}$ is a $\mathbb{Z}$-basis for $\tilde{H}_Z$.

Remark 5.1. As a $\mathbb{Z}$-module, $\tilde{H}_Z$ is the direct sum of $A^+_x$ and of the $\mathbb{Z}$-module with basis $(\mathcal{B}^+_{x_0}(e^\lambda w_0))$ where $\lambda$ ranges over $X_*(T)$ and $w_0$ over the set of elements in $\tilde{\mathfrak{m}}$ the projection of which in $\mathfrak{m}$ is nontrivial. Applying (1.3), we obtain that the $\mathbb{Z}$-module $A^+_x$ is a direct summand of $\tilde{H}_Z$ as well.

Remark 5.2. Let $d \in \mathcal{D}$ and $\tilde{d} \in \tilde{\mathfrak{m}}$ a lift for $d$. Write $\tilde{d} = e^\lambda w_0$ with $w_0 \in \tilde{\mathfrak{m}}$, $\lambda \in X^+_T(T)$ and $\ell(e^\lambda) = \ell(d) + \ell(w_0)$ (Proposition 1.3). Then in $\tilde{H}_Z \otimes \mathbb{Z}[q^{\pm 1/2}]$, we have

$$\mathcal{B}^+_{x_0}(\tilde{d}) = q^{(\ell(d) - \ell(w_0))/2} \tau^{-1}_{\ell^{-1} e^\lambda w_0} = q^{\ell(d)\tau^{-1}_{\ell^{-1} d} = (-1)^{\ell(d)} \tau_d}.$$  

5.2. Topology on the pro-$p$ Iwahori-Hecke algebra in characteristic $p$. We consider the (finitely generated) ideal $\mathfrak{I}$ of $\mathcal{Z}^0(\tilde{H}_k)$ generated by all $z_\lambda$ for $\lambda \in X^+_T(T)$ such that $\ell(e^\lambda) > 0$ and the associated ring filtration of $\mathcal{Z}^0(\tilde{H}_k)$. A $\mathcal{Z}^0(\tilde{H}_k)$-module $M$ can be endowed with the $\mathfrak{I}$-adic topology induced by the filtration

$$M \supset M^\mathfrak{I} \supset M^\mathfrak{I}^2 \supset ...$$

An example of such module is $\tilde{H}_k$ itself. We define on $\tilde{H}_k$ another decreasing filtration $(F_n\tilde{H}_k)_{n \in \mathbb{N}}$ by $k$-vector spaces where

$$F_n\tilde{H}_k := k$$-vector space generated by all $\mathcal{B}^+_{x_0}(w)$ for $w \in \tilde{\mathfrak{m}}$ such that $\ell(w) \geq n$.

Lemma 5.3. The filtration (5.2) is a filtration of $\tilde{H}_k$ as a $A^+_x$-module. In particular, it is a filtration of $\tilde{H}_k$ as a (left and right) $\mathcal{Z}^0(\tilde{H}_k)$-module. It is compatible with the $\mathfrak{I}$-filtration: for all $n \in \mathbb{N}$, we have

$$(F_n\tilde{H}_k) \mathfrak{I} = \mathfrak{I} (F_n\tilde{H}_k) \subseteq F_{n+1}\tilde{H}_k.$$  

Proof. Let $\lambda \in X_*(T)$ and $w \in \tilde{\mathfrak{m}}$. From the definition of $\mathcal{B}^+_{x_0}$, we see that

$$\mathcal{B}^+_{x_0}(\lambda) \mathcal{B}^+_{x_0}(w) = q^{(\ell(e^\lambda) + \ell(w) - \ell(e^\lambda w))/2} \mathcal{B}^+_{x_0}(e^\lambda w)$$

and therefore, in $\tilde{H}_k$ we have: $\mathcal{B}^+_{x_0}(\lambda) \mathcal{B}^+_{x_0}(w) = 0$ if $\ell(e^\lambda) + \ell(w) > \ell(e^\lambda w)$ and $\mathcal{B}^+_{x_0}(\lambda) \mathcal{B}^+_{x_0}(w) = \mathcal{B}^+_{x_0}(e^\lambda w)$ if $\ell(w) + \ell(e^\lambda) = \ell(e^\lambda w)$. It proves the claims.

Proposition 5.4. The $\mathfrak{I}$-adic topology on $\tilde{H}_k$ is equivalent to the topology on $\tilde{H}_k$ induced by the filtration $(F_n\tilde{H}_k)_{n \in \mathbb{N}}$. In particular, it is independent of the choice of the uniformizer $\varpi$. 
Proof. We have to prove that given $m \in \mathbb{N}$, $m \geq 1$, there is $n \in \mathbb{N}$ such that $F_n \tilde{H}_k \subseteq \mathfrak{I}^m \tilde{H}_k$.

**Fact iii.** For $\lambda \in X_+(T)$ such that $\ell(e^\lambda) > 0$ and for $m \geq 1$, we have $\mathcal{B}_{x_0}^+((m+1)\lambda) \in \mathfrak{I}^m \tilde{H}_k$.

**Proof of the fact.** We check that for $m \in \mathbb{N}$ we have $\mathcal{B}_{x_0}^+((m+1)\lambda) = z^m \mathcal{B}_{x_0}^+ (\lambda)$. Notice that $\mathcal{B}_{x_0}^+(2\lambda) = \mathcal{B}_{x_0}^+(\lambda) \mathcal{B}_{x_0}^+(\lambda) = z\mathcal{B}_{x_0}^+(\lambda)$ by (2.4) and Lemma 3.4. Now let $m \geq 2$. We have $\mathcal{B}_{x_0}^+((m+1)\lambda) = \mathcal{B}_{x_0}^+(m\lambda) \mathcal{B}_{x_0}^+(\lambda) = z^m \mathcal{B}_{x_0}^+(\lambda)$ by induction.

$\square$

**Fact iv.** Let $m \geq 1$. There is $A_m \in \mathbb{N}$ such that for any $\lambda \in X_+(T)$, if $\ell(e^\lambda) > A_m$ then $\mathcal{B}_{x_0}^+(\lambda) \in \mathfrak{I}^m \tilde{H}_k$.

**Proof of the fact.** Let $\{z_{\lambda_1}, \ldots, z_{\lambda_r}\}$ be a system of generators of $\mathcal{W}$ where $\lambda_1, \ldots, \lambda_r \in X_+(T)$. Let $A_m := m \sum_{i=1}^r \ell(e^{\lambda_i})$. Let $\lambda \in X_+(T)$ such that $\ell(e^\lambda) > 0$. It is $\mathcal{W}$-conjugate to an element $\lambda_0 \in X_+(T)$ and one can write $\lambda = w_0.\lambda_0$ with $w_0 \in \mathcal{W}$ and $\lambda_0 = \sum_{i=1}^r a_i \lambda_i$ with $a_i \in \mathbb{N}$ (not all equal to zero). If $\ell(e^{\lambda_0}) > A_m$, then there is $i_0 \in \{1, \ldots, r\}$ such that $a_{i_0} > m$ and $\mathcal{B}_{x_0}^+(\lambda) = \prod_{i=1}^r \mathcal{B}_{x_0}^+(a_i(\lambda_0.\lambda_i)) \subseteq \mathcal{I}^m \tilde{H}_k$ by Fact iii. We know turn to the proof of the proposition. Let $m \geq 1$. To any $w_0 \in \mathcal{W}$ corresponds, by [32, (1.6.3)], a finite set $X(w_0)$ of elements in $X_+(T)$ such that for all $\lambda \in X_+(T)$ there is $\mu \in X(w_0)$ such that $\ell(e^{\lambda} w_0) = \ell(e^{\lambda-\mu}) + \ell(e^\mu w_0)$.

Let $\bar{w} \in \tilde{W}$ with image $w_0$ by the projection $\tilde{W} \rightarrow \mathcal{W}$. Its image $w$ by $\tilde{W} \rightarrow W$ has the form $w = e^\lambda w_0 \in X_+(T) \rtimes \mathcal{W}$ and there is $\mu \in X(w_0)$ such that $\ell(w) = \ell(e^{\lambda-\mu}) + \ell(e^\mu w_0)$. Choose lifts $\tilde{e}^{\lambda} w_0$ and $\tilde{e}^{\lambda-\mu}$ in $\tilde{W}$ for $e^{\lambda} w_0$ and $e^{\lambda-\mu}$. The product $\tilde{e}^{\lambda-\mu} e^\mu w_0$ differs from $\bar{w}$ by an element in $T^0/T^1$ (which has length zero). Therefore, $\mathcal{B}_{x_0}^+(\bar{w}) \in \mathcal{B}_{x_0}^+(\lambda - \mu) \tilde{H}_k$ (see the proof of Lemma 5.3 for example). If $\ell(\tilde{w}) > A_m(w_0) := A_m + \max \{\ell(e^{\mu'} w_0), \mu' \in X(w_0)\}$, then $\ell(e^{\lambda-\mu}) > A_m$ and $\mathcal{B}_{x_0}^+(\tilde{w}) \in \mathfrak{I}^m \tilde{H}_k$ by Fact iv. We have proved that $n > \max \{A_m(w_0), w_0 \in \mathcal{W}\}$ implies $F_n \tilde{H}_k \subseteq \mathfrak{I}^m \tilde{H}_k$.

$\square$

5.3. The category of finite length modules over the pro-$p$ Iwahori-Hecke algebra in characteristic $p$. We consider the abelian category $\text{Mod}_{fg}(\tilde{H}_k)$ of all $\tilde{H}_k$-modules with finite length.

For a $\tilde{H}_k$-module, having finite length is equivalent to being finite dimensional as a $k$-vector space ([34, 5.3] or [26, Lemma 6.9]). Therefore, any irreducible $\tilde{H}_k$-module is finite dimensional and has a central character, and any module in $\text{Mod}_{fg}(\tilde{H}_k)$ decomposes uniquely into a direct sum of indecomposable modules.
5.3.1. The category of finite dimensional $\mathcal{Z}^\circ(\tilde{H}_k)$-modules. Let $\Mod_{fd}(\mathcal{Z}^\circ(\tilde{H}_k))$ denote the category of finite dimensional $\mathcal{Z}^\circ(\tilde{H}_k)$-modules. For $\mathfrak{M}$ a maximal ideal of $\mathcal{Z}^\circ(\tilde{H}_k)$, we consider the full subcategory

$$\mathfrak{M} - \Mod_{fd}(\mathcal{Z}^\circ(\tilde{H}_k))$$

of the modules $M$ of $\mathfrak{M}$-torsion, that is to say such that there is $e \in \mathbb{N}$ satisfying $M\mathfrak{M}^e = 0$. The category $\Mod_{fd}(\mathcal{Z}^\circ(\tilde{H}_k))$ decomposes into the direct sum of all $\mathfrak{M} - \Mod_{fd}(\mathcal{Z}^\circ(\tilde{H}_k))$ where $\mathfrak{M}$-ranges over the maximal ideals of $\mathcal{Z}^\circ(\tilde{H}_k)$.

5.3.2. Blocks of $\tilde{H}_k$-modules with finite length. For $\mathfrak{M}$ a maximal ideal of $\mathcal{Z}^\circ(\tilde{H}_k)$, we say that a $\tilde{H}_k$-module with finite length is a $\mathfrak{M}$-torsion module if its restriction to a $\mathcal{Z}^\circ(\tilde{H}_k)$-module lies in the subcategory $\mathfrak{M} - \Mod_{fd}(\mathcal{Z}^\circ(\tilde{H}_k))$. We denote by

$$(5.3) \quad \mathfrak{M} - \Mod_{fg}(\tilde{H}_k)$$

the full subcategory of $\Mod_{fg}(\tilde{H}_k)$ whose objects are the $\mathfrak{M}$-torsion modules.

**Lemma 5.5.** Let $\mathfrak{M}$ and $\mathfrak{N}$ be two maximal ideals of $\mathcal{Z}^\circ(\tilde{H}_k)$. If there is a nonzero $\mathfrak{M}$-torsion module $M$ and a nonzero $\mathfrak{N}$-torsion module $N$ such that $\Ext^r_{\tilde{H}_k}(M,N) \neq 0$ for some $r \geq 0$, then $\mathfrak{M} = \mathfrak{N}$.

**Proof.** For any $\tilde{H}_k$-modules $X$ and $Y$, the natural morphisms of algebras $\mathcal{Z}^\circ(\tilde{H}_k) \to \End_{\tilde{H}_k}(X)$ and $\mathcal{Z}^\circ(\tilde{H}_k) \to \End_{\tilde{H}_k}(Y)$ equip $\Hom_{\tilde{H}_k}(X,Y)$ with a structure of central $\mathcal{Z}^\circ(\tilde{H}_k)$-bimodule. The space $\Ext^r_{\tilde{H}_k}(M,N)$ is therefore naturally a central $\mathcal{Z}^\circ(\tilde{H}_k)$-bimodule. It is an $\mathfrak{M}$-torsion module and a $\mathfrak{N}$-torsion module: it is zero unless $\mathfrak{M} = \mathfrak{N}$. □

Since $\mathcal{Z}^\circ(\tilde{H}_k)$ is a central finitely generated subalgebra of $\tilde{H}_k$, an indecomposable $\tilde{H}_k$-module with finite length is a $\mathfrak{M}$-torsion module for some maximal ideal $\mathfrak{M}$ of $\mathcal{Z}^\circ(\tilde{H}_k)$.

**Remark 5.6.** A $\tilde{H}_k$-module with finite length $M$ lies in the block corresponding to some maximal ideal $\mathfrak{M}$ if and only if all the characters of $\mathcal{Z}^\circ(\tilde{H}_k)$ contained in $M$ have kernel $\mathfrak{M}$.

**Remark 5.7.** The blocks (5.3) are not indecomposable. They can for example be further decomposed via the idempotents introduced in 1.2.8.

5.3.3. The supersingular block.

**Definition 5.8.** We call a maximal ideal $\mathfrak{M}$ of $\mathcal{Z}^\circ(\tilde{H}_k)$ supersingular if it contains the ideal $\mathfrak{I}$ defined in 5.2. A character of $\mathcal{Z}^\circ(\tilde{H}_k)$ is called supersingular if its kernel is a supersingular maximal ideal of $\mathcal{Z}^\circ(\tilde{H}_k)$.
Given a character $\omega$ of the connected center $Z$ of $G$, there is a unique supersingular character $\zeta_\omega$ of $Z(\tilde{H}_k)$ satisfying $\zeta_\omega(z\lambda) = \omega(\lambda(\varpi))$ for any $\lambda \in X^+_c(T)$ with length zero. A character of the center of $\tilde{H}_k$ is called “null” in [33] if it takes value zero at all central elements (2.2) for all $\mathfrak{M}$-orbits $O$ in $\tilde{X}_c(T)$ containing a coweight with length $\neq 0$.

Lemma 5.9. A character $Z(\tilde{H}_k) \to k$ is “null” if and only if its restriction to $Z^0(\tilde{H}_k)$ is a supersingular character in the sense of Definition 5.8.

Proof. Consider a character $\zeta : Z(\tilde{H}_k) \to k$ whose restriction to $Z^0(\tilde{H}_k)$ is supersingular. We want to prove that $\zeta$ is “null”. The $\tilde{H}_k$-module $\tilde{H}_k \otimes_{Z(\tilde{H}_k)} \zeta$ being finite dimensional, it contains a character $\hat{\zeta}$ for the commutative finitely generated $k$-algebra $(A^+_c)_{x_0}$ and the restriction of $\hat{\zeta}$ to $Z(\tilde{H}_k)$ coincides with $\zeta$. Let $\lambda \in X^+_c(T)$ with $\ell(e^\lambda) \neq 0$; by (2.4), there is at most one $\mathfrak{M}$-conjugate $\lambda'$ of $\lambda$ such that $\hat{\zeta}(B^+_c e^\lambda') \neq 0$ and if there exists such a $\lambda'$, then $\hat{\zeta}(z\lambda) = \zeta(z\lambda) \neq 0$, which is a contradiction: we have proved that $\hat{\zeta}(B^+_c e^\lambda') = 0$ for all $\lambda' \in X_c(T)$ with $\ell(e^\lambda') \neq 0$ which implies that it is also the case for $\lambda' \in \tilde{X}_c(T)$ with $\ell(e^\lambda') \neq 0$. Therefore, $\zeta$ is “null”.

□

A finite dimensional $\tilde{H}_k$-module $M$ with central character is called supersingular in [33] if this central character is “null”. We extend this definition.

Proposition-Definition 5.10. A finite length $\tilde{H}_k$-module is in the supersingular block and is called supersingular if and only if equipped with the discrete topology, it is a continuous module for the $I$-adic topology on $\tilde{H}_k$ or equivalently, for the topology induced by the filtration (5.2).

Proof. An indecomposable $\tilde{H}_k$-module $M$ with finite length is in the supersingular block if and only if there is $m \geq 1$ such that $M\mathfrak{M}^m = \{0\}$. Then use Proposition 5.4. □

5.4. Classification of the simple supersingular modules over the pro-$p$ Iwahori-Hecke algebra in characteristic $p$. We establish this classification in the case where the root system of $G$ is irreducible which we will suppose in 5.4.4. Until then the results are valid without further assumption on the root system.

5.4.1. Denote by $\tilde{H}_k^{aff}$ the natural image in $\tilde{H}_k$ of the affine Hecke subring $\tilde{H}_Z^{aff}$ of $\tilde{H}_Z$ defined in 1.2.7. We generalize [24, Theorem 7.3]:

Proposition 5.11. A finite length $\tilde{H}_k$-module in the supersingular block contains a character for the affine Hecke subalgebra $\tilde{H}_k^{aff}$.
Proof. Let $M$ be a $\tilde{\mathbb{H}}_k$-module with finite length in the supersingular block. By Proposition 5.10, there is $n \in \mathbb{N}$ such that, for any $w \in \tilde{W}$, if $\ell(w) > n$ then $MB_{x_0}^+(w) = 0$. Let $x \in M$ supporting a character for $\tilde{S}_k$ (see 1.2.9) and let $d \in D$ with maximal length such that $xB_{x_0}^+(d) \neq 0$ where $\tilde{d} \in \tilde{W}$ denotes a lift for $d$ (the property $xB_{x_0}^+(\tilde{d}) \neq 0$ does not depend on the choice of the lift $\tilde{d}$).

As in the proof of [24, Theorem 7.3], we prove that $x' := xB_{x_0}^+(\tilde{d})$ supports a character for $\tilde{\mathbb{H}}_k^{aff}$ which is the $k$-algebra generated by all $\tau_t$ and all $\tau_s$ for $t \in T^0/T^1$ and $s \in S_{aff}$ with chosen lift $\tilde{s} \in \tilde{W}$ (see paragraph 1.2.7). From the relations (1.11) we get that $x'\tau_t = x_{\tau_t}B_{x_0}^+(\tilde{d})$ is proportional to $x'$. Now let $s \in S_{aff}$. If $\ell(ds) = \ell(d) - 1$, then $ds \in D$ after Proposition 1.3 and, by (5.1), the element $x'$ is equal to $x_t(\tau_{\tilde{d}s})t(\tau_{\tilde{s}})$ (up to an invertible element in $k$), so $x'\tau_s = 0$ by Remark 1.8. If $\ell(ds) = \ell(d) + 1$ and $ds \in D$, then $xB_{x_0}^+(\tilde{d}s)$ is equal to zero on one side and, by (5.1), to $x't(\tau_{\tilde{s}})$ (up to an invertible element in $k$) on the other side. It proves that $x'\tau_s$ is proportional to $x'$ by Remark 1.8. If $\ell(ds) = \ell(d) + 1$ and $ds \not\in D$ then there is $s' \in S$ such that $ds = s'd$ by Proposition 1.3, and $x't(\tau_{\tilde{s}})$ is proportional to $x_t(\tau_{\tilde{s}})B_{x_0}^+(\tilde{d})$ and therefore to $x'$ because $t(\tau_{\tilde{s}}) \in \tilde{S}_k$. We conclude that $x'\tau_s$ is proportional to $x'$ by Remark 1.8.

\[\square\]

5.4.2. Characters of $\tilde{\mathbb{H}}_k^{aff}$. We call character of $\tilde{\mathbb{H}}_k^{aff}$ a morphism of $k$-algebras $\tilde{\mathbb{H}}_k^{aff} \to k$. A character $\mathcal{X}$ of $\tilde{\mathbb{H}}_k^{aff}$ is completely determined by:

- the unique $\xi \in \hat{\text{T}}(\mathbb{F}_q)$ such that $\mathcal{X}(\epsilon\xi) = 1$ (see notation in 1.2.8). This $\xi$ is defined by $\xi(t) = \mathcal{X}(\tau_t)$ where $t \in T^0/T^1 \simeq \hat{\text{T}}(\mathbb{F}_q)$ and we call it the restriction of $\mathcal{X}$ to $k[T^0/T^1]$.
- the values $\mathcal{X}(\tau_{nA})$ for all $A \in S_{aff}$, which, by the quadratic relations (1.15) satisfy:
  $\mathcal{X}(\tau_{nA}) \in \{0, -1\}$ if $\xi$ is trivial on $T_A$ and $\mathcal{X}(\tau_{nA}) = 0$ otherwise.

Conversely, one checks that any such datum of $\xi \in \hat{\text{T}}(\mathbb{F}_q)$ and values $\mathcal{X}(\tau_{nA})$ for all $A \in S_{aff}$ satisfying the above conditions defines a character $\mathcal{X}'$ of $\tilde{\mathbb{H}}_k^{aff}$.

Example. The pro-$p$ Iwahori-Hecke ring $\tilde{\mathbb{H}}_Z \to Z$ defined by

$\tau_w \mapsto q^{\ell(w)}$ and $\tau_w \mapsto (-1)^{\ell(w)}$.

We denote by $\mathcal{X}_{\text{triv}}$ and $\mathcal{X}_{\text{sign}}$ the characters of $\tilde{\mathbb{H}}_k$ that they respectively induce, as well as their restrictions to characters of $\tilde{\mathbb{H}}_k^{aff}$. The former can be described by: $\xi = 1$ and $\mathcal{X}_{\text{triv}}(\tau_{nA}) = 0$ for all $A \in S_{aff}$; the latter by $\xi = 1$ and $\mathcal{X}_{\text{sign}}(\tau_{nA}) = -1$ for all $A \in S_{aff}$.

Let $\mathcal{X}$ be a character of $\tilde{\mathbb{H}}_k^{aff}$ and $\xi$ the corresponding element in $\hat{\text{T}}(\mathbb{F}_q)$.

- Let $\xi_0 \in \hat{\text{T}}(\mathbb{F}_q)$ and suppose that $\xi_0$ is trivial on $T_\alpha$ for all $\alpha \in \Pi$. Then one can consider the twist $(\xi_0)\mathcal{X}$ of $\mathcal{X}$ by $\xi_0$ in the obvious way. The restriction of $(\xi_0)\mathcal{X}$ to $k[T^0/T^1]$ is the product $\xi_0\xi$ and $(\xi_0)\mathcal{X}$ coincides with $\mathcal{X}$ on the elements of type $\tau_{nA}$ for $A \in S_{aff}$.
By twist of the character $\chi$ we mean from now on a twist of $\chi$ by an element in $\mathcal{T}(\mathbb{F}_q)$ that is trivial on $T_\alpha$ for all $\alpha \in \Pi$.

- The involution $\iota_C$ extends to an involution of the $k$-algebra $\tilde{H}_k^\text{aff}$. The composition $\chi \circ \iota_C$ is then also a character for $\tilde{H}_k^\text{aff}$. Note that $\chi$ and $\chi \circ \iota_C$ have the same restriction to $k[T^0/T^1]$ (Remark 1.7). Furthermore, if $\chi(\tau_{n,\lambda}) = 1$ for some $\lambda \in S_{aff}$, then $\chi \circ \iota_C(\tau_{n,\lambda}) = 0$ (use Remark 1.8). For example, $\chi_{\text{triv}} = \chi_{\text{sign}} \circ \iota_C$.

- There is an action of $\tilde{\Omega}$ by conjugacy on $\tilde{W}_\text{aff}$. Since the elements in $\tilde{\Omega}$ have length zero, this yields an action of $\tilde{\Omega}$ on $\tilde{H}_k^\text{aff}$ and its characters. For $\omega \in \tilde{\Omega}$, we denote by $\omega \cdot \chi$ the character $\chi(\tau_{\omega^{-1}} \cdot \tau_{\omega})$.

Lemma 5.12. A simple $\tilde{H}_k$-module containing a twist of the character $\chi_{\text{triv}}$ or of the character $\chi_{\text{sign}}$ of $\tilde{H}_k^\text{aff}$ is not supersingular.

Proof. Let $M$ a simple $\tilde{H}_k$-module. Suppose that it contains a twist of the character $\chi_{\text{sign}}$ supported by the nonzero vector $m \in M$. In particular, $m$ supports the character of $\tilde{H}_k$ parametrized by (a twist of) the trivial character of $\tilde{T}_k^\text{aff}$ and its characters. For $\omega \in \tilde{\Omega}$, we have

$$m z_\lambda = m B^\lambda_C(\omega)$$

for all $\lambda \in X^+_C(T)$. There is $\omega \in \tilde{\Omega}$ and $w \in \tilde{W}_\text{aff}$ such that the element $\lambda(\omega^{-1}) \mod T^1$ corresponds to $w \omega \in \tilde{W}$. Since $B^\lambda_C(\omega) = \tau_{\lambda(\omega^{-1})}$, the element $m B^\lambda_C(\omega)$ is equal to $(-1)^{\ell(w)} m \tau_{\omega}$ (up to multiplication by an element in $k^*$) and we recall that $\tau_{\omega}$ is invertible in $\tilde{H}_k$. We have proved that $m z_\lambda \neq 0$ and $M$ is not supersingular.

Now if $M$ contains a twist of the character $\chi_{\text{triv}}$, then $\iota_C^* M$ contains a twist of the character $\chi_{\text{sign}}$ and is not supersingular (notation in the proof of Proposition 3.3). By Proposition 3.2, it implies that $M$ is not supersingular either. □

5.4.3. Consider the image of $\tilde{\Omega}$ in $\tilde{H}_k$ via $\omega \mapsto \tau_{\omega}$. For $\chi$ a character of $\tilde{H}_k^\text{aff}$, denote by $\tilde{\Omega}_\chi$ its fixator under the action of $\tilde{\Omega}$. It obviously contains $T^0/T^1$ as a subgroup. We consider the set $\mathcal{P}$ of pairs $(\chi, \sigma)$ where $\chi$ is a character of $\tilde{H}_k^\text{aff}$ and $(\sigma, V_\sigma)$ an irreducible finite dimensional $k$-representation of $\tilde{\Omega}_\chi$ (up to isomorphism) whose restriction to $T^0/T^1$ coincides with the inverse of the restriction of $\chi$: for any $t \in T^0/T^1$ and $v \in V_\sigma$, we have $\sigma(t) v = \chi(\tau_{t^{-1}}) v$.

The set $\mathcal{P}$ is naturally endowed with an action of $\tilde{\Omega}$: for $(\chi, \sigma) \in \mathcal{P}$ and $\omega \in \tilde{\Omega}$, denote by $\omega \cdot (\chi, \sigma)$ the representation of $\tilde{\Omega}_{\omega \cdot \chi}$ given by $\omega \cdot (\chi, \sigma) := (\omega \cdot \chi, \omega \cdot \sigma) \in \mathcal{P}$.

Let $(\chi, \sigma) \in \mathcal{P}$. Consider the subalgebra $\tilde{H}_k(\chi)$ of $\tilde{H}_k$ generated by $k[\tilde{\Omega}_\chi]$ and $\tilde{H}_k^\text{aff}$. It is isomorphic to the twisted tensor product of algebras

$$\tilde{H}_k(\chi) \simeq k[\tilde{\Omega}_\chi] \otimes_{k[T^0/T^1]} \tilde{H}_k^\text{aff}$$
where the product is given by $(\omega \otimes h)(\omega' \otimes h') = \omega \omega' \otimes \tau_{\omega}^{-1} h \tau_{\omega} h'$. As a left $\tilde{H}_k(\mathcal{X})$-module, $\tilde{H}_k$ is free with basis the set of all $\tau_{\omega}$ where $\omega$ ranges over a set of representatives of the right cosets $\tilde{\Omega}_{\mathcal{X}} \backslash \tilde{\Omega}$. The tensor product $\sigma \otimes \mathcal{X}$ is naturally a right $\tilde{H}_k(\mathcal{X})$-module: the right action of $\omega \otimes h$ on $v \in V_\sigma$ is given by $\mathcal{X}(h)\sigma(\omega^{-1})v$. The right $\tilde{H}_k(\mathcal{X})$-module $\sigma \otimes \mathcal{X}$ is irreducible. As a $\tilde{H}_k^{aff}$-module, it is isomorphic to a direct sum of copies of $\mathcal{X}$.

**Lemma 5.13.** The isomorphism classes of the simple $\tilde{H}_k$-modules containing a character for $\tilde{H}_k^{aff}$ are represented by the induced modules

$$m(\mathcal{X}, \sigma) := (\sigma \otimes \mathcal{X}) \otimes_{\tilde{H}_k(\mathcal{X})} \tilde{H}_k$$

where $(\mathcal{X}, \sigma)$ ranges over the set of orbits in $\mathcal{P}$ under the action of $\tilde{\Omega}$.

**Proof.** First note that for any $\omega \in \tilde{\Omega}$, the $(\tilde{H}_k^{aff}, \omega \mathcal{X})$-isotypic component of $m(\mathcal{X}, \sigma)$ is isomorphic to $\omega \sigma \otimes \omega \mathcal{X}$ as a right $\tilde{H}_k(\omega \mathcal{X})$-module.

1/ We check that a $\tilde{H}_k$-module of the form $m(\mathcal{X}, \sigma)$ is irreducible. Restricted to $\tilde{H}_k^{aff}$ it is semisimple and isomorphic to a direct sum of $\mathcal{X}$ and of its conjugates. Therefore, a submodule $m$ of $m(\mathcal{X}, \sigma)$ contains a nonzero $(\tilde{H}_k^{aff}, \omega \mathcal{X})$-isotypic vector for some $\omega \in \tilde{\Omega}$ and after translating by $\tau_{\omega}^{-1}$, we see that $m$ contains a nonzero $(\tilde{H}_k^{aff}, \mathcal{X})$-isotypic vector. But the $(\tilde{H}_k^{aff}, \mathcal{X})$-isotypic component in $m(\mathcal{X}, \sigma)$ supports the irreducible representation $\sigma$ of $k[\tilde{\Omega} \mathcal{X}]$. Therefore $m = m(\mathcal{X}, \sigma)$.

2/ Let $m$ be a simple $\tilde{H}_k$-module containing the character $\mathcal{X}$ of $\tilde{H}_k^{aff}$. Its $(\tilde{H}_k^{aff}, \mathcal{X})$-isotypic component contains an irreducible (finite dimensional) representation $\sigma$ of $k[\tilde{\Omega} \mathcal{X}]$ which coincides with the inverse of $\mathcal{X}$ on $k[T^0/T^1]$. Therefore, and using 1/, $m \simeq (\sigma \otimes \mathcal{X}) \otimes_{\tilde{H}_k(\mathcal{X})} \tilde{H}_k$.

3/ Let $\omega \in \tilde{\Omega}$ and $(\mathcal{X}, \sigma) \in \mathcal{P}$. The $(\tilde{H}_k^{aff}, \mathcal{X})$-isotypic component of $m(\omega(\mathcal{X}, \sigma))$ contains the representation $\sigma$ of $k[\tilde{\Omega} \mathcal{X}]$. The simple $\tilde{H}_k$-module $m(\omega(\mathcal{X}, \sigma))$ is therefore isomorphic to $m(\mathcal{X}, \sigma)$ by 2/.

4/ Let $(\mathcal{X}, \sigma)$ and $(\mathcal{X}', \sigma')$ in $\mathcal{P}$ and suppose that they induce isomorphic $\tilde{H}_k$-modules. Looking at the restriction of the latter to $\tilde{H}_k^{aff}$ we see that there is $\omega \in \tilde{\Omega}$ such that $\mathcal{X}' = \omega \mathcal{X}$. Therefore, by 3/, $m(\mathcal{X}, \omega^{-1} \sigma')$ and $m(\mathcal{X}, \sigma)$ are isomorphic and looking at the restriction to the $(\tilde{H}_k^{aff}, \mathcal{X})$-isotypic component shows that $\sigma' \simeq \omega \sigma$. Therefore, $(\mathcal{X}', \sigma')$ and $(\mathcal{X}, \sigma)$ are conjugate. □

5.4.4. **Classification of the simple supersingular $\tilde{H}_k$-modules when the root system of $G$ is irreducible.** We generalize [33, Theorem 5(1)]-24, Theorem 7.3].

**Theorem 5.14.** Suppose that the root system of $G$ is irreducible. A simple $\tilde{H}_k$-module is supersingular if and only if it contains a character for $\tilde{H}_k^{aff}$ that is different from a twist of $\mathcal{X}_{triv}$ or $\mathcal{X}_{sign}$. 

Remark 5.15. This proves in particular (if the root system of G is irreducible) that the notion of supersingularity for Hecke modules does not depend on any of the choices made.

Proof of Theorem 5.14. We already proved in Proposition 5.11 (without restriction on the root system of G), that a simple supersingular module contains a character for \( \tilde{H}_k^{aff} \) and by Lemma 5.12, we know that this character is not a twist of \( X_{triv} \) or \( X_{sign} \).

Conversely, let \( m \) be a simple \( \tilde{H}_k \)-module containing the character \( \chi \) for \( \tilde{H}_k^{aff} \) and suppose that \( \chi \) is not a twist of \( X_{triv} \) or \( X_{sign} \). We want to prove that \( m \) is supersingular. Since, by Proposition 3.2, it is equivalent to showing that \( \iota^*_C m \) is supersingular (notation in the proof of Proposition 3.3), we can suppose (see the discussion before Lemma 5.12) that \( X(\tau_{n_0}) = 0 \) where \( n_0 \) was introduced in 2.1.3.

Let \( m \in \mathfrak{m} \) a nonzero vector supporting \( \chi \). Let \( \chi \) be the restriction of \( \chi \) to \( \tilde{H}_k \) and \( F \chi \) the associated standard facet. Suppose that \( F \chi = x_0 \), then \( \Pi_{\tilde{\chi}} = \Pi_{\chi} = \Pi \) (notation in 1.2.9) and \( \chi(\tau_{n_0}) = 0 \) for all \( \alpha \in \Pi \). Since, by hypothesis, we also have \( \chi(\tau_{n_0}) = 0 \), the character \( \chi \) is equal to \( \chi_{triv} \) up to twist. Therefore, \( F \chi \neq x_0 \). Let \( \lambda \in X_+^*(T) \) with \( \ell(e^\lambda) > 0 \). By Remark 4.2

\[
m.z_\lambda = m.B_{F_\chi}^+ (\lambda).
\]

and since \( F \chi \neq x_0 \), we have \( m.z_\lambda = 0 \) by Lemma 2.4. We have proved that \( Z^\circ(\tilde{H}_k) \) acts on \( m \) and therefore on \( m \) by a supersingular character. \( \square \)

Let \( P^* \) denote the subsets of pairs \( (\chi, \sigma) \) in \( P \) such that \( \chi \) is different from a twist of \( \chi_{triv} \) or \( \chi_{sign} \). It is stable under the action of \( \tilde{\Omega} \). Lemma 5.13 and Theorem 5.14 together give the following:

Corollary 5.16. Suppose that the root system of G is irreducible. The map

\[
(\chi, \sigma) \mapsto m(\chi, \sigma)
\]

induces a bijection between the \( \tilde{\Omega} \)-orbits of pairs \( (\chi, \sigma) \in P^* \) and a system of representatives of the isomorphism classes of the simple supersingular \( \tilde{H}_k \)-modules.

5.5. Pro-p Iwahori invariants of parabolic inductions and of special representations.

5.5.1. In this paragraph, \( k \) is an arbitrary field. Let \( F \) be a standard facet, \( \Pi_F \) the associated set of simple roots and \( P_F \) the group of \( \tilde{F} \)-points of the corresponding standard parabolic subgroup with Levi decomposition \( P_F = M_F N_F \). We use the same notations as in 3.3.1. The unipotent subgroup \( N_F \) is generated by all the root subgroups \( U_\alpha \) for \( \alpha \in \Phi^+ - \Phi^+_F \). Let \( N^-_F \) denote the opposite unipotent subgroup of G. The pro-p Iwahori subgroup \( \tilde{I} \) has the following decomposition:

\[
\tilde{I} = \tilde{I}^+_F \tilde{I}^0_F \tilde{I}^-_F \text{ where } \tilde{I}^+_F := \tilde{I} \cap N_F, \tilde{I}^0_F := \tilde{I} \cap M_F, \tilde{I}^-_F := \tilde{I} \cap N^-_F.
\]
Recall that, by Remark 3.6, the subspace $\tilde{H}_k(M_F)^{-}$ of $\tilde{H}_k(M_F)$ generated over $k$ by all $\tau_w^F$ for all $F$-negative $w \in \tilde{W}_F$ identifies with a sub-$k$-algebra of $\tilde{H}_k$ via the injection

$$j_F : \tilde{H}_k(M_F)^{-} \rightarrow \tilde{H}_k$$

$$\tau_w^F \mapsto \tau_w.$$ 

This endows $\tilde{H}_k$ with a structure of left module over $\tilde{H}_k(M_F)^{-}$.

**Proposition 5.17.** Let $(\sigma, V_{\sigma})$ be a smooth $k$-representation of $M_F$. Consider the parabolic induction $\text{Ind}_{P_F}^G \sigma$ and its $\tilde{I}$-invariant subspace $(\text{Ind}_{P_F}^G \sigma)^\tilde{I}$. There is a surjective morphism of right $\tilde{H}_k$-modules

$$\sigma^0_F \otimes \tilde{H}_k(M_F)^{-} \rightarrow (\text{Ind}_{P_F}^G \sigma)^\tilde{I}$$

sending $v \otimes 1$ to the unique $\tilde{I}$-invariant function with support in $P_F \tilde{I}$ and value $v$ at $1_G$.

**Remark 5.18.** In the case of $G = \text{PGL}_n$ or $\text{GL}_n$, Proposition 5.2 in [24] implies that (5.4) is an isomorphism. This result should be true for a general (split) $G$, but we will only use the surjectivity here.

The proposition follows from the discussion below. All the lemmas are proved in the next paragraph.

**Lemma 5.19.** Let $D_F = \{d \in \mathfrak{m}, d^{-1}\Phi^+ \subseteq \Phi^+\}$.

i. For $d \in D_F$, we have $P_F \tilde{d}\tilde{I} = P_F d \tilde{I}$.

ii. The set of all $\tilde{d} \in G$ for $d \in D_F$ is a system of representatives of the double cosets $P_F \backslash G/\tilde{I}$.

iii. For $d \in D_F$, let $\tilde{d}\tilde{I} = \bigsqcup_y \tilde{d}y$ be a decomposition into right cosets. Then

$$P_F \tilde{d}\tilde{I} = \bigsqcup_y P_F \tilde{d}y.$$

iv. Let $d \in D_F$. By the projection $P_F \rightarrow M_F$, the image of $P_F \cap d\tilde{I}^{-1}$ is $\tilde{I}_F^0$.

An element $m \in M_F$ contracts $\tilde{I}_F^+$ and dilates $\tilde{I}_F^-$ if it satisfies the conditions (see [7, (6.5)]):

$$m\tilde{I}_F^+m^{-1} \subseteq \tilde{I}_F^+, \quad m^{-1}\tilde{I}_F^-m \subseteq \tilde{I}_F^-.$$  

**Remark 5.20.** This property of an element $m \in M_F$ only depends on the double coset $\tilde{I}_F^0 m \tilde{I}_F^0$. Furthermore, if $m \in K \cap M_F$ then $m\tilde{I}_F^+m^{-1} = \tilde{I}_F^+$ and $m^{-1}\tilde{I}_F^-m = \tilde{I}_F^-$.

**Lemma 5.21.** Let $w \in \tilde{W}_F$. The element $\hat{w}$ satisfies (5.5) if and only if $w$ is $F$-negative.
Let \((σ, V_σ)\) as in the proposition. Let \(v ∈ V_σ^0\) and \(d ∈ D_F\). By Lemma 5.19 ii and iv, the \(\tilde{I}\)-invariant function
\[ f_{d,v} ∈ (\text{Ind}_{P_F}^G σ)^{\tilde{I}} \]
with support in \(P_F \tilde{d} \tilde{I}\) and value \(v\) at \(d\) is well-defined and the set of all \(f_{d,v}\) form a basis of \((\text{Ind}_{P_F}^G σ)^{\tilde{I}}\), when \(d\) ranges over \(D_F\) and \(v\) over a basis of \(V_σ^0\).

**Lemma 5.22.**  
\begin{enumerate}[i.]  
\item Let \(w\) an \(F\)-negative element in \(\tilde{W}_F\). Then \(f_{1,v} \cdot τ_w = f_{1,v,τ_w}^\epsilon\).
\item We have \(f_{1,v} \cdot τ_d = f_{d,v}\).
\end{enumerate}

5.5.2. **Proof of the lemmas.** Recall that given \(α ∈ Φ\), the root subgroup \(U_α\) is endowed with a filtration \(U_{(α, k)}\) for \(k ∈ \mathbb{Z}\) (see for example [29, I.1] or [26, 4.2]) and that the product map
\[ \prod_{α ∈ Φ^-} U_{(α,1)} × T^1 × \prod_{α ∈ Φ^+} U_{(α,0)} \sim → \tilde{I} \]
induces a bijection, where the products on the left hand side are ordered in some arbitrary chosen way ([29, Proposition I.2.2]). The subgroup \(\tilde{I}^P_F\) (resp. \(\tilde{I}^-_F\)) of \(\tilde{I}\) is generated by the image of \(\prod_{α ∈ Φ^+} U_{(α,0)}\) (resp. \(\prod_{α ∈ Φ^-} U_{(α,1)}\)). The subgroup \(\tilde{I}^0_F\) of \(\tilde{I}\) is generated by the image of \(\prod_{α ∈ Φ^-} U_{(α,1)} × T^1 × \prod_{α ∈ Φ^+} U_{(α,0)}\).

**Proof of Lemma 5.19.** i. We have \(P_F \tilde{d} \tilde{I} = P_F \tilde{d} \tilde{I} \tilde{d} \tilde{I} \). But for \(α ∈ Φ^+\), we have \(\tilde{d}^{-1} U_{(-α, 1)} \tilde{d} = U_{(-d^{-1} α, 1)} \subseteq \tilde{I} \) so \(\tilde{I}^P_F \tilde{d} \subseteq \tilde{d} \tilde{I}\) and \(P_F \tilde{d} \tilde{I} = P_F \tilde{d} \tilde{I}\). Point ii follows by Bruhat decomposition for \(K\) and Iwasawa decomposition for \(G\). For iii, we first recall that the image of \(P_F \cap K\) by the reduction \(red : K → \mathcal{C}_{x_0}(F_q)\) modulo \(K_1\) is a parabolic subgroup \(P_F(F_q)\) containing \(P(F_q)\) (notations in 1.2). Recall that the Weyl group of \(\mathcal{C}_{x_0}(F_q)\) is \(\mathcal{W}\): for \(w \in \mathcal{W}\) we will still denote by \(w\) a chosen lift in \(\mathcal{C}_{x_0}(F_q)\). The set \(D_F\) is a system of representatives of \(P_F(F_q) \backslash \mathcal{C}_{x_0}(F_q)/\mathcal{N}(F_q)\). For \(d ∈ D_F\) we have, using [8, 2.5.12],
\[ P_F(F_q) \cap d \mathcal{N}(F_q) d^{-1} ⊆ \mathcal{N}(F_q). \]
We deduce that the image of \(P_F \cap \tilde{I} \tilde{d}d^{-1}\) by \(red\) is contained in \(\mathcal{N}(F_q)\) and therefore \(P_F \cap \tilde{I} \tilde{d}d^{-1}\) is contained in \(\tilde{I}\).

Now let \(d ∈ D_F\) and \(y ∈ \tilde{I}\). By the previous observations, \(\tilde{d} ∈ P_F \tilde{I} \tilde{d} \tilde{y} = P_F \tilde{d} \tilde{I} \tilde{d} \tilde{y}\) implies \(\tilde{d} ∈ \tilde{I} \tilde{d} \tilde{y}\).

It proves iii. In passing we proved that \(P_F \cap \tilde{d} d^{-1}\) is contained in \(P_F \cap \tilde{I} = \tilde{I}^- F\). Since \(\tilde{I}^- F\) is contained in \(P_F \cap \tilde{d} d^{-1}\) by definition of \(D_F\), it proves iv.

**Proof of Lemma 5.21.** By Remark 5.20 it is enough to prove the result for \(w = e^λ ∈ X_*(T)\). A lift for \(e^λ\) is given by \(λ(\varpi^{-1})\). The element \(λ(\varpi^{-1})\) satisfies (5.5) if
\[ \text{for all } α ∈ Φ^+ - Φ_F^+ \text{ we have } λ(\varpi^{-1}) U_{(α,0)} λ(\varpi) ⊆ \tilde{I}^P_F \text{ and } λ(\varpi) U_{(-α,1)} λ(\varpi^{-1}) ⊆ \tilde{I}^- F. \]
By [26, Remark 4.1(1)] (for example), \( \lambda(\varpi^{-1}) \mathcal{U}(\alpha,0) \lambda(\varpi) = \mathcal{U}(\alpha,-\langle \alpha,\lambda \rangle) \) and \( \lambda(\varpi) \mathcal{U}(\alpha,-1) = \mathcal{U}(\alpha,-1,-\langle \alpha,\lambda \rangle) \). Condition (5.7) is satisfied if and only if \( \lambda \) is \( F \)-negative (definition in 3.3.1).

\[ \square \]

**Proof of Lemma 5.22.**

\[ \text{i.} \] Let \( w \) be an \( F \)-negative element in \( \hat{W}_F \). The function \( f_{1,v} \cdot \tau_w \) has support in \( P_F \hat{I}_F \hat{w} \hat{I} \). Since \( \hat{w} \) satisfies (5.5), we have \( P_F \hat{I}_F \hat{w} \hat{I} = P_F \hat{w} \hat{I} = P_F \hat{I} \). It remains to compute the value of \( f_{1,v} \cdot \tau_w \) at 1\( _G \) (we choose the unit element \( 1_G \) of \( G \) as a lift for 1 \( \in \mathcal{D}_F \)).

The proof goes through exactly as in [24, 6A.3] where it is written up in the case of \( G = \text{GL}_n \).

\[ \text{ii.} \] Let \( d \in \mathcal{D}_F \). By Lemma 5.19i, the \( \hat{I} \)-invariant function \( f_{1,v} \cdot \tau_d \) has support in \( P_F \hat{d} \hat{I} \) and it follows from Lemma 5.19ii that it takes value \( v \) at \( \hat{d} \).

\[ \square \]

5.5.3. Here we consider again representations with coefficients in the algebraically closed field \( k \) with characteristic \( p \). We draw corollaries from Proposition 5.17.

**Corollary 5.23.** Let \( F \neq x_0 \) be a standard facet. If \( \sigma \) is an admissible \( k \)-representation of \( M_F \) with a central character, then \( (\text{Ind}^G_{P_F} \sigma) \hat{I} \) is a finite dimensional \( \hat{H}_k \)-module whose irreducible subquotients are not supersingular.

**Proof.** The fact that \( (\text{Ind}^G_{P_F} \sigma) \hat{I} \) is finite dimensional is a consequence of the admissibility of \( \sigma \). Let \( \lambda \in X_*(T) \) a strongly \( F \)-negative coweight (see Remark 3.6) and \( \lambda_0 \in X^+_*(T) \) the unique dominant coweight in its \( \mathfrak{M} \)-orbit \( \mathcal{O}(\lambda) \). By Lemma 3.4

\[ z_{\lambda_0} = \sum_{\lambda' \in \mathcal{O}(\lambda)} \mathcal{B}_{F}^{-}(\lambda'). \]

We compute the action of \( z_{\lambda_0} \) on an element of the form \( v \otimes 1 \in \sigma^0 \hat{\otimes} \hat{\otimes} \hat{I} \). We have \( \mathcal{B}_{F}^{-}(\lambda) = \tau_{e,\lambda} \) and therefore,

\[ (v \otimes 1) \mathcal{B}_{F}^{-}(\lambda) = v \otimes \tau_{e,\lambda} = v \otimes j_F(\tau_{e,\lambda}^F) = (v \tau_{e,\lambda}^F) \otimes 1. \]

Recall that \( \tau_{e,\lambda}^F = \tau_{\lambda(\varpi^{-1})}^F \) and that \( \lambda(\varpi^{-1}) \) is a central element in \( M_F \). Therefore, \( v \tau_{e,\lambda}^F = \omega(\lambda(\varpi)) v \) where \( \omega \) denotes the central character of \( \sigma \). By (2.4), it implies in particular that \( (v \otimes 1) \mathcal{B}_{F}^{-}(\lambda') = 0 \) for \( \lambda' \in \mathcal{O}(\lambda) \) distinct from \( \lambda \). We have proved that \( z_{\lambda_0} \) acts by multiplication by \( \omega(\lambda(\varpi)) \neq 0 \) on \( \sigma^0 \hat{\otimes} \hat{\otimes} \hat{I} \) and therefore on \( (\text{Ind}^G_{P_F} \sigma) \hat{I} \) by Proposition 5.17. It proves the claim.

\[ \square \]

**Corollary 5.24.** Let \( F \) be a standard facet. Let \( \text{Sp}_F \) be the generalized special \( k \)-representation of \( G \)

\[ \text{Sp}_F = \frac{\text{Ind}^G_{P_F} 1}{\sum_{F' \neq F \subset P} \text{Ind}^G_{P', F} 1}. \]
where $F'$ ranges over the set of standard facets $\neq F$ contained in the closure of $F$. The $\tilde{I}$-invariant subspace of $\text{Sp}_F$ is a finite dimensional $\tilde{H}_k$-module whose irreducible subquotients are not supersingular.

Proof. Suppose first that $F \neq x_0$. By [11, (18)] (which is valid with no restriction on the split group $G$), $(\text{Sp}_F)^\tilde{I}$ is a quotient of $(\text{Ind}^G_{F_x} 1)^\tilde{I}$. Apply Corollary 5.23. If $F = x_0$, then the special representation in question is the trivial character of $G$ whose $\tilde{I}$-invariant subspace is isomorphic to the trivial character of $\tilde{H}_k$ and is not supersingular (Example 5.4.2 and Lemma 5.12).

□

5.6. On supersingular representations. Let $\rho$ be a weight of $K$. By (4.7), there is a correspondence between the $k$-characters of $\mathcal{H}(G, \rho)$ and the $k$-characters of $\mathcal{Z}(\tilde{H}_k)$, and we will use the same letter $\zeta$ for two characters paired up by (4.7). With this notation, by the work in 4, we have a surjective morphism of representations of $G$:

\[(5.8) \quad \zeta \otimes_{\mathcal{Z}(\tilde{H}_k)} \text{ind}^G_1 \longrightarrow \zeta \otimes_{\mathcal{H}(G, \rho)} \text{ind}^G_K \rho.\]

For $\omega$ a character of the connected center of $G$, let $\zeta_\omega$ the supersingular character of $\mathcal{Z}(\tilde{H}_k)$ as in 5.3.3. Remark that the representation $\zeta_\omega \otimes_{\mathcal{Z}(\tilde{H}_k)} \text{ind}^G_1$ of $G$ has central character $\omega$.

From now on we suppose that the derived group of $G$ is simply connected and that $\mathfrak{F}$ is a finite extension of $\mathbb{Q}_p$.

Lemma 5.25. A character $\mathcal{H}(G, \rho) \to k$ is parametrized by the pair $(G, \omega)$ in the sense of [18, Proposition 4.1] if and only if it corresponds to the supersingular character $\zeta_\omega$ of $\mathcal{Z}(\tilde{H}_k)$ via (4.7).

Proof. In this proof we denote by $\psi : \mathcal{H}(G, \rho) \to k$ and $\zeta : \mathcal{Z}(\tilde{H}_k) \to k$ a pair of characters corresponding to each other by (4.7). Recall that $\mathcal{T}$ denotes the inverse Satake isomorphism (4.4). By [18, Corollary 4.2] (see also Corollary 2.19 loc.cit), the character $\psi : \mathcal{H}(G, \rho) \to k$ is parametrized by the pair $(G, \omega)$ if and only if $\psi \circ \mathcal{T}(\lambda) = 0$ for all $\lambda \in X^+_s(T)$ such that $\ell(e^\lambda) \neq 0$ and if $\psi \otimes_{\mathcal{H}(G, \rho)} \text{ind}^G_K \rho$ has central character equal to $\omega$ (see Lemma 4.4 and its proof loc.cit). Since, for all $\lambda \in X^+_s(T)$, we have $\zeta(z_\lambda) = \psi \circ \mathcal{T}(\lambda)$ and since $\psi \otimes_{\mathcal{H}(G, \rho)} \text{ind}^G_K \rho$ is a quotient of $\zeta \otimes_{\mathcal{Z}(\tilde{H}_k)} \text{ind}^G_1$, we have proved (using the remark before the statement of this lemma) that $\psi$ is parametrized by the pair $(G, \omega)$ if and only if $\zeta = \zeta_\omega$.

□

A smooth irreducible admissible $k$-representation of $G$ has a central character. A smooth irreducible admissible $k$-representation $\pi$ with central character $\omega : Z \to k^\times$ is called supersingular.
with respect to \((K, T, B)\) ([18, Definition 4.7]) if for all weights \(\rho\) of \(K\), any map \(\text{ind}^G_K\rho \to \pi\) factorizes through

\[
\zeta_\omega \otimes_{\mathcal{H}(G, \rho)} \text{ind}^G_K\rho \longrightarrow \pi.
\]

Note that if the first map is zero, then the condition is trivial. By (5.8), a supersingular representation with central character \(\omega : Z \to k^\times\) is therefore a quotient of \(\zeta_\omega \otimes_{Z^\circ(\tilde{H}_k)} \text{ind}_I^G\) and, by Definition 5.8, of

\[\text{ind}_I^G/\mathfrak{I}\text{ind}_I^G.\]

Remark 5.26. i. The representation \(\text{ind}_I^G/\mathfrak{I}\text{ind}_I^G\) depends only on the conjugacy class of \(x_0\). It is independent of all the choices if \(G\) is of adjoint type or \(G = \text{GL}_n\).

ii. An irreducible admissible representation \(\pi\) of \(G\) is a quotient of \(\text{ind}_I^G/\mathfrak{I}\text{ind}_I^G\) if and only if \(\pi^\mathfrak{I}\) contains a supersingular \(\tilde{H}_k\)-module. Recall that when the root system of \(G\) is irreducible, we have proved that the notion of supersingularity for \(\tilde{H}_k\)-modules is independent of all the choices made.

Theorem 5.27. If \(G = \text{GL}_n(\mathfrak{F})\) or \(\text{PGL}_n(\mathfrak{F})\), a smooth irreducible admissible \(k\)-representation \(\pi\) is supersingular if and only if \(\pi^\mathfrak{I}\) contains a supersingular \(\tilde{H}_k\)-module, that is to say if and only if \(\pi\) is a quotient of

\[\text{ind}_I^G/\mathfrak{I}\text{ind}_I^G.\]

Proof. Let \(\pi\) be a smooth irreducible admissible \(k\)-representation of \(G\) with central character \(\omega\). If it is a quotient of \(\text{ind}_I^G/\mathfrak{I}\text{ind}_I^G\) then it is a quotient of \(\zeta_\omega \otimes_{Z^\circ(\tilde{H}_k)} \text{ind}_I^G\), and \(\pi^\mathfrak{I}\) contains the supersingular character \(\zeta_\omega\) of \(Z^\circ(\tilde{H}_k)\). Therefore it contains a supersingular \(\tilde{H}_k\)-module. By Corollaries 5.23 and 5.24, it implies that \(\pi\) is neither a representation induced from a strict parabolic subgroup of \(G\) nor (a twist by a character of \(G\) of) a generalized special representation. By [18, Theorem 1.1] that classifies all smooth irreducible admissible \(k\)-representation of \(G\), we conclude by elimination that the representation \(\pi\) is supersingular.

The results of [18] have been generalized to the case of a \(\mathfrak{F}\)-split connected reductive group \(G\) in [1]: the classification of the smooth irreducible admissible representations of \(G\) is quite similar to the case of \(\text{GL}_n(\mathfrak{F})\) (except for a certain subtlety when the root system of \(G\) is not irreducible). Based on this classification and on Corollaries 5.23 and 5.24, N. Abe confirmed that the space of \(\mathfrak{I}\)-invariant vectors of a nonsupersingular representation does not contain any supersingular \(\tilde{H}_k\)-module. Therefore, Theorem 5.27 is true for a general split group with simply connected derived subgroup.
