PAPER

Metal–organic Kagome lattices $M_3(2,3,6,7,10,11$-hexaiminotriphenylene)$_2$ (M = Ni and Cu): from semiconducting to metallic by metal substitution†

Shuang Chen, Jun Dai and Xiao Cheng Zeng*

Motivated by recent experimental synthesis of a semiconducting metal–organic graphene analogue ($J$. Am. Chem. Soc., 2014, 136, 8859), i.e., Ni$_3$(2,3,6,7,10,11-hexaiminotriphenylene)$_2$ [Ni$_3$(HITP)$_2$], a new Kagome lattice, Cu$_3$(HITP)$_2$, is designed by substituting the coordination of Ni by Cu. Such substitution results in interesting changes in electronic properties of the M$_3$(HITP)$_2$ bulk and two-dimensional (2D) sheets. In Ni$_3$(HITP)$_2$, each Ni atom adopts the dsp$_2$ hybridization, forming a perfect 2D conjugation, whereas in Cu$_3$(HITP)$_2$, each Cu atom adopts the sp$^3$ hybridization, resulting in a distorted 2D sheet. The M$_3$(HITP)$_2$ bulks, assembled from M$_3$(HITP)$_2$ sheets via both strong π–π interaction and weak metal–metal interaction, are metallic. However, the 2D Ni$_3$(HITP)$_2$ sheet is a semiconductor with a narrow band gap whereas the 2D Cu$_3$(HITP)$_2$ sheet is a metal. Remarkably, both the 2D M$_3$(HITP)$_2$ Kagome lattices possess Dirac bands in the vicinity of the Fermi level. Additional ab initio molecular dynamics simulations show that both sheets exhibit high thermal stability at elevated temperatures. Our theoretical study offers new insights into tunability of electronic properties for the 2D metal–organic frameworks (MOFs).

Introduction

Two-dimensional (2D) functional materials, including graphene,$^1$ graphene derivatives,$^2$ layered metal chalcogenides,$^3$ and 2D covalent-organic frameworks (COFs),$^4,5$ have attracted intensive attention owing to their novel electronic, optical, and mechanical properties for future device applications. Graphene, a single layer of sp$^2$-bonded carbon atoms in a honeycomb lattice, is a 2D carbon allotrope. However, the lack of a bandgap limits its device application.$^6$ Graphene derivatives possess a bandgap but at the expense of decreased charge carrier mobility.$^2$ Two new classes of 2D materials, transition metal chalcogenides$^7–10$ and COFs,$^{11,12}$ are also viewed as potential alternatives to graphene derivatives since the transition metal chalcogenides can be easily produced in large areas with controlled thicknesses$^{13}$ while the organic COFs can be chemically modified.$^{11}$ However, the chemical functionalization of metal chalcogenides is difficult and the carrier mobility of COFs tends to be depressed due to the reduction of in-plane conjugation resulting from COFs own flexibility or the presence of functional groups in the building blocks. A new class of metal–organic frameworks (MOFs) assembled from square-planar metal ions and aromatic organic moieties, such as o-semiquinone,$^{14}$ dithiolene,$^{15,16}$ and iminotriphenylene,$^{17}$ has emerged recently to combine advantages of both inorganic and organic materials. These MOFs exhibit high electrical conductivity due to full charge delocalization in the 2D plane or π–π stacking along the stacked columns.$^{14–17}$ Interestingly, a previous theoretical investigation predicted that the 2D π-conjugated nickel-bis-dithiolene monolayer may possess a non-zero bandgap and even behave as a topological insulator.$^{18}$ Thus, these 2D MOFs could be potential candidates for future electronics.

In this study, we select the recently synthesized semiconducting MOF, Ni$_3$(2,3,6,7,10,11-hexaiminotriphenylene)$_2$ [Ni$_3$(HITP)$_2$],$^{17}$ as a model system. Our goal is to investigate the effect of substitution of coordinated metal ions, e.g. from Ni to Cu in the MOF, on the structural and electronic properties of the MOF bulks and 2D sheets. We note that these 2D M$_3$(HITP)$_2$ sheets exhibit the Kagome-lattice pattern. By changing every coordinated metal site, the metal coordination (dsp$^2$ → sp$^3$ hybridization), the geometry of in-plane network (planar → buckled), and the electronic properties (semiconducting → metallic) of 2D M$_3$(HITP)$_2$ sheets are modified as shown in Fig. 1. Our theoretical work suggests high tunability of 2D MOFs with exotic electronic properties by metal substitution.
The previous experimental study showed that the Ni₃(HITP)₂ crystal favored the slipped-parallel orientation between neighboring Ni₃(HITP)₂ layers. In the same work, the computational study (based on PBE-D2 functional) also suggested that the 3D structure of Ni₃(HITP)₂ in which one layer was shifted laterally with respect to the neighboring layer by about 1.8 Å along the a axis, or both ab axes, has the lowest energy. Here, our DFT geometry optimization of both 3D Ni₃(HITP)₂ and Cu₃(HITP)₂ sheets using ab initio molecular dynamics (AIMD) simulations at elevated temperatures. The AIMD simulations are performed using the QUICKSTEP program implemented in the CP2K software package. Within the framework of the Kohn–Sham formulation of DFT and the Gaussian plane-wave (GPAW) method, the core electrons are described by the Goedecker–Teter–Hutter (GTH) norm-conserving pseudopotential, and the wave functions of valence electrons are expressed by the combination of the polarized double-ζ quality Gaussian basis and a plane-wave basis set (with an energy cutoff of 330 Ry). The dispersion-corrected PBE-D3 method is selected. For the Cu₃(HITP)₂ sheet, the spin-polarized computation is applied. The AIMD simulations are performed in the constant-volume and constant-temperature ensemble with the temperature controlled at 500 K and 1000 K, respectively, for each sheet. For each temperature, ten ps simulation is carried out with the time step of 1.0 fs.

Results and discussion

3D metallic M₃(HITP)₂ bulks

The previous experimental study showed that the Ni₃(HITP)₂ layer was slipped relative to a neighboring layer by about 1.8 Å along the a or b vectors gave the lowest energy on the PES. For computation of electronic properties (including band structures, density of states (DOS), and charge density distribution), the Perdew–Burke–Ernzenhof (PBE) form for the exchange–correlation functional within the framework of the generalized gradient approximation (GGA) is employed. Grimme’s correction (D3) is also adopted to account for weak van der Waals interactions within the organic materials. The electron–ion interaction is described by the projector augmented wave (PAW) potentials with an energy cutoff of 500 eV. For geometry optimization, the total energy change is set to less than 10⁻⁶ eV and the magnitude of the largest force acting on the atoms is set to less than 0.02 eV Å⁻¹. The Brillouin zones are sampled using a 2 × 2 × 6 or 4 × 4 × 1 k-point mesh in the Monkhorst-Pack scheme for 3D bulks or 2D sheets, respectively. For more accurate calculations of electronic properties of M₃(HITP)₂ bulks or sheets, a twice denser k-point mesh is used, and the convergence criterion of self-consistent field (SCF) computation is set to 10⁻⁶ eV. For the M₃(HITP)₂ 3D bulks and 2D sheets, the spin-polarized computation is also performed to examine their magnetic properties. In addition, the effects of spin–orbit coupling (SOC) are considered to examine the possible non-collinear magnetic states of the Cu₃(HITP)₂ sheet, as well as to estimate the opening of a small bandgap in the Kagome bands of the 2D M₃(HITP)₂ sheets.

Computational details

Density functional theory (DFT) methods implemented in the Vienna Ab Initio Simulation Package (VASP 5.3.5) are used to optimize the three-dimensional (3D) M₃(HITP)₂ (M = Ni and Cu) bulks and 2D sheets. Before the DFT optimization of the periodic systems, the molecular units of M₃(HITP)₂ (see ESI† for optimization, the total energy change is set to less than 10⁻⁶ eV and the magnitude of the largest force acting on the atoms is set to less than 0.02 eV Å⁻¹. The Brillouin zones are sampled using a 2 × 2 × 6 or 4 × 4 × 1 k-point mesh in the Monkhorst-Pack scheme for 3D bulks or 2D sheets, respectively. For more accurate calculations of electronic properties of M₃(HITP)₂ bulks or sheets, a twice denser k-point mesh is used, and the convergence criterion of self-consistent field (SCF) computation is set to 10⁻⁶ eV. For the M₃(HITP)₂ 3D bulks and 2D sheets, the spin-polarized computation is also performed to examine their magnetic properties. In addition, the effects of spin–orbit coupling (SOC) are considered to examine the possible non-collinear magnetic states of the Cu₃(HITP)₂ sheet, as well as to estimate the opening of a small bandgap in the Kagome bands of the 2D M₃(HITP)₂ sheets.

We also examined thermal stability of both 2D M₃(HITP)₂ sheets using ab initio molecular dynamics (AIMD) simulations at elevated temperatures. The AIMD simulations are performed using the QUICKSTEP program implemented in the CP2K software package. Within the framework of the Kohn–Sham formulation of DFT and the Gaussian plane-wave (GPAW) method, the core electrons are described by the Goedecker–Teter–Hutter (GTH) norm-conserving pseudopotential, and the wave functions of valence electrons are expressed by the combination of the polarized double-ζ quality Gaussian basis and a plane-wave basis set (with an energy cutoff of 330 Ry). The dispersion-corrected PBE-D3 method is selected. For the Cu₃(HITP)₂ sheet, the spin-polarized computation is applied. The AIMD simulations are performed in the constant-volume and constant-temperature ensemble with the temperature controlled at 500 K and 1000 K, respectively, for each sheet. For each temperature, ten ps simulation is carried out with the time step of 1.0 fs.

Results and discussion

3D metallic M₃(HITP)₂ bulks

The previous experimental study showed that the Ni₃(HITP)₂ crystal favored the slipped-parallel orientation between neighboring Ni₃(HITP)₂ layers. In the same work, the computational study (based on PBE-D2 functional) also suggested that the 3D structure of Ni₃(HITP)₂ in which one layer was shifted laterally with respect to the neighboring layer by about 1.8 Å along the a axis, or both ab axes, has the lowest energy. Here, our DFT geometry optimization of both 3D Ni₃(HITP)₂ and Cu₃(HITP)₂ sheets using ab initio molecular dynamics (AIMD) simulations at elevated temperatures. The AIMD simulations are performed using the QUICKSTEP program implemented in the CP2K software package. Within the framework of the Kohn–Sham formulation of DFT and the Gaussian plane-wave (GPAW) method, the core electrons are described by the Goedecker–Teter–Hutter (GTH) norm-conserving pseudopotential, and the wave functions of valence electrons are expressed by the combination of the polarized double-ζ quality Gaussian basis and a plane-wave basis set (with an energy cutoff of 330 Ry). The dispersion-corrected PBE-D3 method is selected. For the Cu₃(HITP)₂ sheet, the spin-polarized computation is applied. The AIMD simulations are performed in the constant-volume and constant-temperature ensemble with the temperature controlled at 500 K and 1000 K, respectively, for each sheet. For each temperature, ten ps simulation is carried out with the time step of 1.0 fs.
bulks indicates that the shift of the second layer in the unit cell along the $b$ axis gives rise to the lowest-energy structure among the three possible crystal structures (see ESI,† Fig. S2). Based on the lowest-energy crystal structures, the computed electronic band structures, DOS, and the charge density isosurface for the bands crossing the Fermi level are presented in Fig. 2. As shown in Fig. 2a and c, both 3D Ni$_3$(HITP)$_2$ and Cu$_3$(HITP)$_2$ crystals are metallic with a band crossing the Fermi level along $M(1/2, 0, 0)$–$L(1/2, 0, 1/2)$ and $H(2/3, 1/3, 1/2)$–$K(2/3, 1/3, 0)$. The predicted metallic property of Ni$_3$(HITP)$_2$ is consistent with the excellent bulk and thin film conductivity of 2 and 40 S cm$^{-1}$ obtained from the two-probe and van der Pauw electrical measurements, respectively.\cite{17} Moreover, the band structures exhibit relatively strong dispersions within the $M$–$L$ or $H$–$K$ region (see Fig. 2a and c), indicating strong $\pi$–$\pi$ interaction between metal–organic sheets along their stacking direction ($c$ axis). We also plot the charge density isosurface for the M$_3$(HTIP)$_2$ bulks in Fig. 2b and d. These bands are mainly contributed from the out-of-plane Ni-$d$, C-$p$, and N-$p$ delocalized states (no contribution from H atoms), consistent with interlayer metal–metal and $\pi$–$\pi$ interactions. Indeed, according to the cell parameters of M$_3$(HTIP)$_2$ bulks (ESI,† Fig. S2), the interlayer distance between two M$_3$(HTIP)$_2$ sheets is about 3.3 Å, which is within the van der Waals interaction distance of 2D conjugated carbon layers, and the closest Ni···Ni and Cu···Cu distances between two sheets are 3.809 Å and 3.952 Å, respectively, indicating strong $\pi$–$\pi$ interaction and weak metal–metal ($d$–$d$) interaction between the two sheets.

### 2D semiconducting Ni$_3$(HITP)$_2$ sheets versus metallic Cu$_3$(HITP)$_2$ sheets

The reduced dimensionality from 3D M$_3$(HITP)$_2$ bulks to 2D sheets leads to a significant change in the electronic properties. As shown in Fig. 3a and d, the Ni$_3$(HITP)$_2$ sheet is a semiconductor with a small bandgap of 0.13 eV, while the Cu$_3$(HITP)$_2$ sheet is still metallic. For the Ni$_3$(HITP)$_2$ sheet (Fig. 3a), its valence band maximum (VBM) is located at the $K$ point while its conduction band minimum (CBM) is located at the $\Gamma$ point, suggesting Ni$_3$(HITP)$_2$ is an indirect semiconductor. The direct bandgap at the $\Gamma$ point is about 0.23 eV, slightly larger than the indirect bandgap. Since the Kohn–Sham bandgaps generally underestimate the physical bandgaps, the HSE06 functional\cite{33–35} is also employed to compute the band structures of the Ni$_3$(HITP)$_2$ sheet. As shown in (ESI†) Fig. S3, the occupied valence bands computed from the HSE06 functional exhibit a downward shift while the unoccupied conduction bands show an upward shift, compared to the PBE-D3 bands. The shift of the VBM and CBM is quite small, and the HSE06 functional results in an indirect bandgap of 0.20 eV and a direct bandgap of 0.19 eV at the $\Gamma$ point, close to the PBE-D3 bandgaps. As indicated by the charge-density isosurface...
of the highest occupied valence band (HOVB) and of the lowest unoccupied conduction band (LUCB) for the Ni₃(HTTP)₂ sheet in Fig. 3b and of the band crossing the Fermi level for the Cu₃(HTTP)₂ sheet in Fig. 3c, these bands stem mainly from the M-d, C-p, and N-p states (no contribution from H atoms). Furthermore, the projected density of states (PDOS) of these bands (ESI,† Fig. S4) show that both 2D MOFs exhibit typical π-conjugated characteristics, since their PDOS near the Fermi level are almost fully contributed by the pₓ, pᵧ, and p_z orbitals of C and N atoms as well as the delocalized d orbitals of metal atoms. For the delocalized d orbitals, only the dₓz and dᵧz orbitals of Ni atoms provide contribution to both the HOVB and LUCB. In addition, the contributions of dₓz and dᵧz to the HOVB or LUCB of the Ni₃(HTTP)₂ sheet are nearly the same as one another. For the Cu₃(HTTP)₂ sheet, the four d orbitals of Cu atoms contribute to the band crossing the Fermi level except dᵧz. Furthermore, the NBO analysis, we know that the Ni atoms in the Ni₃(HTTP)₂ sheet adopt the dsp² hybridization to form the square-planar geometry with the organic moieties. The Ni₃(HTTP)₂ sheet has a perfectly 2D conjugated plane, and its HOVB and LUCB show π-bonding and π-antibonding characteristics, respectively. On the other hand, each Cu atom adopts the sp³ hybridization. The coordination geometry of Cu atoms in the Cu₃(HTTP)₂ sheet is slightly distorted, and thus the 2D sheet is slightly buckled.

A previous tight-binding model predicted that typical Kagome bands consist of one flat band above two Dirac bands.¹⁶ The 2D metal–organic nickel-bis-dithiolen (Ni₃C₁₂S₁₂) lattice also exhibits similar Kagome bands with three spin degenerated bands above the Fermi level.¹⁸ The bandgap of the Dirac bands is about 13.6 meV (Åₒ), while the bandgap between the flat band and the top branch of the Dirac bands is about 5.8 meV (Åₒ).¹⁸ Moreover, the Ni₃C₁₂S₁₂ Kagome lattice was predicted to be a 2D organic topological insulator due to the intrinsic spin–orbit coupling of Ni ions.¹⁸ Compared to the Ni₃C₁₂S₁₂ Kagome lattice, the Ni₃(HTTP)₂ sheet has different aromatic organic moieties from dithiolen to iminotriphenylene with a larger conjugated C core and different coordinated organic sites from the S atom to the NH group. As shown in Fig. 3c, the Ni₃(HTTP)₂ sheet has similar Kagome bands above the Fermi level as Ni₃C₁₂S₁₂. The higher flat band meets the top branch of the Dirac bands at the Γ point with the SOC gap (Åₒ) of 34.0 meV. The bandgap of Dirac bands is 8.7 meV (Åₒ). With substitution of the metal sites, the band structures of the Cu₃(HTTP)₂ sheet near the Fermi level become quite different from those of Ni₃(HTTP)₂ [see Fig. 3d]. As shown in Fig. 3f, the Cu₃(HTTP)₂ sheet still has three degenerate Kagome bands and the same Dirac bandgap (Åₒ) as Ni₃(HTTP)₂. Differently, the higher flat band meets the top branch of the Dirac bands at the M point with a quite small SOC gap (Åₒ = 4.6 meV). Similar to Ni₃C₁₂S₁₂, the Fermi level of the Cu₃(HTTP)₂ sheet is not located in the SOC gap. Hence, doping two (or four) electrons per unit cell in the M₃(HTTP)₂ sheet is needed. For Ni₃C₁₂S₁₂, the doping concentration was predicted to be about 2 × 10¹⁴ cm⁻².¹⁸ The M₃(HTTP)₂ sheets have a longer lattice constant (about 22 Å) than the lattice constant of Ni₃C₁₂S₁₂ (about 15 Å). So less doping concentration, estimated to be about 8 × 10¹³ cm⁻², is needed for the M₃(HTTP)₂ sheets. For real device application, the electrostatic gating is required to achieve the doping effect.

Lastly, our AIMD simulations show that both 2D metal–organic Kagome lattices exhibit quit high thermal stability. Snapshots of M₃(HTTP)₂ sheets at 500 K and 1000 K after 10 ps AIMD simulations are shown in Fig. 4. Clearly, the overall framework of both 2D MOFs, become more flexible as the temperature increases. Moreover, compared to the initial average coordinated M–N (M = Ni or Cu) bond lengths, both Ni–N and Cu–N bonds become longer as the temperature increases. The change in Cu–N bonds is slightly larger than that of Ni–N bonds. Nevertheless, both metal–organic networks still keep their structures even at 1000 K. It appears that their thermal stability is better than 2D organic COFs because the COFs are typically stable only up to 700 K.¹²

Conclusions

The metal substitution results in interesting changes in both geometry and electronic properties of 3D M₃(HTTP)₂ bulks and 2D sheets. For Ni₃(HTTP)₂, each Ni atom adopts the dsp² hybridization, leading to a perfect 2D conjugation. However, for Cu₃(HTTP)₂, each Cu atom adopts the sp³ hybridization to form a specific square-grid coordination geometry, leading to a distorted 2D sheet. The M₃(HTTP)₂ bulks, assembled from M₃(HTTP)₂ sheets via both strong π–π interaction and weak metal–metal interaction, are metallic. For 2D MOFs, the Ni₃(HTTP)₂ sheet is a semiconductor with a narrow bandgap, while the Cu₃(HTTP)₂ sheet is metallic. Importantly, the M₃(HTTP)₂ sheets possess the Dirac bands near the Fermi level. Moreover, 2D MOFs show higher thermal stability than 2D COFs. As such, the M₃(HTTP)₂ sheets can be promising 2D materials in place of pure 2D organic materials. With other metal ions or organic moieties as the 2D metal–organic Kagome lattices by design, new electronic or even exotic magnetic properties may be uncovered for future device applications.
