Abstract

We review the relation between scale and conformal symmetries in various models and dimensions. We present a dimensional reduction from relativistic to non-relativistic conformal dynamics.

PACS number: 02.20.Sv

1. Introduction

These days mathematical physicists are closely investigating scale and conformal transformations. Familiarity with theories that are invariant against these transformations—at least on the classical, pre-quantized level—extends for over a hundred years. Nevertheless there remain features, not unknown to some [1], that generally have fallen into obscurity. Therefore we take this occasion of an anniversary meeting to bring into the light some of these topics.

We shall describe the relation between scale and conformal symmetries and call attention to the dimensional peculiarities and universalities of scale and conformal transformations.

Consider a multicomponent field \( \Phi \), transforming conventionally under Poincaré transformations, which leave invariant the action for \( \Phi \),

\[
\delta_T \Phi(x) = \partial^\sigma \Phi(x),
\]

Lorentz rotations:

\[
\delta_L \Phi(x) = (x^\sigma \partial^\tau - x^\tau \partial^\sigma + \Sigma^{\sigma \tau}) \Phi(x),
\]

where \( \Sigma^{\sigma \tau} \) represents Lorentz rotations on the components of \( \Phi \); i.e. \( \Sigma^{\sigma \tau} \) is the spin matrix appropriate to \( \Phi \).

In addition to the Poincaré transformations we consider further transformations.

Scale transformations (dilations):

\[
\delta_S \Phi(x) = (x^\tau \partial_\tau + d) \Phi(x),
\]

* Sodano Fest, Perugia, Italy, January 2011.
where $d$ is the scale dimension of the field $\Phi$. (We assume that the $\Phi$-multiplet carries the same scale dimension for all its components.) $d$ is chosen so that the kinetic term in the action for $\Phi$ is invariant against dilations. We shall be concerned only with bosonic scalar and vector fields, whose kinetic term is bilinear in fields and derivatives. This is scale invariant in $D$-dimensional spacetime when

$$d = \frac{D - 2}{2}.$$  

(4)

This scale dimension correctly matches the power-law behavior of the correlation function for a free massless field: \(\langle \Phi(x)\Phi(y) \rangle \sim \int d^D k \frac{e^{ik(x-y)}}{k^2} \sim (x-y)^{-D+2}.\)

The additional transformations that we examine comprise the special conformal, acting on $\Phi$ as

$$\delta^C\Phi(x) = (2x^\sigma x^\tau - g^\sigma\tau x^2)\partial_\tau \Phi(x) + 2x_\tau (\partial^\tau d - \Sigma_\tau^\sigma)\Phi(x),$$  \hspace{1cm} (5)

where $g_{\alpha\beta} = \text{diag}(1,-1,...)$. Fields that respond to conformal transformations by (5) are called ‘primary’. There also exist non-primary fields, for example the derivative of a primary field is non-primary.

Poincaré transformations are described by the ISO(D−1,1) group, with $D(D+1)/2$ generators. With the addition of scale and $D$ conformal transformations, the group becomes $SO(D,2)$ with $(D+1)(D+2)/2$ generators.

The first topic that we address in sections 1.1 and 1.2 concerns the relationship between dilations and conformal transformations. Specifically when dynamics is invariant against these transformations, we consider the following questions: what are the conserved currents and what is their relation to the energy–momentum tensor $\theta^{\mu\nu}$, which is conserved and symmetric owing to Poincaré invariance?

Section 2 is devoted to our second topic: a dimensional reduction of the conformal group, which results in the non-relativistic conformal group.

1.1. Relation between scale and conformal symmetries

Group structure requires that a Poincaré invariant theory that is also conformally invariant necessarily enjoys scale invariance. This is seen from the Lie algebra, which follows from (1)–(3), (5):

$$[\delta^C, \delta^C] = -2 g^{\sigma\tau} \delta^\sigma + 2 \delta^\sigma \delta^\tau.$$  \hspace{1cm} (6)

But group theory does not establish conformal invariance from scale and Poincaré invariance; rather one must look at dynamics, which for our purpose is described by a Lagrange density depending on $\partial_\mu \Phi$ and $\Phi: \mathcal{L}(\partial_\mu \Phi, \Phi)$.

It was shown some time ago [2, 3] that conformal invariance holds in a Poincaré and scale invariant theory provided the quantity

$$V^\alpha = \frac{\partial \mathcal{L}}{\partial \partial^\mu \Phi} (g^{\mu\alpha} d - \Sigma^{\mu\alpha}) \Phi$$  \hspace{1cm} (7a)

is a total divergence,

$$V^\alpha = \partial_\mu \sigma^{\mu\alpha}.\hspace{1cm} (7b)$$

We call $V^\nu$ the ‘field virial’. (A related structure is seen in (5).) Moreover when (7b) holds it is always possible to improve a symmetric and conserved energy momentum tensor so that it becomes traceless [2, 3],

$$\theta^{\mu\nu} \rightarrow \theta^{\mu\nu}_{\ast}, \hspace{1cm} g_{\mu\nu} \theta^{\mu\nu}_{\ast} = 0,$$  \hspace{1cm} (8)

where $\theta^{\mu\nu}_{\ast}$ is defined in [4].
With this improved traceless tensor, the conserved scale and conformal currents are constructed as follows. Upon naming the infinitesimal coordinate change as \(-f^\mu(x)\)

\[
\delta x^\mu = -f^\mu(x)
\]

\[
f^\mu(x) = a^\mu, \omega^{\mu\alpha} x_\alpha (\omega^{\mu\alpha} = -\omega^{\alpha\mu}), c x^\mu, 2c, x^\alpha x^\mu - c^\mu x^2 \tag{9}
\]

for translations, Lorentz rotations, scale and conformal transformations, respectively, the currents take the Bessel–Hagen form:

\[
J^\mu_f = \theta^{\mu\nu} CCJ f^\nu. \tag{10}
\]

To verify conservation, we use the fact that the \(f^\mu\) in (9) are conformal Killing vectors,

\[
\partial^\mu f^\nu + \partial^\nu f^\mu = 2 D g^\mu\nu \partial_{\alpha} f^\alpha \tag{11}
\]

and \(\theta^{\mu\nu} CCJ\) is conserved, symmetric and traceless.

However, if a theory is scale invariant but not conformal invariant, namely the field virial does not satisfy \((7b)\), then no traceless energy–momentum tensor can be constructed and the conserved scale current cannot be presented solely with the energy–momentum tensor.

To summarize, in a Poincaré invariant theory conformal transformations are symmetries provided two conditions are met.

(i) Scale symmetry must hold—this is a group theoretic requirement.

(ii) The field virial \(V^\alpha\) must be a total divergence as in \((7)\)—this is a dynamical requirement.

It happens that in many scale non-invariant models the field virial does satisfy \((7b)\), then no traceless energy–momentum tensor can be constructed and the conserved scale current cannot be presented solely with the energy–momentum tensor.

1.2. Scale invariant but conformally non-invariant models

1.2.1. Scalar field. In \(D\) dimensions a single scalar field \(\phi\), governed by a Lagrangian with the structure

\[
\mathcal{L}(\partial_{\mu} \phi, \phi) = \mathcal{L} \left( \frac{\partial_{\mu} \phi \partial^{\mu} \phi}{\phi^{2n}} \right) \phi^{\frac{2n}{D}}, \tag{12}
\]

is scale invariant for arbitrary function \(\mathcal{L}(z)\), but is conformally invariant only when \(\mathcal{L}(z)\) is a combination of terms linear in or independent of \(z\), corresponding to a conventional kinetic term and self-interaction. For other forms of \(\mathcal{L}\) the field virial does not satisfy \((7b)\) and conformal invariance is absent. However, forms for \(\mathcal{L}(z)\) other than \(L_0 + L_1 z\) lead to dynamics with unconventional kinetic terms, and doubts can be expressed about the consistency of such unconventional dynamics, especially within quantum mechanics \([5]\). Therefore we now present a completely conventional and physically transparent model that shows similar behavior as regards scale and conformal symmetry.

1.2.2. Maxwell field. Consider free Maxwell theory in \(D\)-dimensional spacetime, which describes upon quantization \(D - 2\) non-interacting photons. The theory is formulated in terms of a field strength \(F_{\alpha\beta} = -F_{\beta\alpha}\), satisfying the equations

motion : \(\partial_{\alpha} F^{\alpha\beta} = 0\) \(\tag{13}\)

Bianchi : \(\partial_\gamma F_{\beta\gamma} + \partial_\beta F_{\gamma\alpha} + \partial_\alpha F_{\alpha\beta} = 0\) \(\tag{14}\)
These imply that the symmetric, conserved energy–momentum tensor takes the Maxwell form in any dimension,

$$\theta^{\mu\nu} = -F^{\mu\alpha} F_\alpha^\nu + \frac{g^{\mu\nu}}{4} F^{\alpha\beta} F_{\alpha\beta}$$

$$\partial_\nu \theta^{\mu\nu} = 0$$

but is traceless only in four dimensions,

$$\theta_\mu^\mu = (-1 + D/4) F^{\alpha\beta} F_{\alpha\beta}.$$  \hspace{1cm} (16)

There does not appear any way to ‘improve’ this into a traceless expression (as is possible in the scalar field case; but see section 1.2.3), so we anticipate interesting behavior with scale and conformal transformations.

The conventional approach to symmetries via Noether’s theorem, etc requires an action/Lagrangian formulation. This is achieved for the Maxwell theory by solving the Bianchi condition (14) in terms of a vector potential $A_\alpha$,

$$F_{\alpha\beta} = \partial_\alpha A_\beta - \partial_\beta A_\alpha.$$ \hspace{1cm} (17)

$A_\alpha$ is taken to be the fundamental dynamical variable. Then the equation of motion (13) follows by varying the Lagrange density

$$L = -\frac{1}{4} F^{\alpha\beta} F_{\alpha\beta} = -\frac{1}{2} \partial_\beta (\partial_\alpha A_\beta - \partial_\beta A_\alpha)$$

with respect to $A_\alpha$. Thus the scale and conformal transformations act on $A_\alpha$. (For a different approach in $D = 3$, see section 1.2.3.)

For dilations we adopt the following transformation laws, according to (3) and (4),

$$\delta_S A_\alpha(x) = \left( x^\tau \partial_\tau + D - \frac{2}{2} \right) A_\alpha(x)$$

$$\delta_S F_{\alpha\beta}(x) = \left( x^\tau \partial_\tau + D \frac{2}{2} \right) F_{\alpha\beta}(x),$$

which leave the action invariant,

$$\delta L = \partial_\mu (x^\mu L).$$ \hspace{1cm} (21)

Thus dilations are symmetries of the free Maxwell theory. A conserved dilation current is constructed by Noether’s theorem and an ‘improvement’,

$$j_S^\mu = \frac{\partial L}{\partial \partial_\mu A_\alpha} \delta_S A_\alpha - x^\mu L$$

$$= -F^{\alpha\beta} \left( x^\beta F_{\beta\alpha} + x^\beta \partial_\alpha A_\beta + D - \frac{2}{2} A_\alpha \right) - x^\mu L$$

$$= \theta^\alpha_{\alpha} x^\alpha + \frac{4 - D}{2} F^{\alpha\beta} A_\alpha + \partial_\alpha (F^{\alpha\beta} x^\beta A_\beta).$$ \hspace{1cm} (22)

To arrive at the last line, we use definition (15) for $\theta^{\mu\nu}$ and the equation of motion (13). We recognize that the current (22) may be improved by dropping the last term in (22), because it is a divergence of an anti-symmetric tensor, and hence trivially conserved. Thus we arrive at the final form for the scale current in $D$-dimensional free Maxwell theory,

$$J_S^\mu(x) = \theta^\alpha_{\alpha}(x) x^\alpha + \frac{4 - D}{2} F^{\alpha\beta}(x) A_\alpha(x).$$ \hspace{1cm} (23)

That $J_S^\mu(x)$ is conserved follows from (15) and (16).
Several noteworthy features characterize the scale current. First, $J_\mu^S$ is gauge variant,

$$A_\alpha \rightarrow A_\alpha + \delta_\alpha \Omega \Rightarrow J_\mu^S \rightarrow J_\mu^S + \frac{4-D}{2} F^{\mu\sigma} \delta_\alpha \Omega$$

$$= J_\mu^S + \left( \frac{4-D}{2} F^{\mu\sigma} \Omega \right). \quad (24)$$

But the gauge change introduces a trivially conserved term, which will not affect the dilation charge (provided surface terms are irrelevant),

$$Q_S \rightarrow Q_S + \int d^{D-1} x \left[ \frac{4-D}{2} F^{0\mu} \Omega \right] = Q_S. \quad (25)$$

Second, the $D \neq 4$ scale current involves terms additional to the energy–momentum tensor, which are needed when $\theta_\mu^\mu$ fails to vanish. Indeed, as will be seen presently, the last term in $J_\mu^S$ is precisely the Maxwell theory field virial. That $\theta_\mu^\mu$ is non-vanishing and that the field virial is not a total divergence indicates that conformal symmetry is absent in the above, vector-potential formulated, Maxwell theory.

The conformal transformation (5) when specialized to a vector potential, as a primary field $\Phi_1 \rightarrow A_\mu$, reads

$$\delta^C_\sigma A_\sigma(x) = (2x^\nu x^\nu - g^{\sigma \nu} x^2) \partial_\nu A_\sigma(x) + (D-2)x^\sigma A_\sigma(x) - 2x_\sigma A^\sigma(x) + 2g_\sigma^\mu x^\mu F_\nu(x). \quad (26)$$

For the field strength $F_{\alpha \beta}$ (26) implies

$$\delta^C_\sigma F_{\alpha \beta}(x) = (2x^\sigma x^\tau - g^{\sigma \tau} x^2) \partial_\tau F_{\alpha \beta}(x) + D x^\sigma F_{\sigma \beta}(x) + 2g_\sigma^\mu x^\mu F_{\alpha \tau}(x) + 2g_\sigma^\mu x^\mu F_{\beta \tau}(x) - 2x_\sigma F_{\alpha \beta}(x) - 2x_\alpha F_{\beta \sigma}(x) + (D-4)(g_\sigma^\alpha A_\beta(x) - g_\beta^\alpha A_\sigma(x)). \quad (27)$$

Because $F_{\alpha \beta}$ involves derivatives of the primary field $A_\alpha$, the transformation rule (27) describes a non-primary field for $D \neq 4$. If $F_{\alpha \beta}$ were primary, it would transform, according to (5) with $\Phi_1 \rightarrow F_{\alpha \beta}$, as

$$\Delta^C_\sigma F_{\alpha \beta} = (2x^\nu x^\nu - g^{\sigma \nu} x^2) \partial_\nu F_{\alpha \beta} + D x^\sigma F_{\sigma \beta} + 2g_\sigma^\mu x^\mu F_{\alpha \tau}(x) + 2g_\sigma^\mu x^\mu F_{\beta \tau}(x) - 2x_\sigma F_{\alpha \beta}(x) - 2x_\alpha F_{\beta \sigma}(x). \quad (28)$$

Evidently

$$\delta^C_\sigma F_{\alpha \beta} = \Delta^C_\sigma F_{\alpha \beta} + (D-4)(g_\sigma^\alpha A_\beta - g_\beta^\alpha A_\sigma). \quad (29)$$

The transformation rule (27) implies that the Lagrange density (18) changes as

$$\delta^C_\sigma L = \partial_\sigma [(2x^\nu x^\nu - g^{\nu \mu} x^2) L] + (4-D) F^{\sigma \tau} A_\tau. \quad (30)$$

The last contribution shows that the action is not invariant at $D \neq 4$. The same conclusion is reached from the field virial, which here reads

$$V^\alpha = \frac{4-D}{2} F^{\alpha \beta} A_\beta$$

—an expression which we have seen previously forming part of the scale current (23). Since $V^\alpha \neq \partial_\beta \sigma A^\alpha$, conformal symmetry is absent for $D \neq 4$.

One may ask whether the conformal transformation leaves invariant the equations of motion, even though the action is not invariant. For this to be true $\partial_\alpha \delta^C_\sigma F^{\alpha \beta}$ must vanish. But it does not; from (25) we have

$$\partial_\alpha \delta^C_\sigma F^{\alpha \beta} = (D-4)(\partial^\beta A^\sigma - g^{\beta \sigma} \partial_\tau A^\tau) \neq 0. \quad (32)$$

(A curious observation is that if we adopt for $F_{\alpha \beta}$ (without justification) the primary field transformation rule $\Delta^C_\sigma F_{\alpha \beta}$ in (28), then

$$\Delta^C_\sigma L = \partial_\sigma [(2x^\nu x^\nu - g^{\nu \mu} x^2) L] \quad (33)$$

5
and the action is invariant. But this does not lead to a conserved current, because $\nabla^\mu F_{\mu\nu}$ cannot be obtained from a transformation on a vector potential, the fundamental variable, whose variation leads to the equation of motion (13). In other words, $\nabla^\mu F_{\mu\nu}$ does not respect the equation of motion nor the Bianchi identity.)

Note that the Poincaré and dilation currents can be presented as

$$J_\mu = \theta_\mu A_\mu + \frac{4 - D}{2D} \partial_\mu f^\alpha F^{\alpha\beta} A_\beta,$$  \hspace{1cm} (34)

where $f^\mu$ is the coordinate transformation, defined in (9). The divergence of (34) reads

$$\partial_\mu J_\mu = \theta_\mu \partial_\alpha f^\alpha + \frac{4 - D}{4D} \partial_\alpha f^\alpha F^{\alpha\beta} F_{\mu\beta} + \frac{4 - D}{2D} \partial_\alpha \partial_\beta f^\alpha F^{\alpha\beta} A_\beta,$$  \hspace{1cm} (35)

where the Killing equation (11) and the field equation (13) are used. The first two terms on the right-hand side of (35) cancel; in the last term $\partial_\mu \partial_\beta f^{\alpha}$ vanishes for Poincaré and scale transformations. But for conformal translations $\partial_\mu \partial_\beta f^{\alpha} = 2Dc_\mu$ and $J_\mu = (4 - D)c_\mu F^{\mu\beta} A_\beta$ in agreement with (30). Thus we may consider (34) as a generalization of the Bessel–Hagen formula, producing conserved Poincaré and scale currents and a non-conserved conformal current when $D \neq 4$.

One further observation on the response of a vector field to the transformations (9) is that the infinitesimal change of $A_\alpha$ does not coincide with the Lie derivative when $D \neq 4$. Rather we have

$$\delta f A_\mu = L_f A_\mu + \frac{D - 4}{2D} \partial_\mu f^\alpha A_\alpha,$$  \hspace{1cm} (36)

where

$$L_f A_\mu = f^\alpha \partial_\alpha A_\mu + \partial_\mu f^\alpha A_\mu.$$  \hspace{1cm} (37)

$\partial_\mu f^\alpha$ vanishes for Poincaré transformations, but survives for scale and conformal transformations, and moves the transformation law away from the Lie derivative, thereby assigning to $A_\mu$ the scale dimension $\frac{D - 2}{2}$. In contrast, geometric arguments would assign a unit scale dimension to a vector potential, which naturally belongs with the unit-dimensional derivative. Also when $\partial_\mu f^\alpha \neq 0$ and $D \neq 4$ the transformation law (36) interferes with gauge covariance: one expects $\delta f A_\mu$ to be gauge invariant up to a gauge transformation. The Lie derivative (37) preserves this requirement, because it may be presented as

$$L_f A_\mu = f^\alpha F_{\mu\alpha} + \partial_\alpha (f^\mu A_\mu).$$  \hspace{1cm} (38)

But the term in $\delta f A_\mu$ beyond $L_f A_\mu$ is gauge non-invariant.

1.2.3. Secret conformal symmetry of $D = 3$ Maxwell theory. We have seen that conformal symmetry is incompatible with a vector potential formulation of Maxwell theory in $D \neq 4$. But in $D = 3$, a scalar potential formulation is available and conformal invariance can be implemented. To achieve an action/Lagrangian formulation of the free Maxwell theory, we may present in $D = 3$ the anti-symmetric $F_{\alpha\beta}$ as

$$F_{\alpha\beta} = \varepsilon_{\alpha\beta\mu} \partial^\mu \varphi,$$  \hspace{1cm} (39a)

$$\partial^\mu \varphi = \frac{1}{2} \varepsilon^{\mu\alpha\beta} F_{\alpha\beta}.$$  \hspace{1cm} (39b)

Now $\varphi$ is the fundamental dynamical variable, and it describes the single ‘photon’ degree of freedom in $D = 3$, without the redundancy of a vector potential.

The Maxwell field equation (13) becomes the identity $\varepsilon_{\alpha\beta\mu} \partial^\beta \partial^\alpha \varphi = 0$, while the Maxwell Bianchi identity becomes the free field equation for $\varphi$.

$$\Box \varphi = \frac{1}{2} \partial_\mu \varepsilon^{\mu\alpha\beta} F_{\alpha\beta} = 0.$$  \hspace{1cm} (40)
Such an interchange is characteristic of a dual relation. (In a Euclidean formulation this is analogous to presenting a source-free, three-dimensional magnetic field in terms of a magnetic scalar potential.)

The Lagrange density now reads
\[ L = -\frac{1}{4} F^{\alpha\beta} F_{\alpha\beta} = -\frac{1}{2} \partial^\mu \varphi \partial_\mu \varphi \] (41)
and the dynamics enjoyed by \( \varphi \) leads to the conventional, conserved and symmetric energy–momentum tensor
\[ \theta^{\mu \nu} = \partial^\mu \varphi \partial^\nu \varphi - \frac{1}{2} g^{\mu \alpha} \partial^\alpha \varphi \partial_\nu \varphi \] (42)
which may be improved, so it is traceless,
\[ \theta^{CCJ \mu \nu} = \theta^{\mu \nu} + \frac{1}{8} (g^{\mu \nu} \Box - \partial^\mu \partial^\nu) \varphi^2 \]
\[ g_{\mu \nu} \theta^{CCJ \mu \nu} = 0. \] (43)
The scale transformation on \( \varphi \) follows (3) and (4) (with \( D = 3 \))
\[ \delta_S \varphi(x) = \left( x^\tau \partial_\tau + \frac{1}{2} \right) \varphi(x) \] (44)
while the conformal transformation reads from (5)
\[ \delta^{C \sigma} \varphi(x) = (2x^\sigma x^\tau - g^{\sigma \tau} x^2) \partial_\tau \varphi(x) + x^\sigma \varphi(x). \] (45)
Equation (45) now determines the conformal transformation rule for the field strength (39a)
\[ \delta^{C \sigma} F_{\alpha\beta}(x) = \left( 2x^\sigma x^\tau - g^{\sigma \tau} x^2 \right) \partial_\tau F_{\alpha\beta}(x) + 3x^\sigma F_{\alpha\beta}(x) + 2 \delta^{\sigma}_{\alpha} x^\tau F_{\beta}(x) \]
\[ + 2 \delta^{\sigma}_{\beta} x^\tau F_{\alpha}(x) - 2 x_\alpha F^{\sigma}_{\beta}(x) - 2 x_\beta F^{\sigma}_{\alpha}(x) + \varepsilon^{\sigma \alpha \beta} \varphi(x). \] (46)
The overbar on \( \delta^{C \sigma} \) distinguishes the present scalar potential-based transformation on \( F_{\alpha\beta} \) from the earlier vector potential-based formula (27). According to the new transformation law (46), \( F_{\alpha\beta} \) remains non-primary, since \( \varphi \) enters the transformation. The present analog to (29) is
\[ \delta^{C \sigma} F_{\alpha\beta} = \Delta^\sigma F_{\alpha\beta} + \varepsilon^{\sigma \alpha \beta} \varphi. \] (47)
The action is invariant,
\[ \delta^{C \sigma} L = \partial_\tau \left( (2x^\sigma x^\tau - g^{\sigma \tau} x^2) L - g^{\sigma \tau} \varphi^2 \right)/2. \] (48)
The conformal symmetry current is constructed in the usual way from the improved, traceless energy–momentum tensor (43) [4], which can be presented by virtue of (39) in terms of \( F_{\alpha\beta} \) as
\[ \theta^{CCJ \mu \nu} = -\frac{3}{4} F^{\mu \alpha} F_{\nu}^\alpha + \frac{1}{4} \delta^{\mu \nu} F^{\alpha \beta} F_{\alpha \beta} - \frac{\varphi}{16} (\partial^\mu \varepsilon^{\nu \alpha \beta} F_{\nu \alpha \beta} + \partial^\nu \varepsilon^{\mu \alpha \beta} F_{\nu \alpha \beta}). \] (49)
Note that the dependence on \( \varphi \) remains.

A comparison of the vector potential-based formulation with the scalar-based one indicates that there is a non-local relation between \( A_\mu \) and \( \varphi \), which implements the duality
\[ \varepsilon^{\mu \alpha \beta} \partial_\alpha A_\beta \geq \partial^\mu \varphi \] (50)
Whether conformally symmetric dual formulations for the free Maxwell theory exist in other dimensions remains an open question. So a conformally invariant potential formulation for Maxwell theory at \( D > 4 \) remains unknown.
2. Dimensional reduction of the conformal group

The second topic that we address concerns the universality across dimensions of scale/conformal transformations/invariances. We consider an \( N \)-component multiplet of scalar fields \( \Phi_i \) with interactions that preserve scale and conformal symmetries (see (12))

\[
\mathcal{L} = \frac{1}{2} \partial_\mu \Phi \cdot \partial^\mu \Phi - \lambda (\Phi \cdot \Phi)^{D-2} - \Phi (x) \\
\delta_S \Phi(x) = x^\tau \partial_\tau \Phi(x) + \frac{D-2}{2} \Phi(x) \\
\delta_C \Phi(x) = (2x^\sigma x^\tau - g^{\alpha \tau} x^2) \partial_\alpha \Phi(x) + (D-2)x^\sigma \Phi(x).
\]

As stated earlier, the ISO \((D-1, 1)\) Poincaré invariance is enlarged to the \( SO(D, 2) \) conformal group, and formulas (51)–(53) hold for arbitrary \( D > 2 \). The independent variable \( x^\mu \) describes time at \( \mu = 0 \) and there are \( D-1 \) spatial coordinates \( x \). \( D = 2 \) does not fit the above scheme\(^1\), but let us continue to \( D = 1 \). There the spatial coordinates disappear and the ‘field’ \( \Phi \) becomes an \( N \)-component quantity—we shall rename it \( q \)—which depends on the surviving variable \( t \). The Lagrange density (51) at \( D = 1 \) reduces to

\[
L = \frac{1}{2} \frac{d}{dt} q \cdot \frac{d}{dt} q - \lambda / q^2.
\]

The Poincaré transformations contract to time translations generated by the Hamiltonian \( H \)—the only Poincaré generator that survives in the \( D = 1 \) limit. The reduced scale transformation (52) reads

\[
\delta_S q(t) = t \partial_t q(t) - \frac{1}{2} q(t).
\]

Only a single conformal transformation remains from (53)

\[
\delta_C q(t) = t^2 \partial_t q(t) - t \quad q(t).
\]

We now recognize (54)–(56) as a non-relativistic energy-conserving system in \( N \) spatial dimensions, enjoying the most general velocity-independent scale and conformal symmetries [7]. It is amusing that such mundane mechanics can be attained as a limit of a relativistic, conformally invariant quantum field theory.

Acknowledgments

We thank S Deser and M Shifman for discussions about the dual formulation of the \( D = 3 \) Maxwell theory. This work is supported by the US Department of Energy (DoE) under the cooperative research agreement DE-FG02-05ER41360.
