ERp29 regulates TNT formation

The chaperone ERp29 is required for tunneling nanotube formation by stabilizing MSec

Key words: Tunneling nanotubes, intercellular communication, MSec, Endoplasmic Reticulum (ER), chaperone, endoplasmic reticulum protein 29 (ERp29), protein disulfide isomerase (PDI), TNF alpha induced protein 2 (TNAIP2), interactome, post-translational regulation.

Abstract
Tunneling NanoTubes (TNTs) are membrane conduits that mediate long-distance intercellular crosstalk in several organisms and play vital roles during development, pathogenic transmission, and cancer metastasis. However, the molecular mechanisms of TNT formation and function remain poorly understood. The protein MSec (also known as TNFα-induced protein 2 [TNAIP2] and B94) is essential for TNT formation in multiple cell types. Here, using affinity protein purification, mass spectrometric identification, and confocal immunofluorescence microscopy assays, we found that MSec interacts with the endoplasmic reticulum (ER) chaperone ERp29. siRNA-mediated ERp29 depletion in mammalian cells significantly reduces TNT formation, whereas its overexpression induces TNT formation, but in a strictly MSec-dependent manner. ERp29 stabilized MSec protein levels, but not its mRNA levels, and the chaperone activity of ERp29 was required for maintaining MSec protein stability. Subcellular ER fractionation and subsequent limited proteolytic treatment suggested that MSec is associated with the outer surface of the ER. The ERp29-MSec interaction appeared to require the presence of other bridging protein(s), perhaps triggered by post-translational modification of ERp29. Our study implicates MSec as a target of ERp29 and reveals an indispensable role for the ER in TNT formation, suggesting new modalities for regulating TNT numbers in cells and tissues.

Introduction
Eukaryotic cells communicate by several means depending on organism and cell type. Intracellular communication plays an important role in the physiological processes of multi-cellular organisms. Diverse signaling pathways have been documented for the exchange of molecular information between cells, including direct interaction (1,2), gap junctions (3,4), extracellular vesicles including exosomes (5,6) and plasmodesmata (7). A novel mechanism for intercellular communication named Tunneling NanoTubes (TNTs) was recently discovered in several organisms and cell types (8,9). TNTs constitute a diverse variety of long, membrane-enclosed, tubular cytoplasmic conduits that connect eukaryotic cells several hundred
ERp29 regulates TNT formation

micrometers apart (8,10,11) and mediate a wide spectrum of critical cellular functions. These include ion signaling (12), antigen presentation (13), intercellular organelle transfer (14), morphogen transfer during development (15,16), astrocyte-neuron communication (17), metastatic cell homing (18), intercellular viral transmission (19-21), prion protein transfer (22) and bacterial surfing between cells (10). TNTs are also induced in response to cellular stress (23,24). TNTs are usually open at both ends with a propensity to “hang” between the connected cells above the substratum in culture and use distinct actin-regulators for their formation (25-27) which are some of the properties that distinguish them from other similar cellular extensions like filopodia and cytonemes (in Drosophila), even though they are morphologically similar. TNTs thus represent a novel mode of intercellular communication across various in vitro and in vivo systems that are rapidly gaining widespread importance in biology (15,16,28-35).

Despite their demonstrated importance in health and disease as exemplified above, there is little mechanistic understanding of the formation, growth, maintenance and function of TNTs. Several questions of importance remain unanswered: which proteins regulate TNT formation? What are the reliable biochemical markers for TNTs? What is the order, strength, and nature of interactions between these proteins? What is the mechanism of membrane addition in elongating TNTs? Are these molecules and mechanisms conserved across evolution? Recently, the protein MSec (also called TNFAIP2/B94) was reported to be essential for TNT formation (36,37). MSec interacts with a few key proteins that help mediate TNT formation, including the Exocyst complex, the small GTPase RalA and LST1 in macrophages (36,38). The GTPase activity of RalA is required for TNT formation through the engagement of the Exocyst complex, which is a known effector of RalA (36). RalA-Exocyst is known to induce membrane addition in other contexts such as epithelial membrane trafficking and anchorage independent growth signaling (39,40). It is therefore likely that other protein(s) such as MSec may recruit the RalA-Exocyst complex specifically at sites of TNT formation on the plasma membrane. Given the wide spectrum of functions performed by TNTs in a variety of cell lines and organisms (41), it is likely that a larger set of cellular proteins interacts with MSec to assist it in TNT formation and possibly to enable TNTs to function as transport conduits. In an effort to understand the molecular mechanisms of TNT formation, we determined the cellular interactome of MSec from a human osteosarcoma cell line (U2OS) by mass spectrometric analysis. Here, we characterize the function and mechanism of one of the novel interactors of MSec, the endoplasmic reticulum (ER)-based chaperone ERp29 and demonstrated that it is required for the induction of TNT formation. ERp29 is a 29 kD ER-resident protein and is well studied as an unconventional chaperone of the Protein Disulfide Isomerase (PDI) family that binds with, stabilizes and escorts various protein substrates (42-45). In this study we show that ERp29 regulates TNT formation through stabilization of MSec and thus reveal a new role for the ER in TNT induction. Our study suggests that the underlying mechanisms of TNT formation span a wider molecular spectrum than so far anticipated.

Results

Stably expressing TAP-tagged MSec induces TNT formation in U2OS cells

Earlier studies have demonstrated that MSec is required for TNT formation (41). Depletion of MSec from cells leads to a reduction in TNT numbers, while overexpression leads to increased TNT numbers (36). Given the importance of MSec-induced TNTs across a diverse functional spectrum, we hypothesized that MSec interacts with a larger set of cellular proteins to mediate TNT formation than is currently known. In order to identify new interaction partners of MSec, we generated a mammalian U2OS cell line (human osteosarcoma origin) stably expressing MSec fused with a multifunctional tag containing a C-terminal Yellow Fluorescent Protein (YFP) tag with an embedded Tandem Affinity Purification (TAP) tag consisting of octa-His, FLAG and Streptavidin Binding Peptide (SBP) biochemical tags (mVenus-MTAP, (46) that has been used successfully for interactomic as well as imaging studies in human cells. Mouse MSec (mMSec, residues 42-691, kind gift from H. Ohno, (36)
ERp29 regulates TNT formation

cDNA was cloned into this vector to generate MSec-MTAP (Fig. 1A, supplementary table S1). This fragment of mouse MSec can complement the loss of human MSec and can efficiently induce TNT formation (36). We determined the expression levels of both endogenous MSec and transgenic MSec-MTAP by Western blotting with an antibody that recognizes MSec, and chose a clonally selected cell line (clone-1) that stably expressed the empty MTAP (eMTAP) vector as a negative control (fig. 1B, right bottom panel). The tagged MSec-MTAP protein induced TNTs significantly as reported earlier for MSec with other tags (36,37) in comparison to the tag (empty vector) alone (fig. 1C, 1D), demonstrating that the transgenic MSec-MTAP construct was functional in respect of its ability to induce TNT formation.

We performed a series of standard assays in order to validate that the tubes under study were indeed TNTs. First, we established through x-z/y-z visualization of confocal z-stacks that the tubes counted in both cell lines (MSec-MTAP and eMTAP) did not contact the substratum, but rather “hung” between the two connected cells (fig. 1C, and supplementary fig. S2), a well-documented characteristic of bonafide TNTs (26,36). In order to ascertain the function of these tubes, we performed live cell, time-lapse confocal imaging to visualize the transport of mitochondria (labelled with Mitotracker red), a well-known cargo transported through TNTs (47,48). We could clearly observe the transport of mitochondria from one cell to another in both stable cell lines (fig. 1E, supplementary movies 1 and 2). Another well-documented cargo of TNTs is the HIV-1 virus (21). We infected U2OS cells with HIV-1 (JRFL envelope pseudo-typed virus) and immunostained for the virus using an established antibody (49). We could clearly observe HIV-1 immunofluorescence in TNTs emanating from infected cells, but not in TNTs arising from uninfected cells (supplementary fig. S3A). Y-z projection clearly showed the TNTs “hanging” between the two cell bodies with the HIV-1 signal appearing to transfer from the infected towards the uninfected cell through the TNT (supplementary fig. S3A, box). In addition, TNT formation in U2OS cells was reduced significantly among cells treated with a validated TNT-inhibitor (supplementary fig. S3B, C; (21)). Together, the above experiments confirmed the identity of these tubes in our study as TNTs.

**ERp29 is a Novel Interactor of MSec**

We used MSec-MTAP as the bait to identify its cellular interactome using methods adapted from earlier reports that have successfully used such multifunctional tags for interactomic analyses (46,50-54). We lysed the U2OS cells stably expressing either MSec-MTAP or the MTAP tag alone under cryogenic conditions to help preserve the integrity of protein-protein interactions and subjected cell lysates to Streptavidin Binding Peptide (SBP) affinity purification on a Streptactin column. We analyzed trypsinized eluates by Electrospray Ionization-Liquid Chromatography Mass Spectrometry (ESI-LC-MS, supplementary fig. S4A) and evaluated the MS data with optimal search parameters (Materials and Methods) for the identification of the MSec interactome. The interactome obtained using the control tag (eMTAP) was subtracted from the MSec-MTAP interactome (supplementary fig. S4B). Analysis of the unique interactome of MSec appearing in at least three experiments (supplementary table S2, supplementary fig. S4C) with the help of the STRING (www.string-db.org) and PANTHER (www.pantherdb.org) databases revealed that the interactors grouped into various functional classes (supplementary fig. S4D, supplementary tables S3, S4), suggesting that MSec has a broad crosstalk with various functional pathways in the cell. One of the interacting proteins of MSec that appeared consistently and specifically only in the MSec-MTAP experiments was the endoplasmic reticulum chaperone ERp29, belonging to the class of unconventional protein chaperones belonging to the Protein Disulfide Isomerase (PDI)-like family (42,55). We confirmed the specificity of the interaction of ERp29 with MSec by immunoprecipitation, which validated that ERp29 interacted specifically with MSec-MTAP, but not with the empty vector (fig. 2A). ERp29 is well known as a marker for the endoplasmic reticulum (ER) and is hence highly enriched in this compartment at the perinuclear region.
ERp29 regulates TNT formation

We observed strong ER enrichment of MSec in U2OS cells as well as prominent co-localization with ERp29 at the perinuclear boundary through confocal microscopy (fig. 2B), suggesting that MSec is associated with the ER. This data is supported by distinct ER-like localization of MSec-MTAP as well (supplementary fig. S3B, lower panel). In order to biochemically ascertain whether MSec localized with the ER, we performed subcellular fractionation of cell lysates and isolated the rough ER (as explained in the Materials and Methods). Western blot analysis confirmed that MSec was present in the rough ER fraction in U2OS cells, MSec-MTAP-U2OS cells, HeLa cells and MDA-MB-231 cells (fig. 2C, supplementary fig. S5). These observations suggested that a substantial fraction of cellular MSec is associated strongly with the ER in multiple human cell types.

ERp29 is required for TNT formation

In order to probe whether ERp29 plays a functional role in TNT formation, we depleted it from U2OS cells using sequence-specific siRNAs. We confirmed depletion of protein levels using Western blotting (supplementary fig. S6). Confocal microscopic analysis revealed that ERp29 depletion led to a significant loss in the number of TNTs formed by these cells (fig. 3A, B). Conditions such as serum deprivation, oxidative stress, pH changes and nutrient shortage are known to induce the formation of TNTs (23,24,57-59), although the detailed cellular mechanisms have not been elucidated. We assessed whether ERp29 was required for induction of TNTs when cells were subjected to stress due to serum starvation. Control siRNA treated cells cultured under stress conditions (2.5% serum, low-serum) induced more TNTs as compared to the optimal serum levels (10% serum). However, while serum starvation induced a marked increase in TNT numbers in control siRNA treated cells, they failed to elicit this response upon either ERp29 depletion or MSec depletion (fig. 3A, B). Notably, we observed similar reduction in TNT numbers upon ERp29 depletion as seen for MSec depletion. Similarly, we repeated this experiment in HeLa cells, which also showed a significant reduction in their ability to form TNTs upon the depletion of ERp29 (supplementary fig. S7).

ERp29 influences TNT formation through its action on MSec

The above data clearly demonstrated that ERp29 was required for TNT formation. As a corollary, we tested whether ERp29 over-expression could induce the formation of a higher number of TNTs. We therefore transfected an exogenous ERp29 construct (EGFP-ERp29, (43)) into U2OS cells and compared the ability of the cells to induce TNT formation in comparison to cells transfected with a vector expressing EGFP alone. Confocal imaging of the cells followed by quantification showed that exogenous expression of ERp29 in U2OS cells led to a significant (almost 2-fold) increase in the number of TNTs formed per cell in comparison to cells treated with the empty vector alone (fig. 4A top panel, 4B). This result confirmed that the ability of the cells to form TNTs was directly proportional to the cellular expression levels of ERp29. We also asked whether exogenous expression of ERp29 could induce TNT formation even in the absence of MSec. To test this, we depleted MSec in U2OS cells using siRNA treatment and simultaneously over-expressed exogenous ERp29 (fig. 4C). Despite robust expression of the exogenous ERp29 (fig. 4C), induction of TNTs was dramatically reduced upon depletion of MSec (fig. 4A bottom panel, 4B, 4C). This observation suggested that ERp29 could induce TNTs only in the presence of MSec in the cell. We performed live cell, time-lapse confocal microscopy in eMTAP cells and observed that most of the TNTs formed were through the dislodgement of adjacent cells in culture, a mode of TNT formation already documented (27). ERp29 depleted cells appeared to move apart to shorter distances than the control cells, leading to the formation of shorter TNTs on average (supplementary fig. S8A). This effect could be due to the direct effect of ERp29 on MSec, which has been shown to have a role in cell migration (60). We observed that ERp29 depletion led to a reduction in the overall lifetime of TNTs (supplementary fig. S8B), suggesting that ERp29 may modulate TNT stability. We also measured the rate of elongation of growing TNTs, which did not show any measurable differences between
ERp29 regulates TNT formation

the control and ERp29 depleted cells (supplementary fig. S8C). These results together suggested that ERp29 may not be required for the elongation of growing TNTs, but may instead be needed for stabilizing already formed TNTs, in addition to its effect on TNT initiation. Further detailed investigation would be needed to build upon these observations on the precise role of ERp29 in regulating TNT stability.

ERp29 stabilizes MSec protein but not its mRNA
ERp29 is reported as a predominantly ER-resident protein and is an atypical chaperone that stabilizes and escorts various protein substrates. These include, integral plasma membrane proteins like connexin 43, e-cadherin, occludin, cystic fibrosis transmembrane receptor (CFTR) and epithelial sodium channel (ENaC) and secreted proteins like thyroglobulin (43,44,61,62). A third major class of ERp29 substrates are localized at the cortex in the cytosol, e.g. beta-catenin, par3, scribble and zona occludens 1 (ZO1) (61). ERp29 shares structural similarity with the PDI family of chaperones. However, it lacks the cysteine-binding residues common to PDIs and also does not have the ability to hydrolyze ATP, a common feature of several cellular chaperones, due to which it is named an unconventional PDI-like chaperone (63,64). The mode of action of ERp29 appears to be to bind, stabilize and escort its substrates to the correct destinations in the cell. Given that the effect of ERp29 on TNT formation was dependent on the presence of MSec (fig. 4), we checked whether the levels of MSec were reduced upon ERp29 depletion in U2OS cells. Western blot analysis following siRNA treatment revealed that the levels of MSec protein in cell lysates reduced considerably upon ERp29 depletion, almost mimicking siRNA-mediated depletion of MSec itself (fig. 5A, 5B). However, the converse was not true; depletion of MSec did not change the protein levels of ERp29 (fig. 5A), indicating that the loss of ERp29 could be de-stabilizing MSec but not vice versa.

In order to test whether the reduction of MSec protein levels was due to transcriptional downregulation or due to regulation at the level of translation, we quantified the mRNA levels of both genes upon depletion of the other using RT-qPCR. Both MSec and ERp29 mRNA levels remained essentially unchanged upon siRNA-mediated depletion of the other mRNA using sequence-specific siRNAs (fig. 5C), indicating that loss of ERp29 protein led only to reduced MSec protein levels. We tested whether loss of ERp29 could also impact the stabilization of other MSec-associated proteins required for TNT formation, namely subunits of the Exocyst complex and the small GTPase RalA (36). We depleted ERp29 in U2OS cells and checked the protein levels of RalA and Exocyst complex components Exoc2 (Sec5), Exoc3 (Sec6) and Exoc4 (Sec8). Western blot analysis revealed that depletion of ERp29 did not affect the protein stability of RalA and Exocyst complex (supplementary fig. S8). Conversely, we also tested whether increased expression of ERp29 would stabilize MSec and increase its cellular mRNA or protein levels. Indeed, exogenous expression of EGFP-ERp29 elevated the protein levels of endogenous MSec significantly while not affecting the endogenous ERp29 levels (fig. 5D, 5E). RT-qPCR analysis revealed that over-expression of EGFP-ERp29 did not enhance the mRNA expression of MSec (fig. 5F), demonstrating that the higher levels of MSec observed were not due to transcriptional upregulation. ERp29 has been reported to bind to protein substrates through its C-terminal domain (43,55,65). We therefore tested whether an ERp29 construct with a truncated C-terminus (EGFP-ERp29-NTD, residues 33 to 153, (43)) could also stabilize MSec in a manner similar to full length ERp29. We observed that over-expression of EGFP-ERp29-NTD failed to lead to an increase in MSec protein levels (fig. 5D). Taken together, the above results suggest that ERp29 stabilized the MSec protein while not impacting its transcription, and that the C-terminal domain of ERp29 was important for this function.

The chaperone function of ERp29 is required for TNT formation
ERp29 has been well studied as an unconventional chaperone that binds with and stabilizes various protein substrates (42-45). We therefore predicted that the chaperone function of ERp29 may be required for it to stabilize MSec. While the C-terminal domain of ERp29 is
ERp29 regulates TNT formation

required for stabilizing the MSec protein, several amino acid residues within the N-terminal domain have been implicated in its chaperone-like activity or in stabilization of the ERp29 protein itself (43,65,66). Mutations at these residues are known to abrogate or reduce the chaperone activity and/or stability of ERp29 (45,62,65). We generated individual site-directed mutants of ERp29 at these various conserved residues (chaperone mutants D61A, Y64S, Y66K, Y96Q, P116D and a de-stabilizing mutant C157S, fig. 6A) in a mammalian expression vector with an N-terminal EGFP tag. The mutated fusion constructs when transfected individually in U2OS cells expressed and localized to the perinuclear region like the native wild type construct (ERp29 FL), indicative of normal ER localization (fig. 6B). We performed an analysis of the number of TNTs formed upon expression of each of these constructs. Expression of the wild type EGFP-ERp29 led to a marked increase in the ability of cells to induce TNTs (fig. 6B, 6C, fig. 4). In comparison, none of the mutants was able to induce any appreciable increase in the number of TNTs over control EGFP (vector only) transfected cells (fig. 6B, 6C) despite the proteins being expressed (fig. 6B, 6D) for most of the mutants. Closer analysis revealed that the protein levels of the D61A, Y64S, and Y66K mutants of ERp29 appeared to be lower than the wild type and the other mutants (data not shown). These mutants of ERp29 have been shown earlier to co-degrade with their substrates through the proteasome (45). To test this possibility, we treated cells with the proteasome inhibitor MG132 and observed that the expression levels of these three mutants were restored to levels similar to the wild type ERp29 and its other mutants (data not shown). We tested whether the chaperone mutants were capable of stabilizing endogenous MSec protein levels the way full length ERp29 could (fig. 5), by assessing the levels of MSec expression by Western blotting. None of the chaperone mutants was able to stabilize MSec protein levels over control (EGFP vector alone) levels, suggesting that their chaperone activity was abolished (fig. 6D). These results together confirmed that the chaperone activity of ERp29 was required for induction of TNT formation through the stabilization of the MSec protein.

Characterization of the ERp29-MSec interaction

The strong binding of ERp29 to MSec (fig. 2A), its ability to stabilize MSec levels (fig. 5) and its requirement for TNT formation (fig. 6) prompted us to characterize its physical interaction with MSec. To examine whether ERp29 interacts with MSec directly, we purified hexa-histidine tagged MSec (His-MSec in the pET28a vector), glutathione-S-transferase tagged MSec (GST-MSec) and GST-tagged ERp29 (GST-ERp29) as recombinant proteins as well as GST alone as control (fig. 7A). We first ascertained whether the bacterially purified recombinant proteins would directly bind to each other. Surprisingly, purified MSec did not bind to GST-ERp29 with any higher efficiency than to the GST tag alone (fig. 7B), precluding a direct interaction between the two proteins. We reasoned that the apparent absence of any detectable interaction could be due to the need for post-translational modification(s) (PTMs) on either or both proteins, which is absent during bacterial expression. In order to test whether PTMs on MSec could be important for this interaction, we passed U2OS cell lysates on beads that had GST-ERp29 immobilized. We again found that the MSec from cell lysates did not bind to GST-ERp29 (fig. 7B). We therefore tested the opposite possibility, namely whether purified GST-MSec immobilized on beads could capture ERp29 from U2OS cell lysates. Indeed, we found that ERp29 from cell lysates could bind to bacterially purified GST-MSec, whereas the GST tag alone could not (fig. 7C). This result suggested that post-translational modification(s) of ERp29 is likely to be required for its interaction with MSec. It also left open the possibility of one or more additional proteins assisting the MSec-ERp29 interaction, perhaps triggered by the initial PTM(s) on ERp29. However, the exact identities of the PTM(s) and of any other potential protein(s) remain to be identified.

MSec is strongly associated with the ER fraction (fig. 2; supplementary fig. S3B lower panel and fig. S5). However, MSec is reported as a predominantly cytosolic protein in the literature (21,36,37,67), while ERp29 is believed to be mainly localized to the ER lumen (42,56,68). We therefore asked whether the ERp29-MSec interaction occurs in the ER lumen or in the...

ERp29 regulates TNT formation

cytosol, or whether they could interact across the ER membrane. To test this, we isolated ER microsomes by subcellular fractionation from U2OS cell lysates and subjected them to a protease protection assay. Briefly, ER microsomes were subjected to limited proteolysis with proteinase-K to digest all proteins/protein domains associated with the outer ER membrane facing the cytosol (69,70). As controls, we confirmed through Western blot analysis that the cytosolic domain of the Sec61β subunit of the translocon was completely digested, while the luminal ER protein calnexin remained intact as it was inaccessible to the protease (fig. 7D). Similar to the Sec61β cytosolic domain, MSec was also almost completely digested by the protease, both in plain U2OS cells (fig. 7D) and in U2OS cells stably expressing MSec-MTAP or HA-MSec (supplementary fig. S10). These results confirmed that MSec is associated with the ER towards its cytosolic site and is unlikely to enter the ER lumen. Overall, these results suggest that ERp29 (which largely resides in the ER lumen), interacts with MSec (which is largely cytosolic) indirectly through a third (ER transmembrane) protein, which may require certain PTM(s) on ERp29.

Discussion
Tunneling nanotubes (TNTs) mediate the long distance communication between animal cells and serve to facilitate the exchange of intracellular material between cells in normal physiological conditions as well as in disease conditions like cancer (13,71-76). These structures are also implicated in the intercellular transmission of a variety of pathogenic organisms (10,19-21,77-81) and could serve as transport channels used by pathogens to evade extracellular defence responses of the body in combating pathogenic infection. It is therefore of prime importance to elucidate the (presently poorly understood) molecular mechanisms that underlie the formation and function of these enigmatic structures. Such knowledge would help to gain a fundamental understanding of this new form of intercellular communication, as well as to devise strategies to modulate their numbers as a way of controlling the spread of several diseases.

MSec, also known as TNFAIP2 and B94, is a protein with well-established functions in vasculogenesis, inflammation, wound healing, focal adhesion formation, cell migration, invasion and metastasis during cancer (60,82-92). Thus, MSec plays key roles in vital physiological processes. Interestingly, MSec was also established as a key component in the machinery required for TNT formation in multiple cell lines (21,36-38,67), which establish MSec as one of the most important proteins required for TNT formation. Tubulogenesis from the plasma membrane is a complex cellular process that requires the concerted action of various cellular mechanisms (93-96). We hypothesized that the small list of known cellular interactors of MSec (38,67) would not be sufficient to explain its role in TNT formation, especially in the context of the upstream regulation of MSec itself. We therefore performed whole proteome interactomic analyses for MSec, which unveiled the role of the ER chaperone ERp29 in the formation of TNTs (fig 2).

ERp29 appeared as a reproducible novel interactor of MSec in our interactomic experiments (fig. 2) and is well-known to localize in the ER (42,56). We observed the co-localization of MSec with ERp29 at the perinuclear region, strongly reminiscent of the ER (fig. 2B and supplementary fig. S3B lower panel). The subcellular rough ER fraction also showed an enrichment of both endogenous MSec and MSec-MTAP in our biochemical assays in multiple cell lines (fig. 2C and supplementary fig. S5). These results together with the observation of a cellular interaction between the two proteins suggests that MSec interacts with ERp29 as a prerequisite for it to eventually localize at the plasma membrane and initiate TNT formation. It is worth noting that ERp29 is unable to exert any measurable influence on TNT formation in the absence of MSec (fig.4). This observation again confirmed that the interaction of MSec with ERp29 is required prior to the initiation of TNT formation. It was instructive that we observed similar levels of disruption of TNT formation upon ERp29 depletion as seen for MSec depletion (fig. 3). Thus, interaction of MSec with ERp29 appears to be a requirement for TNT formation.
The pronounced effect of ERp29 on the protein levels of MSec but not on its mRNA levels suggested that the action of ERp29 on MSec was as a protein chaperone (figs. 5, 6), an activity of ERp29 previously demonstrated and characterized on several other substrates (42-45). The chaperone activity was consistently observed upon both depletion of ERp29 (leading to reduction in MSec protein levels, fig. 5) or conversely, upon exogenous expression of ERp29 (leading to increased MSec protein levels, fig. 5, 6). C-terminally truncated ERp29 (ERp29-NTD) could not stabilize MSec levels the way full length ERp29 could (fig. 5D, 6D), with cell death observed upon exogenous expression of this construct (empirical observations, not shown), suggesting a dominant negative effect (43). We generated point mutants of ERp29 known to abolish its chaperone activity. Expression of each of these chaperone-defective mutants of full length ERp29 led to lower cellular levels of MSec protein as well as to significantly lower TNT numbers (fig. 6). Interestingly, the point mutants of ERp29 at sites D61A, Y64S and Y66K themselves showed lower protein levels as also seen for the substrate MSec, suggesting that these ERp29 mutants might co-degrade along with MSec (data not shown). This phenomenon has been reported for another ERp29 substrate as well (45). Indeed, upon MG132 treatment to block proteasome activity and hence prevent protein degradation, the levels of these mutants and of MSec went back to normal (data not shown). These experiments also revealed that in the absence of ERp29, MSec is degraded by the proteasome as has been shown for other ERp29 substrates like Pipe (45), presumably because MSec does not get properly folded.

The ERp29-MSec interaction observed from cell lysates (fig. 2A) was not recapitulated with the purified proteins, or when MSec from cell lysates was incubated with purified ERp29 (fig. 7B). Interestingly, purified MSec could only interact with ERp29 from cellular lysates (fig. 7C). These results suggest that the MSec-ERp29 interaction could require post-translational modification(s) on ERp29. The exact identity and site(s) of this PTM(s) would be an interesting and valuable future pursuit to delineate the mechanism of MSec stabilization by ERp29. These results could also be interpreted to conclude that there is possibly a third protein(s) from the cell lysate that is required for this interaction and/or stabilization, perhaps dependent on the initial PTM(s). Our imaging and biochemical experiments suggested that MSec is strongly present either inside the lumen or on the surface of the ER, or possibly both (fig. 2B-C, S3B, S5). However, limited proteolytic treatment of ER microsomes to “shave” off ER-associated surface proteins facing the cytosol revealed that MSec is present only on the surface of the ER and not in the lumen (fig. 7D, S10). These results suggest two possible models for the action of ERp29 on MSec. The largely ER-lumen-resident ERp29 could interact with ER-surface-localized MSec through a bridging transmembrane-ER protein(s) that remains to be identified. An alternative, though less likely possibility is that a small cytosolic fraction of ERp29 (97,98) stabilizes MSec. Further detailed studies will be needed to reveal the exact mechanism of MSec stabilization by ERp29. However, our study possibly suggests a generic mechanism that could be employed by ERp29 to stabilize a cohort of substrates that are known to localize at the cortex in the cytoplasm (e.g. beta catenin, ZO1, scribble, par3).

The stabilization of MSec by ERp29 is reminiscent of the well-documented interactions of ERp29 with other important proteins that reach the vicinity of the plasma membrane like connexin 43, thyroglobulin, par3, scribble, zona occludens 1 (ZO-1), occludin and beta catenin, which are all substrates of ERp29 (43,61,65). It has been suggested that several of these substrates of ERp29 may follow broadly similar routes to traffic through the cell from the ER to the plasma membrane following stabilization through their interactions with ERp29 (61). However, at or near the plasma membrane, these proteins reach one among the following distinct destinations: 1) integral to the plasma membrane [connexin 43, CFTR, occludin - (43,44,61)], 2) secreted out of the cell [thyroglobulin (42,65)] or 3) localized to the sub-cortical region of the plasma membrane [MSec – this study, beta catenin, scribble, par3, ZO1-(61)]. It is intuitive to rationalize that the first two of these classes of proteins would be accessed by ERp29 in the lumen of the ER (43,44,61,65). Following stabilization, these
ERp29 regulates TNT formation

proteins follow the classical secretory pathway and reach the plasma membrane (43,44) or the exterior of the cell (65). However, if cortical substrates belonging to the third class first enter the ER lumen for interaction with ERp29, it is unclear how they would exit the endomembrane system to reach the cytosol following stabilization by ERp29 (61). Most of these proteins are also not reported to show ER-surface localization as observed for MSec (fig. 2B, S3B). The possibility that a small fraction of ERp29 may be present in the cytosol, probably coming through ERAD pathway, to stabilize MSec as well as other substrates cannot be ruled out (97,98). However, it is not clear how and where these proteins access ERp29 for their stabilization and is a subject worthy of detailed independent investigation.

Among the proteins known so far to be important for TNT formation (Exocyst complex, Ral A, cdc42, LST1, filamin, connexin 43, (17,36,67,99), only connexin 43 is a known substrate of ERp29 (43). Our study adds MSec as a new member in this category, making it attractive to hypothesize that ERp29, and perhaps the Endoplasmic Reticulum itself, could be a vital cog in the cellular machinery required for TNT formation through its action on multiple protein substrates. However remained possible that other known cortical inducers of TNT formation like RalA and the Exocyst complex are also chaperone substrates of ERp29. However, our results unequivocally show that protein levels of neither RalA nor multiple Exocyst complex subunits get affected upon ERp29 depletion (fig. S9), suggesting that MSec is one of the central targets of ERp29 in the regulation of TNT formation in addition to connexin 43.

Overall, this study reveals a novel role for the Endoplasmic Reticulum in directly controlling TNT formation through one of its chaperones ERp29. We show that MSec interacts with ERp29 and is stabilized by the resulting interaction, which is a pre-requisite for MSec to be properly localized at the plasma membrane. In the absence of this stabilizing interaction, MSec is incapable of inducing TNT formation. We establish a hitherto unknown but essential role for the chaperone activity of ERp29 in inducing TNTs, by using an array of chaperone-defective ERp29 point mutants. We also show that in the absence of MSec, ERp29 has virtually no role in TNT formation. Thus, our study delineates an essential upstream molecular mechanism that regulates TNT formation through stabilization of MSec. The work highlights that the molecular mechanisms of TNT formation and function may be more complex than so far anticipated. Further fundamental mechanistic studies would reveal the contributions of other important proteins and processes in TNT biology. This knowledge offers an opportunity for the design and development of precisely targeted methods of modulating TNT numbers both for basic studies and for therapeutic purposes in TNT-mediated diseases.

Materials and Methods

Cell lines
The U2OS cell line (kind gift from Stephen J Doxsey, University of Massachusetts Medical School), HeLa cells and MDAMB231 cells were cultured in DMEM supplemented with 10% fetal bovine serum and 1x antibiotic solution (100x, 10,000U penicillin and 10mg Streptomycin per mL; (HiMedia). Cells were maintained at 37°C with 5% CO2 and 95% humidity.

Generation of stably expressing MSec cell lines
Mouse MSec (NM_009396.2; nucleotides: 124-2076) was cloned into the mammalian expression vector pcDNA4-TO-Hygromycin-mVenus-MAP (Addgene), which we then named the MSec-MTAP construct (supplementary table S1). Sanger sequencing was performed to rule out any inadvertent mutations. The recombinant construct was transfected into U2OS cells using the X-tremeGENE HP DNA transfection reagent (Roche/ Sigma). Cells stably expressing MSec-MTAP were selected after culturing the transfected cells under selection media containing antibiotic (hygromycin B, 300 µg/mL, TOKU-E) over a month. Surviving cells were sorted by serial dilution (one cell per well in a 24-well plate) into individual clones expressing different levels of the transgene MSec-MTAP and confirmed by Western blotting (supplementary Fig. S1). From these clones, we selected a clone (clone-1) expressing the transgene MSec-MTAP.
ERp29 regulates TNT formation at levels comparable to endogenous MSec, which was used for proteomic and functional studies. A U2OS cell line stably expressing the empty vector (eMTAP) was generated in parallel to use for control experiments.

**Transfection of HIV-1 (JRFL) into U2OS**

For making the pseudotyped virus, we co-transfected U2OS cells with two plasmids, one that expresses HIV-1 JRFL envelope (gp160) and one (pSG3deltaenv) that expresses all the genes of HIV-1 with a premature stop codon at the env gene as described previously (100-102). Transfection was performed in a 6-well cell culture plate using a FuGENE6 transfection kit (catalog number: E2691, Promega Inc.). After 48 hours of transfection, the supernatant was removed and cells were washed twice with 1x Phosphate Buffer Saline (1x PBS) and immunostained and imaged as explained under “immunofluorescence and confocal microscopy”.

**Experimental design and statistical rationale for proteomics**

**Affinity purification**

The stably expressing (MSec-MTAP) U2OS cells were cultured in large scale in selection media for affinity purification. Cultured cells were harvested in resuspension buffer containing 50 mM Tris-HCl, pH 7.5, 125 mM NaCl, 1 mM EDTA, 5% glycerol, Igepal CA-630 (0.025% - 0.2%) and a protease inhibitor cocktail (Roche). Harvested cells were lysed cryogenically by grinding them (using a mortar and pestle under liquid nitrogen) to preserve the integrity of protein complexes. The total cell lysate was centrifuged at 14,000 x g for 30 min at 4°C to separate insoluble material. The supernatant was subjected to streptavidin binding peptide (SBP)-based affinity purification using a StrepTrap HP 1 ml column (GE Healthcare Life Sciences). The affinity column was equilibrated with resuspension buffer at a flow rate of 0.5 ml/ min and the supernatant applied to it at a flow rate of 0.3 ml/ min. The supernatant was incubated for 30 min, drained and the column subsequently washed with wash buffer containing 50 mM Tris-HCl, pH 7.5, 250 mM NaCl, Igepal CA-630 (0.05%) and protease inhibitor cocktail. Bound protein was eluted in elution buffer containing 25 mM Tris-HCl, pH 7.5, 125 mM NaCl, 2.5 mM desthio-biotin and protease inhibitor cocktail. Four biological experiments were performed at varying Igepal CA-630 concentrations from 0.025% to 0.2% to identify protein interactions consistently observed over this range of detergent concentrations.

**Mass spectrometry**

After affinity elution, the protein solution (eluate) was concentrated using Amicon-Ultra centrifugal filters (Millipore). Concentrated protein was estimated by using the bicinchoninic acid kit (BCA, Thermo Scientific) and subsequently processed by the filter-assisted sample preparation (FASP protocol, (103)) followed by digestion with trypsin using Trypsin-Gold (Promega) at 37°C for 14-16 hours. Trypsinized peptides were desalted using ZipTips (Millipore) and analysed by electrospray ionization liquid chromatography mass spectrometry (ESI-LC-MS) by injecting a total of 1µg peptides on to a nano-reverse phase high performance liquid chromatography (RP-HPLC) C18 column (Thermo Scientific) equilibrated with buffer-A (2% acetonitrile + 0.1% formic acid in water). Peptides were eluted using a gradient of buffer-B (98% acetonitrile + 0.1% formic acid in water) applied at a flow rate of 200nl/min over 80 min.

**Search parameters and acceptance criteria (for MS/MS data)**

The results obtained from the mass spectrometry experiments (peptide and fragmentation spectra) were analyzed through the peaklist-generating software, ProteinPilot™ (version 4.5) and Mascot search engine (version 2.3.02) with optimal parameters as follows; sequence database used for protein search was SwissProt 57.15. The number of entries in the database were 515,203 sequences (181,334,896 residues). The taxonomy (species) of the database used to analyze the data was Homo sapiens (human). The protease used to generate peptides was Trypsin-gold (Promega, V528A). The number of missed and/or non-specific cleavages permitted was one. Fixed and variable modifications considered were carbamidomethyl (C) and oxidation (M) respectively. Mass tolerance for precursor and fragment ions was ± 0.5 Da and ± 0.2 Da respectively. The threshold score (confidence
ERp29 regulates TNT formation

threshold) for accepting individual spectra was 5%. The estimated false discovery rates for peptide and protein identifications were 5% based on the significance threshold (p<0.05). The positive hits present in the bait (MSec-MTAP) experiments with a significant score from each of the four experimental conditions were overlapped using the Venny 2.1 software (http://bioinfogp.cnb.csic.es/tools/venny/index.html) and selected for further classification into various functional categories by using the PANTHER database (http://www.pantherdb.org/) and to assess for protein-protein interactions through the STRING database (www.string-db.org). Further details of the unique MSec interactome appearing in at least three experiments are listed in supplementary table S2. The mass spectrometry proteomics data have been deposited to the ProteomeXchange Consortium via the PRIDE (104) partner repository with the dataset identifier PXD012441.

RNA interference and real time quantitative PCR (RT-qPCR)
Cells growing at approximately 40% confluence were transfected with 67 nM gene-specific (ERp29/ MSec/ control Luciferase) siRNAs (Dharmacon) using the Lipofectamine RNAiMax (Invitrogen) transfection reagent. After 48 hours of transfection, cells were harvested and the efficiency of knock down was confirmed by Western blotting. Alternatively, total RNA was extracted using NucleoSpin RNA isolation kit (Macherey Nagel) after 48 hours of siRNA transfection. 1 µg of total RNA was used to synthesize complementary DNA (cDNA) using the iScript cDNA Synthesis Kit (BioRad). RT-qPCR was conducted using a 7500 fast real time PCR system (Applied Biosystems/ Life technologies). 100 ng cDNA per reaction was used for real time amplification using SYBR® Premix Ex Taq™ II reagents (TaKaRa). PCR conditions used were - initial denaturation at 95°C for 2 min, at the cycling stage denaturation at 95°C for 5 sec, annealing and extension at 60°C for 30 sec for a total of 40 cycles. The C_T value was normalized to that of 18S mRNA. Three biological experiments (each with three technical replicates) were performed. Primers used for qPCR amplification are listed in supplementary table S5.

Western blotting
Cultured cells were harvested and lysed and the total protein concentration was estimated using the CB-X™ protein assay kit (G-Biosciences) and an equal amount of total protein was loaded in each lane. Proteins were resolved by SDS-PAGE and transferred onto a PDVF membrane. The PVDF membranes were incubated in blocking buffer (5% skimmed milk & 0.1% Tween-20 in 1X PBS) at room temperature for 2-3 hours and then probed with specific primary antibodies (at 4°C overnight) and secondary antibodies (at room temperature for one hour). The antibodies used were: rabbit anti-TNFAIP2 (1:200, Santacruz Biotechnology, catalog sc-30138), mouse anti-TNFAIP2-F6 (1:200, Santacruz, Biotechnology, catalog number sc-
ERp29 regulates TNT formation

(28318), rabbit anti-ERp29 (1:2000, Abcam, catalog number ab11420), mouse anti-β-actin (1:2000, Sigma, catalog number A3853), rabbit anti-GFP (1:2000, Abcam, catalog number ab6556), rabbit anti-Calnexin (1:4000, Abcam, catalog number ab22595), mouse anti-FlagM2 (1:4000, Sigma, catalog number F1804), rabbit anti-GM130 (1:2000, Abcam, catalog number ab52649), rabbit anti-Histone-3 (1:20000, Abcam, catalog number ab1791), rabbit anti-EGFR (1:2000, Abcam, catalog number ab52894), mouse anti-RalA (1:4000, BD Transduction Laboratory, catalog number 610221), rabbit anti-Sec5 (1:1000, proteintech, catalog number 12751-1-AP), mouse anti-Sec6 (1:200, ThermoFisher Scientific, catalog number MA1-25480), mouse anti-Sec8 (1:1000, ENZO Life sciences, catalog number ADI-VAM-SV016), mouse anti-Sec61β (1:100, 1:2000, Santa Cruz Biotechnology, catalog number sc-393633), anti-mouse m-IgGk BP-HRP (1:2000, Santa Cruz Biotechnology, catalog number sc-516102), donkey anti-rabbit IgG-HRP (1:10000, Jackson Immunoresearch, catalog number 711-035-152). Chemiluminescent signals were developed using HRP substrate (Merck Millipore, catalog number WBLUF0500) and the signals were analysed using an ImageQuant™ LAS-4000 gel documentation system (GE healthcare). Protein band intensity was quantified using the ImageJ software.

Immunofluorescence and confocal microscopy
Cells were cultured in 6-well plates on sterilized glass coverslips. After 48 hours of incubation, cells were washed twice with 1X PBS and fixed with 3.7% paraformaldehyde (PFA) for 4-5 min. Alternatively, MSec-MTAP cells were fixed with chilled methanol for 30 minutes at -20°C. After two washes with 1X PBS, cells were permeabilized with 0.1% Triton X-100 for 10 min. After two more washes with 1X PBS, cells were blocked with 5% (w/v) bovine serum albumin (BSA) in 1X PBS for 45 min. Cells were incubated with primary antibodies [VRC01 (1:200, obtained from NIH AIDS reagent programme, (49), mouse anti-TNFAIP2-F6 (1:100, Santacruz, Biotechnology, catalog number sc-28318), rabbit anti-ERp29 (1:200, Abcam, catalog number ab11420), rabbit anti-GFP antibody (1:1000, Abcam, catalog number ab6556, for visualizing EGFP-ERp29 constructs)], for 60-90 min followed by three washes with 1X PBS. Coverslips were incubated with the corresponding secondary antibodies, [goat anti-Human (1:250, Jackson Immunoresearch, catalog number 109-095-064), m-IgGk BP-CFL 555 (1:100, Santacruz Biotechnology, sc-516177)], donkey anti-rabbit DL 488 (1:800, Jackson Immunoresearch, catalog number 711-485-152) for 60 min followed by three washes with 1X PBS. F-actin filaments were stained with Alexafluor™594 conjugated phallolidin (1:20, Invitrogen, catalog number A12381) for 40-60 min. Cells were then incubated with DAPI to stain the nucleus for 2-3 min. After three final washes with 1X PBS, the coverslips were mounted onto glass slides using ProLong™ Gold or ProLong™ Diamond antifade mounting medium (Invitrogen). All steps were performed at ambient room temperature and all antibody dilutions were made in 5% BSA in 1X PBS. Both fixed and live cells were imaged using a Leica TCS SP8 confocal microscope (Leica Microsystems). Mitochondria were labeled with Mitotracker red (Thermo, catalog number M22425) for 30 min and live cell imaging performed subsequently. The TNT inhibitor (TNTi) was used at 10 µM for 24 hours as previously used (21). Image analysis was performed by the LASX offline analysis software (Leica), ImageJ and the IMARIS software suite (Bitplane).

Isolation of Endoplasmic Reticulum (ER) microsomes and proteinase-K treatment
Rough ER was isolated by the protocol outlined in the Sigma catalog (product number ER0100), with manual preparation of the recommended solutions required for isolation. Briefly, cells were harvested and washed with 10 volumes of ice-cold 1X PBS. The cell pellet was resuspended in three volumes of 1X hypotonic buffer and incubated at 4°C for 20 min. Swollen cells were micro-centrifuged at 600 x g for 5 min at 4°C and the cell pellet was resuspended in two volumes of 1X isotonic buffer. Cells were disrupted (lysed) using a micro-pestle and the cell homogenate was micro-centrifuged at 1000 x g for 10 min at 4°C. The post nuclear supernatant was micro-
ERp29 regulates TNT formation

centrifuged at 12000 x g for 15 min at 4°C to separate the post-mitochondrial fraction (PMF). The PMF was then titrated drop-wise with 8 mM CaCl₂ (7.5 times the volume of PMF) with gentle mixing with a suitable magnetic spin bar. After titration, the sample was micro-centrifuged at 8000 x g for 10 min at 4°C to pellet down the rough ER microsomes which were then resuspended in 2X Laemli sample buffer and boiled at 95°C for 5 min. Alternatively, (for the protease protection assay) the PMF was ultra-centrifuged at 1,00,000 x g in a preparative ultracentrifuge (Hitachi, model number: CP100WX) at 4°C for 60 min. The pellet containing the ER microsomes was resuspended in the 1X isotonic buffer and subjected to proteinase-K treatment (final concentration 20ng/µL, Sigma, catalog number P2308) for 10 min on ice. After incubation, 2X Laemli sample buffer was added and the sample boiled at 95°C for 5 min. The samples were then resolved by SDS-PAGE, transferred onto a PVDF membrane and analysed by Western blotting.

Generation of ERp29 mutant constructs by site directed mutagenesis

The recombinant human ERp29 full-length construct (EGFP-ERp29FL) was a kind gift from Dr. Michael Koval (43). Using this construct as a template, various ERp29 single point mutant (D61A, Y64S, Y66K, Y96Q, P116D and C157S) constructs were generated using standard site directed mutagenesis protocol with primers incorporating desired mutations. Primers used are listed in supplementary table S5.

Purification of recombinant (His-, GST-tagged) proteins and GST pull down assay

ERp29 cDNA was cloned into a bacterially expressed pGEX6P1 vector and MSec cDNA was cloned into both pGEX6P1 and pET28a vectors to impart the respective tags (GST or 6-His) for affinity purification and for subsequent interaction studies. After sequencing to rule out inadvertent mutations, these recombinant vectors were transformed and expressed in Rosetta cells. GST-tagged proteins (GST-ERp29, GST-MSec and GST alone) were purified by using GSTPrep™ FF 16/10 column (GE healthcare). Briefly, the GSTPrep column was equilibrated with 10 column volumes of resuspension/binding buffer (50mM Tris-HCl, pH 8.0; 300mM NaCl; 5mM 2-mercaptoethanol; protease inhibitors, PMSF and pepstatin). The supernatant containing bacterially expressed recombinant proteins was applied by pumping it onto the column using the sample pump (of the FPLC, AKTA Explorer, GE) at a flow rate of 0.3 ml per minute. The column was washed with 10 column volumes of resuspension buffer at a flow rate of 3 ml per minute to remove unbound protein. Bound protein was eluted with five column volumes of elution buffer (50mM Tris-HCl, pH 8.0; 300mM NaCl; 5mM 2-mercaptoethanol; 10mM reduced glutathione) at a flow rate of 2 ml per minute. Fractions containing GST-tagged protein were collected by applying UV absorption at 280 nm into a pre-chilled 50 ml tube. To cleave the GST tag from the protein of interest, PreScission protease (GE) was added to GST-tagged protein (eluate) and subjected to dialysis against a buffer containing 50mM Tris-HCl, pH 8.0; 300mM NaCl; 5mM 2-mercaptoethanol; 1mM EDTA; 0.02% Igepal CA-630 overnight at 4°C, with buffer changes at regular intervals. After overnight dialysis, the sample was applied to an equilibrated GSTprep column to remove the GST tag from the protein of interest. The flow-through (containing the protein of interest) was collected and the GST tag from the protein of interest was removed. Protein was concentrated using Amicon-ultra centrifugal filters (Millipore). His-tagged MSec was purified by Ni-NTA (nickel-nitrilotriacetate) affinity chromatography. Briefly, Ni-NTA beads (Qiagen) were equilibrated with resuspension/binding buffer and incubated with the supernatant (as prepared above) for 2-3 hours at 4°C with gentle rotation. The lysate–Ni-NTA mixture was loaded into a filter column and the flow-through collected. Protein bound Ni-NTA beads were washed with wash buffer (50mM Tris-HCl, pH 8.0; 300mM NaCl; 5mM 2-mercaptoethanol; 20mM imidazole) and bound protein eluted in elution buffer (50mM Tris-HCl, pH 8.0; 300mM NaCl; 5mM 2-mercaptoethanol; 500mM Imidazole) and dialyzed (50mM Tris-HCl, pH 8.0; 300mM NaCl; 5mM 2-mercaptoethanol) to remove imidazole. Dialyzed His-MSec was
ERp29 regulates TNT formation

further purified by anion exchange chromatography (Mono-Q 10/100, GE). Briefly, the anion exchange column was equilibrated with 10 column volumes of buffer containing 50 mM Tris-HCl, pH 8.0, 5mM 2-mercaptoethanol; 100 mM NaCl. The dialysed sample was applied to the anion exchange column at a flow rate of 1-2 ml per minute. Unbound protein was washed out with five column volumes of the equilibration buffer. A linear gradient of 100 mM to 500 mM NaCl (in the equilibration buffer) over 20 column volumes was used to elute the protein. Eluted fractions containing the protein of interest were collected by monitoring UV absorption at 280 nm into fresh micro-centrifuge tubes. The purity of the eluted protein was analyzed by SDS-PAGE. Fractions containing highly pure (>95%) protein of interest were pooled into a pre-chilled tube. Both His-tagged and GST-tagged proteins were further purified by size exclusion chromatography [(Superdex 200 16/60 GL (preparative) and Superdex 200 10/300 GL (analytical), GE]. Briefly, size exclusion columns were equilibrated with one column volume of buffer-C (50 mM Tris-HCl, pH 8.0; 5mM 2-mercaptoethanol; 150 NaCl) at a flow rate of 0.5 ml per minute. A concentrated protein sample of interest was injected on to the column and run at a flow rate of 0.5 ml per minute. Eluted fractions containing protein of interest were collected, analyzed by SDS-PAGE, pooled and concentrated as above. Protein concentration was estimated using the bicinchoninic acid (BCA) assay kit (Thermo Scientific, catalog number 23227). 10% glycerol was added as cryoprotectant and stored in the -80°C freezer after snap freezing in liquid-nitrogen until further use.

Statistical analysis
All results of cell culture experiments were performed in three independent biological repeats and expressed as the mean ± standard deviation (SD). RT-qPCR experiments were carried out in triplicates and repeated at least thrice, and expressed as mean ± standard error (SE). Paired test (two tailed), one-way- or two-way- ANOVA were used to analyze the significance of variance and P<0.05 was considered as significant. GraphPad Prism-7 software was used for analysis and plotting the graphs.

Acknowledgements
We thank Dr. Hiroshi Ohno for the gift of the mMsec construct (residues 42-691), Vandana Thakur for help with cloning MTAP-MSec and Dr. Michael Koval for sharing ERp29 constructs (EGFP-ERp29-FL and EGFP-ERp29-NTD). The HIV-1 SG3 ΔEnv non-infectious molecular clone was obtained through the NIH AIDS Reagent Program, Division of AIDS, NIAID, NIH from Drs. John C. Kappes and Xiaoyun Wu. We thank Dr. Nirpendra Singh, Madhava Rao M. and Nagavaraprasad G. for advice and assistance with mass spectrometry, and Suraj Tewari for assistance with confocal microscopy. We are grateful to the Regional Centre for Biotechnology (RCB) for providing the requisite infrastructure and the members of the Laboratory of Cellular Dynamics, RCB for critical comments and suggestions during the study. PR received support from fellowships through the Department of Biotechnology (DBT) and the Indian Council of Medical research (ICMR), Government of India. SD and HK received fellowship support from RCB. The HIV experiments were supported by research funding from the DBT National Bioscience Grant Award (BT/HRD/NBA/34/01/2012) to JB. This work was supported by institutional funding to SVSM from RCB.

Competing interests
The authors declare that they have no conflicts of interest.

Author contributions

14
PR and SD designed and conducted experiments and analyzed data. HK and RK conducted experiments. JB helped in the conceptualization and execution of HIV-1 experiments. SVSM conceptualized and supervised the entire study, designed experiments and analyzed the data. PR and SVSM wrote the manuscript. All authors reviewed the results and approved the final version of the manuscript.

Figures

Figure 1

**Figure 1.** Stably expressed affinity tagged MSec induces TNT formation in U2OS cells. **A** MSec was cloned into a mammalian expression vector that imparts a multi-affinity tag (His-SBP-Flag) embedded inside a fluorescent (mVenus) tag. **B** Expression levels of stably expressing empty vector (eMTAP) and exogenous mouse MSec (MSec-MTAP) equivalent to the endogenous human MSec assessed by immunoblotting. **C** Live confocal microscope images taken from stably expressing MSec-MTAP and empty-MTAP cells (both green). TNTs are indicated by arrows. The analysed TNTs were not adhered to the substratum. X-Z/ Y-Z visualization of confocal Z-stacks of TNTs that were counted in both cell lines (MSec-MTAP and eMTAP). Scale bar, 20µm. **D** Quantification of the number of TNTs per 100 cells from the confocal images. Data represent mean ± SD based on three independent experiments, 100 cells counted per experiment. (Paired t test, two-tailed; **P<0.01). **E** Time lapse confocal images showing the transport of mitochondria from one cell to another. Arrowheads indicate the position of the mitochondria.
**Figure 2.** ERp29 interacts with MSec. 

**A**) FLAG immunoprecipitates of the MSec-MTAP and empty-MTAP U2OS cell lysates probed for ERp29 by immunoblotting. 

**B**) Confocal images showing co-localization of MSec (red) with ERp29 (green) in the ER region. Pearson’s correlation coefficient (Rcoloc) of the whole frame is 0.6766 and that of the selected cell is 0.6866. Scale bar, 20 µm. 

**C**) Western blots of the whole cell lysate and rough endoplasmic reticulum fractions from U2OS cells probed for the respective proteins as indicated. ER positive markers - Calnexin, and ERp29; cytosolic marker - β-actin; Golgi complex marker - GM130; nuclear marker - Histone-3 and cell membrane marker - EGFR.
ERp29 regulates TNT formation

Figure 3

**Figure 3.** ERp29 is required for TNT formation. **A** Confocal microscopy images of cells co-stained with AlexaFluor™ 594 conjugated phalloidin (red, to visualize F-actin) and DAPI (blue, to visualize the nucleus) after 48 hours of the indicated siRNA transfection. Arrows indicate TNTs connecting neighboring cells. Scale bar, 20 μm. **B** Quantification of the number of TNTs per 100 cells from the confocal images in both normal (10% serum) and stress (2.5% serum) conditions respectively. Data represent mean ± SD based on three independent experiments, 100 cells counted per experiment. (Paired t test, two-tailed, **P<0.01).
Figure 4. ERp29 overexpression induces TNTs in an MSec-dependent manner. A) U2OS cells transiently expressing either EGFP-ERp29 or luminal EGFP (control vector) were treated with siRNAs against MSec or luciferase (control) and co-stained with anti-GFP antibody (green) and phalloidin conjugated with AlexaFluor™594 (red). Cells were imaged using confocal microscopy, arrows indicate TNTs connecting neighboring cells. Scale bar, 20µm. B) Quantification of the number of TNTs per 100 cells from the confocal images. Data represent mean ± SD based on three independent experiments, 100 cells counted per experiment. (Two-way ANOVA, Sidak’s multiple comparisons test, *P<0.05, ****P<0.0001). C) Efficiency of over-expression of EGFP-ERp29 and depletion of MSec analyzed by immunoblotting with their corresponding antibodies.
Figure 5. ERp29 stabilizes MSec protein levels but not its mRNA. A) siRNA-mediated depletion of ERp29 or MSec in U2OS cells using sequence-specific siRNAs. Control = luciferase siRNA. Efficiency of knock down was analyzed by immunoblotting with anti-ERp29, anti-MSec and anti-β-actin (loading control) antibodies respectively. B) Fold change in protein expression of MSec quantified from the immunoblots using densitometry. C) Relative mRNA expression levels of ERp29 and MSec (for the samples in A) quantified by RT-qPCR after respective siRNA treatment. D) Immunoblots depicting exogenous expression of EGFP-ERp29 or EGFP-ERp29-NTD, endogenous ERp29 levels and endogenous MSec levels in U2OS cells. Loading control = β-actin. E) Fold change in protein expression of MSec quantified from the immunoblots using densitometry. F) Relative mRNA expression levels of ERp29 and MSec (for the samples in D) quantified by RT-qPCR after respective siRNA treatment. Data (in B and E) were analyzed by ordinary one-way ANOVA, Dunnett’s multiple comparisons test) and represent mean ± SD based on three independent experiments. Data (in C and F) were analyzed by 2-way ANOVA, Sidak’s multiple comparisons test) represent mean ± SE based on three independent experiments with three technical replicates each (*P<0.05; **P<0.01; ****P<0.0001).
ERp29 regulates TNT formation

Figure 6

A) Sequence alignment of ERp29 from multiple species showing conservation of chaperone (highlighted in red) and stabilization (highlighted in green) residues. B) Confocal microscopy images of cells expressing either luminal-EGFP (control) or the various chaperone point mutants of EGFP-ERp29 and co-stained with AlexaFluor™594 conjugated phalloidin (red, to visualize F-actin) and anti-GFP antibody (green, to visualize the EGFP/EGFP-ERp29 proteins). Arrows indicate TNTs connecting neighboring cells. Scale bar, 20 µm. C) Quantification of the number of TNTs per 100 cells from the confocal images. Data was analyzed by the paired two-tailed t-test, and represents mean ± SD based on three independent experiments, 100 cells counted per experiment. **P<0.01; ***P<0.001. D) Immunoblots showing expression levels of endogenous MSec, EGFP-ERp29 constructs and endogenous ERp29 probed with the respective antibodies as indicated upon expression of the EGFP-ERp29 wild type and various mutant constructs. Loading control = β-actin.
Figure 7. Characterization of the ERp29-MSec interaction. A) SDS-PAGE profiles (Coomassie stained) of the purified recombinant MSec and ERp29 proteins as indicated. B) Purified ERp29 shows no interaction with either purified MSec or with MSec from cell lysate. Bottom strips show immunoblots with the respective antibodies as indicated. C) Purified MSec does not interact with purified ERp29 but interacts with ERp29 from cell lysate. Bottom strips show immunoblots with the respective antibodies as indicated. D) Protease protection assay with proteinase-K reveals that MSec is associated with the ER surface towards its cytosolic side. Markers used in immunoblots – Calnexin (ER lumen) and Sec61β-cytosolic side (ER surface).
The chaperone ERp29 is required for tunneling nanotube formation by stabilizing MSec.
