Homocoupling of CO and isocyanide mediated by a C,C′-bis(silylenyl)-substituted ortho-carborane†

Yun Xiong, a Shenglai Yao, a Tibor Szilvási, b Ales Ruzicka c and Matthias Driess a *

The unexpected reactivity of the o-carborane supported bis-silylene [LSi]C2B10H10 1 (L= PhC(tBuN)2) towards carbon monoxide and 2,6-dimethylphenyl isocyanide is reported. While the reaction of 1 with CO leads selectively to the novel head-to-head coupling and C–O cleavage product 2 from two molecules 1 and four molecules CO, the reaction of 1 with 2,6-dimethylphenyl isocyanide affords solely the 1:2 molar head-to-tail coupling product 3 with a Si=C bond.

The activation of important small molecules such as CO, H2 and N2 was earlier considered to be a domain of transition metals. However, the last decade witnessed increasing achievements in the chemistry of main-group element (MG) compounds that mediate the cleavage of strong bonds in small molecules.1–7 Featuring a lone pair of electrons and a vacant p-orbital at the silicon center, silylenes are particularly reactive species which belong to the rare examples of low-valent MG compounds being suitable for the activation of unreactive bonds and thus represent versatile building blocks for the synthesis of value-added organosilanes. Since the isolation of the first isolable N-heterocyclic silylene (NHSi) by West et al. in 1994,8 the chemistry of stable silylenes has flourished substantially. Several cyclic9–13 and acyclic14–18 silylenes have been successfully synthesised and their reactivity towards numerous small molecules such as O2, N2O, S8, P4, NH3, CO2, and even H2 has been developed.5,15–17,19 Nevertheless, the very strong triple bonds of CO cannot be activated easily; one very recent example represents the homocoupling of CO molecules to OCCO moieties mediated by an acyclic monosilylene reported by Aldridge and co-workers.20

In order to learn whether two silylene (NHSi) moieties could be cooperative in cleaving unreactive bonds, we synthesised several chelating bis-NHSis.21–24 To our delight, preliminary investigations revealed that the xanthene and ferrocene supported bis-NHSi A23a and B21b,c can even cleave the strong C≡O bond (1072 kJ mol−1) and mediates the deoxygenative coupling of two CO molecules under mild reaction conditions (room temperature, 1 atm) to yield the ketene species C and D, respectively (Scheme 1).23b,c Moreover, the reaction of bis-silylene A with an equimolar amount of the isoelectronic 2,6-dimethylphenyl isocyanide resulted in the dearomatised silene derivative E.23b Moreover, the reaction of A with two molar equivalents of 2,6-dimethylphenyl isocyanide afforded F and G.

Scheme 1 Bis-silylenes A, B and 1 as well as the products C–G resulting from the reaction of A and B with CO and 2,6-dimethylphenyl isocyanide, respectively.

† Electronic supplementary information (ESI) available: Experimental and computational details. CCDC 1963423 and 1963424. For ESI and crystallographic data in CIF or other electronic format see DOI: 10.1039/c9cc08680c
Compared to the bis-silylene \( A \), the ortho-carborane supported bis-NHSi \( 1 \) is more rigid, and we wondered its reactivity towards CO and the isoelectronic 2,6-dimethylphenyl isocyanide. Isocyanide furnishes similar or different coupling products. Herein, we report the unexpected novel coupling products in compound \( 2 \) with CO to afford \( 2' \) and \( 2'' \).

Exposure of the yellow solution of \( 1 \) in toluene to CO (1 atm) at \(-20^\circ C\) leads to a colour change from yellow to brown. The reaction mixture was allowed to warm to room temperature to give a brown solution, from which the unprecedented coupling product \( 2 \) could be crystallised after one day at ambient temperature in the form of colourless crystals in 62% yields (Scheme 2). In contrast to the reaction of \( 1 \) and CO, the corresponding disilaketene could even not be observed as intermediates, presumably owing to the rigidity and steric hindrance of the o-carborane backbone.

In compound \( 2 \), the two different sorts of \( ^{29}\text{Si} \) nuclei give rise to different \( ^{29}\text{Si} \) NMR resonances. The resonance at \( \delta = -62.27 \text{ppm} \) can be assigned to the Si atoms of the CSiO \(_2\) moiety, whereas that at \( \delta = -108.44 \text{ppm} \) corresponds to the C\(_2\)SiO \(_2\) units; the latter value is close to the \( ^{29}\text{Si} \) NMR resonance of C (\( \delta = -91.4 \text{ppm} \)). Interestingly, the C–C–O moieties in \( 2 \) resonate at 22.34 and 173.78 ppm in the \( ^{13}\text{C} \) NMR spectrum, which are reminiscent of those observed for the ketene moiety in C (19.7 and 165.5 ppm).

A single crystal X-ray diffraction analysis revealed a polycyclic skeleton in \( 2 \) as depicted in Fig. 1. Compound \( 2 \) crystallises in the triclinic space group \( P\bar{1} \). Its molecular structure consists of an eight-membered Si\(_2\)C\(_4\)O\(_2\) ring and two four-membered SiOSiC rings. The penta-coordinate Si1 and Si3 atoms in the eight-membered ring feature a distorted trigonal bipyramidal coordination geometry with the N1–Si1–C3 angle of 172.2(1) and the N6–Si3–C6 angle of 170.6(1) in the axial direction, respectively. In comparison, the Si2 and Si4 atoms are also penta-coordinated (ON\(_2\)C\(_2\)), but adopt a stronger distorted trigonal bipyramidal geometry with the C8–Si4–O3 angle of 162.1(1) and the N3–Si2–C3 angle of 161.3(1), respectively. The Si–O distances, ranging from 1.683(3) to 1.728(2) Å, are in the common range of Si–O bonds. The Si–C distances with the carborane C atoms (Si2–C1 2.042(3) and Si4–C8 2.070(3) Å) are significantly longer than those of the C atoms in the eight-membered Si\(_2\)C\(_4\)O\(_2\) ring (1.876(3) to 1.905(3) Å). The C4–C2 (1.537(3) Å) and C5–C7 (1.536(4) Å) interactions, bridging the eight-membered ring and the two carborane clusters, represent C–C single bonds. However, the C–C distances within the eight-membered ring C3–C4 (1.324(4) Å) and C5–C6 (1.337(4) Å) are significantly shorter and indicative of C=C bonds. It is worthy of note that the C4–O4 (1.361(3) Å) and C5–O2 bonds (1.346(4) Å) are much shorter than a C–O bond in ethers, implying considerable electron delocalisation in those C=C–O moieties.

The reactivity of \( 1 \) towards the isoelectronic 2,6-dimethylphenyl isocyanide has also been investigated (Scheme 3). \(^1\text{H} \) NMR measurements showed that compound \( 3 \) is formed as sole product independent of the molar ratio of the starting reactants.
materials chosen. Thus reaction of 1 with two molar equivalents of isocyanide at −20 °C in toluene affords 3 in 78% isolated yields. This is in stark contrast to the reactions of bis-NHSi A with the same isocyanide, 23b which led to E, F, and G (Scheme 1) as products depending on the molar ratio of the starting materials and the reaction conditions.

The 29Si NMR spectrum of 3 shows two resonances at δ = −32.3 ppm (Si=C) and −60.0 ppm (SiC2N), assignable to the four- and five-coordinate Si atoms, respectively. The 13C{1H} NMR spectrum exhibits a signal at δ = 181.7 ppm for Si=C-Si and 190.4 ppm for R-N=C-Si (R = 2,6-dimethylphenyl), respectively. A single-crystal X-ray diffraction analysis revealed that 3 crystallises in the monoclinic space group 1/c.

The molecular structure of 3 (Fig. 2) shows that the two molecules in the asymmetric unit are related by a crystallographic twofold axis normal to the (010) plane. The four-coordinate Si2 atom features a distorted tetrahedral coordination environment, the five-coordinate Si1 atom features also a longer Si1–C5 distance (2.054(2) Å) than that of the four-coordinate Si2 atom in the Si2–C6 bond (1.905(2) Å). The shortest Si2–C3 distance (1.724(2) Å) among all Si–C distances in 3 lies even in the range of Si=C bond distances of silaethylene.25 Similarly, the relatively short C2–N6 (1.281(2) Å) distance compared with that of C3–N5 (1.474(2) Å) suggests C=N bond character. It is noteworthy that compound 3 represents an unique example of head-to-tail coupling product of isocyanide compared to those usual head-to-head coupling products.26

Because all attempts to detect an intermediate even at −78 °C by means of multi nuclear NMR spectroscopy were unsuccessful, Density Functional Theory (DFT) calculations were performed to gain insight into the mechanism of the formation of 2 and 3. The DFT-derived mechanism leading to 2 (Scheme 2 and Fig. S3 in ESI†) follows initially similar reaction steps that have been uncovered previously for the reaction of CO and bis-NHSi A to give C (Scheme 1).23b In contrast to the former case, however, the disilaketene analogue of C (compound 2′, Scheme 2) is a reactive intermediate which undergoes migration of one of the carbons of the carborane from Si to the central carbon of the ketene moiety to afford another intermediate (compound 2″) with a Si=C=C=O moiety; head-to-tail dimerisation of the latter furnishes the final product 2. We think that the newly observed cleavage of the |carbon−Si bond is the consequence of the weaker and more polar nature of the C-Si bond as indicated by the lower Wiberg Bond Index (WBI, 0.53 in 1) compared to the WBI of 0.69 in both A and B. In addition, the proposed ketene intermediate 2′ is energetically 32.5 kcal mol−1 less stable than its dimer 2 in part owing to the steric congestion of 2′ caused by both bridged μ-C=C−O and μ-O. In case of the reaction of 1 with 2,6-dimethylphenyl isocyanide, the isocyanide moiety reacts rapidly with 1 to form 3′ which is attacked by an additional 2,6-dimethylphenyl isocyanide molecule to give 3 (Fig. 3). The latter reaction step shows a very small energy barrier of 1.9 kcal mol−1 that is consistent with the experimental fact that the conversion proceeds at −20 °C. NBO analysis (Tables S5–S7, ESI†) reveals the zwitterionic nature of 3′ (Fig. 3) that enables the reactivity of 3′ towards an additional isocyanide.

In conclusion, the o-carborane supported bis-NHSi 1 is more reactive towards CO and 2,6-dimethylphenyl isocyanide than the previously reported bis-NHSi A and B.21b Owing to the different steric and electronic effects of the o-carborane backbone, the outcome of the reaction of 1 with CO affords solely, via a cascade of cleavage and coupling reactions, the new bis-silylene-mediated polycyclic CO coupling product 2 as the final product. The reaction of 1 with 2,6-dimethylphenyl isocyanide furnishes the new Si=C containing coupling product 3, irrespective of the chosen molar ratio of 1 to isocyanide. The unexpected head-to-head of CO and head-to-tail of isocyanide homocoupling products represent new reactivity features of a
bis-NHSi towards small molecules. More investigations concerning the remarkable reactivity of bis-NHSi 1 to furnish new classes of organosilicon compounds are currently in progress.
