A counterexample to a conjecture of Ghosh

Hung Hua, Elliot Krop, and Christopher Raridan

Abstract. We answer two questions of Shamik Ghosh in the negative. We show that there exists a lobster tree of diameter less than 6 which accepts no $\alpha$-labeling with two central vertices labeled by the critical number and the maximum vertex label. We also show a simple example of a tree of diameter 4, with an even degree central vertex which does not accept a maximum label in any graceful labeling.

Keywords: graceful labeling, Graceful Tree Conjecture, Bermond’s Conjecture, lobster

1. Introduction

For basic graph theoretic notation and definitions we refer to West [4]. The well-known graceful tree conjecture states that for any tree $T$ on $n$ vertices, there exists an injective vertex-labeling from $\{0, \ldots, n-1\}$, so that the set of edge-weights, defined as absolute difference on the labels on incident vertices for each edge, is $\{1, \ldots, n-1\}$.

We call a labeling $f$ bipartite, if there exists an integer $c$ such that for any edge $uv$, either $f(u) \leq c < f(v)$ or $f(v) \leq c < f(u)$. A bipartite labeling that is graceful is called an $\alpha$-labeling. We call the number $c$, the critical number.

For any tree $T$, let $P$ be a longest path in $T$ and call $T$ a $k$-distant tree if all of its vertices are a distance at most $k$ from $P$. At this time, the conjecture is unknown for any trees with tree distance at least 2. For 2-distant trees, or lobsters, the problem is known as Bermond’s conjecture[1].

Recently, in the pursuit of obtaining graceful lobsters from smaller graceful lobster, Ghosh [2] asked two questions, which if answered in the affirmative, could have led to the solution of Bermond’s conjecture. We address both of these questions:
Question 1. [2] Does there exist an \( \alpha \)-labeling of a lobster of diameter at most 5 such that the central vertices are labeled by the critical number and the maximum label?

Question 2. [2] For any tree \( T \) of diameter 4, with central vertex \( v \) of even degree, does there exist a graceful labeling of \( T \) such that the label on \( v \) is the maximum label?

Note: The trees considered in Question 1 were those with two central vertices. In the argument below we answer this as well as another related question.

Definition 1.1. A vertex \( v \) in a tree \( T \) is an almost central vertex, if \( v \) is adjacent to a central vertex and lies on a longest path of \( T \).

Question 3. Does there exist an \( \alpha \)-labeling of a lobster of diameter at most 5 such that the central vertex and an almost central vertex is labeled by the critical number and the maximum label, respectively?

2. An example

Let \( T \) be the following simple 1-distant tree.

![Figure 1. T](image)

Van Bussel [3] showed that \( T \) is not 0-centered, that is, does not accept a graceful labeling with central vertex \( v \) labeled 0. By considering the complementary labelings (vertices relabeled by \( n-1 \) minus their old labels), we conclude that the central vertex cannot be labeled by the maximum label, \( n-1 \). This observation gives a negative answer to Question 2.

We consider Question 3 and again refer to \( T \). If this question is to be answered in the affirmative, \( v \) must be labeled by the critical number \( c \). Since we are looking for an \( \alpha \)-labeling, and if \( v \) is in the lesser labeled partite set, we must have \( c = 3 \). There are only a few cases left to consider; either \( v_1 \) or \( v_2 \) is labeled by the maximum label 5. Since the vertex with the maximum label must be adjacent to the vertex labeled 0, it is easy to verify that there is no graceful labeling of \( T \) whether we label \( v_1 \) or \( v_2 \) by 5.

To answer Question 1, we need another simple example.
Let $S$ be the following simple 1-distant tree.

![Tree Image]

**Figure 2.** $S$

We notice that for an $\alpha$-labeling of $S$, the bipartitions are \{$u_1, u_2, v, u_3$\} and \{$v_1, v_2, v_3$\}.

Assume first that $v$ is labeled by the maximum label, 6. In this case the critical number is 2, so to satisfy the conditions of Question 1, label $v_2$ by 2. Since the vertex with the maximum label must be adjacent to the vertex labeled 0 in any graceful labeling, $v_1$ must be labeled 0. Since $v_3$ is in the bipartition with the lower labels, the label 1 is forced on $v_3$. Notice that in this case, $u_3$ cannot be labeled 5, otherwise the weight 4 would be on two edges. Furthermore, it is easy to check that either a label of 3 or 5 on $u_3$ would produce two edges of the same weight in $S$.

Next, consider the case when $v_2$ is labeled by 6. In this case, the critical number is 3, so we label $v$ by 3. Arguing as above, $u_3$ must be labeled 0, which leads to labeling $u_1$ and $u_2$ by 1 and 2. This leaves only two possibilities. Either $v_1$ is labeled 4 or 5, and in either case the labeling is not graceful.

We note, as suggested by the anonymous referee, that this example is vertex minimum in the sense of Question 1. That is, it is impossible to delete $u_1$ (for example) since this would produce $P_6$, which does accept an $\alpha$-labeling such that the central vertices are labeled by the critical number and the maximum label. Furthermore, there are $\alpha$-labelings of $S$ in which $v_2$ receives either the critical number or the maximum label.

### 3. Acknowledgements

We would like to thank Shamik Ghosh for his valuable comments. We would also like to thank the anonymous referee for the explanation of Question 1, an argument for why the answer is no, and for providing such a helpful review.
