DOI: https://doi.org/10.22271/chemi.2020.v8.i3y.9474

Abstract
Cereal grains are the most important staple foods for mankind worldwide. The constantly increasing annual production and yield is matched by demand for cereals, which is expected to increase drastically along with the global population growth. A critical food safety and quality issue is to minimize the microbiological contamination of grains as it affects cereals both quantitatively and qualitatively. Microorganisms present in cereals can affect the safety, quality, and functional properties of grains. Therefore, it is essential to reduce cereal grain contamination to the minimum to ensure safety both for human and animal consumption. Current production of cereals relies heavily on pesticides input; however, numerous harmful effects on human health and on the environment highlight the need for more sustainable pest management and agricultural methods.

Keywords: Cereal grains, food safety, microorganisms, mycotoxin, human health.

Introduction
Cereals are one of the most important agricultural products in the world, both as human foods and as the main constituent of animal feed. Development of agriculture in prehistoric times was heavily associated with domestication of cereal grains and since their first cultivation most civilizations have become dependent upon cereals for the majority of its food supply (Cordain, 1999) [5]. Cereal grains are the most commonly consumed food group worldwide and they are grown on about 60% of the cultivated land in the world (Koehler and Wieser, 2013) [14]. In order to meet the requirements of a growing world population, worldwide production and yield of cereals has been increased for the last 50 years. Major types of cereal grains include maize, rice, wheat, barley, sorghum, millet, oats, and rye (FAO, 2017) [8]. The potential sources for the contamination of grains are mostly environmentally based and include air, dust, soil, water, insects, rodents, birds, animals, microbes, humans, storage and shipping containers, and handling and processing equipment. Most contamination is of a microbiological nature but heavy metals and process contaminants play a role, too. The secondary metabolites produced by fungi which can grow on grain (or mycotoxins) belong to the most toxic contaminants occurring in a wide range of food commodities (Bennett and Klich, 2003) [2]. Some molds can potentially produce harmful mycotoxins and pose a serious health risk for consumers. Losses of cereal grains during storage are estimated between 5 and 30% due to molds and mycotoxins, 5% for insects and 2% for rodents, with an average yield loss of 1% for developed and 10% to 30% for developing countries. Depending on climatic conditions during growth, grains carry a microbial load with a high diversity of potential spoilage organisms when harvested. In addition, post-harvest contamination during transport is possible. This microbial load consists of bacteria, yeasts, and filamentous fungi belonging to many different genera. The activity of these micro-organisms during storage and, accordingly, the shelf life of the crop is dependent on a range of factors. Amongst the most influential parameters are moisture content and water availability during storage. As a result, grains are usually stored at low moisture contents of 12–13% and a water activity of <0.70.

Sources of microbial contamination of cereal grains
Microbial contamination of cereal grains occurs during crop growth, harvesting and postharvest drying and storage (Magan and Aldred, 2006) [10] and it derives from several sources,
including air, dust, water, soil, insects, birds and rodents feces as well as contaminated equipment and unsanitary handling. The type of microbial contamination varies according to the growing region and is heavily influenced by environmental conditions such as drought, rainfall, temperature, and sunlight, as well as unsanitary handling, harvesting and processing equipment, and poor storage conditions (Bullerman and Bianchini, 2009) [3]. High rainfall just before harvest is a factor inducing extensive colonization of the grain ears by Alternaria spp., causing black fungi discoloration, that can be observable both on the surface of the kernels and as beneath the pericarp.

Table 1: Sources of microbial contamination of cereal grains

| Type of microorganisms | Name of microorganisms                                                                 | References                                                                 |
|------------------------|----------------------------------------------------------------------------------------|----------------------------------------------------------------------------|
| Bacteria               | Salmonella, Escherichia coli, Bacillus cereus, Erwinia herbicola, Xanthomonas campestris, Azotobacter, Pseudomonas, Micrococcus, Lactobacillus | Laca et al., 2006 [13]; Harris et al., 2013 [11]                              |
| Filamentous fungi and yeasts | Eurotium, Aspergillus, Penicillium, Rhizopus, Mucor, Alternaria, Cladosporium, Fusarium, Helminthosporium, Sporobolomyces Rhodotorula, Hansenula, Torulopsis, Candida, and Saccharomyces | Harris et al., 2013 [11]; Pitt and Hocking, 2009 [21]; Bullerman and Bianchini, 2009 [13] |

Table 2: Mycotoxins in cereal grains

| Mycotoxin                      | Fungal source(s)                                                                 | Effects of ingestion for humans                                                                 | Commodity                   |
|--------------------------------|---------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------|-----------------------------|
| Deoxynivalenol/nivalenol        | Fusarium graminearum, Fusarium crookwellense, Fusarium culmorum                  | Human toxicoses e.g. nausea, vomiting, diarrhoea, headache, fever                               | Wheat, maize, barley        |
| Zearalenone                     | Fusarium graminearum, Fusarium crookwellense, Fusarium culmorum                  | Identified by the International Agency for Research on Cancer (IARC 1994) as a possible human carcinogen | Maize                       |
| Ochratoxin A                   | Aspergillus ochraceus, Penicillium verrucosum                                   | Suspected by IARC as human carcinogen                                                         | Barley, wheat, and many other commodities |
| Fumonisin B1                   | Fusarium moniliforme plus several less common species                            | Suspected by IARC as human carcinogen                                                         | Maize                       |

Techniques for control of microbial spoilage of cereal grains

Certain technologies applied to control microbial spoilage of cereals successfully reduce the microbial load.

Table 3: Current methods and technologies used for cereal grains preservation

| Method/Technology | Description                                                                 | Limitations                                                                 | References                                                                 |
|-------------------|-----------------------------------------------------------------------------|---------------------------------------------------------------------------|--------------------------------------------------------------------------|
| Pesticides        | Chemicals designed to prevent and control the occurrence of pests causing harm to crops - molds (fungicides), weeds (herbicides) and insects (insecticides) | High environmental impacts Direct negative impact on human health Increasing resistance against pesticides | Liu et al. (2015) [10]; Jess et al. (2014) [12]                             |
| Drying            | Grains are dried to a low moisture content                                  | Lack of uniformity of the process Over-drying may damage the grains and cause economic losses as well as increase mycotoxin contamination | Varga et al. (2010) [25]; Magan and Aldred, 2006 [19]                      |
| Debranning        | Process during which the bran layers are removed from the endosperm by friction and abrasion | Not completely suitable for wheat due to the crease on the wheat kernels Whole-grain demand in the market | Laca et al. (2006) [15]                                                   |
| Chlorine and hypochlorite | Due to their oxidizing capacity, chlorine and hypochlorite treatments are one of the most widely used processes for microbial control | Low inactivation of fungal spores on cereal grains and generation of toxic by-products after the treatment | Delaquis and Bach (2012) [10]; Virto et al. (2005) [26]; Andrews et al. (1997) [1] |
| Irradiation       | Exposing food to a certain amount of ionizing radiation                     | Can negatively modify the quality and technological properties of cereals and cereal products | Lung et al. (2015) [17]; Farkas et al. (2014) [9]                          |
| Ozone             | Triatomic oxygen formed by addition of a free radical of oxygen to molecular oxygen | The cost of treatment can be relatively high due to complex technology | Greene et al. (2012) [10]; Environmental Protection Agency [EPA] (1999) [7] |

Future trends for decontamination of cereal grains

Table 4: Potential methods and technologies for cereal grains preservation

| Method/ Technology | Description                                                                 | Limitations                                                                 | References                  |
|--------------------|-----------------------------------------------------------------------------|---------------------------------------------------------------------------|----------------------------|
| Microwave (MW) treatment | Electromagnetic waves with frequency within 300 MHz to 300 GHz; microbial inactivation based mainly on thermal effect | Seed viability and seedling vigour can be increased after the treatment Higher microbial reduction levels in presence of other stresses, such as acidic pH or increased temperature | Chandrasekaran et al. (2013) [10]; Reddy et al. (1998) [22]; |
| Pulsed UV light | Short-duration, high-power pulses of a broad spectrum of white light from the UV (50% of the spectrum), to the near infrared region | Low ability to penetrate grains because of their irregular and complex surface Can decrease germination rate of the seeds | Maftei et al. (2013) [15]; Keklik et al. (2012) [13] |
Conclusion
At a time of rapid growth in global populations, sufficient nutritional supply to humanity has become increasingly challenging. On the basis of their long tradition as global staples of the human diet and livestock feed, agricultural crops such as cereals will have a key role in satisfying this growing nutritional need. However, global agricultural area is limited, making it difficult to expand cereal production. Considering that approximately 15% of all cereals worldwide are lost due to microbial pests, the most sensible approach to combat this issue is to increase both food safety and sustainability to reduce economic losses. Pre- and post-harvest microbial spoilage counts as one of the predominant factors in crop loss all over the world. Various strategies to prevent microbial contamination in the field have been investigated and reviewed. However, even the best management practices cannot completely eliminate the risk of contamination. Because of the permanent and ubiquitous presence of microorganisms and fungal spores in the environment, cereals always carry a certain microbial load when harvested. Additionally, climatic conditions, such as temperature and humidity that are not under human control may be crucial for contamination with moulds. Therefore, appropriate post-harvest crop treatment, before and during storage, is as important as pre-harvest strategies in the prevention of microbial spoilage.
