Abstract: In this paper, a nonovershooting tracking controller is proposed for the continuous infusion of multiple drugs that have interactive effects. The proposed controller design method exploits the freedom of eigenstructure assignment pertinent to the design of feedback controllers for multi-input, multi-output (MIMO) systems. For drug dosing, a nonovershooting tracking controller restricts the undesirable side effects of drug overdosing. The proposed tracking controller is based on an estimate of the full state using a hybrid extended Kalman filter (EKF) that is used to reconstruct the system states from the measurable system outputs. An integral control action is included in the controller design to achieve robust tracking in the presence of patient parameter uncertainty. Simulation results and performance analysis of the proposed control strategy are also presented using 20 simulated patients.

Keywords: Nonovershooting control, active drug dosing, biomedical control.

1. INTRODUCTION

Even though the critical task of anesthesia administration has been widely discussed in the literature and studied using clinical trials over the last few decades, several recent reviews on the existing methods highlight various aspects of the problem that needs further research attention [Van Den Berg et al. (2017), Ionescu et al. (2014)]. In the case of patients in ICU’s, anesthetic and analgesic drugs are often required for several hours or days to facilitate cooperative treatment. Overdosing of such drugs have several side effects such as nausea, hypotension, delayed weaning from mechanical ventilation, immunosuppression, and in certain cases is even fatal to patients [Mehta et al. (2006)]. For continuous infusion of anesthetic and analgesic drugs for long periods, it is apparent that an appropriate closed-loop control strategy can be used to enhance patient safety.

We use a common sedation assessment measure such as the bispectral index (BIS) to quantify the sedation level of the patient. The primary hurdle in the design of a closed-loop controller for analgesic administration is the lack of a reliable pain assessment model. The most reliable and valid indicator of pain is the patient’s self-report [Mehta et al. (2006)]. However, critically ill patients are often unable to verbally communicate the level of pain. In an attempt to identify novel and reliable tools to assess pain, several indices using the electroencephalogram (EEG), electromyogram (EMG), heart rate, respiratory rate, skin conductivity, and facial expression have been proposed [Mehta et al. (2006), Jin et al. (2016)].

A semi-adaptive controller which relies on the remifentanil induced respiratory depression of the patient for the closed-loop drug titration is proposed in Jin et al. (2016). However, as pointed out in Ionescu et al. (2014), in the case of ICU patients who are supported by mechanical ventilators, respiratory depression may not be a reliable measure to assess analgesic concentration. Furthermore, it is risky to use heart rate and mean arterial pressure as feedback parameters for analgesic titration; this is primarily due to the variation caused by the concomitant infusion of cardiac depressive sedatives or underlying illness of the patient. Several studies point out the association of remifentanil concentration in the blood with muscle activity of a patient [Mehta et al. (2006), Van Den Berg et al. (2017)]. The EMG-based analgesic index proposed in Ionescu et al. (2014) relates analgesic concentration to EMG. Given that this variable is suitable for conducting in silico trials and also measurable, in this paper we use the EMG-based analgesic index to regulate the analgesic drug infusion rate.

In this paper, we develop a nonovershooting tracking controller for the combined administration of multiple drugs with interactive effects. The proposed controller can track desired outputs such as BIS levels and pain levels without incurring an overshoot in the system response by accounting for synergistic drug interaction, and hence, avoiding drug overdosing. Compared to the design strategies proposed for the combined administration of propofol and remifentanil in Ionescu et al. (2014) and Mahfouf et al. (2005), the advantage of the proposed method is its nonovershooting and robustness properties. The remainder of this paper is organized as follows. Section 2 presents an introduction to the drug kinetics and dynamics for the disposition of propofol and remifentanil followed by the design of...
the nonovershooting controller for the simultaneous infusion of these interactive drugs. Simulation results and statistical analysis using the proposed controller for 20 simulated patients are given in Section 3. Conclusions are presented in Section 4.

2. METHODS

2.1 Drug disposition model

We use a three-compartment model to represent the drug disposition in the human body, where Compartment 1 models the intravascular blood, Compartment 2 models muscle tissue, and Compartment 3 models fat. An effect-site compartment is also used to account for the drug dynamics at the locus of the drug effect [Haddad et al. (2010)]. The mass balance equations used to model the drug transfer between the various compartments are given by [Ionescu et al. (2014)]

\[ \dot{x}_1(t) = -(k_{10} + k_{12} + k_{13})x_1(t) + k_{21} \frac{v_S}{v_1} x_2(t) + k_{31} \frac{v_S}{v_1} x_3(t) + u^S(t), \quad x_0(0) = x_{10}, \quad t \geq 0, \]

\[ \dot{x}_2(t) = k_{12} \frac{v_S}{v_2} x_1(t) - k_{22} x_2(t), \quad x_2(0) = x_{20}, \]

\[ \dot{x}_3(t) = k_{13} \frac{v_S}{v_3} x_1(t) - k_{33} x_3(t), \quad x_3(0) = x_{30}, \]

\[ c_{s\text{eff}}(t) = c_{s0\text{eff}}(t) - k_{50} c_{s\text{eff}}(t), \quad c_{s\text{eff}}(0) = c_{s0\text{eff}}, \]

\[ \dot{x}_4(t) = -(k_{10} + k_{15} + k_{16})x_4(t) + k_{21} \frac{v_A}{v_1} x_5(t) + k_{31} \frac{v_A}{v_1} x_6(t) + u^A(t), \quad x_4(0) = x_{40}, \quad t \geq 0, \]

\[ \dot{x}_5(t) = k_{15} \frac{v_A}{v_2} x_4(t) - k_{25} x_5(t), \quad x_5(0) = x_{50}, \]

\[ \dot{x}_6(t) = k_{16} \frac{v_A}{v_3} x_4(t) - k_{36} x_6(t), \quad x_6(0) = x_{60}, \]

\[ c_{A\text{eff}}(t) = c_{A0\text{eff}}(t) - k_{50} c_{A\text{eff}}(t), \quad c_{A\text{eff}}(0) = c_{A0\text{eff}}, \]

where \( x_i(t), i = 0, 1, 2, 3 \), represent the masses of the sedative drug and \( x_i(t), i = 0, 1, 2, 3 \), correspond to the masses of the analgesic drug in the first, second, and third compartment, respectively, \( c_{s\text{eff}}(t) \), \( c_{A\text{eff}}(t) \), \( k_{ij}, i \neq j \), \( i, j = 1, 2, 3 \), are the rate of mass transfer between the ith and jth compartments, \( v_i \) and \( v_A \), \( v_i \) and \( v_A \), \( i = 1, 2, 3 \), are the volume of three compartments, and \( u^S(t), u^A(t) \), \( t \geq 0, t \geq 0 \), are the infusion rates of the sedative and analgesic drug, respectively. Thus, the state vector is given by \( x(t) = [x_1(t), x_2(t), x_3(t), c_{s\text{eff}}(t), x_4(t), x_5(t), x_6(t), c_{A\text{eff}}(t)]^T \).

In Table 1, \( lbm = 1.07 \text{weight} - 148 \text{(weight}^2/\text{height}^2) \), where \( lbm \) is the lean body mass of the patient, \( k_{00} \) is the effect-site elimination rate constant, \( C_1 \) is the rate at which the drug is cleared from the body by the elimination process, and \( C_2 \) and \( C_3 \) are the rates of drug clearances between the central compartment and Compartments 2 and 3, respectively. When two drugs with synergistic interactive effects are administered simultaneously, the effect of each drug varies according to the ratio of the two drugs and their normalized drug concentration. The measured value of the BIS index, denoted as BIS, ranges from 0 to 100. The net sedative effect of an anesthetic drug when administered along with an analgesic drug having a synergistic interactive effect is given by [Ionescu et al. (2014)]

\[ BIS(t) = BIS_0 \left( 1 - \frac{(U^{S}(t)+U^{A}(t))}{2} \right) \gamma(\phi(t)), \]

where \( \phi(t) = \frac{U^{S}(t)}{U^{S}(t)+U^{A}(t)}, \gamma(\phi(t)), \gamma(0), \) is the steepness of the concentration-response relation at ratio \( \phi(t) \), and \( U_{50}(\phi(t)) \) is the number of units associated with 50% of maximum effect at ratio \( \phi(t) \). Furthermore, \( U^{S}(t), u_0 \), and \( U^{A}(t), u_0 \), are the normalized drug concentrations of the sedative and analgesic drugs and are given by \( U^{S}(t) = \frac{c_{s}^{S}(t)}{c_{S}^{0}} \) and \( U^{A}(t) = \frac{c_{A}^{S}(t)}{c_{A}^{0}} \), where \( c_{S}^{0} \) and \( c_{A}^{0} \) are the drug concentrations of the sedative and analgesic that cause 50% drug effects, respectively.

Remifentanil causes pain reduction as well as muscle relaxation and the percentage of muscle relaxation indicates the amount of remifentanil in the blood. We use the EMG index proposed in Ionescu et al. (2014), which relates the effect-site remifentanil concentration to electromyographic measurements. The relationship between the EMG index and remifentanil concentration is given by

\[ \text{EMG}(t) = \frac{100 \times c_{A}^{0\text{eff}}(t)}{3.4 \times c_{A}^{0\text{eff}}(t) + 0.0063}. \]

The value of the EMG index, \( t \geq 0 \), indicates the percentage of muscle relaxation and varies from 0% to 100%, and hence, (1)–(10) can be written as

\[ x(t) = Ax(t) + Bu(t), \quad x(0) = x_0, \quad t \geq 0, \]

\[ y(t) = h(x(t)), \]

where \( A \in \mathbb{R}^{8 \times 8} \) is a state transition matrix, \( B \in \mathbb{R}^{8 \times 2} \) is an input matrix, \( x(t) \in \mathbb{R}^8, t \geq 0 \), is the state vector, \( u(t) = [u^S(t), u^A(t)]^T \) is the control input, and \( y(t) = \text{[BIS(t), EMG(t)]}^T \) is the system measurement.

As shown in the next section, in order to design a nonovershooting controller, a linear approximation of the measurements (9)

| Parameter | Sedative | Analgesic | Unit |
|-----------|-----------|-----------|------|
| v_1       | 4.27      | 5.1       | 0.0021/(age - 40) + 0.072/lbm - 55 | 1   |
| v_2       | 18.9 - 0.391(age - 53) | 9.82 - 0.0811/(age - 40) + 0.108/lbm - 55 | 1   |
| v_3       | 2.38      | 5.42      | 1    |
| C_1       | 1.89      | +         | 2.6 - 0.0162/(age - 40) + 0.0191/lbm - 55 | 1 min^-1 |
|           | 0.0456(weight - 77) | -         | 0.681/lbm - 59 + 0.0264/(height - 177) | 1 min^-1 |
| C_3       | 0.836     | 0.076     | 2.05 - 0.0301/(age - 40) | 1 min^-1 |
| v_0       | 0.456     | 0.595 - 0.007(age - 40) | 1 min^-1 |
| k_{10}    | C_1/v_1   | C_1/v_1   | min^-1 |
| k_{12}    | C_2/v_1   | C_2/v_1   | min^-1 |
| k_{13}    | C_3/v_1   | C_3/v_1   | min^-1 |
| k_{31}    | C_3/v_3   | C_3/v_3   | min^-1 |
and (10) is required. Using a linear regression model in the region of the required maintenance value for \(BIS(t), t \geq 0\), and EMG(t), \(t \geq 0\), (9) and (10) can be represented as
\[
\begin{bmatrix}
  y_1(t) \\
  y_2(t)
\end{bmatrix} = \begin{bmatrix} m_1 & m_2 \\
  m_1 & m_2
\end{bmatrix} \begin{bmatrix} S^e(t) \\
  e^e(t)
\end{bmatrix} + \begin{bmatrix} c_1 \\
  c_2
\end{bmatrix}. \tag{13}
\]

The parameter values \(m_i, i = 1, 2, \) and the constants \(c_i, i = 1, 2\), in (13) can be determined by multiple linear regression using a least squares method on randomly selected patient data relating the patient’s pharmacokinetic and pharmacodynamic parameters and measured responses [Ionescu et al. (2014)]. Consequently, the linearized patient dynamical model can be written as
\[
x(t) = Ax(t) + Bu(t), \quad x(0) = x_0, \quad t \geq 0, \tag{14}
\]
\[
y(t) = Cx(t) + d, \tag{15}
\]
where \(C = \begin{bmatrix} 0 & 0 & 0 & m_1 & 0 & 0 & m_2 \\
  0 & 0 & 0 & 0 & m_3
\end{bmatrix}\) and \(d = [c_1, c_2]^T\).

2.2 Nonovershooting controller design

The aim is to design a tracking controller in which the patient responses \(BIS(t), t \geq 0\), and EMG(t), \(t \geq 0\), asymptotically approach the desired target values \(BIS_{\text{target}}\) and \(EMG_{\text{target}}\) without any overshoot. The key idea behind the nonovershooting controller design is to obtain a state feedback gain that achieves a specific closed-loop eigenstructure such that the selected modes of the closed-loop system appear in each component of the output [Schmid and Ntogramatzidis (2010)]. In order to achieve robust tracking in the presence of system parameter uncertainty, an integral control action is included in the controller. We define the integral of tracking error as
\[
e(t) = \int_0^t [y_d - y(t)] \, dt, \tag{16}
\]
where \(y_d = [y_d, y_d]^T\) and \((y_d) = [y_1(t), y_2(t)]^T\) are the desired response and the measured response, respectively. Note that \(e(t), t \geq 0\), is given by
\[
e(t) = y_d - y(t), \quad e(0) = 0, \quad t \geq 0. \tag{17}
\]
Next, using (14), (15), and (17) the augmented system \(\Sigma_a\) is given by
\[
x_a(t) = A x_a(t) + B u(t) + H y_d - H d, \quad x_a(0) = x_{a0}, \tag{18}
\]
\[
y(t) = C x_a(t) + d, \tag{19}
\]
where \(x_a(t) = [x(t), e(t)]^T \in \mathbb{R}^n, t \geq 0, n = p + n, H = [0 \ I]^T\),
\[
A_a = \begin{bmatrix} A & 0 \\
  -C & 0
\end{bmatrix}, \quad B_a = \begin{bmatrix} B \\
  0
\end{bmatrix}, \quad C_a = [C, 0_{p \times p}]. \tag{20}
\]

The aim here is to design a control input \(u(t) = K x_a(t)\) such that \(A_a + B_a K_a\) is asymptotically stable and the output \(y(t), t \geq 0\), tracks the reference input \(y_d\) without any overshoot. Since \(\Sigma_a\) is a MIMO system, we can associate multiple sets of \(n\) eigenvectors for a given set of \(n\) eigenvalues. We use this flexibility in eigenvector assignment to achieve the desired nonovershooting property. Specifically, we choose eigenvectors such that a specific set of closed-loop modes appear in the output. Note that for a specific set of \(n\) eigenvalues \(J = \{\lambda_1, \ldots, \lambda_n\}\) and linearly independent eigenvectors \(Y = \{y_1, \ldots, y_n\}\), the associated feedback gain matrix \(K_a\) is unique.

The number of closed-loop modes that can be annihilated from the output signal depends upon the number of invariant zeros of (18) in the left-half plane (LHP). For an open-loop system with \(n - lp\) invariant zeros in the LHP, denoted as \(z_i, i = 1, \ldots, n - lp\), the closed-loop eigenvalues are chosen such that \(\lambda_i = z_i, i = 1, \ldots, n - lp\) [Schmid and Ntogramatzidis (2010)]. The remaining closed-loop poles \(\lambda_i, i \in \{n - lp + 1, \ldots, n\}\), can be chosen to be real and asymptotically stable. Finally, define the Rosenbrock system matrix \(P_{K_a} \triangleq \begin{bmatrix} A_a - B_a C_a \\
  0
\end{bmatrix}\).

Next, let \(\mathcal{J} = \{s_1, \ldots, s_n\} \subset \mathbb{R}^p\), where
\[
s_i = \begin{bmatrix} 0 \\
  i \in \{1, \ldots, n - lp\}, e_1, i \in \{n - lp + 1, n - lp + 2, \ldots, n - lp + l\}, \\
  \vdots \\
  \vdots \\
  \vdots \\
  e_p, i \in \{n - l + 1, \ldots, n\}, \quad (20)
\]
eigenvalues, and \(e_1, \ldots, e_p\) are basis vectors in \(\mathbb{R}^p\). Furthermore, assume that, for \(1 \leq i \leq n\), the matrix equation
\[
\begin{bmatrix} A_a - B_a C_a \\
  0
\end{bmatrix} v_i = \begin{bmatrix} 0 \\
  s_i
\end{bmatrix}. \tag{21}
\]
has a solution characterized by \(\mathcal{J} = \{v_1, \ldots, v_n\} \subset \mathbb{R}^n\) and \(\mathcal{W} = \{w_1, \ldots, w_n\} \subset \mathbb{C}^n\). Now, if the vectors in \(\mathcal{J}\) are linearly independent, then there exists a unique feedback gain matrix \(K_a\) such that, for all \(i \in \{1, \ldots, n\}\),
\[
(A_a + B_a K_a) v_i = \lambda_i v_i, \quad C_a v_i = s_i. \tag{22}
\]
Now, solving (22) for the vectors in \(\mathcal{J}\), we obtain \(\mathcal{J} = \{v_1, \ldots, v_n\}\) and \(\mathcal{W} = \{w_1, \ldots, w_n\}\), where
\[
\begin{bmatrix} v_1 \\
  w_1 \\
  v_i \\
  w_i
\end{bmatrix} = \begin{bmatrix} \mathcal{A}(P_{K_a}(\lambda_i)) & i \in \{1, \ldots, n - lp\} \\
  P_{K_a}^{-1} & i \in \{n - lp + 1, \ldots, n\}
\end{bmatrix}, \tag{23}
\]
and \(\mathcal{A}()\) denotes the null space. Thus, vectors in \(\mathcal{J}\) satisfy \(s_i = C_a v_i\) for all \(i = 1, \ldots, n\).

If the vectors in \(\mathcal{J}\) are linearly independent, then applying Moore’s algorithm we obtain \(K_a\) as
\[
K_a = \mathcal{W} \mathcal{W}^{-1}, \tag{24}
\]
where \(A_a + B_a K_a\) has distinct eigenvalues corresponding to linearly independent eigenvectors given by \(\mathcal{J}\) and \(\mathcal{W}\), respectively. The solution \(v_i \subset \mathbb{C}^n\) and \(w_i \in \mathbb{C}^n\) is in the null space of \(P_{K_a}\) for \(s = \lambda_i, i = 1, \ldots, n - lp\). Now, let \(v_1, v_2, \ldots, v_l\) and \(\lambda_1, \lambda_2, \ldots, \lambda_l\) be the vectors in \(\mathcal{J}\) with their respective eigenvalues associated with the standard basis vector \(\epsilon_k, k = 1, \ldots, p\).

Since the eigenvalues of the closed-loop system are asymptotically stable, it follows that the tracking error \((y_d - y(t)) \rightarrow 0\) as \(t \rightarrow \infty\). Next, define
\[
\hat{A} = A_a + B_a K_a, \quad \hat{H} = H y_d - H d. \tag{25}
\]
so that (18) can be rewritten as
\[
x_a(t) = \hat{A} x_a(t) + \hat{H}, \quad x_a(0) = x_{a0}, \quad t \geq 0, \tag{26}
\]
\[
y(t) = C_a x_a(t) + d, \tag{27}
\]
where \(x_a(t) = e^{\hat{A} t} x_{a0} + e^{\hat{A} t} \hat{A}^{-1} \hat{H} - \hat{A}^{-1} \hat{H} \). Note that the state transition matrix can be written as \(e^{\hat{A} t} = V e^{\hat{V} t} V^{-1}\), where \(\Lambda\) is a diagonal matrix with the eigenvalues \(\lambda_i, i = 1, \ldots, n\), on the diagonal and \(V\) is a matrix composed of the associated eigenvectors. Thus,
\[
x_a(t) = V e^{\hat{V} t} V^{-1} x_{a0} + V e^{\hat{V} t} V^{-1} \hat{A}^{-1} \hat{H} - \hat{A}^{-1} \hat{H}. \tag{28}
\]
Now, defining
\[
\alpha \triangleq \begin{bmatrix} \alpha_1 & \cdots & \alpha_{n-l} p & \alpha_1 & \cdots & \alpha_{p} & \cdots & \alpha_{p,l}
\end{bmatrix}^T = V^{-1} x_{a0}, \tag{29}
\]
and
\[ \beta \triangleq V^{-1} \hat{A}^{-1} a \hat{H} a, \quad (30) \]
the system output \( y(t), t \geq 0, \) is given by
\[
y(t) = \sum_{i=\hat{n}-l+1}^{\hat{n}} e^{-i(\hat{n}-l)p} \alpha_i e^{\lambda_i t} + \sum_{i=\hat{n}}^{n} e^{-i(\hat{n}-l)p} \beta_i e^{\lambda_i t},
\]
\[ \quad - \sum_{i=\hat{n}-l+1}^{\hat{n}} e^{-i(\hat{n}-l)p} \beta_i + d, \]
\[ = \sum_{i=\hat{n}-3p+1}^{\hat{n}} e^{-i(\hat{n}-l)p} \beta_i e^{\lambda_i t} - \sum_{i=\hat{n}-3p+1}^{\hat{n}} e^{-i(\hat{n}-l)p} \beta_i + d, \]
with \( x_0 = 0, \) \( \alpha = 0, \) which implies that \( \hat{n} - lp \) terms are annihilated at the system output \( y(t), t \geq 0, \) and the remaining \( lp \) number of terms are distributed evenly into the \( p \) components of \( y(t), t \geq 0 \) [Schmid and Ntogramatzidis (2010)].

Now, using Lemma A.2 of Schmid and Ntogramatzidis (2010), we can identify conditions to check the monotonicity of (31).

Let \( \hat{A}_1 < \hat{A}_2 < \hat{A}_3 < 0 \) and define
\[ f(t) \triangleq \beta_1 e^{\lambda_1 t} + \beta_2 e^{\lambda_2 t} + \beta_3 e^{\lambda_3 t}, \quad (32) \]
Note that \( f(t) \) has a sign change for some \( t > 0 \) if and only if one of the following conditions hold:

i) \( \beta_1 \beta_2 > 0, \beta_1 \beta_3 > 0, < 0, \) \( |\beta_1| + |\beta_2| > |\beta_3| \).

ii) \( \beta_2 \beta_3 > 0, \beta_1 \beta_3 > 0, \) \( \beta_1 > |\beta_2| + |\beta_3| \).

iii) (a) \( \beta_1 \beta_2 > 0, \beta_1 \beta_3 > 0, \) \( \beta_2 > |\beta_1| + |\beta_3| \);

(b) \( \beta_1 \beta_3 > 0, \beta_1 \beta_2 > 0, \) \( |\beta_2| > |\beta_3| > |\beta_1| \) and \( t^* > 0, \) \( |g_c(t^*)| > \beta_1 + \beta_2 + \beta_3 \), where
\[ t^* = \frac{1}{A_2 A_3 - A_1 A_3} \ln \left( \frac{\beta_3 (A_1 - A_2)}{\beta_1 (A_2 - A_3)} \right) \quad \text{and} \quad g_c(t) = \beta_1 (1 - e^{-A_1 t}) + \beta_2 (1 - e^{-A_2 t}) + \beta_3 (1 - e^{-A_3 t}). \]
 Conditions i)-iii) give necessary and sufficient conditions under which an output of the form (32) changes sign [Schmid and Ntogramatzidis (2010)].

Even though the aforementioned design is based on the linearized model, the closed-loop is implemented using the measured variables \( BIS(t), t \geq 0, \) and \( EMG(t), t \geq 0, \) which are nonlinear functions of the system states. Hence, we use a hybrid extended Kalman filter (EKF) to estimate the system states that are required for state feedback. The discrete-time samples of the measured outputs \( BIS(t), t \geq 0, \) and \( EMG(t), t \geq 0, \) at the \( k \)th time step is given by
\[ y_k = [BIS(x(kT)), EMG(x(kT))]^T, \quad k = 1, 2, \ldots, \quad (33) \]
where \( T \) is the sampling time.

### 2.3 The hybrid extended Kalman filter [Simon (2006)]

Based on the continuous-time dynamics (11), discrete-time measurement (33), and including the process and measurement noise, we have
\[ x(t) = Ax(t) + Bu(t) + w(t), \quad x(0) = x_0, \quad t \geq 0, \]
\[ y_k = h(x_k) + v_k, \quad k = 1, 2, \ldots, \]
where \( x_k = x(kT), w(t) \sim N(0, Q) \) is a continuous-time white noise with covariance \( Q, \) and \( v_k \sim N(0, R) \) is a discrete-time white noise with covariance \( R. \) The hybrid extended Kalman filter for the above system is given as follows:

1. Initialize the filter as follows: \( \hat{x}_0^0 = E[x_0] \) and \( P_0^+ = E[(x_0 - \hat{x}_0^0)(x_0 - \hat{x}_0^0)^T], \) where \( E[\cdot] \) denotes expectation.

2. For \( k = 1, 2, \ldots, \) perform the following:
   a. Integrate the continuous-time model of the state estimate and its covariance as follows:
\[
\dot{\hat{x}}(t) = A \hat{x}(t) + Bu(t), \quad \dot{\hat{x}}((k-1)T) = \hat{x}_k^-,
\]
\[
\dot{P}(t) = AP(t) + P(t)A^T + Q, \quad P((k-1)T) = P_k^-,
\]
where \( (k-1)T < t < kT, \) \( \hat{x}_k^- \) and \( P_k^- \) are the initial conditions at the beginning of this integration process and at the end of this integration we have \( \hat{x}_k^+ = \tilde{\sigma}(kT) \) and \( P_k^+ = \hat{P}(kT). \)
   b. At time \( k, \) incorporate the measurement \( y_k \) into the state estimate and estimation covariance as follows:
\[
\hat{x}_k^+ = \hat{x}_k^- + K_k \left( y_k - h(\hat{x}_k^-) \right), \quad (34)
\]
\[
P_k^+ = (I - K_k J_k) P_k^-,
\]
where \( K_k = P_k^- J_k^T (J_k P_k^- J_k^T + R)^{-1}, \) \( J_k \) is the partial derivative of \( h(x_k) \) with respect to \( x_k \) evaluated at \( \hat{x}_k^- \).

### 3. RESULTS AND DISCUSSION

For our simulations, we consider two cases. Namely, (1) a design for the controller and observer for each patient using the respective patient model, and (2) a design for the controller and observer using a nominal patient model.

**Case 1:** First, we consider the pharmacokinetic models of 10 patients obtained using the model (1)–(8) with parameters and patient features given in Table 1 and 2, respectively. The pharmacokinetic model of each patient is used to derive the controller gain \( K_k \) and estimator gain \( K_k \), \( k = 1, 2, \ldots. \) Patients in the ICUs often require moderate sedation and analgesia for several hours. Hence, for our simulations, we set the desired target values to \( BIS_{target} = 60 \) and \( EMG_{target} = 29. \)

The value of the parameters \( m_i, i = 1, 2, \) and \( 3, \) and constants \( c_i, i = 1, 2, \) and \( 3, \) in (13) can be estimated using the multiple linear regression method. The patient response for different combinations of effect-site concentrations \( c_{\text{eff}}(t), t \geq 0, \) and \( c_{\text{eff}}(t), t \geq 0, \) are obtained using the pharmacodynamic model (9) and (10). For regression, we set the values of the pharmacodynamic parameters to \( C_{50} = 3.1 \mu g/mL, C_{50} = 34 ng/mL, \) and \( \gamma(\phi(t)) = 0.9, \) the range of effect-site concentrations to \( c_{\text{eff}}(t) = 0, 30 \) \mu g/mL and \( c_{\text{eff}}(t) = 0, 25 \) ng/mL. The value of \( U_{50}(\phi(t)), t \geq 0, \) in (9) is calculated using the approximation \( U_{50}(\phi(t)) \approx 1 - \theta(\phi(t)) + \theta^2(\phi(t)), \) where \( \theta = 0.22. \) Using a linear regression, we obtain \( m_1 = -1.3263 \times 10^4, m_2 = -1.1910 \times 10^3, m_3 = 1.5561 \times 10^4, c_1 = 84.98, \) and \( c_2 = 0.0068. \)

**Table 2:** Patient features used to generate 10 simulated patients. Pharmacodynamic parameters of all the 10 patients are set to \( C_{50} = 3.1 \mu g/mL, C_{50} = 34 ng/mL, \) \( \gamma(\phi(t)) = 0.9, \) and \( \theta = 0.22 [Ionescu et al. (2014)].\)
As mentioned earlier, for Case 1, we use the pharmacological features of the simulated patients 1 to 10 given in the Table 2 however, for brevity, we present the calculations involved in the design of nonovershooting controller for Patient 1. Using the system dynamics (1)–(8) and (13) we calculate the values of the system matrices $A_n, B_n, \text{and } C_n$. The controllability matrix with respect to the pair $(A_n, B_n)$ has full rank, and hence, the system is controllable. The stable invariant zeroes of the open loop system given by $z_i, i \in \{1, \ldots, 4\}$, as the desired closed-loop poles of the system i.e. $z_i = \lambda_i, i = 1, \ldots, 4$. Since the system is completely controllable, we can arbitrarily choose the remaining 6 poles such that the closed-loop system is asymptotically stable. We choose the remaining closed-loop poles $\lambda_i, i = 5, \ldots, 10$, to be $\lambda = [-0.7125, \ldots, -0.5445, -0.7139, -0.5510, -0.4, -0.9]$. Now, using (20), we get $s_i = 0$, for $i \in \{1, \ldots, 4\}$, $s_i = e_1$, for $i \in \{5, 6, 7\}$, and $s_i = e_2$, for $i \in \{8, 9, 10\}$. Notice that, since $s_i = 0$, for $i \in \{1, \ldots, 4\}$, the corresponding closed-loop mode associated with $\lambda_i, i \in \{1, \ldots, 4\}$, does not appear at the system output.

Now, using (30) we get
\[
\beta = \left[ \beta_1, \beta_2, \beta_3, \beta_4, \beta_{1,1}, \beta_{1,2}, \beta_{1,3}, \beta_{2,1}, \beta_{2,2} \right]
\]
\[
= \left[ 0 \ 0 \ 0 \ 0 \ -4.128 \times 10^5 \ 4.446 \ 4.086 \times 10^6 \ 1.961 \ -1.886 \ -0.362 \right].
\]

Next, to check the system output for sign changes, we consider the exponential term in (31) given by $\sum_{i=0}^{\infty} e_i \lambda_i^{i-1}$ and use value of $\beta$ to define
\[
\frac{\beta_{1,1}}{(1) \beta_{1,1} e^{\lambda_1} + \beta_{1,2} e^{\lambda_2}} + \beta_{1,3} e^{\lambda_3} + \beta_{2,1} e^{\lambda_2} e^{\lambda_1} + \beta_{2,2} e^{\lambda_2} e^{\lambda_2} + \beta_{2,3} e^{\lambda_2} e^{\lambda_3} \triangleq f_1(t) \frac{f_1(t)}{f_2(t)}.
\]

Note that $f_1(t), i = 1$ and 2, is in the form of (32). Now, it can be easily verified that none of the Conditions (i)–(iii) are met for $f_1(t), t \geq 0$, and $f_2(t), t \geq 0$, with $\beta$ given, and hence, (36) does not possess any sign changes implying that system output (31) is monotonic.

It is clear from Figures 1 and 2, that the responses of all 10 patients are monotonic without any overshoot. All 10 patients have similar responses due to the fact that the closed-loop poles $\lambda_i, i = 5, \ldots, 10$, are chosen to be the same for all the 10 patients. Moreover, since the pharmacodynamic parameters for all the 10 patients are assumed to be the same, the values of the effect-site concentrations that are required to track given target values are the same for all the patients; see Figure 1.

Case 2: To analyze the robustness of the nonovershooting controller to pharmacokinetic and pharmacodynamic variability from the nominal model (Patient 1), we consider 10 patients with parameters given in Table 3. We use the controller gain $K_n$ and estimator gain $K_n, k = 1, 2, \ldots$ derived using the model of Patient 1 to control the continuous infusion of propofol and remifentanil in Patients 11 to 20. To ensure that the infusion rates are positive, we use the control input $u(t) = \max\{0, u(t)\}$, $t \geq 0$. Figures 3 and 4 show the responses of the 10 patients with different pharmacokinetic and pharmacodynamic parameters. Moreover, note that the controller is designed based on the approximated linear pharmacodynamic model given by (13). Hence, Figures 3 and 4 show an achieved robustness of the proposed nonovershooting controller with respect to interpatient variability. Next, to quantify the performance of the proposed nonovershooting controller for closed-loop control of multiple drugs, we can use the median performance error (MDPE), median absolute performance error (MDAPE), root mean square error (RMSE), interquartile range (IQ), minimum and maximum values of the controlled variable (min-max), induction duration (ID), percentage undershoot (US), percentage overshoot (OS), and percentage of time in adequate range (PTAR) [Soltesz et al. (2013)]. The instantaneous performance error is defined as $PE_i(j) = \frac{\text{Measured Value } j - \text{Target Value}}{\text{Target Value}} \times 100$, where $i \in \{1, \ldots, 10\}$ represents the $i$th patient, $j = 1, \ldots, N$, represents the set of PE measurements for an indi-

In this paper, a nonovershooting controller for the simultaneous infusion of sedatives and analgesics is proposed. Simulation results using 20 patients with varying pharmacokinetic and pharmacodynamic parameters show that the proposed nonovershooting controller design method is promising. Our simulation results show that the nonovershooting controller is robust to system parameter uncertainties. Including additional vital physiological parameters such as heart rate and respiratory rate in the controller design will be considered as a future research direction for this work.
