Nuclear Field Theory and Chiral Symmetry on a Calabi-Yau Manifold

Author: J. Anthony de Wet

Abstract

The purpose of this contribution is to show how a nuclear field theory follows naturally from the structure of four-dimensional Riemannian geometry. A Yang-Mills field is introduced by constructing fibres that include all possible exchanges of spin, parity and charge such that the collective quantum numbers remain the same. In this way O(4) internal symmetry transformations are found and a connection is obtained by exponentiation of a CP-invariant operator C associated with the ground state. The metric is Calabi-Yau and Einstein. Carbon 13 is chosen as an example because it is the lightest nucleus to exhibit small spin mutations even though there is no deformation parameter in the O(4) commutation relations. Instead a supersymmetric transformation replaces a quantum group. Mirror symmetry is also discussed.

1 Introduction

de Wet (1996) considered an example of how a $\mathbb{Z}_2$-graded algebra, specifically the Lie algebra of $O(4)$, leads naturally to the well known angular momentum matrices $\sigma_i$ of a coupled system of $P$ protons and $N$ neutrons, namely

$$\sigma_i = E_N \otimes P\Gamma_i + N\Gamma_i \otimes E_P, \ i = 1, 2, 3$$

(1)
where \( P \Gamma_i, N \Gamma_i \) are \((P + 1)\)-, \((N + 1)\)-dimensional Lie operators of \( so(3) \); \( E_P, E_N \) are \((P + 1), (N + 1)\) unit matrices.

Essentially a \( \mathbb{Z}_2 \)-graded algebra splits a bundle \( \Lambda^2 \) into the direct sum

\[
\Lambda^2 = \Lambda^2_+ + \Lambda^2_-
\]  

of self-dual and anti-self-dual 2-forms respectively. An example of this grading is the decomposition

\[
so(4) \cong so(3) + so(3)
\]

into bundles of three-dimensional Lie algebras which were long ago identified by de Wet (1971) with spin and isospin (based upon some ideas of Eddington). In a seminal paper Atiyah et al. (1978) uses this decomposition on the Lie group level to introduce, at least locally, the two complex spinor bundles \( V_+ \) and \( V_- \) : the bundles of self-dual and anti-self-dual spinors. Then \( V = V_+ + V_- \) is isomorphic to the complexified Clifford algebra bundles of one forms \( \Lambda^1 \) (Eddington (1946) called the Clifford algebra \( C_4 \) a Sedenion algebra and we will use his transparent Sedenion, or \( E \)-number, notation).

The purpose of this contribution is to show how a nuclear field theory follows naturally from the structure of four-dimensional Riemannian geometry and to this end we shall consider the Hodge star mapping

\[
* : \Lambda^2 \rightarrow \Lambda^2
\]

as transforming a nucleus into its mirror image i.e. \( (P, N) \rightarrow (N, P) \).

Under these conditions

\[
\text{spin}(\sigma) \rightarrow \text{spin}(\sigma) : \text{isospin}(T_3) \rightarrow -\text{isospin}(T_3)
\]

are the self–dual and the self–anti–dual forms. An example is given by the first and fourth columns of Table I of section 3. (Here we have denoted parity by \( p \) and the spin by \( s \) and in §2 we shall see how the nuclear charge–spin–parity states are labelled by the partition \([\lambda_1 \lambda_2 \lambda_3 \lambda_4]\) of \( A = N + P \) and its four permutations that appear in (18)). Furthermore Atiyah et al. (1978) consider the decomposition of the complexified Clifford algebra bundle

\[
\Lambda^1 = \Lambda^0_c + \Lambda^1_c
\]

2
such that the image of $V_-$ in $\Lambda^1$ is the subspace $\Lambda^{1,0}$ of $(1,0)$ forms that defines a complex structure of the kind considered by de Wet (1995,96). Now a complex manifold in turn decomposes into a sum of the spaces $\Lambda^{1,0}$ and $\Lambda^{0,1}$ of $(1,0)$ and $(0,1)$ forms (Kobayashi and Nomizu (1969) ch. IX) so it is natural to identify the space $\Lambda^{0,1}$ with the self–dual form $\sigma$ associated with $V_+$. Then its conjugate

$$\pi_i = E_N \otimes ^P \Gamma_i - N \Gamma_i \otimes E_P \quad (i = 1, 2, 3)$$

lies in $\Lambda^{1,0}$ (Ibid). We shall see in $\S 2$ how $\pi$ is parity but for the moment simply observe that this definition is also consistent with Table I as described in $\S 3$. The six operators $\sigma_i, \pi_i$ are generators of $O(4)$.

Now a complex structure occurs only on fermions (odd $A$), the even $A$ nuclei being characterised by shell structure, and an example of the decomposition of the 2 complex manifolds carrying $^9Li, ^9C$ is

$$^9Li : 6C_{[3303]} = 34(\sigma + \pi) + 9(\sigma \pi^2 + \sigma^2 \pi) + (\sigma^3 + \pi^3)$$

$$^9C : 6C_{[3033]} = 34(\sigma - \pi) + 9(\sigma \pi^2 - \sigma^2 \pi) + (\sigma^3 - \pi^3)$$

which is manifestly CP–symmetric because $T_3 \to -T_3$ is accompanied by $\pi \to -\pi$. Equation (7) confirms the decompositions given by Kobayashi and Nomizu (1969) and Salamon (1989) where the Wigner coefficients are the number of times the irreducible spin representations

$$S^{1,1} = (\sigma + \pi), \; S^{2,1} = (\sigma \pi^2 + \sigma^2 \pi), \; S^{3,0} = (\sigma^3 + \pi^3)$$

are contained in the subspaces $\Lambda^{1,1}, \Lambda^{2,1}, \Lambda^{3,0}$ of $\Lambda^3$ which are embedded in the Clifford algebra of the $A$ coordinates of $\sigma, \pi$ and their products (cf. Lawson and Michelsohn (1989) for the isomorphism between Clifford algebras and exterior products).

An inspection of (7), (8) shows clearly that fermion CP-invariance follows from the decompositions $S^{1,1}, S^{2,1}, S^{3}$ of the complex manifold. Moreover since such a decomposition applies only to the state $[3303]$ we will associate the ground state with the label $[\Lambda] \equiv [\Lambda_1 \Lambda_2 \Lambda_3 \Lambda_4]$. Then higher energy states will be labelled by $[\lambda] \equiv [\lambda_1 \lambda_2 \lambda_3 \lambda_4]$. These, however, are characterized by the decay of the ground state so can no longer be in a complex manifold.
In section 3 it will be shown that the fermion manifolds have a Ricci-flat Kaehler metric and are therefore Calabi–Yau. Recently there have been several studies of the mirror symmetry of Calabi–Yau spaces (cf. e.g. Strominger et. al. (1996)) but the mirror nuclear manifolds appear to be isomorphic. For example, in section 3 the matrix representations of the CP–invariant operators $C_{[4324]}$, $C_{[4234]}$ of respectively $^{13}C$, $^{13}N$ are identical up to interchange of rows and columns. These representations are derived by substituting (1),(6) into the equations (36),(37) (which are the analogues of (7),(8)) and their rotational eigenvalues $C'_{[\lambda]}$ appear in the last column of Table I. However we can substitute directly in (36),(37) using (38) which is derived from a canonical labelling scheme suggested by (18) of section 2. Again this labelling gives rise to an isomorphism with almost identical rotational eigenvalues $C_{[\lambda]}$ in the penultimate column of Table I.

In fact there are only tiny spin mutations (marked by asterisks) associated with the states $[2533]$, $[4333]$ of $^{13}C$. As discussed in section 3 these are believed to be due to Yang–Mills interaction even though the group $O(4)$ has no deformation parameter $q$ in its commutation relations and is not a quantum group. Instead interaction simply changes the spins of two neutrons in paired states so we have replaced quantum group theory by supersymmetry!

In line with the aims of this contribution we have outlined several correspondences between nuclear theory and the structure of $\mathbb{Z}_2$–graded algebras which of course also plays a role in quantum group theory as outlined by Manin(1991) chapter 4. We can now move on to how a Yang–Mills field is incorporated.

## 2 FIELD THEORY

The basic theory has been reviewed in section 1 of de Wet (1994) so only an outline will be given here. The method used constructs tensor products in the enveloping algebra $A(\gamma)$ of the Dirac ring of an irreducible self–representation

$$\frac{1}{4}\Psi = (iE_4\psi_1 + E_{23}\psi_2 + E_{14}\psi_3 + E_{05}\psi_4)e$$

(10)
with itself. Here Eddington’s E-numbers are related to the Dirac matrices by
\[ \gamma_\nu = i E_{\sigma \nu}, \quad E_{\mu \nu} = E_{\sigma \mu} E_{\sigma \nu}, \quad E^2_{\mu \nu} = -1, \quad E_{\mu \nu} = -E_{\nu \mu} \quad \mu < \nu = 1, \ldots, 5 \]
and the commuting operators \( E_{23}, E_{14}, E_{05} \) are respectively, independent infinitesimal rotations in 3–space, 4–space and isospace that correspond to the spin \( \sigma \), parity \( \pi \), and charge \( T_3 \) carried by a single nucleon. The parameters \( \psi_1, \psi_2, \psi_3 \) are half angles of rotation and \( e \) is a primitive idempotent of the Dirac ring; \( E_4 \) is the unit matrix.

A rotation of 180° about \( x \) will change spin up to spin down and if this is followed by a rotation of 180° about \( t \), \( x \) can go to \(-x\) without inverting time, but instead changing to a left–handed coordinate system. Thus we associate the rotation \( E_{14} \) about \( x \) in 4–space with a parity reversal \( E_{14} \rightarrow -E_{14} \), and this way the time coordinate is ‘rolled up’ so that the Lorentz-invariant representation (10) can describe a nucleon in 3–space.

The basis elements of \( A(\gamma) \) are the \( 4^A \times 4^A \) matrices (\( A=N+Z \))
\[ E^l_{\mu \nu} = E_4 \otimes \cdots \otimes E_4 \otimes E_{\mu \nu} \otimes E_4 \otimes \cdots \otimes E_4 \]
with \( E_{\mu \nu} \) in the \( l \)th position. The elements \( E^l_{\mu \nu}, E^{l+1}_{\mu \nu} \) commute, and \( A(\gamma) \) is found to have the following generators
\[ \Gamma^{(A)}_{\nu} = \frac{1}{2}(E^1_{0 \nu} + E^2_{0 \nu} + \cdots + E^A_{0 \nu}), \quad \nu = 1, \ldots, 5 \quad (11) \]
\[ \sigma^{(A)}_{\mu \nu} = [\Gamma^{(A)}_{\mu}, \Gamma^{(A)}_{\nu}] = (E^1_{\mu \nu} + E^2_{\mu \nu} + \cdots + E^A_{\mu \nu})/2 \quad (12) \]
\[ \eta^{(A)}_{l \nu} = E_{0 \nu} \otimes \cdots \otimes E_{0 \nu} = E^1_{0 \nu} E^2_{0 \nu} \cdots E^A_{0 \nu} \quad (13) \]
\[ \eta^{(A)}_{\mu \nu} = \eta^{(A)}_{l \mu} \eta^{(A)}_{l \nu} = E^1_{\mu \nu} E^2_{\mu \nu} \cdots E^A_{\mu \nu}, \quad \mu < \nu = 1, \ldots, 5. \quad (14) \]

Then the irreducible representations, or minimal left ideals, of \( A(\gamma) \) are
\[ \Psi^{(A)} = \sum_\lambda C_{[\lambda]} P_{[\lambda]} \quad (15) \]
with
\[
C[\lambda] = i^{\lambda_1} C(E_{23}^{\lambda_2} \cdots E_{14}^{\lambda_2+1} \cdots E_{05}^{\lambda_2+\lambda_3} E_{05}^{\lambda_2+\lambda_3+1} \cdots E_{05}^{A-\lambda_1})
\] (16)
if \(C\) denotes summation over the \(N[\lambda] = A!/(\lambda_1!\lambda_2!\lambda_3!\lambda_4!\) combinations of the basis elements appearing in the bracket. Here \([\lambda] \equiv [\lambda_1\lambda_2\lambda_3\lambda_4]\) is a partition \(\lambda_1 + \lambda_2 + \lambda_3 + \lambda_4 = A\) (17) and
\[
P[\lambda] = i^{-A}(i^A \psi_1^{\lambda_1} \psi_2^{\lambda_2} \psi_3^{\lambda_3} \psi_4^{\lambda_4} + \eta_{23}^{(A)} \psi_2^{\lambda_1} \psi_1^{\lambda_2} \psi_4^{\lambda_3} \psi_3^{\lambda_4})
\]
(18)
is a projection operator satisfying
\[
P^2[\lambda] \psi = P[\lambda] \psi, \quad \psi \equiv \psi_1 \psi_2 \psi_3 \psi_4.
\] (19)
Also \(\epsilon_A = e \otimes \cdots \otimes e = e^1 e^2 \cdots e^A\) is a primitive idempotent in \(A(\gamma)\) so that (18) has the same form for \(A\) nucleons as the basic representation (10).

By studying (18) it can be shown that a canonical labelling scheme associates \((\lambda_3 + \lambda_4)\) with the number of nucleons with a positive charge (i.e. the first two terms represent a nucleus and the last two terms its mirror image), \((\lambda_2 + \lambda_3)\) the number with a given spin \(\sigma\), and \((\lambda_2 + \lambda_4)\) with a particular parity \(\pi\). Thus each partition (17) represents a charge-spin-parity state of a nucleus, and by choosing \(4 \times 4\) matrix representations for \(E_{23}, E_{14}, E_{05}\) and constructing fibres that include every possible exchange of spin, parity and charge between nucleons such that the collective quantum numbers remain the same, it may be shown that \(C[\lambda]\) partitions beautifully into a de Rham decomposition of isobaric multiplets. Under these conditions the \(4^A \times 4^A\) matrices (11),(12) shrink to (1),(6) with rows labelled by the fibres \([\lambda]\); where \(\sigma_1 = \sigma_{23}^{(A)}, \pi_1 = \sigma_{14}^{(A)}\) are two of the six generators \(\sigma_j, \pi_j\) of \(O(4)\).

In this way the nucleons interact by means of a Yang–Mills gauge field which can be determined by calculating the connections in the fibre bundle. This has been done by de Wet (1996) by exponentiating \(C[\Lambda]\) and finding the Ricci–flat Kaehler metric of the resulting Calabi–Yau space or torus. In §3
this will be shown to be Einstein which ties in with the ideas of Capovilla et. al. (1990) that say that an $SU(2)$ connection characterises a solution of the source-free Einstein field equations. In fact a compact 4–manifold acted on by a group $SU(2)$ must be a Ricci–flat torus (cf. Salamon (1989) p.106). In other words the nuclear metric is a solution of the source-free Einstein equations!

From another point of view we can regard the Dirac algebra as the infinitesimal ring of Minkowski space and therefore as a tangent space to 4–dimensional space–time in the spirit of Ashtekar (1988). The representations of the tangent space that give us the internal symmetries $\sigma, \pi, T$ are by construction a soldering form (cf. Ashtekar et. al. (1988)) and exponentiation must necessarily take us back to source–free Einstein space.

Returning to (16) the bases of the form $\Lambda^{\lambda_2,\lambda_3}$ are contained in $C_{[\lambda]}$ without the $E_{05}$ elements which as we shall see are needed only to characterise a particular member of an isobaric multiplet. Thus in the next section, where an outline of the decomposition (7),(8) is given, it will become clear that a new $(p,q)$ subspace appears whenever the products $\sigma_0^p \pi_0^q$ of

$$\sigma_0 = 2\sigma_1 = (E_{23}^1 + \cdots + E_{23}^A), \quad \pi_0 = 2\pi_1 = (E_{14}^1 + \cdots + E_{14}^A)$$

contains terms with the same indices. Under these conditions $p + q \leq \lambda_2 + \lambda_3$.

Although a general nuclear state is labelled by $[\lambda]$, there is only one state $[\Lambda] = [\lambda_1 \lambda_2 \lambda_3 \lambda_4]$ having the decomposition (7) associated with the ground state. Then $[\Lambda]$ itself carries all the spin–parity states $[\lambda]$ of Table I. These label the rows of a submatrix

$$\mu = \left[ \begin{array}{c} -B \\ B \end{array} \right]$$

of $C_{[\Lambda]}$ which has the holomorphic coordinates $z_k = \pm i\lambda_k$ where $\lambda_k$ is the eigenvalue associated with $[\lambda]_k$ by means of the correspondence (38) and is real for the submatrix $B$.

In fact $z_k, \overline{z}_k$ characterize the horizontal subspace of a complex Grassmann or Kaehler manifold (Kobayashi and Nomizu (1969), Chapter IX) and because
it is also Ricci-flat and Kaehler it is a twistor space (using the definition of Lawson and Michelsohn (1989) Chapter IV section 9). We shall see how a metric is obtained.

3 AN EXAMPLE: CARBON 13.

In this section the ideas already outlined will be brought together with an example that exhibits spin mutation and at the same time illustrates in more detail how the decomposition (7), (8) of a complex manifold is obtained.

We begin by replacing (16) with

$$C_\lambda = i^\lambda_1 \sigma_0^\lambda_2 \pi_0^\lambda_3 T_0^\lambda_4 - \sum_\lambda i^\lambda_1 \sigma_0^\lambda_2 \pi_0^\lambda_3 T_0^\lambda_4$$

(22)

where in addition to (20)

$$T_0 \equiv 2\Gamma_5^{(A)} = (E_{05}^1 + \cdots + E_{05}^A).$$

The real quantum numbers $s$, $p$ and $T_3 = \frac{1}{2}(Z - N)$ of spin, parity and charge are

$$\sigma_0 = 2is, \quad \pi_0 = 2ip, \quad T_0 = 2iT_3 = i(Z - N)$$

(23)

which show how the quantum numbers of individual nucleons are additive.

The summation contains all those terms arising from repeated indices $E_{23}^j E_{23}^i; E_{23}^j E_{14}^i; E_{23}^j E_{05}^i; E_{14}^j E_{05}^i$ that yield a single term according to the multiplication table

| $E_{23}^j$ | $E_{14}^j$ | $E_{05}^j$ |
|------------|------------|------------|
| $E_{23}^j$ | $i^2$      | $iE_{05}^j$| $iE_{14}^j$ |
| $E_{14}^j$ | $iE_{05}^j$| $i^2$      | $iE_{23}^j$ |
| $E_{05}^j$ | $iE_{14}^j$| $iE_{23}^j$| $i^2$      |

(24)

An elementary example is

$$\sigma_0 T_0 = P(E_{23}^j E_{05}^j) + i\pi_0$$

(25)

where $P$ denotes summation over the $A!/(A - n)!$ permutations of the $n$ generators in the bracket. Then

$$C_{[(A-2)101]} = i^{A-2} P(E_{23}^i E_{05}^j) = i^{A-2}(\sigma_0 T_0 - i\pi_0)$$

(26)
and if \( A = 3, Z = 1; T = -i \) so

\[
C_{[1101]} = (\sigma_0 + \pi_0)
\]  

(27)

which characterizes the ground state of \(^3H\). Now interchange \( \sigma_0 \leftrightarrow \pi_0 \) in (26) to get

\[
C_{[(A-2)011]} = i^{A-2}(\pi_0 T_0 - i\sigma_0)
\]  

(28)

Then if \( A = 3, Z = 2; T = i \) we have

\[
C_{[1011]} = (\sigma_0 - \pi_0)
\]  

(29)

which characterizes the ground state of \(^3He\). Equation (27) is the irreducible spin representation \( \Lambda^1 \) of (9) which occurs once only and (25) is an example of a single term \( \pi_0 \) arising from \( E_{14}^i = E_{23}^i E_{05}^i \) \((i = 1, \ldots, A)\). Because \( T_0 \) is a scalar this term dictates the size of the subspace \( \Lambda^1 \).

Let us now ‘add’ another nucleon by multiplying (25) by \( \pi_0 = (E_{14}^i + \cdots + E_{14}^A) \) to obtain

\[
\sigma_0 \pi_0 T_0 = P(E_{23}^i E_{14}^i E_{05}^i) + i\{P(E_{23}^i E_{23}^j) + P(E_{14}^i E_{14}^j) + P(E_{05}^i E_{05}^j)\} + Ai^2
\]  

(30)

where

\[
\sigma_0^2 = P(E_{23}^i E_{23}^j) + Ai^2; \quad \pi_0^2 = P(E_{14}^i E_{14}^j) + Ai^2; \quad T_0^2 = P(E_{05}^i E_{05}^j) + Ai^2
\]  

(31)

thus

\[
C_{[(A-3)111]} = i^{A-3}P(E_{23}^i E_{14}^i E_{05}^i)
\]  

\[
= i^{A-3}[\sigma_0 \pi_0 T_0 - i(\sigma_0^2 + \pi_0^2 + T_0^2 - 3Ai^2) - Ai^3]
\]  

(32)

Then if \( A = 4, Z = 2, T_0 = 0 \)

\[
C_{[1111]} = \sigma_0^2 + \pi_0^2 + 8
\]  

(33)

which characterizes the ground state of \(^4He\) found to have only one spin configuration. In this case there is no mirror nucleus and \( A \) is even so there is no decomposition like that of (7),(8). We are in fact in a vertical subspace \( h \) of the tangent space to the boson manifold with a matrix representation

\[
\begin{bmatrix}
A & C \\
C & A
\end{bmatrix}
\]  

(34)
Clearly the process may be continued until ultimately the invariant operator for $^9\text{Li}$ is

$$C_{[3303]} = i^3 P(E_{23}^i E_{23}^j E_{05}^k E_{05}^m E_{05}^n)/(3! 3!) \quad (35)$$

which yields (7) after writing $T = i(Z - N) = -3i$ and making use of subsidiary relations such as (31).

When $A = 13$ we find

$$13C : -12C_{[4324]} = 3089(\sigma_0 - \pi_0) + 151(\sigma_0^2 - \sigma_0^3) + 3(\sigma_0^2 \pi_0 - \sigma_0^2 \pi_0^1) + (\sigma_0^4 \pi_0 - \sigma_0^5 \pi_0^1) \quad (36)$$

$$13N : -12C_{[4234]} = 3089(\sigma_0 + \pi_0) + 151(\sigma_0^2 \pi_0 + \sigma_0^3 \pi_0) + 3(\sigma_0^2 \pi_0 + \sigma_0^3 \pi_0) + (\sigma_0^4 \pi_0 + \sigma_0^5 \pi_0) + (\sigma_0^4 \pi_0^1 + \sigma_0^5 \pi_0^1) \quad (37)$$

and once again we have precisely the decomposition given by Salamon (1989, p33) of $\Lambda^5 = \Lambda^2 + \Lambda^3$.

Now if we assume, in accord with the canonical labelling suggested by (18), that $(\lambda_2 + \lambda_3)$ is the number of nucleons with negative spin $\sigma$ and $(\lambda_2 + \lambda_4)$ that number with positive parity $\pi$ then we can determine the eigenvalues of $C_{[\lambda]}$ associated with each configuration $[\lambda]$ simply by substitution of

$$\sigma_0 = \{A - 2(\lambda_2 + \lambda_3)\}i, \quad \pi_0 = \{2(\lambda_2 + \lambda_4) - A\}i \quad (38)$$

in (36),(37). These are eigenvalues without any interaction because as yet no use has been made of (1),(6). However we can also substitute directly from these equations (remembering from (20) that $\sigma_0 = 2\sigma_1, \pi_0 = 2\pi_1$) and use the standard representations of $so(3)$ for $\Gamma^i$ to find a matrix representation $\mu$ of $C'_{[\lambda]}$. The matrix representations of $^{13}N$ and $^{13}C$ are identical up to an exchange of rows and columns and Table I (which does not show repeated eigenvalues) compares the eigenvalues of $C_{[\lambda]}$ and $C'_{[\lambda]}$. Because of the parity change columns 1 and 4 will also yield the same eigenvalues, as will columns 2 and 3 up to a sign change caused by $\sigma_0 \rightarrow -\sigma_0$. Those states associated with the matrix representation $C'_{[\lambda]}$ in the last column are marked by an asterisk and have repeated eigenvalues except when $\lambda_3 = \lambda_4 = 3$.

It is apparent that only the spin-parity states $[2333], [4333]$ exhibit a tiny
mutation of $2/900$. However if the eigenvalues of these states are interchanged so that the ground state $[4333]$ has the value $-460$ instead of $-468$, and $[2533]$ assumes $468$ not $460$ the mutations disappear. Thus these two states are paired, differing only in the number of neutrons with negative spin, so the introduction of a Yang–Mills field simply changes the spin of the two neutrons in the paired states which amounts to a supersymmetric transformation. Another example of paired states is given by Fig. 1 of de Wet (1995, 96) where $X_4$ is the the ground state $[3303]$ of $^9$Li and $X_5$ could be the state $[3321]$.

Yang–Mills fields do not change the energy so there can be no dissipation due to spin–mutations (this would lead to the collapse of nuclei to a zero–spin state). Thus there must either be supersymmetry or the mutation is carried by nucleons moving on two–dimensional toroidal surfaces in such a way as to be anyons.

To find the Kaehler metric on the fermion manifolds we need first to find $exp(C_{[Λ]} \theta)$ which has been treated in some detail by de Wet (1994, 1995, 1996). Specifically

$$e^{\mu \theta} = \mu \sum_{k=0,1,\ldots}^{n} \frac{F_k(\mu) \cos \lambda_k \theta}{i \lambda_k F_k(i \lambda_k)} + i \sum_{k=1,2,\ldots}^{n} \frac{F_k(\mu)}{F_k(i \lambda_k)} \sin \lambda_k \theta \quad (39)$$

where $\mu$ is an irreducible subspace containing $[Λ]$ of $C_{[Λ]}$, $\{1; \lambda_2; \ldots, \lambda_n\}$ are normalised positive, distinct and real eigenvalues of the subspace $B$ of (21), and

$$F_0(\mu) \equiv F(\mu)/\mu, \quad F_k(\mu) \equiv F(\mu)/(\mu^2 + \lambda_k^2), \quad F_k(\mu)F_l(\mu) = 0$$

if

$$F(\mu) \equiv \mu(\mu^2 + 1)(\mu^2 + \lambda_2^2) \cdots (\mu^2 + \lambda_n^2) = 0 \quad (40)$$

Writing (39)

$$e^{\mu \theta} = Z_0(\cos \theta) + Z_1(\sin \theta) = \begin{bmatrix} Z_0 & Z_1 \\ -Z_1 & Z_0 \end{bmatrix}$$

we can now follow Kobayashi and Nomizu(1969) Chapter IX §6 and Wong(1967)
to find the metric on a complex Grassmann manifold, i.e.

$$ds^2 = T_t \frac{dT}{(1 + TT^t)} \frac{dT^t}{(1 + TT^t)}$$ (41)

Where

$$T \equiv Z_1 Z_0^{-1} = -T^t = \mu \sum_{k=1,2,\ldots}^{n} \frac{i(F_k(\mu)/\mu)}{F_k(i\lambda_k)} \tan \lambda_k \theta$$ (42)

$$TT^t = \sum_{k=1,2,\ldots}^{n} K_k(\mu) \tan^2 \lambda_k \theta$$ (43)

Here $T^t, dT^t$ are the conjugate transposes of $T, dT$ and

$$K_k(\mu) = i\lambda_k F_k(\mu)/F_k(i\lambda_k) \mu$$ (44)

is idempotent, so that (41) reduces to the flat measure carried by a torus, namely

$$ds^2 = \sum_{k=1,2,\ldots}^{p} dz_k d\bar{z}_k, \; z_k = i\lambda_k \theta$$ (45)

However a translation to the normalized canonical form

$$\{0; 1; \lambda_2; \ldots; \lambda_n\} \; n \leq p$$ (46)

where $\{\lambda_2; \ldots; \lambda_n\}$ are all positive, involves adding or subtracting an angular momentum $\lambda_0$ and then dividing by $\lambda_f = (\lambda_1 + \lambda_0)$ which may be absorbed in $\theta$ and does not change the geodesics although there is a frequency change in the wave function $e^{i\theta}$. Examples of the translation are the last columns of Table I.

The effect of the translation is to multiply (42) by $\tan \lambda_0 \theta$ which introduces the new distorted metric

$$ds^2 = g_{kk} d(\lambda_k \theta) d(-\lambda_k \theta)$$

$$= d(\lambda_k \theta) d(-\lambda_k \theta) \sum_k \frac{\mu}{\lambda_k} K_k(\mu) g(\lambda_k \mu) \sum_k \frac{\lambda_k}{\mu} K_k(\pi) g(-\lambda_k \theta)$$ (47)

with

$$g(\lambda_k \theta) = -g(-\lambda_k \theta) = \tan \lambda_0 \theta \sec^2(\lambda_k \theta)/(1 + \tan^2 \lambda_0 \theta \tan^2 \lambda_k \theta).$$
Here $\mu = -\overline{\mu}$, $K_k(\mu) = K(\mu)$ and $k = \lambda_k \theta$ are the $p$ distinct coordinates of $B$ in (21), $\overline{\mu} = -\lambda_k \theta$ and $\mp i \lambda_k$ are the coordinates of $\mu$.

The metric (47) was used by de Wet (1996) to find peaks or horns on the manifold of $^9Li$ which could represent instantons that become quarks or leptons at energies sufficiently high to break Yang–Mills symmetry; but for the purposes of this contribution we simply observe that (47) is Einstein according to the definition of Atiyah et al. (1978) because only even products of $\mu$ occur which means a diagonal representation like (34). In other words the fermion metric is a solution of the source–free Einstein equations.

This also ensures that the Ricci tensor vanishes but the sectional curvature

$$K = R_{kkkk} = \frac{\partial^2 g_{kk}}{\partial k \partial k} - \sum_{l=1}^{p} \frac{\partial^2 g_{ll}}{\partial l \partial l}$$

does not because curvature is determined by the orientation of the remaining $p$–planes. Thus a spinor field corresponding to the state $[\lambda]_k$ and propagated parallelly only around the section $kk$ will return to its original value which is precisely the condition found by Green et al. (1993, chapter 15) to show that a Calabi–Yau space or $K^3$ surface carries a string field.

**ACKNOWLEDGEMENT**

It is a pleasure to thank Peter Hall of the University of Port Elizabeth for his help.
