Abstract

Background: Subfertility and infertility treatment can be stressful to a woman trying to conceive. It is not clear whether each predisposes to postpartum mental illness.

Our objective was to quantify the association between subfertility, with or without infertility treatment, and newly diagnosed mental illness after birth.

Methods: This was a population-based cohort study of women without known preexisting mental illness, and who gave birth in Ontario, Canada, 2006-2014. Exposures were: (i) Subfertility without infertility treatment (N = 78,283); (ii) Non-invasive infertility treatment, namely, ovulation induction +/- intrauterine insemination (N = 9178); (iii) Invasive infertility treatment, namely, in vitro fertilization (N = 9633). Each was compared to (iv) women who gave birth following spontaneous conception (N = 688,970).

The primary outcome was new-onset postpartum mental illness ≤ 365 days after birth, defined as either ≥ 2 outpatient visits, any ED visit or a hospitalization, with a diagnosis of a mood or anxiety disorder, psychotic disorder, substance use disorder, self-harm event, or other mental illness.

Results: Women who conceived spontaneously had a rate of postpartum mental illness of 60.8 per 1000 births. Relative to these women, those with subfertility not receiving infertility treatment had a higher aRR of the composite outcome of 1.14 (95% CI 1.10-1.17), as did those who received non-invasive (1.12, 95% CI 1.04-1.21) or invasive (1.14, 95% CI 1.05 to 1.24) infertility treatment.

Interpretation: Women with a history of subfertility or infertility treatment show a somewhat higher risk of mental illness after birth and may benefit from increased monitoring.
Introduction

Pregnancy and childbirth are vulnerable periods for the development of mental illness. Peripartum depression affects 1 in 10 women, with adverse sequelae for mother and child. The US Preventive Services Task Force emphasizes the importance of identifying women at risk for peripartum depression, since appropriate treatment can improve their mental health trajectory. A significant proportion of postpartum emergency department (ED) visits within Canada are due to maternal mental health concerns, while 5% of maternal deaths in the first year postpartum, and a majority of direct, late maternal deaths are attributed to suicide.

Infertility treatments are increasingly used worldwide. Up to 4% of births in Canada are conceived using some form of infertility treatment. Women with a history of infertility, i.e., those who do not conceive after 12 months of unprotected intercourse, may be at higher risk of mental illness, whether or not they use infertility treatment. Potential mechanisms include psychological distress from infertility, adverse effects from hormonal therapy, a higher rate of perinatal loss, and a greater predisposition to medical complications arising in pregnancy or at birth. Prior studies, hampered by cross-sectional designs, have not evaluated more specific psychiatric endpoints, such as emergency department (ED) visits, hospitalization for severe mental illness, or suicidality. Furthermore, previous studies included women with prevalent mental illness and did not assess whether having conceived with or without treatment influenced the outcome. We therefore assessed the incidence of new-onset mental illness within 1 year postpartum in relation to subfertility and type of infertility treatment.

Methods

Study cohort and data sources
This population-based cohort study considered hospital births in Ontario, Canada, 2006 to 2014. During this period, consulting with a physician about infertility issues and monitoring of non-invasive infertility treatment were covered under the province’s universal health insurance plan; however, use of in vitro fertilization (IVF) was largely self-paid.\(^{16,17}\)

Data were analyzed at ICES - an independent, not-for-profit research institute that securely houses an accessible array of Ontario's health-related data [http://www.ices.on.ca](http://www.ices.on.ca). ICES is a prescribed entity under Section 45 of Ontario’s Personal Health Information Privacy Act, in which consent is not required for use of personal data. We followed the Strengthening the Reporting of Observational Studies in Epidemiology (STROBE) guideline.\(^{18}\) The study had research ethics approval by Queen’s University, the Children’s Hospital of Eastern Ontario, and McGill University Health Centre.

At ICES, patient-level records from several databases are linked using unique encoded identifiers. These databases include administrative and health information on care received under the publicly-funded Ontario Health Insurance Program (OHIP). Births and infertility treatments were identified using the Better Outcomes Registry & Network (BORN) Ontario database, which captures 99% of maternal and newborn health records for in-hospital births.\(^{19}\) Other data sources are listed in eTable 1.

This study considered all women in Ontario who had a livebirth or stillbirth at $\geq 20$ weeks’ gestation, between April 1, 2006 and March 31, 2014. We restricted the study to women aged 18 to 55 years who had a valid OHIP number, and also excluded women with pregnancies that ended as induced abortions, surrogate carrier births, as well as women with any diagnosis of mental illness within the 2 years before the estimated date of conception (calculated from the
index birth date minus gestational age in weeks). Each woman was followed for 365 days following delivery hospitalization discharge date, or, very rarely, if her OHIP eligibility ended or she died (<0.5% of the cohort).

**Exposures**

We categorised the type of conception among the women in the study population as follows: i) *spontaneous conception* (the referent), which was contrasted with ii) conception following *subfertility without infertility treatment* (i.e., women who had an infertility consult with a physician within 2 years before the estimated date of conception, based on ICD-9 diagnostic code 628, and who did not receive any infertility treatment); iii) conception following *non-invasive infertility treatment* (i.e., ovulation induction or intrauterine insemination [IUI] only); and iv) conception following *invasive infertility treatment* (i.e., IVF or intracytoplasmic sperm injection [ICSI]) (eTable 2).

**Outcomes**

The primary composite mental illness outcome included a diagnosis of a mood or anxiety disorder, psychotic disorder, substance use disorder, self-harm event, or other conditions, such as an eating disorders or an obsessive-compulsive disorder – identified based on a single ED visit or hospitalization, or ≥ 2 outpatient visits, within 365 days following maternal discharge date from hospital following the index delivery (eTable 3). These algorithms for identifying mental health conditions have been previously used, and their results align with worldwide estimates of postpartum mental illness.20-23 As a proxy for more severe mental illness, we
restricted the analysis to diagnoses based on ED visits and hospitalizations, and excluded
women identified only in outpatient settings.

Covariates

Among available potential confounders, we considered those that may have, directly or
indirectly, influenced infertility and access/use of infertility treatment, as well as mental health.
These included maternal age at index delivery, parity, a diagnostic code for chronic
hypertension, diabetes, or obesity in the 2 years prior to estimated date of conception, income
quintile, urban vs. rural residence, and immigrant status (immigrant vs. Canadian-born) (eTable
4).

The following covariates were not adjusted for in our main models due to the fact that they
were factors in the causal pathway: multiple gestation (vs. singleton), very pre-term delivery (<
34 weeks vs. ≥ 34 weeks), stillbirth vs. livebirth, the presence of an indicator of severe maternal
morbidity (SMM) composite arising in the pregnancy or ≤ 42 days postpartum (vs. none). We
considered these covariates primarily as effect modifiers. We further stratified results based on
eligibility for Ontario Drug Benefit Plan (ODB - a public drug funding system available to persons
above age 65 years or those requiring social assistance).

Data analyses

Descriptive statistics included proportions for categorical variables and means (SD) or
medians (interquartile range [IQR]) for continuous variables. Starting from their date of
discharge for the index hospital delivery, and with a follow up for 365 days thereafter,
cumulative incidence rates of maternal mental illness were calculated per 1000 deliveries.

Unadjusted and adjusted risk ratios (aRRs) and 95% confidence intervals (CIs) were calculated using modified Poisson regression, with robust error variance, which can account for more than one delivery per woman in the study period (n=196,466 repeat deliveries to 172,633 women).

We used a change-in-estimate (CIE) approach to determine inclusion of variables in the final model. We further examined whether the association changed when stratifying by effect modifiers as listed above. We performed a complete case analysis. An additional analysis was done, including women with a diagnosis of mental illness in the 2 years preceding the date of conception, in order to assess mental health exacerbations as well as de novo mental illness.

Analyses were carried out using SAS Enterprise Guide, version 7.1 (Cary, NC, USA).

Results

Of the 1,080,726 deliveries in the study period, 786,064 deliveries to 589,598 women were eligible for the study. These included 78,823 deliveries to women with subfertility without infertility treatment, 9178 deliveries following non-invasive infertility treatment, 9633 deliveries receiving invasive infertility treatment, and 688,970 deliveries with no indication of subfertility or infertility treatment (i.e., deliveries following spontaneous conception; Figure 1).

Women who conceived spontaneously tended to be younger, and were more likely to have resided in a rural area, been eligible for the ODB program, and less likely to be primiparous, have SMM or a stillbirth (Table 1). In contrast, a greater proportion of women who conceived by invasive infertility treatment resided in a high-income quintile area. Complications during pregnancy, and multiple gestation were more common among women who conceived following
invasive infertility treatment, as was the proportion of primiparas. Women who received a non-invasive infertility treatment had a higher prevalence of obesity (Table 1).

The overall incidence of any mental illness within 1 year postpartum was 61 per 1000 deliveries, corresponding to 47493 women with outpatient and/or severe events captured within an ED visit or hospitalization. The majority of events (89.6%) were diagnosed in an outpatient setting. Events occurred a median (IQR) of 5.2 (2.3 to 8.4) months after discharge from hospital for delivery, but occurred on average earlier among those with subfertility or infertility treatment than among those who conceived spontaneously (Table 2). Non-psychotic disorders were most frequently observed in the outpatient setting, with the highest cumulative incidence (63.0 per 1000 deliveries, 95% CI 57.8 to 68.1) seen among those who received non-invasive infertility treatment. Severe mental illness requiring mental health hospitalization or ED visit was much less common, occurring more frequently among those who conceived spontaneously (7.0 per 1000 deliveries, 95% CI 6.8 to 7.2) than in other groups. The most common diagnosis requiring hospitalization or ED visit was a mood or anxiety disorder (4260 women [80.1%]). Deliberate self-harm was rare (Table 2).

Main outcomes

The cumulative incidence of the mental illness composite outcome among women who conceived spontaneously was 60.8 per 1000 births (Figure 2 top). Relative to these women, those with subfertility but no infertility treatment had a higher risk of the composite outcome (62.1 per 1000, aRR 1.14, 95% CI 1.10 to 1.17), with a similar aRR for those with non-invasive infertility treatment (65.8 per 1000, aRR 1.12, 95% CI 1.04 to 1.21). Women who conceived by
invasive infertility treatment had a lower crude absolute risk, but higher adjusted relative risk of
the mental illness composite outcome relative to those conceiving spontaneously (60.4 per
1000, aRR 1.14, 95% CI 1.05 to 1.24).

While no associations were seen between mode of conception and the severe mental health
outcome (Figure 2, middle), the pattern seen for mental illness diagnosed as an outpatient
paralleled that for the composite (Figure 2, lower).

Stratified and additional analyses

Although the absolute rates of the composite mental illness outcome were mostly higher in
women who experienced SMM, gave birth before 34 weeks, had a multifetal pregnancy, or who
were eligible for ODB, the aRRs were similar across the three different fertility groups,
compared with those who conceived spontaneously. Results were unchanged when restricted
to women with a live birth. Due to small numbers, data cannot be presented for women who
experienced a stillbirth.

When we included 137,611 women with a diagnosis of mental illness in the 2 years preceding
the index date of conception, the rate of the composite outcome was substantially higher in all
exposure groups (eFigure 1). Women with subfertility but no infertility treatment had an aRR of
the composite outcome of 1.10 (95% CI 1.08 to 1.13), an aRR of outpatient mental illness of
1.11 (1.08-1.13) and an aRR of severe mental illness of 0.91 (95% CI 0.83-0.99) (eFigure 1).

Interpretation
In this cohort of 786,064 births in Ontario, Canada, the risk of new-onset mental illness was slightly higher in women who experienced subfertility, including among those who did and did not receive infertility treatment to conceive. Most mental health outcomes were mood or anxiety disorders, diagnosed in outpatient settings approximately 4 to 5 months after giving birth.

IVF, typically characterized by repeated rounds of high dose ovarian stimulation and intense hormonal fluctuations, has been postulated to contribute to increased peripartum mood disorders, although not consistently so. IVF-treated women in our cohort experienced a low absolute rate of postpartum mental illness, but a higher relative risk of postpartum mental illness when compared with spontaneous births after adjustment for confounders. A prior systematic review found that women who use IVF are not at higher risk of postpartum mental illness. In our cohort, IVF-treated women were socially advantaged, resided in higher income neighborhoods, and thus able to afford the cost of IVF therapy. Second, IVF necessitates closer medical follow-up, and in some cases, more intense screening for “readiness” for pregnancy, including both physical and mental health fitness. However, the slightly higher relative risk that we found indicates “reverse confounding”, in that after adjustment for maternal age and social determinants of health, there exists an underlying predisposition towards adverse postpartum mental health.

Our findings suggest that women with subfertility, independent of treatment, may experience new-onset mental illness. Previous studies have documented high rates of depressive and anxiety symptoms among individuals seeking assistance for infertility. In our cohort, women with subfertility were more likely to be smokers, and to have antecedent cardiovascular disease.
risk factors, suggesting that pre-existing poor physical health could contribute to both reduced fertility and onset of mental illness postpartum.\textsuperscript{30,31} Women using non-invasive infertility treatment also experienced a higher risk of the composite of postpartum mental illness. IUI-assisted conception is often required among women with polycystic ovarian syndrome,\textsuperscript{32} and 15\% of women in the non-invasive infertility group were obese. Both obesity and polycystic ovarian syndrome are independent risk factors for mood and anxiety disorders.\textsuperscript{33}

Our findings align with existing estimates of the rate of postpartum mental illness in approximately 6\% of women following delivery.\textsuperscript{21-23} In keeping with the work of others,\textsuperscript{34} our stratified analyses suggest that obstetric factors, especially preterm birth < 34 weeks’ gestation, some of which are a consequence of the exposure, are significant determinants of postpartum mental illness.

\textit{Strengths and limitations}

This study has a number of strengths, such as its large sample size, accrued from a multi-ethnic population in the setting of universal provincial health coverage. The ability to categorize women according to the type of infertility treatment, and the possibility of capturing objective psychiatric outcomes were additional strengths. We were also able to evaluate subfertility without treatment, which studies have not done.

This study has several limitations related to the use of administrative health data; namely, misclassification and residual confounding. Exposure to treatment was captured by chart review by trained abstractors at the time of birth, and is therefore likely to be highly reliable, as
are other data elements in our data source\textsuperscript{35}. However, it is possible that some women who conceived by IVF or IUI were not captured with this approach, resulting in non-differential misclassification and a possible underestimate of the effect on mental health. We examined those with \textit{subfertility}, rather than with \textit{infertility}, as we lacked information on time to pregnancy. While we could only capture a subset of women who experienced problems conceiving, we believe nevertheless that our definition is likely a specific indicator of infertility.\textsuperscript{36-38} A further study limitation was the absence of information on cause of infertility, clinical parameters such as body mass index and blood pressure, specific fertility medications, partner experience, and patient-reported outcomes. Finally, we did not have data beyond 2014, thereby limiting our ability to examine the associated effect of the Ontario IVF program\textsuperscript{17} -- launched in 2015 and provided specified IVF services at no costs to all infertile couples -- on mental illness.

\textit{Conclusion}

Women who give birth following a history of subfertility may be more vulnerable to mental illness after birth. It remains to be determined whether these women should receive enhanced resources to optimize peripartum mental health. Future studies should also examine access to infertility treatments among women with mental illness.

aFrom 20 weeks’ gestation up to 42 days postpartum (eTable 4 contains the respective diagnostic codes).

b Based upon hospitalizations, emergency room visits or outpatient physician visits from within 2 years before conception, up to 19 weeks’ gestation.

cDiagnosis of obesity if maternal body mass index > 30 at time of birth or OHIP billing code for obesity (dxcode=278) in 2-year lookback period prior to estimated date of conception

dIncludes any marijuana, cocaine, gas/glue, hallucinogens, methadone, narcotics, opioids and other substance use.
Table 2. Rate of maternal mental illness health outcome within 365 days after the index birth, in relation to type of pregnancy conception. Shown is the severe mental illness outcome and the outpatient mental illness composite outcome, as well as the time to diagnosis of each after the index obstetric birth hospital discharge. All data presented as a rate per 1000 births, unless otherwise indicated. Fewer than 6 outcome events are suppressed.

| Outcome                                      | Spontaneous conception (N = 688,970) | Subfertility without infertility treatment (N = 78,283) | Non-Invasive infertility treatment (N = 9178) | Invasive infertility treatment (N = 9633) |
|----------------------------------------------|--------------------------------------|--------------------------------------------------------|------------------------------------------------|----------------------------------------|
|                                              | N | Rate per 1000 (95 CI) | N | Rate per 1000 (95 CI) | N | Rate per 1000 (95 CI) | N | Rate per 1000 (95 CI) |

CI: confidence interval; IQR: interquartile range

<sup>a</sup>Defined by the presence of 1 or more inpatient hospitalizations or emergency department visits for a substance-related and addictive disorder, schizophrenia spectrum and other psychotic disorder, mood disorder and anxiety disorder, deliberate self-harm event, or other mental illness (eTable 3 contains the respective diagnostic codes).

<sup>b</sup>Defined by the presence of 2 or more outpatient visits for a substance use disorder, psychotic disorder, or a non-psychotic disorder (eTable 3 contains the respective diagnostic codes).
**Figure 1.** Study flow chart.

Births from April 1, 2006 to March 31, 2014  
(N = 1,080,726)

Excluded by study entry criteria  
(N = 249,647)

- Maternal age < 18 or > 55 y
- Gestational age < 20 weeks
- < 2 y of OHIP eligibility
- Induced abortion
- Surrogate pregnancy
- History of mental illness

Excluded for other reasons  
(N = 45,015)

- Unable to link records
- Births outside Ontario

Births conceived spontaneously  
(N = 688,970)

Births with a history of an infertility consult  
(N = 78,283)

Births conceived through non-invasive infertility treatment  
(N = 9178)

Births conceived through invasive infertility treatment  
(N = 9633)

OHIP Ontario Health Insurance Plan; EDC estimated date of conception.
Figure 2: Risk of a maternal mental illness outcome within 1 year after birth in relation to type of pregnancy conception. Shown is the composite mental health outcome of any severe mental health or outpatient mental health encounter (upper); the severe mental health outcome (middle); and the outpatient mental health outcome (lower), as described in eTable 3.a

|          | No. with outcome / No. at risk | Rate /1000 | Unadjusted RR (95% CI) | Adjusted RR (95% CI) |
|----------|--------------------------------|------------|------------------------|----------------------|
| Spontaneous: | 41894 / 688970 | 60.8 | 1.00 (ref) | 1.00 (ref) |
| Subfertile without IT: | 4863 / 78183 | 62.1 | 1.02 (0.99, 1.05) | 1.14 (1.10-1.17) |
| Non-Invasive IT: | 604 / 9178 | 65.8 | 1.08 (1.00, 1.17) | 1.12 (1.04-1.11) |
| Invasive IT: | 582 / 9633 | 60.4 | 0.99 (0.92, 1.08) | 1.14 (1.05-1.14) |
| Spontaneous: | 4832 / 688970 | 7.0 | 1.00 (ref) | 1.00 (ref) |
| Subfertile without IT: | 349 / 78283 | 4.5 | 0.64 (0.57, 0.71) | 1.03 (0.59-1.15) |
| Non-Invasive IT: | 53 / 9178 | 5.8 | 0.82 (0.63, 1.08) | 1.30 (0.99-1.71) |
| Invasive IT: | 36 / 9633 | 3.7 | 0.53 (0.38, 0.74) | 1.15 (0.66-1.66) |
| Spontaneous: | 3847 / 688970 | 57.3 | 1.00 (ref) | 1.00 (ref) |
| Subfertile without IT: | 4713 / 78283 | 60.2 | 1.05 (1.02, 1.08) | 1.13 (1.10-1.17) |
| Non-Invasive IT: | 589 / 9178 | 64.2 | 1.12 (1.04, 1.19) | 1.12 (1.04-1.11) |
| Invasive IT: | 565 / 9633 | 58.7 | 1.02 (0.94, 1.11) | 1.12 (1.03-1.11) |

aRelative risks are adjusted for maternal age, income quintile, rurality, immigrant status, parity, chronic hypertension, diabetes mellitus, and obesity.

RR relative risk; CI confidence interval; IT infertility treatment.
Figure 3: Risk of the composite maternal mental health outcome of any severe mental illness or outpatient mental health encounter within 1 year after birth in relation to type of pregnancy conception, further stratified by patient and pregnancy characteristics.a

|                   | No. with outcome/No. at risk | Rate/1000 | Adjusted RR (95% CI) |
|-------------------|-----------------------------|-----------|----------------------|
| Spontaneous       | 40809/676246                | 60.4      | 1.00 (ref)           |
| Subfertile without IT | 4682/76356                  | 61.3      | 1.13 (1.10-1.16)    |

| Non-Invasive IT    | 551/8549                    | 64.5      | 1.14 (1.05-1.24)    |
| Invasive IT        | 529/8850                    | 59.1      | 1.11 (1.02-1.21)    |
| ODB Eligible b     | 8715/76423                  | 114.0     | 1.00 (ref)           |
| Subfertile without IT | 519/5379                   | 96.5      | 1.03 (0.94-1.12)    |
| Non-Invasive IT    | 53/629                      | 84.3      | 0.84 (0.65-1.09)    |
| Invasive IT        | 53/683                      | 77.6      | 0.86 (0.66-1.11)    |

Relative risks are adjusted for maternal age, income quintile, rurality, immigrant status, parity, chronic hypertension, diabetes mellitus, and obesity.

Ontario Drug Benefit Programme (ODB) eligibility was based on a woman having ≥ 1 ODB-insured medication claim between the estimated date of conception and 1 year after the index birth.

RR relative risk; CI confidence interval; IT infertility treatment; SMM severe maternal morbidity, ODB Ontario Drug Benefit Programme.
### Supplement eTable 1: Data Sources accessed at ICES.

| Dataset                          | Description                                                                                                                                                                                                 |
|---------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| **Health Services**             |                                                                                                                                                                                                             |
| Canadian Institute for Health Information Discharge Abstract Database (CIHI DAD) | A dataset that captures administrative, clinical, and demographic information on hospital discharges, including deaths, sign-outs, and transfers.                                                             |
| National Ambulatory Care Reporting System (NACRS) | A dataset that contains data on hospital-based and community-based ambulatory care: day surgery, outpatient and community-based clinics, and emergency departments.                                           |
| Ontario Health Insurance Plan Claims Database (OHIP) | A dataset that records all claims for reimbursement by Ontario physicians for inpatient and ambulatory visits, consultations and procedures. The data also include claims from optometrists for publicly funded reimbursement and from laboratories for all diagnostic tests performed. |
| Ontario Drug Benefit Claims (ODB) | The Ontario Drug Benefit (ODB) database contains claims for prescription drugs received under the Ontario Drug Benefit program. The Ontario Drug Benefit is a public drug funding system that is only available to persons under the age of 65 who are in special access drug programs or who receive social assistance through the provincial government. |
| Ontario Mental Health Reporting System (OMHRS) | The Ontario Mental Health Reporting System (OMHRS) in Ontario officially collects data on patients in adult designated inpatient mental health beds. This includes beds in General, Provincial Psychiatric, and Specialty Psychiatric facilities. |
| **Population and Demographics** |                                                                                                                                                                                                             |
| Registered Persons Database (RPDB) | A dataset that provides demographic information about all individuals who have received an Ontario health card number, including their date of birth, sex, and home address.                                      |
| Vital Statistics – Office of the Registrar General – Deaths (ORGD) | ORGD is an annual dataset containing information on all deaths registered in Ontario starting on January 1 1990. Information on cause of death is included.                                                  |
| Postal Code Conversion File (PCCF) | A digital file which provides a correspondence between the Canada Post Corporation (CPC) six-character postal code and Statistics Canada’s standard geographic areas for which census data and other statistics are produced. |
| Immigration, Refugees and Citizenship Canada Dataset (IRCC) | A dataset that provides information on permanent and temporary residents of Canada, in addition to immigration and citizenship programs.                                                                 |
| Patient Contact and Eligibility Yearly Files (CONTACT) | Once a person becomes eligible for OHIP an initial record is created with a start date and an infinite end date. When eligibility ends a second record is created with the same start date but a finite end date. |
| **ICES Derived Cohorts**        |                                                                                                                                                                                                             |
| Ontario Asthma dataset (ASTHMA) | The Ontario Asthma Database contains all Ontario asthma patients identified since 1991. A patient is said to be asthmatic if s/he had one hospital admission with an asthma diagnosis or two OHIP claims with asthma diagnosis within two years. |
| Congestive Heart Failure (CHF)  | The Ontario Congestive Heart Failure Database contains all Ontario individuals identified as having CHF since 1991. A patient is said to have CHF if s/he had one hospital admission (either from the DAD or from OMHRS) with a CHF diagnosis or an OHIP claim/NACRS ED record with a CHF diagnosis followed within one year by either a second record with a CHF diagnosis from any source. |
| Chronic Obstructive Pulmonary Disease (COPD) | The database was created using hospital discharge abstracts from the CIHI database (including same day surgery), physician service claims from the OHIP database and information regarding the demographics of persons eligible for health care coverage in Ontario from the Registered Persons Database (RPDB). A patient is said to have COPD if s/he had |
| Dataset                                      | Description                                                                                                                                                                                                 |
|----------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Ontario HIV Database (HIV)                   | The database was created using physician claims in the OHIP database. Persons enter the HIV database as incident cases when they have 3 physician claims in 3 years with a diagnosis code of “042”, “043”, or “044”. |
| Ontario Hypertension Dataset (HYPER)         | A dataset of all of the people in Ontario identified as having hypertension.                                                                                                                                  |
| Linked Delivering Mothers and Newborns (MOMBABY) | A dataset that is derived within ICES to link the inpatient admission records of delivering mothers and their newborns.                                                                                       |
| Ontario Diabetes Dataset (ODD)               | A dataset of all of the people in Ontario diagnosed with diabetes.                                                                                                                                            |
| Acquired Cohorts                              |                                                                                                                                                                                                             |
| Better Outcomes Registry & Network (BORN) Ontario | A longitudinal administrative data source that collects information related to maternal, perinatal, and newborn health in Ontario. Includes a six-year dataset (2006-2011) of legacy birth record data (formerly collected in the Niday Perinatal Database). |
**Supplement eTable 2: Variables used to define cohort entry, exclusion criteria and study exposures.**

| Assessment | Timing | Disease or procedure or condition | Applicable codes | Data Sources |
|------------|--------|-----------------------------------|-----------------|-------------|
| **Cohort entry criterion** | April 1st, 2006 to March 31st, 2014. | All livebirths and stillbirths at ≥200 weeks gestation among women aged 18-55 years. | -- | BORN |
| **Exclusion Criteria** | At the time of hospitalization for delivery | Inductions for the purposes of termination. | BORN Field= IND_FOR_LBR_INDUCT_PRIM_ID=1014250 OR ALL_IND_FOR_LBR_INDUCT_ID=1014250 | BORN |
| | | | BORN Field= CONCEPTION_TYPE_ID=1013170 | BORN |
| | Same | Surrogate pregnancy. | -- | BORN |
| | Same | Less than 2 years of OHIP eligibility prior to the estimated date of conception. | Calculations for estimated date of conception: NIDAY = date of delivery – (gestational age in weeks*7) BORN = estimated_bdate – (40*7) | RPDB |
| | Same | Birth outside of Ontario. | -- | BORN |
| | Same | No infant record in BORN. | -- | BORN |
| | Same | No IKN or inability to link to ICES datasets. | -- | RPDB |
| | Same | Warning in Niday dataset. | -- | BORN |
| | Same | History of mental health outcome | History of a mental health outcome as defined by one of our study outcomes within the 2 years prior to the estimated date of conception. | OMHRS, DAD, NACRS, OHIP, BORN |
| **Main Study Exposures** | At the index pregnancy | Mode of conception | BORN Field= CONCEPTION_TYPE_ID Niday Field= REPASS | BORN |
| | | | Invasive IT (IVF or IVF-ICSI): BORN=1013130, 1013140 Niday=3,4 | |
| | | | Non-Invasive IT (OI, IUI): BORN=1013110, 1013120, 1013150, 3000006 Niday=2,5 | |
| | | | Subfertile: • Conception type = Spontaneous or Unknown (1013160, 1013180 [BORN] or 1,9,0 [Niday]) AND • History of infertility=YES | |
| | | | Spontaneous: • Conception type = Spontaneous or Unknown (1013160, 1013180 [BORN] or 1,9,0 [Niday]) AND • History of infertility=NO | |
| | Same | History of Infertility | Determined based on OHIP billing codes in the look-back window of 2 years prior to the estimated date of conception. Infertility is to be defined as any occurrence of billing code 628 (all feecodes, include lab, feesuff=A). | OHIP |
**Supplement eTable 3:** Variables used to define study outcome up to 365 days after the maternal date of discharge for the index birth. If date of discharge is missing, assume date of delivery is date of discharge.

| Disease or procedure or condition | Applicable codes                                                                                                                                                                                                                                                                                                                                                                                                                                                                 | Data Sources                          |
