Abstract. Suppose that $f$ is a transcendental entire function. In 2011, Rippon and Stallard showed that the union of the escaping set with infinity is always connected. In this paper we consider the related question of whether the union with infinity of the bounded orbit set, or the bungee set, can also be connected. We give sufficient conditions for these sets to be connected and an example of a transcendental entire function for which all three sets are simultaneously connected. This function lies, in fact, in the Speiser class.

It is known that for many transcendental entire functions the escaping set has a topological structure known as a spider’s web. We use our results to give a large class of functions in the Eremenko–Lyubich class for which the escaping set is not a spider’s web. Finally, we give a novel topological criterion for certain sets to be a spider’s web.

1. Introduction

Let $f$ be an entire function. When studying complex dynamics, it is usual to partition the complex plane into two sets: the Julia set $J(f)$, which contains those points in a neighbourhood of which the iterates of $f$ are chaotic, and its complement the Fatou set $F(f) = \mathbb{C} \setminus J(f)$. The Fatou set is open, and its connected components are called Fatou components. For more information on complex dynamics, including precise definitions and properties of these sets, we refer to [Ber93].

Recently, several authors have worked with an alternative partition. This divides the plane into three sets determined by the nature of the orbits of points; the orbit of a point $z \in \mathbb{C}$ is the sequence $(f^n(z))_{n \geq 0}$ of its iterates under $f$. We define these sets as follows.

Firstly, the escaping set is given by

$$I(f) := \{ z \in \mathbb{C} : f^n(z) \to \infty \text{ as } n \to \infty \}.$$ 

The escaping set for a general transcendental entire function $f$ was first studied by Eremenko [Ere89]. He showed that $I(f) \cap J(f) \neq \emptyset$ and that all components of $\overline{I(f)}$ are unbounded. He also conjectured that the same is true of all components of $I(f)$. 
This conjecture, which is still open, has since been the focus of much research in complex dynamics.

Secondly, the bounded orbit set is defined by

$$BO(f) := \{ z \in \mathbb{C} : \text{there exists } K > 0 \text{ such that } |f^n(z)| < K, \text{ for } n \geq 0 \}. $$

When $f$ is a polynomial, $BO(f)$ is known as the filled Julia set and has been much studied.

The set $BO(f)$ for a transcendental entire function $f$ was studied in, for example, [Ber12, BKZ09, CF96, Osb13, Rem09] and [Sta94].

Finally, the bungee set is defined simply as

$$BU(f) := \mathbb{C} \setminus (I(f) \cup BO(f)).$$

It is easy to see that if $P$ is a polynomial, then there is a punctured neighbourhood of infinity that lies in $I(P)$, and so $BU(P)$ is empty. However, if $f$ is transcendental, then $BU(f)$ is non-empty. In fact, see [OS16, Theorem 5.1], the Hausdorff dimension of $BU(f) \cap J(f)$ is greater than zero. The properties of $BU(f)$ were studied in [Laz17] and in [OS16].

From here onwards we assume that $f$ is transcendental. It is now known that the set $\hat{I}(f) := I(f) \cup \{\infty\}$ is a connected subset of the Riemann sphere; see [RS11, Theorem 4.1]. Moreover, see [ORS17, Theorem 1.1], the same property holds for $I(f) \cup BU(f) \cup \{\infty\}$. Our principal interest in this paper is to ask whether there are conditions that ensure that one or both of the sets

$$\hat{BO}(f) := BO(f) \cup \{\infty\} \text{ and } \hat{BU}(f) := BU(f) \cup \{\infty\}$$

can also be connected. In fact, we have the following result.

**THEOREM 1.1.** There is a transcendental entire function $f$ such that each of the sets $\hat{I}(f)$, $\hat{BO}(f)$ and $\hat{BU}(f)$ is connected.

**Remark.** The function $f$ in Theorem 1.1 has only two singular values (points at which it is not possible to define some inverse branch). It follows that $f$ is in the Speiser class $S$, which consists of those transcendental entire functions for which the set of singular values is finite.

Since $\hat{I}(f)$ is always connected, in order to prove Theorem 1.1 we give sufficient conditions for $\hat{BO}(f)$ or $\hat{BU}(f)$ to be connected. We then show that there is a transcendental entire function with the necessary properties. The first result is as follows.

**THEOREM 1.2.** Suppose that $f$ is a transcendental entire function. If $f$ has an unbounded Fatou component in $BO(f)$ (respectively $BU(f)$), then $\hat{BO}(f)$ (respectively $\hat{BU}(f)$) is connected.

**Remark.** The usefulness of the second part of this theorem is limited by the fact that there are relatively few examples of transcendental entire functions with Fatou components in $BU(f)$. Examples of a transcendental entire function with such a Fatou component were given in [Bis15] and [EL87]. The only examples of Fatou components in $BU(f)$ which are also known to be unbounded were given in [Laz17] and [OS16].
The second result requires the notion of a finite logarithmic asymptotic value, which we define as follows. We use the notation

$$B(a, r) := \{z \in \mathbb{C} : |z - a| < r\} \text{ for } a \in \mathbb{C} \text{ and } r > 0.$$  

**Definition 1.** Suppose that \( f \) is a transcendental entire function. A value \( \alpha \in \mathbb{C} \) is a finite logarithmic asymptotic value of \( f \) if there exist \( r > 0 \) and a component \( U \) of \( f^{-1}(B(\alpha, r)) \) such that the restriction \( f : U \to B(\alpha, r) \setminus \{\alpha\} \) is a universal covering.

Our sufficient condition for the connectedness of \( \hat{B}U(f) \) is as follows.

**Theorem 1.3.** Suppose that \( f \) is a transcendental entire function. If \( f \) has a finite logarithmic asymptotic value \( \alpha \in J(f) \), then \( \hat{B}U(f) \) is connected.

**Remark.** In [OS16] the authors asked if there is a transcendental entire function \( f \) such that \( BU(f) \) is connected. Although this question is still open, these results give at least a partial answer.

Recent study of \( I(f) \) has shown that this set often has a topological structure known as a spider’s web. The following definition of a spider’s web was first given in [RS12].

**Definition 2.** A connected set \( E \subset \mathbb{C} \) is a spider’s web if there exists a sequence of bounded simply connected domains, \( (G_n)_{n \in \mathbb{N}} \) such that

$$\partial G_n \subset E, \ G_n \subset G_{n+1} \text{ for } n \in \mathbb{N} \text{ and } \bigcup_{n \in \mathbb{N}} G_n = \mathbb{C}.$$  

Clearly, if \( I(f) \) is a spider’s web, then neither \( \hat{B}O(f) \) nor \( \hat{B}U(f) \) can be connected. In fact, in some sense, the converse is also true: if \( \hat{B}O(f) \cup \hat{B}U(f) \) is disconnected, then \( I(f) \) is a spider’s web. See Corollary 4.2 below.

There are now many examples of transcendental entire functions \( f \) such that \( I(f) \) is a spider’s web; see, for example, [Evd16], [RS12] and [Six11]. However, none of these examples is in the much studied Eremenko–Lyubich class \( B \); this class consists of those transcendental entire functions for which the set of singular values is bounded. The techniques used to prove our earlier results can be used to show that there is a large subclass of class \( B \) for which the escaping set is not a spider’s web.

**Theorem 1.4.** Suppose that \( f \in \mathcal{B} \) is a transcendental entire function. If \( f \) has a finite logarithmic asymptotic value, then \( I(f) \) is not a spider’s web.

In fact, we conjecture the following.

**Conjecture.** If \( f \in \mathcal{B} \) is a transcendental entire function, then \( I(f) \) is not a spider’s web.

Our final result is the following, which gives a simple topological characterisation of an \( I(f) \) spider’s web, and also an \( A(f) \) spider’s web, for a transcendental entire function \( f \). Here \( A(f) \) is the so-called fast escaping set, which was introduced in [BH99], and can be defined, see [RS12], by:

$$A(f) := \{z \in \mathbb{C} : \text{ there exists } \ell \in \mathbb{N} \text{ such that } |f^{n+\ell}(z)| \geq M^n(R, f), \text{ for } n \in \mathbb{N}\}. \quad (1.1)$$
Here the *maximum modulus function* is defined by $M(r, f) := \max_{|z|=r} |f(z)|$ for $r \geq 0$. We write $M^n(r, f)$ to denote repeated iteration of $M(r, f)$ with respect to the variable $r$. In (1.1), we assume that $R > 0$ is sufficiently large so that $M^n(R, f) \to \infty$ as $n \to \infty$. Finally, we say that a set $E \subset \mathbb{C}$ separates a point $z \in \mathbb{C}$ from infinity if there is a bounded open set $U$ such that $z \in U$ and $\partial U \subset E$.

**Theorem 1.5.** Suppose that $f$ is a transcendental entire function. Then $I(f)$ (respectively $A(f)$) is a spider’s web if and only if it separates some point of $J(f)$ from infinity. If $f$ has no multiply connected Fatou components, then $J(f)$ is a spider’s web if and only if it separates some point of $J(f)$ from infinity.

It is interesting to compare Theorem 1.5 to [ERG17, Theorem 1.5], which states that, in general, a connected subset of the plane is a spider’s web if and only if it separates every finite point from infinity.

**Remark.** It is known that if $f$ is a transcendental entire function, then $I(f)$ contains an unbounded component; see [RS12, Theorem 1.1]. This implies that neither $BO(f)$ nor $BU(f)$ can be a spider’s web.

**Structure of the paper.** The structure of this paper is as follows. Firstly, in §2 we gather some preliminary results. Secondly, in §3 we prove Theorems 1.2 and 1.3 and then use these results to prove Theorem 1.1. Finally, in §4 we prove Theorems 1.4 and 1.5.

2. Preliminary results

We use the following, which is known as the ‘blowing-up’ property of the Julia set; see, for example, [Ber93, Lemma 2.2]. Here an exceptional point is a point with finite backward orbit; there is at most one such point.

**Lemma 2.1.** Suppose that $f$ is a transcendental entire function, and $V$ is an open set that meets $J(f)$. If $K$ is a compact set that does not contain an exceptional point, then there exists $n_0 \in \mathbb{N}$ such that $f^n(V) \supset K$ for $n \geq n_0$.

We also require a result on wandering domains. If $f$ is a transcendental entire function, and $U$ is a Fatou component of $f$, then we say that $U$ is preperiodic if there exist $n, m \in \mathbb{N}$ with $n \neq m$ and $f^n(U) = f^m(U)$. If this is not the case, then we say that $U$ is wandering. We use the following [OS16, Theorem 1.5] which, roughly speaking, says that most points on the boundary of a wandering domain have the same behaviour under iteration as the domain itself. Here, for a transcendental entire function $f$, the *ω-limit set* $\omega(z, f)$ of a point $z \in \mathbb{C}$ is the set of accumulation points of its orbit in $\hat{\mathbb{C}}$. For a wandering domain $U$ of $f$, it follows by normality that $\omega(z_1, f) = \omega(z_2, f)$ for $z_1, z_2 \in U$, so in this case we can write $\omega(U, f)$ without ambiguity.

**Lemma 2.2.** Suppose that $f$ is a transcendental entire function and that $U$ is a wandering domain of $f$. Then the set $\{z \in \partial U : \omega(z, f) \neq \omega(U, f)\}$ has harmonic measure zero relative to $U$.

We need the following, which is [Six15, Lemma 3.1].
LEMMA 2.3. Suppose that \((E_n)_{n \in \mathbb{N}}\) is a sequence of compact sets and \((m_n)_{n \in \mathbb{N}}\) is a sequence of integers. Suppose also that \(f\) is a transcendental entire function such that \(E_{n+1} \subset f^{m_n}(E_n)\) for \(n \in \mathbb{N}\). Set \(p_n = \sum_{k=1}^{n} m_k\) for \(n \in \mathbb{N}\). Then there exists \(\xi \in E_1\) such that

\[
 f^{p_{n}}(\xi) \in E_{n+1} \quad \text{for} \quad n \in \mathbb{N}. \tag{2.1}
\]

If, in addition, \(E_n \cap J(f) \neq \emptyset\) for \(n \in \mathbb{N}\), then there exists \(\xi \in E_1 \cap J(f)\) such that (2.1) holds.

To prove Theorem 1.3 we require the following, which seems to be new.

LEMMA 2.4. Let \(f\) be a transcendental entire function with a finite logarithmic asymptotic value \(\alpha \in \mathbb{C}\). Let \(r > 0\) be sufficiently small so that \(f\) is a universal covering from a component \(T\) of \(f^{-1}(B(\alpha, r))\) to \(B(\alpha, r)\). Then there exist \(R > 0\) and a component \(V\) of \(T \cap B(0, R)\) such that the following holds. Suppose that \(\gamma \subset \mathbb{C}\) is a continuum such that \(V\) lies in a bounded component of \(T \setminus \gamma\). Then the complementary component of \(f(\gamma \cap T)\) containing \(\alpha\) lies in \(B(\alpha, r)\).

Proof. Let \(r\) and \(T\) be as in the statement of the lemma. Now, \(\partial T\) is an unbounded Jordan curve containing infinitely many preimages of \(\partial B(\alpha, r)\), each of which is bounded. Hence, we can choose \(R > 0\) sufficiently large so that there is a component \(V\) of \(T \cap B(0, R)\) such that \(f(V)\) contains an annulus of the form \(A := \{z \in \mathbb{C} : r - \delta < |z - \alpha| < r\}\), for some \(\delta \in (0, r)\).

Now, suppose that \(\gamma \subset \mathbb{C}\) is a continuum such that \(V\) lies in a bounded component of \(T \setminus \gamma\). Let \(S\) be the component of \(\mathbb{C} \setminus f(\gamma \cap T)\) that contains \(\alpha\). We need to show that \(S \subset B(\alpha, r)\). Suppose, therefore, that this is not the case. Then \(S\) contains both \(\alpha\) and a point \(\xi \in A\). Since \(S\) is a domain, we can let \(\Gamma\) be a curve in \(S\) that joins \(\alpha\) and \(\xi\). Without loss of generality (replacing \(\xi\) with some other point of \(\Gamma \cap A\) if necessary), we can assume that \(\Gamma \subset B(\alpha, r)\).

Let \(\zeta' \in V\) be a preimage of \(\xi\), and let \(\Gamma'\) be the component of \(f^{-1}(\Gamma)\) that contains \(\zeta'\). Then \(\Gamma' \subset T\) joins a point in \(V\) to a point in an unbounded component of \(T \setminus \gamma\), which is a contradiction. \(\square\)

3. Results on \(\hat{I}(f), \hat{BO}(f)\) and \(\hat{BU}(f)\)

Theorem 1.2 is a consequence of the following lemma.

LEMMA 3.1. Suppose that \(f\) is a transcendental entire function with an unbounded Fatou component in \(BO(f)\) (respectively \(BU(f)\)). Suppose that \(U\) is a bounded domain that meets \(BO(f)\) (respectively \(BU(f)\)). Then \(\partial U\) also meets \(BO(f)\) (respectively \(BU(f)\)).

Proof. We prove only the case of \(BO(f)\). The case of \(BU(f)\) is very similar and is omitted.

Suppose first that \(U \subset F(f)\). If \(U\) is not itself a Fatou component, then the result follows by normality. Hence, we can assume that \(U\) is a Fatou component of \(f\).

If \(U\) is preperiodic, then it is easy to see that \(\partial U \subset BO(f)\). Hence, we can assume that \(U\) is wandering. The conclusion of the lemma then follows by Lemma 2.2.

We can assume, therefore, that \(U\) meets \(J(f)\). Let \(V\) be the unbounded Fatou component in \(BO(f)\). It follows by Lemma 2.1 that there exists \(n \in \mathbb{N}\) such that
Proof of Theorem 1.2. As in the case of Lemma 3.1, we prove only the case of BO(f). The case of BU(f), which is very similar, is omitted.

Suppose that, with the hypotheses of the theorem, \( \widehat{\text{BO}}(f) \) is not connected. Then there are disjoint open sets \( H_1, H_2 \subset \mathbb{C} \) such that

\[
\widehat{\text{BO}}(f) \subset H_1 \cup H_2 \quad \text{and} \quad \partial H_i \cap \text{BO}(f) = \emptyset \quad \text{for} \quad i \in \{1, 2\}.
\]

Without loss of generality, we can assume that \( H_1 \) is bounded and meets BO(f). It follows by Lemma 3.1 that \( \partial H_1 \) meets BO(f), which is a contradiction, completing the proof.

Theorem 1.3 is a consequence of the following, which clearly is analogous to Lemma 3.1.

**Lemma 3.2.** Suppose that \( f \) is a transcendental entire function, and that \( f \) has a finite logarithmic asymptotic value in \( J(f) \). Suppose that \( U \) is a bounded domain that meets BU(f). Then \( \partial U \) also meets BU(f).

**Proof.** Suppose first that \( U \subset F(f) \). If \( U \) is not itself a Fatou component, then the result follows by normality. Hence, we can assume that \( U \) is a Fatou component of \( f \). It is known [OS16, Theorem 1.1] that \( U \) must be wandering. The result then follows by Lemma 2.2.

We can assume, therefore, that \( U \) meets \( J(f) \). Let \( \alpha \in J(f) \) be a finite logarithmic asymptotic value of \( f \). Let \( r, R > 0 \), let \( T \) be a component of \( f^{-1}(B(\alpha, r)) \), and let \( V \) be the component of \( T \cap B(0, R) \), such that the properties stated in Lemma 2.4 all hold.

Let \( (R_n)_{n \in \mathbb{N}} \) be a sequence of real numbers larger than \( R \) that tend to infinity. Let \( W \) be a bounded open disc containing any exceptional point of \( f \). We can also assume that \( \overline{W} \subset B(0, R_n) \) for \( n \in \mathbb{N} \).

We now construct a point in \( \partial U \cap \text{BU}(f) \). Set \( U_1 := U \). By Lemma 2.1, there exists \( n_1 \in \mathbb{N} \) such that \( B(0, R_1) \setminus W \subset f^{n_1}(U_1) \). Hence, there is a continuum \( E_1 \subset \partial U_1 \) such that \( V \) lies in a bounded component of \( T \setminus f^{n_1}(E_1) \).

Now consider \( f(f^{n_1}(E_1) \cap T) \). It follows by an application of Lemma 2.4 that the complement of \( f(f^{n_1}(E_1) \cap T) \) has a simply connected component containing \( \alpha \) and lying in \( B(\alpha, r) \). Call this component \( U_2 \). Note that \( \partial U_2 \subset f^{n_1+1}(E_1) \).

Since \( U_2 \) meets \( J(f) \) —recall that \( \alpha \in J(f) \) —we can iterate the above construction. We obtain a sequence of integers \( (n_k)_{k \in \mathbb{N}} \) and a sequence of continua \( (E_k)_{k \in \mathbb{N}} \) such that

\[
E_{k+1} \subset f^{n_{k+1}}(E_k), \quad f^{n_k}(E_k) \subset \mathbb{C} \setminus B(0, R_k) \quad \text{and} \quad f^{n_{k+1}}(E_k) \subset B(\alpha, r) \quad \text{for} \quad k \in \mathbb{N}.
\]  

(3.1)

It follows by Lemma 2.3 that there is a point \( \zeta \in E_1 \) and a sequence of integers \( (p_k)_{k \in \mathbb{N}} \) such that \( f^{p_k}(\zeta) \in E_{k+1} \) for \( k \in \mathbb{N} \). It follows from (3.1) that \( \zeta \in \partial U \cap \text{BU}(f) \), as required.

Finally in this section, we use these results to prove Theorem 1.1.
Proof of Theorem 1.1. We construct a transcendental entire function $f$ with a finite logarithmic asymptotic value in $J(f)$ and a second finite logarithmic asymptotic value lying in $F(f) \cap \text{BO}(f)$. It is easy to deduce from the second fact that $f$ has an unbounded Fatou component in $\text{BO}(f)$. The result then follows by Theorems 1.2 and 1.3.

Consider the family of functions

$$f_{\alpha, \beta}(z) := \frac{2\alpha}{\sqrt{\pi}} \int_0^z e^{-w^2} dw + \beta = \alpha \text{erf}(z) + \beta \quad \text{for } \alpha, \beta \in \mathbb{C}, \alpha \neq 0.$$ 

Here erf$(z)$ denotes the error function; see [AS72, p. 297].

Clearly, $f_{\alpha, \beta}$ has no critical values. It can be seen that $f_{\alpha, \beta}$ has two finite logarithmic asymptotic values, which are obtained as $z$ tends to infinity along the real axis in the positive and negative directions. It is a calculation to show that these asymptotic values are equal to $\pm \alpha + \beta$.

We choose values for $\alpha$ and $\beta$ so that $\alpha + \beta \in J(f_{\alpha, \beta})$ and $-\alpha + \beta$ lies in a parabolic basin of $f_{\alpha, \beta}$. First, we let $c$ be a complex solution to erf$(z) = 1$. In particular, we set $c = -1.3548101281 \ldots + 1.9914668428 \ldots i$; see [DLMF, Table 7.13.2]. We then let

$$\alpha = \frac{e^c \sqrt{\pi}}{2} \quad \text{and} \quad \beta = c - \alpha.$$ 

It follows that

$$f_{\alpha, \beta}(\alpha + \beta) = f_{\alpha, \beta}(c) = \alpha + \beta \quad \text{and} \quad f'(\alpha + \beta) = \frac{2\alpha}{\sqrt{\pi}} e^{-c^2} = 1.$$ 

Hence $\alpha + \beta$ is a parabolic fixed point and so lies in the Julia set of $f_{\alpha, \beta}$. It can be seen from Figure 1 that $-\alpha + \beta$ lies in the parabolic basin of this point. This is exactly what we require. \hfill \square

Remarks.
(1) It follows by [RRRS11, Theorem 1.2] that every component of $I(f_{\alpha, \beta})$ is unbounded and path-connected; in the terminology of [Ben17], $f_{\alpha, \beta}$ is criniferous. It can be seen also that this function is postsingularly bounded. We refer to [Ben17] for a definition and further information on functions with this property.

(2) From the computer pictures, it appears that $F(f_{\alpha, \beta})$ is connected, although we have not been able to prove this. If this were indeed the case, then it would follow at once that $\text{BO}(f)$ and $\text{BO}(f)$ are connected.

(3) Clearly, another approach to the proof of Theorem 1.1 would be to find a transcendental entire function $f$ with an unbounded Fatou component in $\text{BO}(f)$ and an unbounded Fatou component in $\text{BU}(f)$; the result would follow by Theorem 1.2. While this seems possible, it is also likely to be more complicated than the example given here because of the difficulty of constructing transcendental entire functions with an unbounded Fatou component in $\text{BU}(f)$.

4. Results on spiders’ webs
Recall that if $f \in \mathcal{B}$, then $I(f) \subset J(f)$; see [EL92, Theorem 1]. It follows that Theorem 1.4 is an immediate consequence of the following.
THEOREM 4.1. Suppose that $f$ is a transcendental entire function with a finite logarithmic asymptotic value $\alpha \notin F(f) \cap I(f)$. Then $I(f)$ separates no finite point from infinity.

Proof. Suppose first that $\alpha \in J(f)$. It follows that $\widehat{BU}(f)$ is connected, by Theorem 1.3. Hence $I(f)$ is not a spider’s web. On the other hand, if $\alpha \in F(f)$, then either $\alpha \in BO(f)$ or $\alpha \in BU(f)$. In these cases, the result follows by Theorem 1.2. \hfill \Box

Next we prove Theorem 1.5.

Proof of Theorem 1.5. One direction is immediate; it is easy to see from the definition that a set separates every point of $\mathbb{C}$ from infinity if it is a spider’s web.
In the other direction, we consider first the case for $I(f)$. Suppose that $I(f)$ separates a point of $J(f)$ from infinity. In other words, there is a bounded open set $U$ that meets $J(f)$, such that the boundary of $U$ lies in $I(f)$. Let $W$ be a disc containing any exceptional point of $f$. Suppose that $R > 0$ is sufficiently large so that $B(0, R) \subset U$. By Lemma 2.1, there exists $n = n(R) \in \mathbb{N}$ such that $B(0, R) \setminus W \subset f^n(U)$. Since $I(f)$ is forward invariant, it follows that for all sufficiently large $R > 0$, there is a bounded simply connected domain $G$ such that $B(0, R) \subset G$ and $\partial G \subset I(f)$.

The fact [RS12, Theorem 1.1] that $I(f)$ contains an unbounded component implies that $I(f)$ contains a spider’s web. The remark [RS12, p. 807] then implies that $I(f)$ is a spider’s web.

The case for $A(f)$ is almost identical to that of $I(f)$ and is omitted. If $f$ has no multiply connected Fatou components, then it follows from [Kis98, Theorem 1] that all components of $J(f)$ are unbounded. The result for $J(f)$ then follows in much the same way as that for $I(f)$.

The following, which was promised in the introduction, is now quite straightforward.

**Corollary 4.2.** Suppose that $f$ is a transcendental entire function. Then $I(f)$ is a spider’s web if and only if $\widehat{BO}(f) \cup \widehat{BU}(f)$ is disconnected.

**Proof.** One direction is immediate, and so we assume that $\widehat{BO}(f) \cup \widehat{BU}(f)$ is disconnected. Then there is a bounded open set $U$ such that $U$ meets $BO(f) \cup BU(f)$ and $\partial U \subset I(f)$. Arguing as in the proof of Lemma 3.1, we can deduce that $U \cap J(f) \neq \emptyset$. The result now follows by Theorem 1.5.

**Acknowledgements.** The author is grateful to Lasse Rempe-Gillen, Phil Rippon, Gwyneth Stallard and John Osborne for useful conversations and also to Ben and Pete Strulo for their help with Figure 1. The author is also grateful to the referee for useful comments.
