SUMMARY 93

BIBLIOGRAPHY 98
INTRODUCTION

It is well-known that, for the systems with finite motion, one can introduce the distinguished set of phase space variables (the “action-angle” variables), such that the “angle” variables parameterize a torus, while their conjugated “action” variables are functions of constants of motion only \[1\]. As a consequence, the Hamiltonian depends only on action variables. The formulation of an integrable system in these variables gives us a comprehensive geometric description of its dynamics. Such a formulation defines a useful tool for the developing of perturbation theory \[1, 2\], since the “action” variables define adiabatic invariants of the system. The action-angle formulation is important from the quantum-mechanical point of view as well, since in action-angle variables the Bohr-Sommerfeld quantization is equivalent to the canonical quantization, with trivial expressions for the wavefunctions. Hence, evaluation of quantum-mechanical aspects of such system becomes quite simple in this approach.

Besides the practical importance, the action-angle formulation has an academic interest as well. From the academic viewpoint, it gives a precise indication of the (non)equivalence of different Hamiltonian systems. Indeed, gauging the integrable system by action-angle variables, we preserve the freedom only in the functional dependence of the Hamiltonian from the action variables, \( H = H(I) \), and in the range of validity of the action variables, \( I_i \in [\beta_i^-, \beta_i^+] \). Hence formulating the systems in terms of action-angle variables, we can indicate the (non)equivalence of different integrable systems. Let us refer, in this respect, to the recent paper \[3\], in which, particularly, the global equivalence of \( A_2 \) and \( G_2 \) rational Calogero models, and their global equivalence with a free particle on the circle, has been established in this way.

Due to the recent progress in nanotechnology, now the fabrication of various low-dimensional systems of complicated geometric form (nanotubes, nanofibers, spherical and cylindrical layers) is becoming possible \[4\]. In these context the methods of quantum mechanics on curved space should be relevant for the description of the physics of nanostructures. The common method for the localizing of the particle in the disc or in the cylinder is that of the two-dimensional
oscillator for the role of the confinement potential. Similarly, for the localization of the particle in quantum lens (e.g. GaAs/In$_{1-x}$Ga$_x$As, see [5]) one can use the Higgs model of the spherical oscillator defined by the potential $V_{\text{Higgs}} = \frac{1}{2}\omega^2 r_0^2 \tan^2 \theta$ [6]. Another confinement potential which could be used for the localization of the (quasi)particles in quantum lens, is the potential of the so-called $CP^1$ oscillator $V_{\text{Higgs}} = 2\omega^2 r_0^2 \tan^2 \theta/2$ [7]. The advantage of the latter potential is that a system with such confinement potential preserves the exact solvability after inclusion of magnetic field, which has a constant magnitude on the sphere surface.

The fabrication of semiconductor ring-shaped systems [8], presently referred to as quantum rings (e.g. In(Ga)As - two-dimensional quantum rings), led to the use of the singular oscillator potential with the role of the confinement one. A pioneering work on the theoretical study of the impact of the magnetic field on the electron properties in a quantum ring was written by Chakraborty and Pietelainen [9]. In that paper the shifted oscillator potential $V_{\text{ChP}} = \beta(r - r_0)^2$ was choosen as the confinement potential restricting the motion of electrons in the quantum ring. The results obtained within this approximation are in a good correspondence with experimental data. The quantum ring model of Chakraborty and Pietelainen is not exactly solvable in the general case, it assumes the use of numerical simulations. The quantum ring model based on the singular oscillator system [10] has been suggested as an analytically solvable alternative to the Chakraborty-Pietelainen model. Although calculations performed within the Chakraborty-Pietelainen model are in better correspondence with experimental data than those within the singular oscillator potential [11], the latter has its own place in the study of quantum rings (see, e.g. [12]).

In analogy with the above models, one can suppose, that singular versions of two-dimensional Higgs and $CP^1$ oscillators may be appropriate candidates for the confinement potential localizing the motion of the electron in the ring of a spherical quantum layer.

In Chapter 1 we start with presenting the general procedure of constructing the action-angle variables for an arbitrary system with finite motion. Then, in Section 1.2 action-angle variables are used for the study of a quantum ring model with two-dimensional singular oscillator poten-
tial, and of its two spherical generalizations, based on the Higgs and $CP^1$ spherical oscillator potentials. It is easy to observe that the (singular) Higgs oscillator does not preserve its exact solvability in the presence of a constant magnetic field, in contrast to the Euclidean one. While the study of quantum dot systems in a magnetic field is of a special physical importance. In contrast with the Higgs oscillator, the singular $CP^1$ oscillator preserves the exact solvability property upon inclusion of the constant magnetic field. These tell us the area of application of the Higgs oscillator potential and of the $CP^1$ oscillator one. The Higgs model is useful for the behavior of the quantum dots systems in the external potential field, e.g., in the electric field. The $CP^1$ model should be applied for the study of the behavior of a spherical quantum dots model in the external magnetic field.

The aim of Chapter 2 is to construct integrable generalizations of the well-known oscillator and Coulomb systems on $N$-dimensional Euclidian space $R^N$, sphere $S^N$ and hyperboloid $H^N$. We show, that if we have an angular (spherical) Hamiltonian, we can add a radial part to it, thus increasing the dimension by one (the phase space dimension is increased by two). We compute the explicit expressions for action-angle variables for systems with oscillator and Coulomb potentials. Using this formulae, we prove the superintegrability of Tremblay-Turbiner-Winternitz (TTW, [13, 14]) and Post-Winternitz (PW, [15]) models. Then we construct the spherical and pseudospherical generalizations of the TTW and PW systems, write down their hidden constants of motion, thus demonstrating the superintegrability of these new systems. Additionally, we provide the action-angle variables for a free particle on the $(N−1)$-dimensional sphere, which yields the complete set of action-angle variables for the $N$-dimensional oscillator and Coulomb systems as well as their spherical and pseudospherical analogs.

Conformal invariance plays an important role in many areas of the quantum field theory and condensed matter physics, especially in the string theory, the theory of critical phenomena, low-dimensional integrable models, spin and fermion lattice systems. The term “conformal mechanics” denotes a system whose Hamiltonian $H$, together with the dilatation generator $D$ and the generator $K$ of conformal boosts forms, with respect to Poisson brackets, the confor-
mal $\text{so}(2,1)$ algebra. This property allows one to introduce a coordinate transformation which transforms the Hamiltonian into the ”conventional” Hamiltonian of (one-dimensional) conformal mechanics \[16\]. This means, that with the corresponding selection of new radial coordinate and momentum, we split the generic conformal mechanical system into a radial and an angular part. The latter defines a new Hamiltonian system on the orbit of the conformal group, with Casimir function $\mathcal{I}$ of the conformal algebra $\text{so}(2,1)$ in the role of the Hamiltonian. Casimir function $\mathcal{I}$ does not depend on the new radial coordinate and momentum, and is called the spherical or angular part of the Hamiltonian. It commutes with all generators of $\text{so}(2,1)$ and defines a constant of motion of the initial Hamiltonian $H$. So, although conformal symmetry is not a symmetry of the Hamiltonian, it equips the system with the additional (to the Hamiltonian) constant of motion.

Chapter 3 is devoted to the study of conformal mechanics. We develop a general approach to the constants of motion for conformal mechanics, based on $\text{so}(3)$ representation theory. We present the procedure of separating the radial and angular parts of conformal mechanics. Then we study the angular part as a new Hamiltonian system (master mechanics) with finite motion. We find the constants of motion of master mechanics from the constants of motion of the initial conformal system. We illustrate the effectiveness of our method on the example of the rational $A_3$ Calogero model and its spherical mechanics (which defines the cuboctahedric Higgs oscillator). For the latter we construct a complete set of functionally independent constants of motion, proving its superintegrability.

The suggested method, i.e., separating the radial and angular parts of conformal mechanics and studying the angular part using the action-angle variables, was effectively implemented in the study of extremal black holes.

The black hole solutions allowed in supersymmetric field theories have an extremality property, that is, the inner and outer horizons of the black hole coalesce. In this case one can pass to the near-horizon limit, which brings us to new solutions of Einstein equations. In this limit (near-horizon extremal black hole) the solutions become conformal invariant. The conformal
invariance was one of the main reasons why the extremal black holes have been payed so much attention to for the last fifteen years. Indeed, due to conformal invariance black hole solutions are a good research area for studying conformal field theories and AdS/CFT correspondence (for the recent review see [17]). The simplest way to research this type of configurations is to study the motion of a (super)particle in this background. The first paper that considered such a problem is [18], where the motion of particle near horizon of extremal Reissner-Nordström black hole has been considered. Later similar problems in various extremal black hole backgrounds were studied by several authors (see [19] [20] [21] and refs therein).

In Chapter 4 we study the conformal mechanics associated with near-horizon motion of massive relativistic particle in the field of extremal black holes in arbitrary dimensions. In 4.1 we prove, that by applying a proper canonical transformation one can bring the above mentioned model to the conventional conformal mechanics form. Important information about the $d$-dimensional system, is thus imprinted in the $(d-2)$-dimensional spherical mechanics. In 4.2 we demonstrate the near-horizon limit of extremal black holes on the cases of 4-dimensional Kerr black hole and higher-dimensional Myers-Perry black holes.

Section 4.3 is devoted to study of the following two 4-dimensional exactly solvable systems:

- Charged particle moving near the horizon of extremal Reissner-Nordström black hole with magnetic momentum,
- Particle moving near the horizon of extremal Clément-Gal’tsov black hole.

We construct the action-angle variables for the angular parts of this systems. We show that the angular part of a charged particle moving near the horizon of Reissner-Nordström black hole is equivalent to the spherical Landau problem, and has a hidden constant of motion. We find a “critical point” that divides the different phases of effective periodic motion. Then we discuss a charged particle moving near the horizon of extremal Clément-Gal’tsov black hole. In contrast with Reissner-Nordström case, this system does not possess hidden constant of motion. We find a critical point that divide the phases (both effectively two-dimensional ones) of rotations
in opposite directions.

In Chapter 5 we analyse the integrability of spherical mechanics models associated with the near horizon extremal Myers-Perry black hole in arbitrary dimension for the special case that all rotation parameters are equal. We prove the superintegrability of the system and show that the spherical mechanics associated with the black hole in odd dimensions is maximally superintegrable, while its even-dimensional counterpart lacks for only one constant of the motion to be maximally superintegrable.
1 ACTION-ANGLE VARIABLES

1.1 Action-angle variables: General description

The well-known Liouville theorem gives the exact criterium of integrability of the $N$-dimensional mechanical system (integrability in the Liouville sense or, so-called, Liouville integrability): that is the existence of $N$ mutually commuting constants of motion $F_1 = H, \ldots, F_n$: $\{F_i, F_j\} = 0, i, j = 1, \ldots, N$. The theorem also states that if the level surface $M_f = ((p_i, q_i) : F_i = \text{const})$ is a compact and connective manifold, then it is diffeomorphic to an $N$-dimensional torus $T^N$. The natural angular coordinates $\Phi = (\Phi_1, \ldots, \Phi_N)$ parameterizing that torus satisfy the motion equations of a free particle moving on a circle. These coordinates form, with their conjugate momenta $I = (I_1, \ldots, I_N)$, a full set of phase space variables called “action-angle” variables.

One of the results of the theorem is that the momenta $I$ depend on constants of motion only: $I = I(F)$ (which makes $I$ a new set of constants of motion). So, there must be a canonical transformation to the new variables $(p, q) \mapsto (I, \Phi)$, in which the Hamiltonian depends on the constants of motion $I$ (which are called action variables) only. Consequently, the equations of motion read

$$
\frac{dI_i}{dt} = 0, \quad \frac{d\Phi_j}{dt} = \frac{\partial H(I)}{\partial I_i} \quad \{I_i, I_j\} = \delta_{ij}, \quad \Phi_i \in [0, 2\pi), \quad i, j = 1, \ldots, N. \quad (1.1)
$$

The formulation of the integrable system in action-angle variables gives us a comprehensive geometric description of its dynamics [1, 2]. Such a formulation defines a useful tool for the developing of perturbation theory, since the “action” variables define adiabatic invariants of the system. The action-angle formulation is important from the quantum-mechanical point of view as well, since in action-angle variables the Bohr-Sommerfeld quantization is equivalent to the canonical quantization, with trivial expressions for the wavefunctions. Hence, evaluation of quantum-mechanical aspects of such system becomes quite simple in this approach.

Besides the practical importance, the action-angle formulation has an academic interest as well. From the academic viewpoint, it gives a precise indication of the (non)equivalence of different
Hamiltonian systems. Indeed, gauging the integrable system by action-angle variables, we preserve the freedom only in the functional dependence of the Hamiltonian from the action variables, \( H = H(I) \), and in the range of validity of the action variables, \( I_i \in [\beta_i^-, \beta_i^+] \). Hence formulating the systems in terms of action-angle variables, we can indicate the (non)equivalence of different integrable systems. Let us refer, in this respect, to the recent paper \[3\], where, particularly, the global equivalence of \( A_2 \) and \( G_2 \) rational Calogero models, and their global equivalence with a free particle on the circle, has been established in this way.

In action-angle variables the Bohr-Sommerfeld quantization is equivalent to the canonical quantization, with a quite simple expression for the wavefunction

\[
\hat{I}_i \Psi(\Phi) = I_i \Psi(\Phi), \quad \hat{I}_i = -i\hbar \frac{\partial}{\partial \Phi_i}, \quad \Psi = \frac{1}{(2\pi)^{N/2}} \prod_{i=1}^{N} e^{-i n_i \Phi_i}, \quad I_i = \hbar n_i, \quad (1.2)
\]

where \( n_i \) are integer numbers taking their values at the range \([\beta_i^-, \beta_i^+]\).

The general prescription for the construction of action-angle variables looks as follows \[1\]. In order to construct the action-angle variables, we should fix the level surface of the Hamiltonian \( F = c \) and then introduce the generating function for the canonical transformation \((p, q) \mapsto (I, \Phi)\), which is defined by the expression

\[
S(c, q) = \int_{F=c} p dq, \quad (1.3)
\]

where \( p \) are expressed via \( c, q \) by the use of the constants of motion. The action variables \( I \) can be obtained from the expression

\[
I_i(c) = \frac{1}{2\pi} \oint_{\gamma_i} p dq, \quad (1.4)
\]

where \( \gamma_i \) is some loop of the level surface \( F = c \). Then inverting these relations, we can get the expressions of \( c \) via action variables: \( c = c(I) \). The angle variables \( \Phi \) can be found from the expression

\[
\Phi = \frac{\partial S(c(I), q)}{\partial I}. \quad (1.5)
\]
1.2 Quantum ring models

So, the action-angle variables form a useful tool for the study of systems with finite motion. But just such systems presently attract much attention because of the progress in mesoscopic physics, where we usually deal with a motion of (quasi)particles localized in quantum dots, quantum layers etc. Due to the recent progress in nanotechnology, now the fabrication of various low-dimensional systems of complicated geometric form (nanotubes, nanofibers, spherical and cylindrical layers) become possible [4]. In these context the methods of quantum mechanics on curved space should be relevant for the description of the physics of nanostructures.

Say, the common method for the localizing of the particle in the disc or in the cylinder is that of the two-dimensional oscillator for the role of the confinement potential. Similarly, for the localization of the particle in quantum lens (e.g. $GaAs/In_{1-x}Ga_xAs$, see [5]) one can use the Higgs model of the spherical oscillator defined by the potential $V_{\text{Higgs}} = \frac{1}{2} \omega^2 r_0^2 \tan^2 \theta$ [6].

Another confinement potential which could be used for the localization of the (quasi)particles in quantum lens, is the potential of the so-called $CP^1$ oscillator $V_{\text{Higgs}} = 2 \omega^2 r_0^2 \tan^2 \theta / 2$ [7]. The advantage of the latter potential is that a system with such confinement potential preserves the exact solvability after inclusion of magnetic field, which has a constant magnitude on the surface of the sphere. Such a magnetic field is precisely the magnetic field of a Dirac monopole located at the center of sphere. So, formally this is not a physical field. However, due to the restriction of the electron in the segment/ring of the spherical layer, it could be viewed as a physical field generated e.g. by the pole of a magnetic dipole.

The fabrication of semiconductor ring-shaped systems [5], presently referred to as quantum rings (e.g. $In(Ga)As$ - two-dimensional quantum rings), led to the use of the singular oscillator potential with the role of the confinement one. A pioneering work on the theoretical study of the impact of the magnetic field on the electron properties in a quantum ring was written by Chakraborty and Pietelainen [9]. In that paper the shifted oscillator potential $V_{\text{ChP}} = \beta (r - r_0)^2$ was choosen as the confinement potential restricting the motion of electrons in the
quantum ring. The results obtained within this approximation are in a good correspondence with experimental data. The quantum ring model of Chakraborty and Pietelainen is not exactly solvable in the general case, it assumes the use of numerical simulations. The quantum ring model based on the singular oscillator system \[10\] has been suggested as an analytically solvable alternative to the Chakraborty-Pietelainen model. Although calculations performed within the Chakraborty-Pietelainen model are in better correspondence with experimental data than those within the singular oscillator potential \[11\], the latter has its own place in the study of quantum rings (see, e.g. \[12\]).

In analogy with the above models, one can suppose, that singular versions of two-dimensional Higgs and \(CP^1\) oscillators may be appropriate candidates for the confinement potential localizing the motion of the electron in the ring of a spherical quantum layer.

In this section we present the action-angle formulations of the two-dimensional singular oscillator and its two spherical generalizations based on Higgs and \(CP^1\) spherical oscillator models. This section is based on the results of \[22\]. The goals of this section are to suggest

- To use the action-angle variables in the study of quantum ring models.
- To use singular spherical oscillator models as confinement potentials in spherical quantum rings.

For the role of the constant magnetic field, the magnetic field of the Dirac monopole located at the center of the sphere is suggested. Surely, the Dirac monopole is a non-physical object. However, since we assume to use it for the description of the particles localized on a part of the sphere, the non-physical nature of the Dirac monopole can be ignored. The monopole can be considered, e.g. as a pole of the magnetic dipole. The possible impact of the Dirac monopole on the properties of quantum dots model has been considered, e.g., in \[23\]. Besides, magnetic monopoles emerge as a class of magnets known as spin ice \[24\].
Singular Euclidean oscillator

Let us demonstrate our approach with the simplest example of the singular oscillator on the two-dimensional Euclidean space, which is defined by the Hamiltonian

\[
H = \frac{p^2}{2} + \frac{\alpha^2}{2r^2} + \frac{\omega^2 r^2}{2}. \tag{1.6}
\]

In polar coordinates this Hamiltonian reads

\[
H = \frac{p_r^2}{2} + \frac{p_\varphi^2 + \alpha^2}{2r^2} + \frac{\omega^2 r^2}{2}, \quad x = r \cos \varphi, \quad y = r \sin \varphi. \tag{1.7}
\]

Taking into account that the angular momentum \( p_\varphi \) is the constant of motion of this system, we can represent its generating function as follows: \( S(p_\varphi, h, \varphi, r) = p_\varphi \varphi + \int_{H=h} p_r dr \). So, for the action variables we get the expressions

\[
I_1 = \frac{1}{2\pi} \int p_\varphi d\varphi = p_\varphi,
\]

\[
I_2 = \frac{1}{2\pi} \int p_r dr = \frac{h}{2\omega} - \frac{\tilde{p}_\varphi}{2}
\]

where \( \tilde{p}_\varphi \equiv \sqrt{p_\varphi^2 + \alpha^2} \)

Respectively, the Hamiltonian takes the form

\[
H_{2d} = \omega \left( 2I_2 + \sqrt{I_1^2 + \alpha^2} \right) \tag{1.9}
\]

The angle variables read

\[
\Phi_1 = \varphi - \frac{p_\varphi}{2\tilde{p}_\varphi} \arcsin \frac{(\tilde{p}_\varphi + \omega r^2) \sqrt{2h^2 - p_\varphi^2} - \omega^2 r^4}{(h + \tilde{p}_\varphi \omega) r^2},
\]

\[
\Phi_2 = - \arcsin \frac{\sqrt{h^2 - p_\varphi^2 \omega^2}}{\sqrt{h^2 - p_\varphi^2 \omega^2}}. \tag{1.10}
\]

For the reduction of this system to a one-dimensional one, we should put \( p_\varphi = 0 \). In that case the Hamiltonian takes the form (where we replaced \( r \) by \( x \)) \( H_{1d} = \omega (2I_2 + \alpha) \equiv 2\omega \tilde{I} \), \( \tilde{I} \in [\alpha/2, \infty) \).
So, in the action-angle variable the one-dimensional singular oscillator is locally equivalent to the nonsingular one. The only difference is in the range of validity of the action variable.

Let us notice that the action variable corresponding to the cyclic coordinate $\varphi$ coincides with the angular momentum $I_1 = p_\varphi$. However, the respective angle variable $\Phi_1$ is different from the initial angle $\phi$. In other words, the “radial” motion, encoded in the dynamic of $I_2$ and $\Phi_2$ variables, has an essential impact on the “angular” motion. While the impact of $\varphi, p_\varphi$ variables in the radial motion is the shift $\alpha^2 \to \alpha^2 + p_\varphi^2$.

The inclusion of the constant magnetic field in the two-dimensional oscillator system does not essentially change its properties. Indeed, it is defined, in the two-dimensional planar system, by the potential

$$\mathcal{A} = \frac{B_0}{2} (x \, dy - y \, dx) = \frac{B_0 r^2}{2} \, d\varphi$$

Hence, including the constant magnetic field in the two-dimensional singular oscillator, we shall get

$$H = \frac{p_\varphi^2}{2} + \frac{(p_\varphi - \frac{B_0 r^2}{2})^2}{2r^2} + \frac{\alpha^2}{2r^2} + \frac{\omega^2 r^2}{2} \quad \Leftrightarrow \quad \tilde{H} = \frac{p_\varphi^2}{2} + \frac{\tilde{p}_\varphi^2}{2r^2} + \frac{\tilde{\omega}^2 r^2}{2}$$

where we use the notation

$$\tilde{p}_\varphi = p_\varphi + \alpha^2, \quad \tilde{\omega}^2 = \omega^2 + \frac{B_0^2}{4}, \quad \tilde{H} = H + \frac{B_0 p_\varphi}{2}$$

Thus, the impact of the magnetic field in the generating function $S(h, p_\varphi, r, \varphi)$ consists in the replacement (1.13). Respectively, the action variables and Hamiltonian are defined by the expressions

$$I_1 = p_\varphi, \quad I_2 = \frac{\tilde{h}}{2\omega} - \frac{\tilde{p}_\varphi}{2} \quad \Rightarrow \quad H = \sqrt{\omega^2 + (B_0/2)^2} \left(2I_2 + \sqrt{I_1^2 + \alpha^2} \right) - \frac{B_0 I_1}{2}$$
The explicit expressions for angle variables reads

\[
\Phi_1 = \varphi - \frac{p_\varphi}{2\tilde{p}_\varphi} \arcsin \left( \frac{(\tilde{p}_\varphi + \tilde{\omega} r^2) \sqrt{2\hbar r^2 - \tilde{p}_\varphi^2 - \tilde{\omega}^2 r^4}}{(\hbar + \tilde{p}_\varphi \tilde{\omega}) r^2} \right),
\]

\[
\Phi_2 = -\arcsin \frac{\tilde{h} - r^2 \tilde{\omega}^2}{\sqrt{\tilde{h}^2 - \tilde{p}_\varphi^2 \tilde{\omega}^2}}. \tag{1.15}
\]

It is seen that the magnetic field yields in the Hamiltonian the term linear on \( I_1 \), in addition to the predictable change of the effective frequency \( \omega \to \sqrt{\omega^2 + B_0^2/4} \).

We have constructed the action-angle variables for the two-dimensional singular oscillator in the constant magnetic field. Now we shall consider a similar formulation for the models of singular spherical oscillators.
Singular Higgs oscillator

Now we shall consider a two-dimensional singular spherical oscillator defined by the following Hamiltonian:

\[ H_{\text{Higgs}} = \frac{p_\theta^2}{2r_0^2} + \frac{p_\varphi^2}{2r_0^2 \sin^2 \theta} + \frac{\alpha^2}{2r_0^2} \cot^2 \theta + \frac{\omega^2 r_0^2}{2} \tan^2 \theta, \quad (1.16) \]

where \( r_0 \) is the radius of the sphere.

This system generalizes the well-known Higgs model of the spherical oscillator \([6]\), whose uniqueness is in the closeness of all trajectories, which reflects the existence of a number of hidden symmetries equal to the those of the Euclidean oscillator. This is the reason why the Higgs oscillator is a convenient background for the developing of perturbation theory. Particularly, it admits the anisotropic modification preserving the integrability of the system \([25]\). Hence, such a model of the spherical ring should be convenient for the study of electrons behavior in external potential fields, e.g., in the electric one. However, it is easy to observe that the (singular) Higgs oscillator does not preserve its exact solvability in the presence of a constant magnetic field, in contrast with the Euclidean one, while the study of quantum dot systems in a magnetic field is of a special physical importance.

In our consideration we assume the unit radius of the sphere, \( r_0 = 1 \). The restoration of the the arbitrary radius can be carried out by the obvious redefinition of the Hamiltonian and the constants \( \alpha, \omega \).

Since the angular momentum \( p_\varphi \) is a constant of motion of the system, the the generating function of the action-angle variables takes the form

\[ S = p_\varphi \varphi + \int_0^\pi p_\theta (h, p_\varphi, \theta) d\theta, \quad (1.17) \]

where \( H_{\text{Higgs}} = h \). From this generating function we get the action variables

\[ I_1 = \frac{1}{2\pi} \int p_\varphi d\varphi = p_\varphi, \]

\[ I_2 = \frac{1}{2\pi} \int p_\theta d\theta = \frac{1}{\pi} \int_{\theta_+}^{\theta_-} \sqrt{2 \left( h - \frac{p_\varphi^2}{2 \sin^2 \theta} - \frac{\alpha^2}{2} \cot^2 \theta - \frac{\omega^2}{2} \tan^2 \theta \right)} d\theta, \quad (1.18) \]
where the integration limits $\theta_{\pm}$ are defined by the condition

$$2h = \frac{p_\phi^2}{\sin^2 \theta_{\pm}} + \alpha^2 \cot^2 \theta_{\pm} + \omega^2 \tan^2 \theta_{\pm}. \quad (1.19)$$

To calculate the integral in the second expression, we introduce the notation

$$a = \sqrt{1 - \frac{2p_\phi^2 + \alpha^2 + \omega^2}{2h + \alpha^2 + \omega^2}} + \left(\frac{p_\phi^2 + \alpha^2 - \omega^2}{2h + \alpha^2 + \omega^2}\right)^2, \quad b = -\frac{p_\phi^2 + \alpha^2 - \omega^2}{2h + \alpha^2 + \omega^2},$$

$$\xi = \frac{1}{a} \left[\cos 2\theta + b\right]. \quad (1.20)$$

In this terms the second integral in (1.18) reads (its value can be found by the use of standard methods, see, e.g. [26, 3])

$$I_2 = \frac{a^2 \sqrt{2h + \alpha^2 + \omega^2}}{2\pi} \int_{-1}^{1} \frac{\sqrt{1 - \xi^2}}{1 - (a\xi + b)^2} d\xi = \frac{1}{2} \left(\sqrt{2h + \alpha^2 + \omega^2} - \sqrt{p_\phi^2 + \alpha^2 - \omega}\right). \quad (1.21)$$

Hence, the functional dependence of the Hamiltonian from the action variables is given by the expression

$$H = \frac{1}{2} \left(2I_2 + \sqrt{I_1^2 + \alpha^2 + \omega^2}\right)^2 - \frac{\alpha^2 + \omega^2}{2}. \quad (1.22)$$

For $\Phi_1$ and $\Phi_2$ we get

$$\Phi_1 = \varphi - \frac{p_\phi}{\bar{p}_\phi} \arcsin \xi + \frac{p_\phi}{\bar{p}_\phi} \arctan \frac{1}{2\bar{p}_\phi} \left[\sqrt{\frac{(2h - p_\phi^2)^2 - 4\omega^2 p_\phi^2}{2h + \alpha^2 + \omega^2}} - \frac{2h + 2\alpha^2 + p_\phi^2}{\sqrt{2h + \alpha^2 + \omega^2}} \frac{1 + \sqrt{1 - \xi^2}}{2\xi}\right] \quad (1.23)$$

$$\Phi_2 = -2 \arcsin \xi$$

Here, as previously, we use the notation

$$\bar{p}_\phi = \sqrt{p_\phi^2 + \alpha^2} \quad (1.24)$$
We presented the action-angle formulation of the singular Higgs oscillator (1.16) on the sphere of unit radius \( r_0 = 1 \). The action-angle formulation of the system on the sphere with arbitrary value of \( r_0 \) could be easily found from (1.21)-(1.23) by the replacement

\[
H_{r_0} = \frac{H}{r_0^2}, \quad \text{with} \quad \omega \to \omega r_0^2.
\]  

(1.25)

In that case the Hamiltonian (1.16) is defined, in the action-angle variables, by the following expression:

\[
H = \frac{1}{2r_0^2} \left( 2I_2^2 + \sqrt{I_1^2 + \alpha^2 + \omega r_0^2} \right)^2 - \frac{\alpha^2}{2r_0^2} - \frac{\omega^2 r_0^2}{2}.
\]  

(1.26)

It is seen that, in the planar limit \( r_0 \to \infty \), it results in the Hamiltonian of the Euclidean singular oscillator (1.14) with \( B_0 = 0 \) (i.e. in the absence of constant magnetic field). However, the singular Higgs oscillator does not respect the inclusion of constant magnetic field, in contrast with the Euclidean one.

Indeed, the magnetic field which has a constant magnitude on the sphere, is the field of a Dirac monopole located at the center of sphere. It is defined by the following one-form:

\[
A_D = s(1 - \cos \theta) d\varphi, \quad s = B_0 r_0^2.
\]  

(1.27)

Hence, the Hamiltonian of the singular Higgs oscillator interacting with a constant magnetic field, is defined by the expression

\[
H = \frac{p_{\varphi}^2}{2r_0^2} + \frac{[p_{\varphi} - s(1 - \cos \theta)]^2}{2r_0^2 \sin^2 \theta} + \frac{\alpha^2}{2r_0^2} \cot^2 \theta + \frac{\omega^2 r_0^2}{2} \tan^2 \theta.
\]  

(1.28)

Writing down the corresponding generating function we shall see that the impact of the magnetic field cannot be absorbed by the proper redefinition of constants. Hence, the inclusion of the magnetic field breaks the exact solvability of the (singular) Higgs oscillator, so that the presented model is not suitable for the study of the properties of spherical bands and length in the external magnetic field. However, this models is relevant for the consideration of their
properties in the external potential, e.g., the electric field. Moreover, one can further modify the Higgs oscillator potential providing it by the anisotropy properties preserving the integrability of the system [25]. Such a system would be useful to consider the quantum dots model restricted from the sphere to the spherical segment.
Singular $CP^1$ oscillator

As we have already mentioned, the (singular) Higgs oscillator does not preserve its exact solvability in the presence of a constant magnetic field, while the study of quantum dot systems in a magnetic field is of a special physical importance. For this reason we consider the alternative model of the singular spherical oscillator, given by the Hamiltonian \[ H_{CP^1} = \frac{\dot{\theta}^2}{2r_0^2} + \frac{\dot{\phi}^2}{2r_0^2 \sin^2 \theta} + \frac{\alpha^2}{4r_0^2} \cot^2 \theta + 2\omega^2 r_0^2 \tan^2 \theta. \] \[ (1.29) \]

It is based on the model of the oscillator on complex projective spaces \[7\] and, in contrast with the (singular) Higgs oscillator, it respects the inclusion of a constant magnetic field (of the Dirac monopole). Respectively, its singular version, defined by the Hamiltonian \[ \text{(1.29)} \] also remains exactly solvable in the presence of a constant magnetic field, at least, classically \[27\]. Since the complex projective plane is equivalent to the two-dimensional sphere, we can use this model for the definition of the two-dimensional magnetic oscillator.

Let us notice that a similar model on the four-dimensional sphere and hyperboloid respects the inclusion of the BPST instanton field \[28\]. Quantum mechanical solutions of \[\text{(1.29)}\] are not constructed yet. But they could be found by a proper modification of the solutions of the corresponding non-singular system (third reference in \[7\]). Because of the absence of hidden symmetries, this model is not convenient for the study of the system in external potential (e.g. electric) fields. But it convenient for the study of the interaction with the external magnetic field.

Inclusion of the constant magnetic field yields the following modification of the Hamiltonian \[\text{(1.29)}\]:

\[ H = \frac{\dot{\theta}^2}{2r_0^2} + \frac{[\dot{\phi} - s (1 - \cos \theta)]^2}{2r_0^2 \sin^2 \theta} + 2\omega^2 r_0^2 \tan^2 \theta + \frac{\alpha^2}{8r_0^2} \cot^2 \theta, \quad s = B_0 r_0^2. \] \[ (1.30) \]

As before, we put, without loss of generality, $r_0 = 1$. The way of the restoring of $r_0$ is obvious. Then, in a completely similar way as in the previous cases, we can construct the action-angle
variables of this system. For the action variables $I_1$ and $I_2$ we get

$$I_1 = p_\varphi,$$

$$I_2 = \frac{1}{\pi} \int_{\theta_-}^{\theta_+} d\theta \sqrt{2h - \frac{[p_\varphi - s (1 - \cos \theta)]^2}{\sin^2 \theta} - 4\omega^2 \tan^2 \frac{\theta}{2} - \frac{\alpha^2}{4} \cot^2 \frac{\theta}{2}}$$ (1.31)

where $\theta_{\pm}$ are defined by the equation

$$h = \frac{[p_\varphi + s (1 - \cos \theta_{\pm})]^2}{2 \sin^2 \theta_{\pm}} + 2\omega^2 \tan^2 \frac{\theta_{\pm}}{2} + \frac{\alpha^2}{8} \cot^2 \frac{\theta_{\pm}}{2}.$$ (1.32)

The explicit expression for the second integral looks as follows:

$$I_2 = \frac{a^2 \sqrt{2h + 4\omega^2 + \frac{\alpha^2}{4} + 2^2}}{\pi} \int_{-1}^{1} \frac{\sqrt{1 - \xi^2}}{1 - (a\xi + b)^2} d\xi =$$

$$= \sqrt{2h + s^2 + \frac{\alpha^2}{4} + 4\omega^2} - \sqrt{\frac{p_\varphi^2 + \alpha^2}{4} - \sqrt{\frac{p_\varphi^2}{2} - s^2}} + 4\omega^2,$$ (1.33)

where we introduced the notation

$$\xi = \frac{1}{a} [\cos \theta - b], \quad b = \frac{8\omega^2 + 2s^2 - 2p_\varphi s - \frac{\alpha^2}{2}}{4h + 8\omega^2 + \frac{\alpha^2}{4} + 2s^2},$$

$$a = \frac{2}{\sqrt{4h + 8\omega^2 + \frac{\alpha^2}{4} + 2s^2}} \sqrt{\frac{4h^2 - (8\omega^2 - p_\varphi s + 2s^2) (\frac{\alpha^2}{4} + p_\varphi s)}{4h + 8\omega^2 + \frac{\alpha^2}{4} + 2s^2} - \frac{p_\varphi^2}{2} + p_\varphi s}.$$ (1.34)

Hence, from (1.33) we get that the explicit expression of the Hamiltonian has the following dependence from the action variables:

$$H = \frac{1}{8} \left( 2I_2 + \sqrt{I_1^2 + \alpha^2 + \sqrt{(I_1 - 2s)^2 + 16\omega^2}} \right)^2 - \frac{s^2}{2} - \frac{\alpha^2}{8} - 2\omega^2$$ (1.35)

The expressions for the angle variables look as follows:

$$\Phi_1 = \varphi - \frac{1}{2} \left( \frac{p_\varphi}{p_\varphi} + \frac{p_\varphi - 2s}{\sqrt{(p_\varphi - 2s)^2 + 16\omega^2}} \right) \arcsin \xi +$$

$$\frac{p_\varphi + s}{\sqrt{(p_\varphi - 2s)^2 + 16\omega^2}} \arctan \eta_+ - \frac{p_\varphi}{p_\varphi} \arctan \eta_-,$$ (1.36)

$$\Phi_2 = \frac{\partial S}{\partial I_2} = -\arcsin \xi.$$
Here we used the notation

\[ \tilde{p}_\varphi \equiv \sqrt{p^2_\varphi + \alpha^2}, \quad \eta_{\pm} \equiv \frac{(1 \pm b) \left( \frac{1}{\xi} \pm \sqrt{\frac{1}{\xi^2} - 1} \right) \pm a}{\sqrt{(1 \pm b)^2 - a^2}} \]  \hspace{1cm} (1.37)

Finally, let us restore the radius \( r_0 \) performing the replacement \( 1.25 \). In that case the Hamiltonian \( 1.30 \) is expressed via action variables as follows:

\[
H = \frac{1}{8 r_0^2} \left( 2I_2 + \sqrt{I_1^2 + \alpha^2 + \sqrt{(I_1 - 2B_0r^2)^2 + 16\omega^2r^4_0}} \right)^2 - \frac{B_0^2r_0^2}{8r_0^2} - \frac{\alpha^2}{8r_0^2} - 2\omega^2r^2_0 \]  \hspace{1cm} (1.38)

It is seen that, in the planar limit \( r_0 \to \infty \), it results in the Hamiltonian of the Euclidean singular oscillator \( 1.14 \).

So, we presented the action-angle formulation of the model of the spherical singular oscillator interacting with a constant magnetic field \( 1.30 \). The Hamiltonian of the model is non-degenerate on both action variables. But it depends on these variables via elementary functions in the presence of a constant magnetic field.

These tell us the area of application of the Higgs oscillator potential and of the \( CP^1 \) oscillator one. The Higgs model is useful for the behavior of the quantum dots systems in the external potential field, e.g, in the electric field. The \( CP^1 \) model should be applied for the study of the behavior of a spherical quantum dots model in the external magnetic field.
2 INTEGRABLE GENERALIZATIONS OF OSCILLATOR AND COULOMB SYSTEMS

In this Chapter we construct new integrable conformal mechanical systems by generalizing the known ones [29, 3]. Namely, we pick a system with compact phase space and add a radial part to it, thus increasing the dimension by one (the phase space dimension is increased by two).

In the Chapter [1] we suggested action-angle variables as a useful tool for the study of systems with compact phase space. So, it is a good idea to use action-angle variables to describe the motion of the initial "angular" part.

So, we pick an integrable system with a $2(N-1)$-dimensional compact phase space

$$\mathcal{H} = \mathcal{H}(I_i), \quad \{I_i, \Phi^0_j\} = \delta_{ij}, \quad \Phi^0_i \in [0, 2\pi), \quad i, j = 1, \ldots, N-1,$$

in terms of its action-angle variables, and add a radial part to it [30, 31],

$$H = \frac{p_r^2}{2} + \frac{\mathcal{H}(I_i)}{r^2} + V(r), \quad \{p_r, r\} = 1, \quad r \in [0, \infty) \text{ or } [0, r_0).$$

Here, we introduced a radial coordinate $r$ and momentum $p_r$ and obtain an extended model with $N$ degrees of freedom. The extended configuration space is a cone over the original compact configuration space. If the latter is just the sphere $S^{N-1}$, we can obtain, in particular, the three model spaces of constant curvature:

$$S^N : \quad r = r_0 \sin \chi, \quad p_r = r_0^{-1} p_\chi, \quad V(r) \to V(r_0 \tan \chi),$$

$$\mathbb{R}^N : \quad r = r_0 \chi, \quad p_r = r_0^{-1} p_\chi, \quad V(r) \to V(r_0 \chi),$$

$$H^N : \quad r = r_0 \sinh \chi, \quad p_r = r_0^{-1} p_\chi, \quad V(r) \to V(r_0 \tanh \chi),$$

where $r_0$ is the radial scale and $\{p_\chi, \chi\} = 1$ is a dimensionless canonical pair. Hence, for a particle on the sphere $S^N$ (the sine-cone over $S^{N-1}$) or on the hyperboloid $H^N$ (the hyperbolic...
cone over $S^{N-1}$) one gets the Hamiltonians

$$H = \frac{p^2}{2r^2_0} + \frac{\mathcal{H}}{r^2_0 \sin^2 \chi} + V(r_0 \tan \chi) \quad \text{and} \quad H = \frac{p^2}{2r^2_0} + \frac{\mathcal{H}}{r^2_0 \sinh^2 \chi} + V(r_0 \tanh \chi), \quad (2.6)$$

respectively.

As an example, when $\mathcal{H}$ defines the Landau problem, i.e. a particle on $S^2$ moving in the magnetic field generated by a Dirac monopole located at the center of sphere, we arrive at the particle on $\mathbb{R}^3$ interacting with this Dirac monopole. The extended system remains integrable for two prominent choices of the radial potential,

$$V(r) = V_{\text{osc}}(r) = \frac{1}{2} \omega^2 r^2 \quad \text{and} \quad V(r) = V_{\text{cou}}(r) = -\gamma \frac{r}{r}, \quad (2.7)$$

with frequency $\omega$ and (positive) coupling $\gamma$, respectively. For $\mathbb{R}^N$, these are the familiar oscillator and Coulomb potentials, while for $S^N$ they have been named Higgs oscillator [6] and Schrödinger-Coulomb [32], respectively.

If the system is spherically symmetric, i.e. $S^{N-1}$ invariant, the compact Hamiltonian $\mathcal{H}$ is just given by the SO($N$) Casimir function $J^2$, which defines the kinetic energy of a free particle on $S^{N-1}$. Deviations from spherical symmetry are encoded in $\mathcal{H}$. In other words, replacing $J^2$ by the Hamiltonian of some compact $N-1$-dimensional integrable system defines a deformation of the $N$-dimensional oscillator and Coulomb systems.

Particular examples with $N=2$ are the so-called Tremblay-Turbiner-Winternitz (TTW) [13] and Post-Winternitz (PW) [15] models, defined on $\mathbb{R}^2$, which have attracted some interest recently (see, e.g. [14] and references therein). In this systems the compact subsystem on the circle $S^1$ is just the famous Pöschl-Teller system [33],

$$\mathcal{H} = \mathcal{H}_{\text{PT}} = \frac{p_{\varphi}^2}{2} + \frac{k^2 \alpha^2}{2 \sin^2 k \varphi} + \frac{2k^2 \alpha^2}{\cos^2 k \varphi} \quad \text{with} \quad k \in \mathbb{N}. \quad (2.8)$$

Assume now that the compact subsystem is already formulated in terms of action-angle variables $(I_i, \Phi^0_i)$, with $i = 1, \ldots, N-1$, while the radial part is given by $(p_r, r)$. We characterize the level
sets by \((H=\mathcal{E}, I_i)\). The generating function for the extended system \((2.2)\) then reads

\[
S(E, I_i, r, \Phi_0) = \sqrt{2} \int dr \sqrt{E - \frac{\mathcal{H}(I)}{r^2}} - V(r) + \sum_{i=1}^{N-1} I_i \Phi_0^i. 
\]  

(2.9)

From this function we immediately get the action variables \(I_i = I_i\) and

\[
I_r(E, I_i) = \frac{\sqrt{2}}{2\pi} \oint dr \sqrt{E - \frac{\mathcal{H}(I)}{r^2}} - V(r). 
\]  

(2.10)

The corresponding angle variables are given by

\[
\Phi_r = \frac{1}{\sqrt{2}} \frac{\partial E}{\partial I_r} \int \frac{dr}{\sqrt{E - \frac{\mathcal{H}(I)}{r^2}} - V(r)} \quad \text{and} \\
\Phi_i = \Phi_0^i + \frac{\partial E}{\partial I_i} \Phi_r - \frac{1}{\sqrt{2}} \frac{\partial \mathcal{H}(I)}{\partial I_i} \int \frac{dr}{r^2 \sqrt{E - \frac{\mathcal{H}(I)}{r^2}} - V(r)}. 
\]  

(2.11)

Making in \((2.9)\) and \((2.11)\) the replacements described in \((2.3)\) or \((2.5)\), we shall get the system on the \(N\)-sphere or -pseudosphere. Of course, for the full construction of the action-angle variables, we need to provide the action-angle variables of the subsystem \(\mathcal{H}\).

In this Chapter we start with computing the explicit expressions for action-angle variables for systems with oscillator and Coulomb potentials \((2.7)\). Then we construct the spherical and pseudospherical generalizations of the TTW and PW systems. We demonstrate the superintegrability of these systems and write down their hidden constants of motion. Additionally, we provide the action-angle variables for a free particle on the \((N-1)\)-dimensional sphere, which yields the complete set of action-angle variables for the \(N\)-dimensional oscillator and Coulomb systems as well as their spherical and pseudospherical analogs.
2.1 Deformed oscillator and Coulomb systems

Here we present the action-angle variables \((I_r, \Phi_r, \Phi_i)\) for the deformed oscillator and Coulomb systems given by the expressions (2.2)–(2.7). The action variables \(I_i\) of the “angular Hamiltonian” \(H\) remain unchanged, while the angle variables \(\Phi_i^0\) receive corrections, as seen in (2.11).

For notational simplicity we abbreviate \(H(p, q) = E\), put \(r_0 = 1\) and drop the argument \(I_i\) of \(H\). In the following, we list the results for each of the six combinations in the table below:

| radial potential | oscillator | Coulomb |
|------------------|------------|---------|
| metric cone: \(\mathbb{R}^N\) | Euclidean osc. | Euclidean Coulomb |
| sine-cone: \(S^N\) | spherical Higgs osc. | spherical Schrödinger-Coulomb |
| hyperbolic cone: \(H^N\) | pseudospherical Higgs osc. | pseudospherical Schrödinger-Coulomb |

Euclidean oscillator

\[
H_{\text{osc}} = \frac{p_r^2}{2} + \frac{H}{r^2} + \frac{\omega^2 r^2}{2} = \omega (2I_r + \sqrt{2H}),
\]

\[
I_r = \frac{E}{2\omega} - \sqrt{\frac{H}{2}},
\]

\[
\Phi_r = -\arcsin \left( \frac{E - r^2 \omega^2}{\sqrt{E^2 - 2H \omega^2}} \right),
\]

\[
\Phi_i = \Phi_i^0 + \frac{1}{2\sqrt{2H}} \frac{\partial H}{\partial I_i} \left[ \Phi_r - \arcsin \left( \frac{E r^2 - 2H}{r^2 \sqrt{E^2 - 2\omega^2 H}} \right) \right].
\]

(2.12)
Euclidean Coulomb

\[ H_{\text{coul}} = \frac{p_r^2}{2} + \frac{\mathcal{H}}{r^2} - \frac{\gamma}{r} = \frac{\gamma^2}{2(I_r + \sqrt{2\mathcal{H}})^2}, \]

\[ I_r = \frac{\gamma}{\sqrt{-2E}} - \sqrt{2\mathcal{H}} \]

\[ \Phi_r = -\frac{2}{\gamma} \sqrt{\mathcal{H}E - Er(Er + \gamma)} - \arcsin \left( \frac{2Er + \gamma}{\sqrt{4\mathcal{H}E + \gamma^2}} \right), \]

\[ \Phi_i = \Phi_i^0 + \sqrt{\frac{2}{\mathcal{H}}} \frac{\partial \mathcal{H}}{\partial I_i} \left[ \Phi_r - \frac{1}{2} \arcsin \left( \frac{\gamma r - 2\mathcal{H}}{r\sqrt{4\mathcal{H}E + \gamma^2}} \right) \right]. \] (2.13)

Spherical Higgs oscillator

\[ H_{\text{higgs}} = \frac{p_\chi^2}{2} + \frac{\mathcal{H}}{\sin^2 \chi} + \frac{\omega^2 \tan^2 \chi}{2} = \frac{1}{2} \left( 2I_\chi + \sqrt{2\mathcal{H} + \omega} \right)^2 - \frac{\omega^2}{2}, \]

\[ I_\chi = \frac{1}{2} \left( \sqrt{2E + \omega^2} - \sqrt{2\mathcal{H} - \omega} \right) \]

\[ \Phi_\chi = -2 \arcsin \left( \frac{(2E + \omega^2) \cos 2\chi + 2\mathcal{H} - \omega^2}{\sqrt{(2E + \omega^2)^2 - 2(2\mathcal{H} + \omega^2)(2E + \omega^2) + (2\mathcal{H} - \omega^2)^2}} \right), \] (2.14)

\[ \Phi_i = \Phi_i^0 + \frac{1}{2\sqrt{2\mathcal{H}}} \frac{\partial \mathcal{H}}{\partial I_i} \left[ \Phi_\chi + \arctan \left( \frac{(E + \mathcal{H}) \cos 2\chi - E + 3\mathcal{H}}{\sqrt{2\mathcal{H} \sqrt{2E - 4\mathcal{H} - \omega^2} - (4\mathcal{H} - 2\omega^2) \cos 2\chi - (2E + \omega^2) \cos^2 2\chi} \right) \right]. \]
Spherical Schrödinger-Coulomb

\[ H_{\text{sch-cou}} = \frac{p_x^2}{2} + \frac{\mathcal{H}}{\sin^2 \chi} - \frac{\gamma}{\cot \chi} = \frac{1}{2} \left( I_x + \sqrt{2\mathcal{H}} \right)^2 - \frac{\gamma^2}{2(I_x + \sqrt{2\mathcal{H}})^2}, \]

\[ I_x = \sqrt{E + \sqrt{E^2 + \gamma^2} - \sqrt{2\mathcal{H}}}, \]

\[ \Phi_\chi = \text{Im} \left[ \frac{2\sqrt{\mathcal{H}(E + i\gamma)}}{\sqrt{E + \sqrt{E^2 + \gamma^2}}} \log \zeta \right] \] (2.15)

\[ \Phi_i = \Phi_i^0 + \frac{1}{2\sqrt{2\mathcal{H}}} \left( \Phi_\chi + \arcsin \left( \frac{2\mathcal{H} \cot \chi - \gamma}{\sqrt{4(E - \mathcal{H})(\mathcal{H} + \gamma^2)}} \right) \right), \]

where \( \zeta = \frac{4}{\sqrt{\mathcal{H}}} e^{(\chi + \frac{\pi}{2})} \sin \left( 1 + \sqrt{\frac{E - \mathcal{H}^2}{\sin^2 \chi} + \gamma \cot \chi} \right) + \frac{(4 - 2i\gamma)\sqrt{E + i\gamma}}{\sqrt{\mathcal{H}(E^2 + \gamma^2)}}. \)

Pseudospherical Higgs oscillator

\[ H_{\text{ps-higgs}} = \frac{p_x^2}{2} + \frac{\mathcal{H}}{\sinh^2 \chi} + \frac{\omega^2 \tanh^2 \chi}{2} = \frac{\omega^2}{2} - \frac{1}{2} \left( I_x + \sqrt{2\mathcal{H}} - \omega \right)^2, \]

\[ I_x = \frac{1}{2} \left( \omega - \sqrt{2\mathcal{H} - \sqrt{\omega^2 - 2E}} \right), \]

\[ \Phi_\chi = -2 \arctan \left( \frac{(1 - \sqrt{1 - \eta^2})(E + \mathcal{H} - \omega^2)}{\eta \omega \sqrt{\omega^2 - 2E}} + \sqrt{\frac{(E + \mathcal{H})^2 - 2\mathcal{H}^2\omega^2}{\omega \sqrt{\omega^2 - 2E}}} \right), \]

\[ \Phi_i = \Phi_i^0 + \frac{1}{2\sqrt{2\mathcal{H}}} \left( \Phi_\chi - 2 \arctan \left( \frac{(1 - \sqrt{1 - \eta^2})(E + \mathcal{H})}{\eta \omega \sqrt{2\mathcal{H}}} + \sqrt{(E + \mathcal{H})^2 - 2\mathcal{H}^2\omega^2}}{\eta \omega \sqrt{2\mathcal{H}}} \right) \] (2.16)

where \( \eta = \frac{\omega^2 \tanh^2 \chi - (E + \mathcal{H})}{\sqrt{(E + \mathcal{H})^2 - 2\mathcal{H}^2}}. \)
Pseudospherical Schrödinger-Coulomb

\[ H_{\text{ps-sch-cou}} = \frac{p_x^2}{2} + \frac{\mathcal{H}}{\sinh^2 \chi} - \gamma \coth \chi = -\frac{1}{2} \left( I_x + \sqrt{2 \mathcal{H}} \right)^2 - \frac{\gamma^2}{2( I_x + \sqrt{2 \mathcal{H}})^2}, \]

\[ I_x = \frac{1}{\sqrt{2}} \left( \sqrt{-E + \gamma} - \sqrt{-E - \gamma} - 2\sqrt{\mathcal{H}} \right) \]

\[ \Phi_x = \frac{\sqrt{-E + \gamma}}{\sqrt{2(\sqrt{-E - \gamma} - \sqrt{-E + \gamma})}} \arctan \left( \frac{\sqrt{4 \mathcal{H}(E + \mathcal{H}) + \gamma^2 - 4 \mathcal{H}(E + \mathcal{H})} + \gamma}{\sqrt{2 \mathcal{H}(\sqrt{-E - \gamma} - \sqrt{-E + \gamma})}} \right) - \frac{\sqrt{-E - \gamma}}{\sqrt{2(\sqrt{-E - \gamma} - \sqrt{-E + \gamma})}} \arctan \left( \frac{\sqrt{4 \mathcal{H}(E + \mathcal{H}) + \gamma^2 + 4 \mathcal{H}(E + \mathcal{H})} + \gamma}{\sqrt{2 \mathcal{H}(\sqrt{-E + \gamma} + \sqrt{-E + \gamma})}} \right), \]

\[ \Phi_i = \phi_i^0 + \frac{1}{\sqrt{2 \mathcal{H}}} \frac{\partial \mathcal{H}}{\partial I_i} \left[ \phi_x + \frac{1}{\sqrt{2}} \arcsin \left( \frac{2\mathcal{H} \cot \chi - \gamma}{\sqrt{4(E + \mathcal{H})^2 + \gamma^2}} \right) \right]. \]
2.2 Generalized Tremblay-Turbiner-Winternitz and Post-Winternitz systems

As mentioned in the Introduction, action-angle variables elegantly explain the superintegrability of the recently suggested deformation of the two-dimensional oscillator system introduced by Tremblay-Turbiner-Winternitz (TTW) \[13\] and also of the Coulomb versions treated by Post-Winternitz (PW) \[15\]. They also allow us to construct analogous deformations of other superintegrable systems.

Our generalizations of the TTW and PW systems are defined by (2.2)–(2.7) with \(N=2\), where the one-dimensional “angular” Hamiltonian \(H\) is given by the generalized Pöschl-Teller system on the circle (2.8) \[33\]. The action-angle variables of this subsystem are given by \[3\]

\[
I_{PT} = \frac{1}{k} \sqrt{2H_{PT} - (\alpha_1 + \alpha_2)} \quad \text{and} \quad \Phi_{PT} = \frac{1}{2} \arcsin \left\{ \frac{1}{a} \left[ \cos 2k\varphi + b \right] \right\}, \quad (2.18)
\]

where

\[
a = \sqrt{1 - \frac{k^2(\alpha_1^2 + \alpha_2^2)}{H_{PT}}} + \left( \frac{k^2(\alpha_1^2 - \alpha_2^2)}{2H_{PT}} \right)^2 \quad \text{and} \quad b = \frac{k^2(\alpha_2^2 - \alpha_1^2)}{2H_{PT}}, \quad (2.19)
\]

so that the Hamiltonian reads

\[
H_{PT} = \frac{1}{2}(kI_{PT})^2 \quad \text{with} \quad I_{PT} \equiv I_{PT} + \alpha_1 + \alpha_2 \in [\alpha_1+\alpha_2, \infty). \quad (2.20)
\]

Clearly, in action-angle variables, the Pöschl-Teller Hamiltonian coincides with the Hamiltonian of a free particle on a circle of radius \(k\), but with a different domain for the action variable. Hence, choosing the potential in (2.2) to be of oscillator or Coulomb type, the extended system will be superintegrable. More precisely, in the variables \((p_r, r, I_{PT}(p_\varphi, \varphi), \Phi_{PT}(p_\varphi, \varphi))\), this system takes the form of a conventional two-dimensional oscillator or Coulomb system on the cone. Hence, for rational values of \(k\) these systems possess hidden symmetries. For the oscillator case, the hidden constants of motion have been constructed in \[34\]. Here, we extend
their results to the Coulomb case \[15\] as well as to the TTW- and PW-like systems on spheres and pseudospheres.

For the three spaces of constant curvature and for the oscillator potential, the action-angle Hamiltonians are

\[
H_\omega = \begin{cases} 
\omega (2I_\chi + k\tilde{I}_{PT}) & \text{for } \mathbb{R}^2 \\
\frac{1}{2}(2I_\chi + k\tilde{I}_{PT} + \omega)^2 - \frac{\omega^2}{2} & \text{for } S^2 \\
-\frac{1}{2}(2I_\chi + k\tilde{I}_{PT} - \omega)^2 + \frac{\omega^2}{2} & \text{for } H^2
\end{cases} \tag{2.21}
\]

and depend only on the combination \(2I_\chi + k\tilde{I}_{PT}\). Thus, the evolution of the angle variables is given by

\[
\Phi_\chi(t) = 2\Omega t \quad \text{and} \quad \Phi_\varphi(t) = k\Omega t \quad \text{with} \quad \Omega = \frac{dH_\omega}{d(2I_\chi + k\tilde{I}_{PT})}. \tag{2.22}
\]

For rational values of \(k\) the trajectories are closed. It then follows that the hidden constant of motion is

\[
I_{\text{hidden}} = \cos(m\Phi_\chi - 2n\Phi_\varphi) \quad \text{for } k = \frac{m}{n}. \tag{2.23}
\]

Explicitly, this hidden constant of motion reads:

**Euclidean TTW system**

\[
I_{\text{add}} = CM_m\left( \frac{Er^2 - 2H_{PT}}{r^2\sqrt{E^2 - 2\omega^2H_{PT}}} \right) CM_n\left( \frac{1}{n} \left[ \cos 2k\varphi + b \right] \right) \\
+ SM_m\left( \frac{Er^2 - 2H_{PT}}{r^2\sqrt{E^2 - 2\omega^2H_{PT}}} \right) SM_n\left( \frac{1}{n} \left[ \cos 2k\varphi + b \right] \right) \tag{2.24}
\]

where we denoted

\[
CM_n(x) = \cos(n \arcsin x) = \sum_{i=0}^{\left[\frac{n}{2}\right]} (-1)^i C_n^{2i} x^{2i} \sqrt{1 - x^{2n - 2i}}, \tag{2.25}
\]

\[
SM_n(x) = \sin(n \arcsin x) = \sum_{i=0}^{\left[\frac{n-1}{2}\right]} (-1)^i C_n^{2i+1} x^{2i+1} \sqrt{1 - x^{2n - 2i - 1}}.
\]
Spherical TTW system

\[ I_{\text{add}} = CM_m \left( \frac{\xi}{\sqrt{\xi^2 + 1}} \right) CM_n \left( \frac{1}{a} [\cos 2k\varphi + b] \right) - SM_m \left( \frac{\xi}{\sqrt{\xi^2 + 1}} \right) SM_n \left( \frac{1}{a} [\cos 2k\varphi + b] \right) \]  \hspace{1cm} (2.26)

where

\[ \xi = \frac{(E + \mathcal{H}_{PT}) \cos 2\chi - E + 3\mathcal{H}_{PT}}{\sqrt{2\mathcal{H}_{PT} \sqrt{2E - 4\mathcal{H}_{PT} - \omega^2 - (4\mathcal{H}_{PT} - 2\omega^2) \cos 2\chi - (2E + \omega^2) \cos^2 2\chi}} \]  \hspace{1cm} (2.27)

Pseudospherical TTW system

\[ I_{\text{add}} = CM_{2m} \left( \frac{\xi}{\sqrt{\xi^2 + 1}} \right) CM_n \left( \frac{1}{a} [\cos 2k\varphi + b] \right) + SM_{2m} \left( \frac{\xi}{\sqrt{\xi^2 + 1}} \right) SM_n \left( \frac{1}{a} [\cos 2k\varphi + b] \right) \]  \hspace{1cm} (2.28)

where

\[ \xi = \frac{\sqrt{(E + \mathcal{H}_{PT})^2 - 2\mathcal{H}_{PT}\omega^2}}{\omega \sqrt{2\mathcal{H}_{PT}}} \frac{\omega^2 \tanh^2 \chi}{\omega^2 \tanh^2 \chi - (E + \mathcal{H}_{PT})} - \frac{E + \mathcal{H}_{PT}}{\omega \sqrt{2\mathcal{H}_{PT}}} \frac{\sqrt{2(E + \mathcal{H}_{PT})\omega^2 \tanh^2 \chi - \omega^4 \tanh^4 \chi - 2\mathcal{H}_{PT}\omega^2}}{\omega^2 \tanh^2 \chi - (E + \mathcal{H}_{PT})} \]  \hspace{1cm} (2.29)

Thus, choosing the Higgs oscillator on the (pseudo)sphere, we get a superintegrable (pseudo)spherical analog of the TTW oscillator.

The construction of superintegrable deformations of the Coulomb system, i.e. the PW model and its generalization to the (pseudo)spherical environment, proceeds completely similarly. The
Hamiltonians

\[ H_x = \begin{cases} 
-\frac{\gamma^2}{2}(I_x + k\tilde{I}_{PT})^{-2} & \text{for } \mathbb{R}^2 \\
-\frac{\gamma^2}{2}(I_x + k\tilde{I}_{PT})^{-2} + \frac{1}{2}(I_x + k\tilde{I}_{PT})^2 & \text{for } S^2 \\
-\frac{\gamma^2}{2}(I_x + k\tilde{I}_{PT})^{-2} - \frac{1}{2}(I_x + k\tilde{I}_{PT})^2 & \text{for } H^2 
\end{cases} \tag{2.30} \]

depend only on the combination \( I_x + k\tilde{I}_{PT} \), and for rational \( k = m/n \) the trajectories are closed, supporting

\[ I_{\text{hidden}} = \cos \left( m\Phi_\chi - n\Phi_\varphi \right). \tag{2.31} \]

Explicitly this constant of motion reads:

**Euclidean PW system**

\[ I_{\text{add}} = CM_{2m} \left( \frac{\gamma r - 2H_{PT}}{r \sqrt{4EH_{PT} + \gamma^2}} \right) CM_n \left( \frac{1}{a} \left[ \cos 2k\varphi + b \right] \right) + SM_{2m} \left( \frac{\gamma r - 2H_{PT}}{r \sqrt{4EH_{PT} + \gamma^2}} \right) SM_n \left( \frac{1}{a} \left[ \cos 2k\varphi + b \right] \right). \tag{2.32} \]

**Spherical PW system**

\[ I_{\text{add}} = CM_{2m} \left( \frac{2H_{PT} \cot \chi - \gamma}{\sqrt{4(E - H_{PT})H_{PT} + \gamma^2}} \right) CM_n \left( \frac{1}{a} \left[ \cos 2k\varphi + b \right] \right) - SM_{2m} \left( \frac{2H_{PT} \cot \chi - \gamma}{\sqrt{4(E - H_{PT})H_{PT} + \gamma^2}} \right) SM_n \left( \frac{1}{a} \left[ \cos 2k\varphi + b \right] \right). \tag{2.33} \]

**Pseudospherical PW system**

\[ I_{\text{add}} = CM_{2m} \left( \frac{2H_{PT} \coth \chi - \gamma}{\sqrt{4(E + H_{PT})H_{PT} + \gamma^2}} \right) CM_n \left( \frac{1}{a} \left[ \cos 2k\varphi + b \right] \right) - SM_{2m} \left( \frac{2H_{PT} \coth \chi - \gamma}{\sqrt{4(E + H_{PT})H_{PT} + \gamma^2}} \right) SM_n \left( \frac{1}{a} \left[ \cos 2k\varphi + b \right] \right). \tag{2.34} \]

Thus, choosing the Schrödinger-Coulomb system on the (pseudo)sphere, we get a superintegrable (pseudo)spherical analog of the PW model.
2.3 Free particle on $S^{N-1}$

Here we recollect the action-angle variables for the “angular Hamiltonian” $H_{PT}$ appearing in every spherically symmetric $N$-dimensional system and defining the free motion of a particle on $S^{N-1}$ with radius $r_0 = 1$. It is given by the Casimir function $L_N^2$ of $SO(N)$,

$$H = \frac{1}{2} L_N^2. \quad (2.35)$$

The embedding of the unit $(N-1)$-sphere into $\mathbb{R}^N$ is given by a set of polar coordinates,

$$\begin{align*}
x_1 &= s_{N-1} s_{N-2} \cdots s_3 s_2 s_1 \\
x_2 &= s_{N-1} s_{N-2} \cdots s_3 s_2 c_1 \\
x_3 &= s_{N-1} s_{N-2} \cdots s_3 c_2 \\
\vdots \\
x_{N-1} &= s_{N-1} c_{N-2} \\
x_N &= c_{N-1}
\end{align*}$$

with $s_k := \sin \theta_k$ and $c_k := \cos \theta_k$

for $\theta_1 \in [0, 2\pi)$, $\theta_{k>1} \in [0, \pi)$ \quad (2.36)

and $k = 1, 2, \ldots, N-1$.

In these coordinates, we have the recursion

$$L_N^2 = p_{N-1}^2 + \frac{L_{N-1}^2}{s_{N-1}^2} \quad (2.37)$$

where $p_{N-1}$ is the momentum conjugate to $\theta_{N-1}$. It is easy to see that the $L_k^2$ for $k = 1, \ldots, N$ are in involution with each other and, therefore, can be used for constructing action-angle variables. Each variable $\theta_k$ defines an independent homology cycle $S_k^1$ of the torus $T^N$. The level surfaces $L_k^2 = \text{constant} =: j_k$ are diffeomorphic to $T^N$.

Following the standard procedure we should compute the $N$ integrals

$$I_k = \frac{1}{2\pi} \oint_{S_k^1} \mathbf{p} \cdot d\mathbf{q} = \frac{1}{2\pi} \oint_{S_k^1} p_k \, d\theta_k = \int_{\theta_k}^{\theta_k'} \sqrt{j_k - \frac{j_{k-1}}{\sin^2 \theta_k}} \, d\theta_k, \quad (2.38)$$

34
where in the second equality we used that the $\theta_k$ are mutually orthogonal and the cycles $S_k^1$ are independent. The integration ranges $[\theta_k^-, \theta_k^+]$ are determined from the condition that the radicants should be non-negative. Substituting

$$u_k = \sqrt{\frac{j_k}{j_k - j_{k-1}}} \cos \theta_k,$$  

we arrive at

$$I_k = 2 \frac{j_k - j_{k-1}}{2\pi \sqrt{j_k}} \int_{\theta_k^-}^{\theta_k^+} \frac{1 - u_k^2}{1 - \frac{j_k - j_{k-1}}{j_k} u_k^2} du_k = \sqrt{j_k} - \sqrt{j_{k-1}}, \quad \text{so that} \quad \sqrt{j_k} = \sum_{m=1}^{k} I_m. \quad (2.40)$$

For the generating function we obtain

$$S = \sum_{l=1}^{N-1} S_l \quad \text{where} \quad S_l = \int d\theta \sqrt{\left( \sum_{m=1}^{l-1} I_m \right)^2 - \sin^2 \theta \left( \sum_{m=1}^{l-1} I_m \right)^2}, \quad (2.41)$$

from which we get the angle variables

$$\Phi_0^k = \frac{\partial S}{\partial I_k} = \frac{\partial S_k}{\partial I_k} + \sum_{l=k+1}^{N-1} \frac{\partial S_l}{\partial I_k} = \int \sqrt{j_k} \frac{d\theta_k}{\sqrt{j_k - \frac{j_k - j_{k-1}}{\sin \theta_k}}} + \sum_{l=k+1}^{N-1} \int \frac{d\theta_l}{\sqrt{j_l - \frac{j_l - j_{l-1}}{\sin \theta_l}}} \left( \sqrt{j_l} - \frac{\sqrt{j_l - j_{l-1}}}{\sin \theta_l} \right). \quad (2.42)$$

The first integral can be included in the first part of the sum (as $l=k$), which yields

$$\sum_{l=k}^{N-1} \int \frac{\sqrt{j_l} \, d\theta_l}{\sqrt{j_l - \frac{j_l - j_{l-1}}{\sin^2 \theta_l}}} = \sum_{l=k}^{N-1} \arcsin u_l. \quad (2.43)$$

After the substitution and abbreviation

$$u_l = \frac{2t_l}{(1+t_l)^2} \quad \text{and} \quad a = \sqrt{\frac{j_l - j_{l-1}}{j_l}} < 1, \quad (2.44)$$

respectively, the second part of the sum in (2.42) becomes

$$\sum_{l=k+1}^{N-1} \sqrt{\frac{j_l - j_{l-1}}{j_l}} \int dt_l \left[ \frac{1}{(t_l-a)^2 + 1 - a^2} + \frac{1}{(t_l+a)^2 + 1 - a^2} \right] =$$

$$= \sum_{l=k+1}^{N-1} \sqrt{\frac{j_l - j_{l-1}}{j_l(1-a^2)}} \left[ \arctan \frac{t_l-a}{\sqrt{1-a^2}} + \arctan \frac{t_l+a}{\sqrt{1-a^2}} \right]. \quad (2.45)$$
Pulling all together, we finally find

$$\Phi_k^0 = \sum_{l=k}^{N-1} \text{arcsin} \, u_l + \sum_{l=k+1}^{N-1} \text{arctan} \left( \sqrt{\frac{j_l-1}{j_l}} \frac{u_l}{\sqrt{1 - u_l^2}} \right),$$  \hspace{1cm} (2.46)

To summarize, the action-angle variables for a free particle on $S^{N-1}$ are given by (2.40) and (2.46), with $j_l = L_1^2(p_1, \ldots, p_l, \theta_1, \ldots, \theta_l)$. The angular Hamiltonian (2.35) can be expressed as

$$\mathcal{H} = \frac{1}{2} L_N^2 = \frac{1}{2} \left( \sum_{m=1}^{N-1} I_m \right)^2.$$  \hspace{1cm} (2.47)
3 CONFORMAL MECHANICS

Conformal invariance plays an important role in many areas of the quantum field theory and condensed matter physics, especially in string theory, the theory of critical phenomena, low-dimensional integrable models, spin and fermion lattice systems. Recently, there has been new interest in so-called “conformal mechanics”. Actually, the conformal group is not an exact symmetry for the conformal mechanical system. It does not commute with the Hamiltonian but, instead, is a symmetry of the action (a symmetry in the field theoretical context[16]).

The Hamiltonian itself forms an \(so(1, 2)\) algebra together with generators of the dilatation and conformal boost, with respect to canonical Poisson brackets. It is interesting that, due to the conformal symmetry, the “angular” part of the Hamiltonian of conformal mechanics is a constant of motion.

The term “conformal mechanics” denotes a system whose Hamiltonian \(H\), together with the dilatation generator \(D\) and the generator \(K\) of conformal boosts forms, with respect to Poisson brackets, the conformal algebra:

\[
\{H, D\} = H, \quad \{D, K\} = K, \quad \{H, K\} = 2D. \tag{3.1}
\]

Such system can always be presented in the form [29]

\[
D = \frac{p_r r}{2}, \quad K = \frac{r^2}{2}, \quad H = \frac{p_r^2}{2} + \frac{2I(u)}{r^2}, \tag{3.2}
\]

where the radial coordinates \((r, p_r)\) and the angular coordinates \((u^\alpha)\) obey the basic Poisson brackets

\[
\{p_r, r\} = 1, \quad \{u^\alpha, p_r\} = \{u^\alpha, r\} = 0. \tag{3.3}
\]

The spherical (or angular) part of the Hamiltonian \(H\),

\[
I = KH - D^2, \tag{3.4}
\]

37
commutes with all generators and defines a constant of motion of the Hamiltonian $H$. Therefore, although conformal symmetry is not a symmetry of the Hamiltonian, it equipped the system with the additional (to the Hamiltonian) constant of motion $I$.

The spherical part of the conformal mechanics, determined by $I$, may be considered as a Hamiltonian system by itself. We refer to it as “spherical mechanics” or ”master mechanics” throughout the paper. It is obvious that integrability of the initial conformal mechanics leads to integrability of the “spherical mechanics”, and vice versa. It is also evident that the constants of motion of the spherical mechanics are constants of motion for the conformal mechanics. Yet, the inverse is generally not true, although there should be a way to construct the “spherical” constants of motion out of the ”conformal” ones. This problem was addressed in [35]. Some of the results of that paper are presented in this Chapter.

The study of the spherical mechanics is relevant for investigations of the Calogero model [36, 37, 38] and its various extensions and generalizations [39] (for a recent review see [40]). Furthermore, the spherical mechanics of the rational $A_N$ Calogero model defines the multi-center (Higgs) oscillator system on the $N-1$-sphere [41, 42]. The well-known series of hidden constants of motion found by Wojcechowski [43] for the Calogero model has a transparent explanation in terms of spherical mechanics, and its analog exists in any integrable conformal mechanical system [29]. Even in the simplest case of $N=2$, the one-dimensional spherical mechanics of the $A_2$ Calogero model shed light on a global aspect of Calogero models, by elucidating the non-equivalence of different quantizations of the Calogero model [44]. The $N=4$ superconformal generalizations of the rational $A_2$ Calogero model, constructed via supersymmetrization of spherical mechanics [45], yielded a scheme for lifting any $N=4$ supersymmetric mechanics to a $D(1, 2|\alpha)$ superconformal one [29]. Finally, a formulation in terms of action-angle variables [3] led to the equivalence of the rational $A_2$ and $G_2$ Calogero models and provided restrictions on the “decoupling” transformation which maps the Calogero model to the free-particle system considered in [46, 47, 48, 49, 42].

In [29] it was demonstrated that all information on a conformal mechanics system is encoded
in its spherical part. In particular, the “conformal” constants of motion with even conformal
dimension were shown to induce constants of motion for \((\omega_0, I)\). However, the authors did not
find the “spherical” constants of motion induced by the odd-dimensional initial constants of
motion. This problem was solved in [35] with the help of \(\text{so}(3)\) representation theory, then, was
continued in [50].

This Chapter contains 3 sections.

In 3.1, following but extending [29], we relate the symmetries of conformal mechanics to the
particular system of differential equations on the spherical phase space. The analysis is simpli-
fied by the use of \(\text{so}(3)\) representations, which clarifies the origin of the spin operators appearing
in the final system.

In 3.2 we construct a series of the constants of motion for the spherical mechanics, which is
induced by the constants of motion (of any conformal dimension) for the conformal system.

In 3.3 we apply our method to the rational \(A_3\) Calogero model and derive the complete set of
functionally independent constants of motion for the cuboctahedric Higgs oscillator.
3.1 The spherical part of conformal mechanics

Here, following \[29\] and \[35\], we relate the constants of motion of the conformal mechanics (3.2) with certain differential equations on the phase space of the associated spherical mechanics.

For any function $f$ on phase space, define the associated Hamiltonian vector field by the Poisson bracket action $\hat{f} = \{f, .\}$. For example, the Hamiltonian vector fields corresponding to the generators $H, D, K$ (3.2), and Casimir element (3.4) read

\[
\hat{H} = p_r \frac{\partial}{\partial r} + \frac{4T}{r^3} \frac{\partial}{\partial p_r} + \frac{2\hat{T}}{r^2}, \quad \hat{K} = -r \frac{\partial}{\partial p_r}, \quad \hat{D} = \frac{r}{2} \frac{\partial}{\partial r} - \frac{p_r}{2} \frac{\partial}{\partial p_r}, \quad (3.5)
\]

and

\[
\tilde{I} = H\hat{K} + K\hat{H} - 2D\hat{D}. \quad (3.6)
\]

Since the assignment $f \mapsto \hat{f}$ is a Lie algebra homomorphism, the vector fields $\hat{H}, \hat{K}, \hat{D}$ satisfy the $so(1, 2)$ algebra (3.1), and the vector field of the Casimir element $\tilde{I}$, of course, commutes with them.

Any constant of motion is the lowest weight vector of the conformal algebra (3.1), since it is annihilated by the Hamiltonian. Without any restriction, one can choose it to have a certain conformal dimension (spin):

\[
\hat{H} I_s = 0, \quad \hat{D} I_s = -2s I_s. \quad (3.7)
\]

A conformal mechanics which describes identical particles and possesses a permutation-invariant cubic (in momenta, $s=3/2$) constant of motion commuting with the total momentum yields the rational Calogero model, which is an integrable system \[51\].

In the following, we consider only nonnegative integer and half-integer values of the spin $s$, so that $I_s$ yields a finite-dimensional (nonunitary) representation of the $so(1, 2)$ algebra (3.5). This includes the $N$-particle rational Calogero model and its extensions, whose Liouville constants of motion are polynomials in the momenta.
Our goal is to derive the constants of motion for the “spherical” Hamiltonian (3.4) from the constants of motion of the initial conformal Hamiltonian. Using (3.2), (3.5), and (3.6) it is easy to see that the conservation condition (3.7) is equivalent to the equation

\[(\hat{I} - \hat{M}) I_s(p_r, r, u) = 0, \quad \text{where} \quad \hat{M} = 2(\hat{S}_- - \hat{I}\hat{S}_z).\]  

(3.8)

Here, the one-dimensional vector fields \(\hat{S}_\pm\) together with \(\hat{S}_z\) are given by

\[
\hat{S}_+ = \frac{1}{r} \frac{\partial}{\partial p_r}, \quad \hat{S}_- = -p_r r^2 \frac{\partial}{\partial r}, \quad \hat{S}_z = -\frac{1}{2} \left( r \frac{\partial}{\partial r} + p_r \frac{\partial}{\partial p_r} \right). \tag{3.9}
\]

Interestingly, they form an \(so(3)\) algebra,

\[
[\hat{S}_+, \hat{S}_-] = 2\hat{S}_z, \quad [\hat{S}_z, \hat{S}_\pm] = \pm \hat{S}_\pm. \tag{3.10}
\]

Note that \(\hat{S}_+\) is generated by the Hamiltonian \(S_+ = -\log(r)\) while the other two vector fields are not Hamiltonian.

The integral (3.7) can be presented as a sum of terms with decoupled radial and angular coordinates and momenta

\[
I_s(p_r, r, u) = \sum_{m=-s}^{s} f_{s,m}(u) R_{s,m}(p_r, r) \quad \text{with} \quad R_{s,m}(p_r, r) = \sqrt{\frac{2s}{s+m}} \frac{p_r^{s-m}}{r^{s+m}}. \tag{3.11}
\]

The radial functions \(R_{s,m}\) form a spin \(s\)-representation \((s = 0, \frac{1}{2}, \ldots)\) of the \(so(3)\) algebra (3.10),

\[
\hat{S}_+ R_{s,m} = \sqrt{(s-m)(s+m+1)} R_{s,m+1}, \quad \hat{S}_- R_{s,m} = \sqrt{(s-m+1)(s+m)} R_{s,m-1}, \quad \hat{S}_z R_{s,m} = m R_{s,m}. \tag{3.12}
\]

Hence, \(\hat{I}\) acts nontrivially only on the angular functions, while the \(\hat{S}_\alpha\) act on the radial ones. Due to the convolution (3.11), one can shift the latter action to the angular functions by

\(^1\) In comparison to the definition of \(f_{s,m}(u)\) in [29], we have multiplied the binomial factor and applied an index shift \(m \rightarrow m - s\). This makes more apparent the \(so(3)\) properties and simplifies further relations.
transposing the $so(3)$ matrices. As a result, the action of $\hat{\mathcal{I}}$ on the spin-$s$ states $f_{s,m}$ is given by

$$\hat{\mathcal{I}} f_{s,m} = \sum_{m'} M_{mm'} f_{s,m'} = 2 \sqrt{(s-m)(s+m+1)} f_{s,m+1} - \mathcal{I} \sqrt{(s-m+1)(s+m)} f_{s,m-1}. \quad (3.13)$$

This is a system of $2s+1$ first-order linear homogeneous differential equations for the angular functions $f_{s,m}(u)$. The coefficients depend only on $\mathcal{I}$, which commutes with the differential operator, and so they can be treated as constants. Note that all angular coefficients must obey the related $(2s+1)$th-order linear homogeneous differential equation

$$\det(\hat{\mathcal{I}} - M) f_{s,m} = 0, \quad (3.14)$$

which is, in fact, equivalent to the system (3.13), since any solution $f$ of (3.14) also generates a solution of the original system. Indeed, using (3.13), one can recursively express each function $f_{s,m}$ as a $(s\pm m)$th-order polynomial in $\hat{\mathcal{I}}$ acting on the function $f_{s,\mp s}$. Diagonalization of the matrix $M$ decouples the system (3.13) into independent equations, pertaining to the eigenvalues and eigenvectors of the vector field $\hat{\mathcal{I}}$.

Consider now some consequences of the relation (3.13). From a constant of motion of the Hamiltonian, one can construct other constants with the same conformal spin by successive application of the vector field generated by the spherical Hamiltonian:

$$I_s \xrightarrow{\hat{\mathcal{I}}} I_s^{(1)} \xrightarrow{\hat{\mathcal{I}}} I_s^{(2)} \xrightarrow{\hat{\mathcal{I}}} \ldots \xrightarrow{\hat{\mathcal{I}}} I_s^{(k)} \xrightarrow{\hat{\mathcal{I}}} \ldots, \quad I_s^{(k)} := \hat{\mathcal{I}}^k I_s. \quad (3.15)$$

In general, the members of this sequence are not in involution. At most the first $2s+1$ integrals can be independent, while the remaining ones are expressed through them linearly with $\mathcal{I}$-dependent coefficients, since the vector field $\hat{\mathcal{I}}$ acts on the $(2s+1)$-vector of constants $I_s^{(k)}$ as a square matrix with $\mathcal{I}$-valued entries. The exact amount of functionally independent integrals depends on the $I_s$ as well as on the concrete realization of the conformal mechanics.
3.2 Constants of motion of the spherical mechanics

The spin-\( j \) representation of the rotation group parameterized by three Euler angles is given by the Wigner \( D \)-matrix [52, 53, 54]. Let us remind some formulae about Wigner (small) \( d \)-matrix.

We only need the (small) \( d \)-matrix, which describes the rotation around the \( y \) axis,

\[
d_m^{s'}(\beta) = \langle sm' | \exp(-i\beta S_y) | sm \rangle, \tag{3.16}
\]

where \( m, m' = -s, \ldots , s \) are the spin \( z \)-projection quantum numbers. Its elements are real and given by [52]

\[
d_s^{m'}(\beta) = \sum_t (-1)^{t+m'-m} \sqrt{\frac{(s+m')!(s-m')!(s+m)!(s-m)!}{(j+m-t)!(m'-m+t)!(j-m'-t)!}} \times \sqrt{\frac{(s+m-m'+2t)!}{(s+m)!}} \times \cos \beta \frac{2s+m-m'+2t}{2} \times \sin \beta \frac{m'-m+2t}{2}, \tag{3.17}
\]

where the sum is over such values of \( t \) that the factorials in the denominator are nonnegative.

The elements obey

\[
d_m^{s'}(\beta) = d_m^{s'}(-\beta) = (-1)^{m-m'} d_m^{s'}(\beta) = d_{-m}^{s'}(-\beta), \tag{3.18}
\]

For \( \beta = \pi/2 \), the above expression simplifies to

\[
d_{m}^{s'}(\pi/2) = 2^{-s} \sum_t (-1)^{t+m'-m} \sqrt{\frac{(s+m')!(s-m')!(s+m)!(s-m)!}{(s+m-t)!(m'-m+t)!(s-m-t)!}} \times \sqrt{\frac{(s+m-m'+2t)!}{(s+m)!}} \times \cos \beta \frac{2s+m-m'+2t}{2} \times \sin \beta \frac{m'-m+2t}{2}, \tag{3.19}
\]

Further simplifications occur when one of the spin-projection quantum numbers vanishes, which is possible for integer spins only:

\[
d_m^{s0}(\pi/2) = (-1)^{\frac{s+m}{2}} \delta_{s-m,2z} \sqrt{\frac{(s-m)!(s+m)!}{2^s \frac{(s+m)!}{(s-m)!}}},
\]

\[
d_0^{s'}(\pi/2) = (-1)^{\frac{s-m}{2}} \delta_{s-m,2z} \sqrt{\frac{(s+m-1)!(s-m-1)!}{(s+m)!(s-m)!}}, \tag{3.20}
\]

\[
d_{00}(\pi/2) = (-1)^{\frac{s}{2}} \delta_{s,2z} \frac{(s-1)!!}{s!!}
\]
The factor $\delta_{s-m,2z}$ excludes odd values of $s-m$, for which the matrix elements vanish. For $\beta = \pi/2$, the relations are supplemented by

$$d^s_{m'm}(\pi/2) = (-1)^{s+m'} d^s_{m'-m}(\pi/2) = (-1)^{s-m} d^s_{-m'm}(\pi/2), \quad (3.21)$$

which can be obtained from $d^s_{m'm}(\pi) = (-1)^{s-m} \delta_{m',-m}$.

Now we shall present the construction of the constants of motion for the spherical mechanics $(\omega_0, \mathcal{I})$ from those for the initial conformal mechanics, based on $so(3)$ group representations. This method yields constants of motion of any conformal dimension and recovers the expressions found in [29].

Any constant of motion $I_s$ of the original Hamiltonian is given by its coefficients in the decomposition (3.11). The related conservation condition (3.8), (3.13), or (3.14) is decoupled into independent equations upon diagonalization of the matrix $M$,

$$\hat{M} = 4\sqrt{-\mathcal{I}} \hat{U} \hat{S}_z \hat{U}^{-1}, \quad \text{where} \quad \hat{U} = (-\mathcal{I})^{\frac{1}{4} \hat{S}_z} e^{-\frac{i \mathcal{I}}{2} \hat{S}_y} \quad \text{with} \quad \hat{S}_y = \frac{1}{2i} (\hat{S}_+ - \hat{S}_-). \quad (3.22)$$

Thus, up to an $\mathcal{I}$-valued factor, the vector field $\hat{M}$ is equivalent to the usual spin-$z$ projection operator. The operator $\exp(-\frac{i \mathcal{I}}{2} \hat{S}_y)$ maps $\hat{S}_z$ to $\hat{S}_x$. The latter is then transformed to $\hat{M}$ by the operator $(-\mathcal{I})^{\frac{1}{2} \hat{S}_z}$, which, for the present, means a formal power series. Together with the factor $i\sqrt{-\mathcal{I}}$ it contains square roots of $\mathcal{I}$. Thus $\hat{M}$ is, in general, complex and multi-valued. When the potential is positive, as is the case in Calogero models, the spherical part is strictly positive, and the operator (3.22) is complex but single-valued. In any case, all square roots will cancel in the final expressions for the constants of motion.

Define now the rotated basis for the algebra (3.10), which is formed by the eigenstates of the operator $\hat{M}$. Using (3.22), we obtain

$$\tilde{R}_{s,m} = (\hat{U} R)_{s,m} = \sum_{m'} U_{m'm} R_{s,m'},$$

$$U_{m'm} = d^s_{m'm}(\pi/2)(-\mathcal{I})^{\frac{s-m}{2}},$$

$$\hat{M} \tilde{R}_{s,m} = m \tilde{R}_{s,m}, \quad (3.23)$$
where \( d^s_{m'm}(\beta) \) is the Wigner’s small \( d \)-matrix, which describes the rotation around the \( y \) axis in the usual spin-\( s \) representation \( (3.12) \).

Note that the functions \( \tilde{R}_{s,m} \) now depend on the angular variables also through \( \mathcal{I} \). The integral \( (3.11) \) of the original Hamiltonian can be presented in terms of the rotated functions as

\[
I_s(p_r, r, u) = \sum_{m=-s}^s \tilde{f}_{s,m}(u) \tilde{R}_{s,m}(p_r, r, \mathcal{I}(u)).
\]

The new coefficients are expressed in terms of old ones by means of the inverse transformation [compare \( (3.11) \) with \( (3.24) \) and \( (3.23) \)]:

\[
\tilde{f}_{s,m} = \sum_{m'} U^{-1}_{mm'} f_{s,m'} = \sum_{m'} (-\mathcal{I})^{-\frac{m'}{2}} d^s_{m'm}(\pi/2) f_{s,m'}.
\]

In the second equation, we have applied the orthogonality condition of the \( d \)-matrix. Substituting the decomposition \( (3.24) \) into \( (3.8) \) and using the eigenvalue-eigenfunction equation form \( (3.24) \), we arrive at a similar eigensystem equation for the vector field \( \hat{\mathcal{I}} \) and the rotated angular coefficients:

\[
\hat{\mathcal{I}} \tilde{f}_{s,m}(u) = 4m \sqrt{-\mathcal{I}(u)} \tilde{f}_{s,m}(u).
\]

This provides a formal solution to the system \( (3.13) \). For systems with positive spherical part, the eigenvalue is a well-defined purely imaginary function, and the evolution of the coefficients driven by the spherical Hamiltonian oscillate with a frequency proportional to \( m \),

\[
\tilde{f}_{s,m}(t) = e^{i\omega_m(t-t_0)} \tilde{f}_{s,m}(t_0) \quad \text{with} \quad \omega_m = 4m \sqrt{\mathcal{I}}.
\]

Various combinations of these quantities give rise to constants of motion for the spherical Hamiltonian. In particular, for integer spin \( s \), the zero-frequency coefficient \( \tilde{f}_{s,0}(u) \) is an integral itself. Using the explicit expression of the Wigner \( d \)-matrix for this case \( (3.20) \), one can express it in terms of the original coefficients:

\[
\mathcal{J}_s(u) = \mathcal{I}(u)^{\frac{s}{2}} \tilde{f}_{s,0}(u) = \sum_{m=-s}^s \frac{(s+m-1)!!(s-m-1)!!}{\sqrt{(2s)!}} \delta_{s-m,2\ell} \mathcal{I}(u)^{\frac{s-m}{2}} f_{s,m}(u)
\]

\[
= \sum_{\ell=0}^s \frac{(2\ell-1)!!(2s-2\ell-1)!!}{\sqrt{(2s)!}} \mathcal{I}(u)^\ell f_{s,2\ell-s}(u).
\]
Here, $\mathbb{Z}$ denotes the set of integer numbers, so that $\delta_{k,2\mathbb{Z}} = 1$ for even values of $k$ and vanishes for the odd values. The supplementary $\mathcal{I}$-dependent factor in front of the angular coefficient eliminates the fractional powers of $\mathcal{I}$, leaving only integral powers of $\mathcal{I}$ in the final expression.

Up to a normalization factor, (3.28) coincides with the expression (5.2) of [29].

For integer values of $s$, the same integral can also be obtained from the equivalent higher-order differential equation (3.14). Indeed, due to (3.22) or (3.26), the related differential operator takes the following form:

$$\text{Det}(\hat{\mathcal{I}} - M) = \prod_{m=-s}^{s} (\hat{\mathcal{I}} - 4m\sqrt{-\mathcal{I}}) = \begin{cases} \hat{\Delta}_s & \text{for } s \in \mathbb{Z}, \\ \hat{\Delta}_s & \text{for } s \in \mathbb{Z} + \frac{1}{2}, \end{cases}$$

with $\hat{\Delta}_s = \prod_{0 < m \leq s} (\hat{\mathcal{I}}^2 + 16m^2\mathcal{I})$.

Therefore, for integer spin value, (3.14) is reduced to

$$\hat{\Delta}_sf_{s,m} \equiv \prod_{m=1}^{s} (M^2 + 16m^2\mathcal{I})f_{s,m} = 0,$$

which implies that $\hat{\Delta}_sf_{s,m}$ is an integral of motion of $\mathcal{I}$. The operator $\hat{\Delta}_s$ projects out all but one of the eigenfunctions $\tilde{f}_{s,m}$,

$$\hat{\Delta}_s\tilde{f}_{s,m} = \delta_{m0}(s!)^2(16\mathcal{I})^sf_{s,m}.$$

Therefore, the above integral has to be proportional to (3.28). This can be verified independently if we apply $\hat{\Delta}_s$ to both sides of the inversion of (3.25) and use (3.23), (3.28), (3.20):

$$\hat{\Delta}_sf_{s,m} = U_{m0}\hat{\Delta}_sf_{s,0} = \delta_{s-m,2\mathbb{Z}}c_{s,m} \mathcal{I}^{\frac{s+m}{2}} J_s$$

with $c_{s,m} = (-8i)^s(s!)^{s+m}(s-m)!(s+m)!$.

How to construct an integral of $\mathcal{I}$ from an integral of $H$ with half-integral conformal spin?

The corresponding representation has no $m=0$ state, but one can consider such a state in the
integral \( I_{2s} = I_s^2 \), which has integral spin value equal to \( 2s \). In general, integrals of \( I \) can be built also by bilinear combinations of \( f_{s,m}(u) \) with opposite values of the spin projection. In fact, any state

\[
J_s^m = (-I)^s \bar{f}_{s,m} \bar{f}_{s,-m} = \sum_{m',m''} \delta_{m''-m',2s} (-1)^{2s+m''} \frac{m''-m'}{2} d_{s,m}(\pi/2) d_{s,m'}(\pi/2) \mathcal{I}^{s-\frac{m''+m'}{2}} f_{s,m'} f_{s,m''}
\]

(3.33)

is an integral of \( I \). In the first equation, we have used the symmetry property (3.21) of the \( d \)-matrix. The Kronecker delta appears after symmetrization over the two summation indices in the first double sum, with the help of

\[
\frac{1}{2}(i^{m''-m'} + i^{m'-m''}) = i^{m''-m'} \frac{1}{2} (1 + (-1)^{m'-m''}) = i^{m''-m'} \delta_{m''-m',2s}.
\]

(3.34)

Therefore, the constant of motion \( J_s^m \) of the spherical Hamiltonian is a real polynomial of order \( 2s \) in \( I \).

There is a clear interpretation of the constructed integrals in terms of representation theory. Take some set of angular functions satisfying (3.8) or (3.13), which means that the related quantity \( I_s \) (3.11) is an integral of \( H \). Then, according to the tensor product of \( so(3) \) representations, one can construct other sets of angular functions,

\[
f_{s,m}(u) = \sum_{m_1+m_2=m} C_{s,m_1,s_2,m_2}^{S,m} f_{s,m_1}(u) f_{s,m_2}(u) \quad \text{with} \quad S = 2s, 2s-2, \ldots,
\]

(3.35)

which satisfy a similar equation.

Clebsch-Gordan coefficients are the expansion coefficients of total-spin eigenstates \( |SM \rangle \) in terms of the product basis \( |s_1m_1s_2m_2 \rangle \) of eigenstates of the two coupled spins,

\[
C_{s_1,m_1,s_2,m_2}^{S,M} = \langle s_1m_1s_2m_2 | SM \rangle.
\]

(3.36)

The general expression is complicated, but special cases are often quite simple like for the
highest total-spin value:

\[ C_{s_1+m_1,s_2+m_2}^{s_1+s_2,m_1+m_2} = \sqrt{\left( \frac{2s_1}{s_1-m_1} \right) \left( \frac{2s_2}{s_2-m_2} \right)} \left( \frac{2s_1+s_2}{s_1+s_2-m_1-m_2} \right). \] (3.37)

The Clebsch-Gordan coefficients have an even-odd exchange symmetry depending on the total-spin value,

\[ C_{s_1,m_1,s_2,m_2}^{s,m} = (-1)^{s_1+s_2-s} C_{s_2,m_2,s_1,m_1}^{s,m}. \] (3.38)

The multiplets with odd values of \( S-2s \) are absent in the symmetric tensor product, due to the exchange symmetry of the Clebsch-Gordan coefficients (3.38). From the angular functions (3.35) one can compose “new” integrals of the original Hamiltonian via

\[ I'_S = \sum_m f_{S,m} R_{S,m}, \quad \text{with} \quad S = 2s, 2s - 2, \ldots, \] (3.39)

each corresponding to a symmetric multiplet in the tensor product of two spin-\( s \) multiplets.

Note that the first integral from this set just coincides with the square of the original integral,

\[ I_{2s}' = I_{2s}^2, \] as can easily be verified using (3.37). Since \( S \) is always integer, the related multiplet contains an \( m = 0 \) state, which is a constant of motion of the spherical Hamiltonian:

\[ F_{S}^{S}(u) = \sum_m C_{S,m,-m}^{0,m} \mathcal{J}_{m}^{S}(u). \] (3.40)

Unwanted fractional powers of \( \mathcal{I} \) cancel as before. These two sets of integrals are, of course, equivalent.

A similar “blending” procedure can be applied to the mixing of two different integrals \( I_{s_1} \) and \( I_{s_2} \) with integer value of \( s_1-s_2 \). The resulting integrals of \( \mathcal{I} \) are parameterized by the whole set of \( 2s_{\text{min}}+1 \) different angular momenta obeying the sum rule.

The construction straightforwardly generalizes also to multilinear forms composed from the angular functions. The expression (3.33) expands to

\[ \mathcal{J}_{s_1 \ldots s_k}^{m_1 \ldots m_k}(u) = \mathcal{I}(u)^{\frac{1}{2}} \sum_{s_1 \ldots s_k} \mathcal{J}_{s_1,m_1}(u) \ldots \mathcal{J}_{s_k,m_k}(u) \quad \text{with} \quad \sum_{\ell=1}^{k} m_\ell = 0, \] (3.41)
where the last relation implies that the total spin $\sum s_\ell$ must be an integer. These observables can be combined into a single multiplet of integer spin $S$ by a $(k-1)$-fold application of the Clebsch-Gordan decomposition. The final set of observables $\tilde{f}_{S,m}$ forms an integral of the original Hamiltonian, while its $m=0$ element corresponds to an integral of the spherical Hamiltonian.

So far, we have only considered products of the angular functions. More generally however, one could also employ fractions of them, with the same spin projection of the numerator and the denominator, such as $\tilde{f}_{s_1,m}/\tilde{f}_{s_2,m}$. Of course, this entails introducing singularities, which might create problems for the quantization due to inverse powers of moments.

It has to be mentioned that the variety of angular constants of motion constructed here are not independent. It may even happen that some of them vanish. Moreover, the compatibility of the integrals of motion for $H$ does not at all yet imply the compatibility of the associated integrals for $I$, as can be seen from (3.33).
Examples

At the end of this section, we demonstrate our method by presenting some simplest examples for the obtained constants of motion.

First we note that there exist two bilinear conserved quantities (3.33) and (3.40), which have a rather simple form in terms of the original angular coefficients. The first one is the canonical “singlet”, which is the same both in the original and the rotated basis,

$$F_s^0(u) \sim \sum_m (-1)^{s-m} \tilde{f}_{s,m} \tilde{f}_{s,-m} = \sum_m (-1)^{s-m} f_{s,m} f_{s,-m}. \quad (3.42)$$

The second one is given by the trivial superpositions of the states (3.33), which is reduced by the orthogonality of the $d$-matrices to

$$\sum_m J^m_s \sim \sum_m I^{s-m} f^2_{s,m}. \quad (3.43)$$

For the integral $I_s$ of the Hamiltonian $H$ with conformal spin $s=\frac{1}{2}$, the general formula (3.33) takes its simplest form, up to a normalization factor,

$$J_{\frac{3}{2}}^\frac{1}{2} \sim I f^2_{\frac{1}{2},-\frac{1}{2}} + f^2_{\frac{3}{2},\frac{1}{2}}. \quad (3.44)$$

Consider now the integral with conformal spin $s=1$ of the original Hamiltonian. The related linear integral of $I$ is (see (3.28))

$$J_1 \sim I f_{1,1} + f_{1,-1}. \quad (3.45)$$

In addition, there are two quadratic integrals given by (3.33), one of which ($J^{m=0}_{s=1}$) is the square of the above integral, while the other one can be identified with either (3.42) or (3.43). The Hamiltonian itself can be considered as a particular case. For $I_1 = H$, the coefficient $f_{10}$ vanishes while the others become constants, so the sole constant of $I$ extracted from $H$ is $I$ itself.
The first nontrivial case corresponds to the next conformal spin $s = \frac{3}{2}$, when there is no linear but two independent quadratic integrals. The simplest choice then are the two functions (3.42) and (3.43).
3.3 Four-particle Calogero model

The (rational) Calogero model \[36\] \[37\] \[38\], which is an integrable \(N\)-particle one-dimensional system with pairwise inverse-square interaction (and its various generalizations related with different Lie algebras and Coxeter groups \[39\]) is a famous example of a conformal mechanical system (for the review, see \[40\]). Usually, Lax-pair and matrix-model approaches are employed for the study of this system. These are common methods which are applied to other integrable models not related to the conformal group. At the same time, many properties of the rational Calogero model are due to its conformal invariance, and they are shared with other conformal mechanical models. For example, the “decoupling transformation” in the Calogero model \[46\] can be formulated purely in terms of conformal transformations \[47\] \[48\] \[49\] (see also \[55\]).

Note that the rational \(N\)-particle Calogero model is a maximally superintegrable system, i.e. it possesses \(N-1\) additional functionally independent integrals apart from the Liouville integrals being in involution \[43\]. Despite an impressive list of references on this subject \[56\], the superintegrability of the Calogero model still seems to be mysterious. Preliminary considerations have indicated a direct connection between the additional constants of motion and the “angular” part of the Calogero model \[41\].

Let us use the general method developed in the previous section to construct the complete set of constants of motion for the spherical mechanics of the four-particle Calogero model after decoupling the center of mass (i.e. of the rational \(A_3\) Calogero model). This spherical mechanics also describes a particle on the two-dimensional sphere, interacting by the Higgs-oscillator law with force centers located in the vertices of a cuboctahedron. By this reason, the system was termed “cuboctahedric Higgs oscillator” \[41\].

We remind that the standard rational Calogero model,

\[
H = \frac{1}{2} \sum_{i=1}^{N} p_i^2 + \sum_{i<j} g^2 \frac{1}{(x_i - x_j)^2},
\]  

(3.46)
has \( N \) Liouville constants of motion, given in terms of a Lax matrix by the expression

\[ I_s = \text{Tr} L^{2s} \quad \text{with} \quad s = \frac{1}{2}, 1, \ldots, \frac{N}{2}, \quad (3.47) \]

where

\[ L_{jk} = \delta_{jk} p_k + (1 - \delta_{jk}) \frac{ig}{x_j - x_k}. \quad (3.48) \]

Hence, \( I_\frac{1}{2} = \sum p_i \) and \( I_1 = \frac{1}{2}H \). Furthermore, the quantities

\[ I_s^{(1)} = \hat{I} I_s \quad \text{for} \quad s \neq 1 \quad (3.49) \]

coincide with Wojciechowski’s additional integrals \[29\]. Together with \( (3.47) \), they form a complete set of functionally independent integrals making the system maximally superintegrable \[43\].

We choose \( N=4 \) and pass to new coordinates

\[ y_0 = \frac{1}{2}(x_1+x_2+x_3+x_4), \quad y_1 = \frac{1}{2}(x_1+x_2-x_3-x_4), \]

\[ y_2 = \frac{1}{2}(x_1-x_2+x_3-x_4), \quad y_3 = \frac{1}{2}(x_1-x_2-x_3+x_4) \]

and associated momenta \( \tilde{p}_i \) with \( i = 0, 1, 2, 3 \). This transformation decouples the center-of-mass coordinate \( y_0 \) and momentum \( \tilde{p}_0 \) from the others. After setting

\[ y_0 = 0, \quad \tilde{p}_0 = 0, \quad (3.51) \]

the Hamiltonian takes the form of the rational \( D_3 \sim A_3 \) Calogero model \[41\]

\[ H = \frac{1}{2} \sum_{i=1}^3 \tilde{p}_i^2 + \sum_{i,j=1}^3 \left( \frac{g^2}{(y_i - y_j)^2} + \frac{g^2}{(y_i + y_j)^2} \right) = \frac{1}{2}p_r^2 + \frac{I(p_\theta, p_\varphi, \theta, \varphi)}{2r^2}. \quad (3.52) \]

In the second equation, we introduced spherical coordinates \((r, \theta, \varphi)\) on \( \mathbb{R}^3(y_1, y_2, y_3) \) together with their conjugate momenta \((p_r, p_\theta, p_\varphi)\), so that
\[ I(p_\theta, p_\phi, \theta, \phi) = p_\theta^2 + \frac{p_\phi^2}{\sin^2 \theta} + \frac{2g^2}{\sin^2 \theta} \sum_{\pm} \left[ \frac{1}{(\cos \phi \pm \sin \phi)^2} + \frac{1}{(\cot \theta \pm \sin \phi)^2} + \frac{1}{(\cot \theta \pm \cos \phi)^2} \right], \]  

(3.53)

According to (3.47) and (3.48), the conformal Hamiltonian (3.52) has two Liouville constants of motion of conformal dimension three and four, given by

\[ I_3^2 = \text{Tr}(L_3^3) = 4 \sum_{i=1}^4 p_{3i}^3 + \ldots = 3\hat{p}_1 \hat{p}_2 \hat{p}_3 + \ldots = \frac{3}{2} p_r^3 \cos \theta \sin^2 \theta \sin 2\phi + \ldots, \]  

(3.54)

\[ I_2^2 = \text{Tr}(L_4^4) = 4 \sum_{i=1}^4 p_{4i}^4 + \ldots = \frac{1}{1}(\hat{p}_1^4 + \hat{p}_2^4 + \hat{p}_3^4) + \frac{3}{2}(\hat{p}_1^2 \hat{p}_2^2 + \hat{p}_1^2 \hat{p}_3^2 + \hat{p}_2^2 \hat{p}_3^2) + \ldots = \frac{1}{4} p_r^4 \left( \sin^2 2\theta + \sin^4 \theta \sin^2 2\phi + 1 \right) + \ldots. \]  

(3.55)

Here, we have written out only the terms of highest order in the momentum. Comparing (3.54) and (3.55) with (3.11), we obtain the spherical functions \( f_s, -s \) as the coefficients of the monomials \( p_r^{2s} \),

\[ f_2(\theta, \phi) = \frac{3}{2} \cos \theta \sin^2 \theta \sin 2\phi, \quad f_2(\theta, \phi) = \frac{1}{4} \left( \sin^2 2\theta + \sin^4 \theta \sin^2 2\phi \right). \]  

(3.56)

Here and in the following, we use for convenience the shorter notation

\[ f_s(\theta, \phi) := f_{s,-s}(\theta, \phi). \]  

(3.57)

The Liouville integrals (3.54) and (3.55) are supplemented by the two related Wojciechowski integrals \( I_{2}^{(1)} \) and \( I_{2}^{(1)} \), whose leading-term coefficients are

\[ g_2 = \hat{\mathcal{I}} f_2 \quad \text{and} \quad g_2 = \hat{\mathcal{I}} f_2. \]  

(3.58)

Note that the \( f_s \) depend on the angles only while the \( g_s \) are linear in the angular momenta. Together with the Hamiltonian (3.52), we obtain a complete set \( \{ H, I_2^2, I_{2}^{(1)}, I_2^{(1)} \} \) of five independent integrals.
In order to derive the Poisson algebra of integrals, we compute first the commutators between the related coefficients:

\[
\begin{align*}
\{ f_3^2, g_3^2 \} &= 18 (f_3^2 - f_2), \\
\{ f_2^2, f_2 \} &= 0, \\
\{ g_3^2, g_2 \} &= 4 (2g_3f_2 - 3f_4g_2), \\
\{ f_3^2, f_2 \} &= 0, \\
\{ g_3^2, g_2 \} &= 8f_2(3f_2 - 1).
\end{align*}
\] (3.59)

Since the map \( I_s \to f_s \) is a Poisson algebra homomorphism [29], we immediately get the analogous relations for the constants of motion by inserting powers of \( 2H \) in order to balance the conformal spins on both sides of the equations (the coefficient for the Hamiltonian (3.52) is a constant: \( f_1 = \frac{1}{2} \)). Thus, the nontrivial Poisson brackets are

\[
\begin{align*}
\{ I_3^2, I_3^{(1)} \} &= 18 (I_3^2 - 2I_2H), \\
\{ I_2, I_2^{(1)} \} &= 8 (4I_2^2 - \frac{2}{3}I_3^2H - 4I_2H^2), \\
\{ I_2^2, I_2 \} &= 8I_2^2(3I_2 - 4H^2), \\
\{ I_3^{(1)}, I_2 \} &= 4(2I_3^{(1)} - 3I_2I_2^{(1)}).
\end{align*}
\] (3.60)

This is a particular realization of part of the quadratic algebra related to the Hamiltonian [57] (see [58] for rational Calogero models based on arbitrary root systems). It is expressed in terms of independent generators, therefore higher orders appear on the right-hand sides.

We now derive a complete set of functionally independent constants of motion for the spherical mechanics of the four-particle Calogero model. The second expression in (3.29) immediately yields the spherical constant of motion associated with (3.55),

\[
J_2 = -\frac{1}{\sqrt{6}} \left( \frac{1}{256} \hat{I}^4 + \frac{5}{16} \hat{I}^2 \hat{I}^2 + 4\hat{I}^2 \right) f_2.
\] (3.61)

Its explicit expression, which can be calculated using (3.53) and (3.56), is highly complicated,

\[
J_2 = \frac{1}{\sqrt{6}} \left[ \frac{1}{16} (3 \cos 4 \varphi - 11) p_\theta^4 - \frac{3}{4} \cot \theta \sin 4 \varphi p_\theta^3 p_\varphi - \left( \frac{11 + 9 \cos 4 \varphi}{8 \sin^2 \theta} + \frac{9}{4} \sin^2 2 \varphi \right) p_\theta^2 p_\varphi^2 + \frac{3 \cos^4 \theta \cos 4 \varphi + 21 \sin^4 \theta - 18 \sin^2 \theta - 11}{16 \sin^4 \theta} p_\varphi^4 \right] + g^2 K_1(\theta, \varphi) p_\theta^2 + g^2 K_2(\theta, \varphi) p_\theta p_\varphi + g^2 K_3(\theta, \varphi) p_\varphi^2 + g^4 K_4(\theta, \varphi).
\] (3.62)
where the functions $K_1(\theta, \varphi), K_2(\theta, \varphi), K_3(\theta, \varphi), K_4(\theta, \varphi)$ are given by

$$
K_1(\theta, \varphi) = \frac{1}{2^{1+4/\theta^2} 2\cos^2 2\varphi (\cos^2 \theta - \sin^2 \theta \cos^2 \varphi)^2(2 \sin^2 \theta \cos 2\varphi + 3 \cos 2\theta + 1)} \times 
(768 (25 + 29 \cos 2\theta) \sin^6 \theta \cos 12\varphi + 96 (1370 + 2327 \cos 2\theta + 1542 \cos 4\theta + 393 \cos 6\theta) \sin^2 \theta \cos 8\varphi
- (119258 + 175774 \cos 2\theta + 45096 \cos 4\theta + 57723 \cos 6\theta - 10242 \cos 8\theta + 5607 \cos 10\theta) \sin^{-2} \theta \cos 4\varphi
+ (1021064 + 365088 \cos 2\theta - 223008 \cos 4\theta - 183840 \cos 6\theta - 61800 \cos 8\theta - 655360 \sin^{-2} \theta) \right),
$$

$$
K_2(\theta, \varphi) = \frac{3 \cot \theta \tan 2\varphi}{8 \sqrt{6} \sin^2 \theta (17 \cos 4\theta + 28 \cos 2\theta - 8 \sin^4 \theta \cos 4\varphi + 19)^2} \times
(351 \cos 10\theta + 1350 \cos 8\theta + 13779 \cos 6\theta + 9992 \cos 4\theta + 35022 \cos 2\theta - 13824 \sin^8 \theta \cos^2 \theta \cos 8\varphi + 5042
- 64 (81 \cos 6\theta + 702 \cos 4\theta + 1071 \cos 2\theta + 962) \sin^4 \theta \cos 4\varphi),
$$

$$
K_3(\theta, \varphi) = \frac{1}{16 \sqrt{6} \cos^2 2\varphi (17 \cos 4\theta + 28 \cos 2\theta - 8 \sin^4 \theta \cos 4\varphi + 19)^2} \times
(162 (13 \sin 2\varphi + \sin 6\varphi)^2 \cos 8\theta + 24 (3898 - 1569 \cos 4\varphi - 282 \cos 8\varphi + \cos 12\varphi) \cos 6\theta
+ 36 (6686 + 1931 \cos 4\varphi - 430 \cos 8\varphi + 5 \cos 12\varphi) \cos 4\theta + 72 (546 + 10587 \cos 4\varphi - 898 \cos 8\varphi + 5 \cos 12\varphi) \cos 2\theta
- (1087746 - 1625907 \cos 4\varphi + 46158 \cos 8\varphi + 483 \cos 12\varphi)
+ 262144 (5 - 4 \cos 4\varphi) \sin^{-2} \theta - 32768 (11 - 3 \cos 4\varphi) \sin^{-4} \theta),
$$

$$
K_4(\theta, \varphi) = \frac{-1}{64 \sqrt{6} \{60 \cos 2\theta + 33 \cos 4\theta + 35 \cos 2\theta - 8 \sin^4 \theta \cos 6\varphi \}^2} \times
64 (335698872 \cos 2\theta + 204278376 \cos 4\theta + 100740648 \cos 6\theta + 30799596 \cos 8\theta + 3629304 \cos 10\theta
+ 515160 \cos 12\theta - 649944 \cos 14\theta - 194463 \cos 16\theta + 197597863 \cos 8\varphi
+ 384 \sin^4 \theta \{(16777297 - 12592957 \cos 4\theta - 10272636 \cos 6\theta - 4821234 \cos 8\theta - 2019708 \cos 10\theta
- 312741 \cos 12\theta - 8174886) \cos 12\varphi - 768 \sin^8 \theta (828 \cos 2\theta + 243 \cos 4\theta + 617) \cos 20\varphi
- 32 \sin^8 \theta (290832 \cos 2\theta + 188916 \cos 4\theta + 81648 \cos 6\theta + 13851 \cos 8\theta + 166129) \cos 16\varphi
+ \sin^{-4} \theta \{(991103400 \cos 2\theta + 11541549238 \cos 4\theta + 10411072176 \cos 6\theta + 8259070392 \cos 8\theta
+ 4658511600 \cos 10\theta + 1965778311 \cos 12\theta + 569460204 \cos 14\theta + 67528026 \cos 16\theta - 29495988 \cos 18\theta
- 8028477 \cos 20\theta + 4163058670) \cos 4\varphi + 62158979032 \cos 2\theta + 46026533130 \cos 4\theta + 27521060688 \cos 6\theta
+ 12943186248 \cos 8\theta + 4533912336 \cos 10\theta + 1033949913 \cos 12\theta - 11388780 \cos 14\theta - 94673178 \cos 16\theta
- 31001292 \cos 18\theta - 6738147 \cos 20\theta + 34004741074 \} \right).$$

The system of equations (3.13) can be applied in order to express the coefficients $f_{\frac{m}{2}, m}$ in terms of the “lowest” one:

$$
f_{\frac{3}{2}, -\frac{1}{2}} = \frac{1}{2} \hat{I}_f f_{\frac{3}{2}}, \quad f_{\frac{3}{2}, \frac{1}{2}} = \left(\frac{1}{8} \hat{I}_f^2 + \frac{\sqrt{2}}{2} \hat{I}_I \right) f_{\frac{3}{2}}, \quad f_{\frac{3}{2}, \frac{3}{2}} = \left(\frac{1}{16} \hat{I}_I^2 + \frac{\sqrt{2}}{12} \hat{I}_I \right) \hat{I}_I f_{\frac{3}{2}}. \quad (3.67)
$$
Then, using (3.53) and (3.56), one obtains the spherical constants of motion (3.33) associated with (3.54), namely $J^\frac{1}{2}$ and $J^\frac{3}{2}$. Their explicit expressions are rather lengthy:

\[
J^\frac{1}{2} = -\frac{3}{32} \sin^2 2\varphi \, p_\theta^6 - \frac{3}{16} \cot \theta \sin 4\varphi \, p_\theta^5 p_\varphi
- \frac{3}{128 \sin^2 \theta} \left( 6 \cos^2 \theta + (13 - 3 \cos 2\theta) \cos 4\varphi \right) p_\theta^4 p_\varphi^2
- \frac{3}{128 \sin^2 \theta} \left( 22 \sin^4 \theta - (43 - 53 \cos 2\theta) \cos 4\varphi \cos^2 \theta + 6 \cos 2\theta \right) p_\theta^2 p_\varphi^4
- \frac{3}{32 \sin^2 \theta} (7 - 9 \cos 2\theta) \cos^3 \theta \sin 4\varphi \, p_\theta^5 p_\varphi^3
+ \text{terms of lower order in } p_\theta \text{ and } p_\varphi. \tag{3.68}
\]

\[
J^\frac{3}{2} = -\frac{9}{32} \sin^2 2\varphi \, p_\theta^6 - \frac{9}{16} \cot \theta \sin 4\varphi \, p_\theta^5 p_\varphi - \frac{9}{64} \left( \frac{5 \cos 4\varphi + 3}{\sin^2 \theta} \right) + 10 \sin^2 2\varphi \right) p_\theta^4 p_\varphi^2
- \frac{9}{64 \sin^2 \theta} \left( 5 \cos^4 \theta \cos 4\varphi + 10 \sin^2 2\varphi - 5 \sin^4 \theta + 3 \right) p_\theta^2 p_\varphi^4 + \frac{9}{16} \cot^5 \theta \sin 4\varphi \, p_\theta^5 p_\varphi^5
+ \frac{9 \cos^2 \theta}{64 \sin^2 \theta} \left( \cos^4 \theta \cos 4\varphi - 6 \sin^2 2\varphi - \sin^4 \theta - 1 \right) p_\varphi^6
+ \text{terms of lower order in } p_\theta \text{ and } p_\varphi. \tag{3.69}
\]

Clearly, $I$, $J_2$, $J_{\frac{1}{2}}$, and $J_{\frac{3}{2}}$ cannot be functionally independent, since our spherical mechanics has a four-dimensional phase space. Indeed, we uncover the following algebraic relation,

\[
J^\frac{3}{2} = \frac{1}{3} J^\frac{1}{2} + 2 \sqrt{\frac{2}{5}} J_2 I + \frac{1}{3} I^3 + 4 g^2 I^2. \tag{3.70}
\]

This is the only relation among the four constants of motion, since (3.68) and (3.69) are not in involution with (3.62). Even their free-particle parts ($g=0$ projects to the terms of highest order in the momenta) do not commute as is easy to verify. Hence, we have found three functionally independent spherical constants of motion for the $A_3$ Calogero model. This confirms the superintegrability of that system.
4 A PARTICLE NEAR THE HORIZON OF EXTREMAL BLACK HOLES

4.1 Conformal mechanics associated with the near horizon geometry

The black hole solutions allowed in supersymmetric field theories have an extremality property, that is, the inner and outer horizons of the black hole coalesce. In this case one can pass to the near-horizon limit, which brings us to new solutions of Einstein equations. In this limit (near-horizon extremal black hole) the solutions become conformal invariant. The conformal invariance was one of the main reasons why the extremal black holes have been payed so much attention to for the last fifteen years. Indeed, due to conformal invariance black hole solutions are a good research area for studying conformal field theories and AdS/CFT correspondence (for the recent review see [17]). The simplest way to research this type of configurations is to study the motion of a (super)particle in this background. The first paper that considered such a problem is [18], where the motion of particle near horizon of extremal Reissner-Nordstr"om black hole has been considered. Later similar problems in various extremal black hole backgrounds were studied by several authors (see [19, 20, 21] and refs therein).

In general, some important features of a black hole are adequately captured in the model of a relativistic particle moving on the curved background [59]. A classic example of such a kind is the discovery of a quadratic first integral for a massive particle in the Kerr space–time [60] which preceded the construction of the second rank Killing tensor for the Kerr geometry [61]. In some instances the argument can be reversed. In Ref. [18] a massive charged particle moving near the horizon of the extremal Reissner-Nordström black hole was related to the conventional conformal mechanics in one dimension [16] by implementing a specific limit in which the black hole mass $M$ is large, the difference between the particle mass and the absolute value of its charge $(m - |e|)$ tends to zero with $M^2(m - |e|)$ fixed. The angular variables effectively decouple in the above mentioned limit and show up only in an indirect way via the effective coupling
constant characterizing the conformal mechanics. In that setting the absence of a normalizable
ground state in the conformal mechanics and the necessity to redefine its Hamiltonian \[16\] were
given a new black hole interpretation \[18\].

It is obvious, that particle moving on conformal-invariant background inherits the property
of (dynamical) conformal symmetry, that is, one can present additional generators \(K\) and \(D\),
which form, together with the Hamiltonian \(H\), the conformal algebra 3.1 (see page 37):

\[
\begin{align*}
\{H, D\} &= H, & \{D, K\} &= K, & \{H, K\} &= 2D.
\end{align*}
\]

Conformal mechanics associated with the near horizon geometry of an extremal black hole is
described by the triple \[59\]

\[
\begin{align*}
H &= r \left( \sqrt{(rp_r)^2 + L(p_a, \varphi^a) - q(p_a, \varphi^a)} \right), \\
K &= \frac{1}{r} \left( \sqrt{(rp_r)^2 + L(p_a, \varphi^a) + q(p_a, \varphi^a)} \right) + t^2 H + 2trp_r, \\
D &= tH + rp_r,
\end{align*}
\]

which involves the Hamiltonian \(H\), the generator of dilatations \(D\), and the generator of special
conformal transformations \(K\).

As proved in Chapter \[3\] one can state that a conformal mechanics can be presented in a
non-relativistic “canonical” form

\[
H = \frac{p_R^2}{2} + \frac{2\mathcal{I}(u)}{R^2}, \quad \Omega = dp_R \wedge dR + \frac{1}{2} \omega_{\alpha\beta}(u) \, du^\alpha \wedge du^\beta.
\]

where \(R\) and \(p_R\) are the new effective radial coordinate and the momentum, and \(\mathcal{I} = HK - D^2\)
is the Casimir element of \(so(2,1)\) algebra. We will show how the new radial coordinate and
momentum \(R\) and \(p_R\) are related to the old ones shortly.

There is no general canonical transformation known which transforms arbitrary conformal me-
chanics to the form (4.2). For the particular case of the near-horizon motion of the particle
in the extremal Reissner-Nordström background such transformation has been suggested in \[62\], while recently it was extended to the case of general four-dimensional near horizon extremal black hole in \[59\]. In the latter the authors, taking into account the integrability of this system, suggested the generic canonical transformation, assuming that the angular system \((\frac{1}{2}\omega_{\alpha\beta}du^\alpha \wedge du^\beta, \mathcal{I}(u))\) is formulated in action-angle variables. They exemplified their scheme, constructing the action-angle variables for a neutral particle near the horizon of extremal Reissner-Nordström black hole, as well as discussed the case of the charged particle near the horizon of extremal Dilaton-Axion (Clément-Gal’tsov) black hole\[63\], without actually constructing the action-angle variables for the second system. Then, the action-angle formulation for the angular part of a near-horizon particle dynamics in the extremal Kerr black hole background has also been presented \[64\].

The functions \(L(p_a, \varphi^a)\) and \(q(p_a, \varphi^a)\) entering Eq. (4.1) depend on the details of a particular black hole under consideration: see \[62, 21\] for the near horizon extremal Reissner-Nordström black hole, \[65\] for the rotating extremal dilaton–axion black hole, \[66\] for the extremal Kerr solution, and \[67\] for the extremal Kerr-Newman and Kerr-Newman-AdS-dS black holes.

Let us denote \(D_0 = D|_{t=0}, K_0 = K|_{t=0}\), where \(t\) is the temporal coordinate. Note that \(H, D_0\) and \(K_0\) obey the structure relations of \(so(2, 1)\) as well. The latter fact allows one to separate the radial canonical pair from the rest by introducing the new radial coordinate \[29\]

\[R = \sqrt{2K_0}, \quad p_R = \frac{2D_0}{\sqrt{2K_0}} \Rightarrow \{p_R, R\} = 1 \quad (4.3)\]

such that

\[H = \frac{1}{2}p_R^2 + \frac{2\mathcal{I}}{R^2}, \quad (4.4)\]

where \(\mathcal{I}\) is the Casimir element of \(so(2, 1)\)

\[\mathcal{I} = HK - D^2 = HK_0 - D_0^2 = L(p_a, \varphi^a) - q(p_a, \varphi^a)^2. \quad (4.5)\]

In general, \(\mathcal{I}\) is at most quadratic in momenta canonically conjugate to the remaining angular
variables.

However, with respect to the Poisson bracket the new radial variables \((R, p_R)\) do not commute with \(p_a, \varphi^a\). In order to split them, we perform a canonical transformation \((r, p_r, \varphi^a, p_a) \rightarrow (R, p_R, \tilde{\varphi}^a, \tilde{p}_a)\), which is defined by \((4.3)\) and by the following transformation of the remaining variables (for related earlier studies see \([62, 68, 21, 59]\))

\[
\tilde{\varphi}^a = \varphi^a + \frac{\partial U}{\partial p_a}, \quad \tilde{p}_a = p_a - \frac{\partial U}{\partial \varphi^a},
\]

\[
U(rp_r, p_a, \varphi^a) \equiv \frac{1}{2} \int_{x=rp_r} dx \log \left( \sqrt{x^2/4 + L(p_a, \varphi^a)} + f(p_a) \right). \tag{4.6}
\]

As a result, \((R, p_R)\) and \((\tilde{\varphi}^a, \tilde{p}_a)\) constitute canonical pairs.

Thus, by applying a proper canonical transformation one can bring the model of a massive relativistic particle moving near the horizon of an extremal black hole to the conventional conformal mechanics form. Important information about the system, which was originally defined in \(d\) dimensions, is thus imprinted in the \((d-2)\)-dimensional spherical mechanics.

In this way the spherical sectors of the conformal mechanics on the Reissner-Nordström, Dilaton-Axion and Kerr backgrounds \([64, 69]\), as well as on the Myers-Perry background with equal rotation parameters \([70]\) were analyzed. Spherical mechanics describing these systems looks as follows \([71]\):

**Reissner-Nordström BH.** The spherical mechanics associated with the near horizon Reissner-Nordström black hole is governed by the Hamiltonian

\[
\mathcal{I} = p_\theta^2 + \frac{(p_\varphi + ep \cos \theta)^2}{\sin^2 \theta} + (mM)^2 - (e q)^2, \quad \omega = dp_\theta \wedge d\theta + dp_\varphi \wedge d\varphi, \tag{4.7}
\]

where \(m\) and \(e\) are the mass and the electric charge of a particle, while \(M\), \(q\) and \(g\) are the mass, the electric and magnetic charges of the black hole, respectively. This is precisely the spherical Landau problem (a particle on a two-dimensional sphere in the presence of a constant magnetic field generated by the Dirac monopole) shifted by the constant \(\mathcal{I}_0 = (mM)^2 - (e q)^2\).
A link between the two systems was discussed in [62, 21].

**Clement-Gal’tsov BH.** This solution of the Einstein–Maxwell–dilaton–axion theory can be viewed as interpolating between the near horizon extremal Reissner-Nordström black hole and the near horizon extremal Kerr black hole [65]. The corresponding spherical mechanics reads

\[ I = p^2 + \frac{(p_\varphi \cos \theta - e)^2}{\sin^2 \theta} + m^2. \] (4.8)

Here \( m \) and \( e \) are the mass and the electric charge of a particle. This system coincides with the planar rotator [59, 69].

**Kerr BH.** Spherical mechanics associated with the near horizon Kerr geometry is defined by the integrable but not exactly solvable system [64]

\[ I = p^2 + [\left( \frac{1 + \cos^2 \theta}{2 \sin \theta} \right)^2 - 1] p^2 + \left( \frac{1 + \cos^2 \theta}{2} \right) (mr_0)^2, \] (4.9)

where \( m \) is the mass of a particle and \( r_0 \) is the horizon radius.

**Kerr-Newman-AdS-dS BH.** The Kerr-Newman-AdS-dS black hole is a solution of the Einstein-Maxwell equations with a non-vanishing cosmological constant [72]. Its near horizon limit has been constructed in [73], while the conformal mechanics on this background was built in [67]. The Hamiltonian of the corresponding spherical mechanics reads

\[ I = \frac{p^2}{\alpha(\theta)} + \left( \frac{\Gamma(\theta)}{\gamma(\theta)} - k^2 \right) [p_\varphi + e\lambda(\theta)]^2 + U(\theta). \] (4.10)

It describes a particle probe on a two-dimensional curved space with the metric

\[ ds^2 = \alpha(\theta)d\theta^2 + \frac{d\varphi^2}{\Gamma(\theta)/\gamma(\theta) - k^2}, \] (4.11)
which moves the in potential and magnetic fields defined by the expressions

\[ U(\theta) = m^2 \Gamma(\theta) - \frac{e^2 k^2 f^2(\theta)}{\Gamma(\theta)/\gamma(\theta) - k^2}, \quad \lambda(\theta) d\varphi = \frac{\Gamma(\theta)f(\theta)}{\Gamma(\theta) - k^2\gamma(\theta)} d\varphi. \] (4.12)

Here we denoted

\[ \Gamma(\theta) = \frac{r_0^2}{1 + \nu_+^2} \left(1 + \nu_+^2 \cos^2 \theta \right), \quad \alpha(\theta) = \left(\frac{r_+^2}{r_0^2}\right)^2 \frac{1 + \nu_+^2}{1 - \nu_0^2 \cos^2 \theta} , \]
\[ \gamma(\theta) = \left[ \frac{r_+(1 + \nu_+^2)}{1 - \nu_0^2} \right] \frac{(1 - \nu_0^2 \cos^2 \theta) \sin^2 \theta}{1 + \nu_+^2 \cos^2 \theta}, \]
\[ f(\theta) = \frac{1 + \nu_+^2}{\nu_+(1 - \nu_0^2)} \frac{a r_+ (1 - \nu_+^2 \cos^2 \theta) + q_m \cos \theta}{1 + \nu_+^2 \cos^2 \theta} \]

and used the following notation for the constant parameters

\[ \nu_+ \equiv \frac{a}{r_+}, \quad \nu_0 \equiv \frac{a}{l}, \quad k \equiv 2 \left(\frac{r_0}{r_+}\right)^2 \frac{1 + \nu_0^2}{\nu_+(1 + \nu_+^2)} , \quad r_0^2 = \frac{(1 + \nu_0^2)(1 - r_+^2/l^2)}{1 + 6r_+^2/l^2 - 3r_+^4/l^4 - q^2/l^2}. \] (4.13)

Above \( m \) and \( e \) are the mass and the electric charge of a particle, \( r_+ \) is the horizon radius and \( l^2 \) is linked to the cosmological constant via \( \Lambda = -3/l^2 \) The parameters \( M, a, q_e \) and \( q_m \) are related to the mass, angular momentum, electric and magnetic charges of the black hole, respectively (for explicit relations see e.g. [73])

\[ a^2 = \frac{r_+^2 (1 + 3r_+^2/l^2) - q^2}{1 - r_+^2/l^2}, \quad M = \frac{r_+[(1 + r_+^2/l^2)^2 - q^2/l^2]}{1 - r_+^2/l^2}. \] (4.15)

This system reduces to the near-horizon Kerr particle when \( q_e = q_m = 0 \) and \( l^2 \to \infty \).

**5d Myers–Perry BH.** In the case of the five-dimensional near horizon Myers–Perry black hole one reveals a three-dimensional integrable system governed by the Hamiltonian

\[ I = \frac{1}{4} p_{\theta}^2 + \frac{\rho_0^4}{4(a + b)^2} \left[ \frac{p_{\phi}^2}{a^2 \sin^2 \theta} + \frac{p_{\psi}^2}{b^2 \cos^2 \theta} - \frac{1}{\rho_0^2} \left( \frac{b}{a} p_{\phi} + \frac{a}{b} p_{\psi} \right)^2 \right] - \]
\[ \frac{1}{4} \left( \sqrt{\frac{b}{a}} p_{\phi} + \sqrt{\frac{a}{b}} p_{\psi} \right)^2 + m^2 \rho_0^2, \quad \rho_0^2 = ab + a^2 \cos^2 \theta + b^2 \sin^2 \theta. \] (4.16)
This system is integrable but not exactly solvable for arbitrary values of rotational parameters \(a, b\). For the special case that the rotation parameters are equal to each other \(a = b\) it becomes exactly-solvable and maximally superintegrable

\[
\mathcal{I} = \frac{1}{4} \left[ p_\phi^2 + \frac{p_\phi^2}{\sin^2 \theta} + \frac{p_\psi^2}{\cos^2 \theta} - \frac{3}{2} (p_\phi + p_\psi)^2 + \frac{8}{3} (2m \rho_0)^2 \right].
\] (4.17)

Fixing the momenta \(p_\phi, p_\psi\) we arrive the one dimensional system on the circle given by the modified Pöshle-Teller potential.

**5d Myers-Perry-AdS-dS BH.** A generalization of the five–dimensional rotating black hole solution by Myers and Perry to include a cosmological constant was constructed in [74]. Its near-horizon limit was built in [75]. The corresponding spherical mechanics reads

\[
\mathcal{I} = \frac{1}{2} \Delta \rho_0^2 + \frac{1}{2} \left( \frac{\rho_0^4}{\Delta \sin^2 \theta} - \frac{(1 + r_0^2/l^2)b^2 \rho_0^2}{\Delta} - \frac{4a^2(r_0^2 + b^2)^2}{4r_0^2} \right) p_\phi^2 +
\]

\[
+ \frac{1}{2} \left( \frac{\rho_0^4}{\Delta \cos^2 \theta} - \frac{(1 + r_0^2/l^2)a^2 \rho_0^2}{\Delta} - \frac{4b^2(r_0^2 + a^2)^2}{4r_0^2} \right) p_\psi^2 -
\]

\[
- \left( \frac{(1 + r_0^2/l^2)ab \rho_0^2}{\Delta} + \frac{4ab(r_0^2 + a^2)(r_0^2 + b^2)}{4r_0^2} \right) p_\phi p_\psi + g^2 \cos^2 \theta.
\] (4.18)

Here \(g^2\) is a coupling constant which vanishes for \(a = b\), \(m\) is the particle mass and we denoted

\[
\Delta = \frac{1}{r^2}(r^2 + a^2)(r^2 + b^2)(1 + r^2/l^2) - 2M, \quad \Delta_{\theta} = 1 - (a^2 \cos^2 \theta)/l^2 - (b^2 \sin^2 \theta)/l^2,
\]

\[
\rho_0^2 = ab + a^2 \cos^2 \theta + b^2 \sin^2 \theta, \quad \Xi_a = 1 - a^2/l^2, \quad \Xi_b = 1 - b^2/l^2.
\] (4.19)

The parameters \(M, a,\) and \(b\) are linked to the mass and the angular momenta (for explicit relations see e.g. [75]). \(l^2\) is taken to be positive for AdS and negative for dS and is related to the cosmological constant via \(\Lambda = -6/l^2\).

**Higher-dimensional rotating BH [76, 70, 77].**
For the extremal black hole with equal rotation parameters the Hamiltonian of a spherical mechanics was derived in [77].

In the case of \( d = 2n + 1 \) dimensions one finds

\[
I = \sum_{i,j=1}^{n-1} (\delta_{ij} - \mu_i \mu_j) p_\mu p_{\mu_j} + \sum_{i=1}^{n} \frac{\mu_{\phi_i}^2}{\mu_i^2} - \frac{(n+1)}{n} \left( \sum_{i=1}^{n} p_{\phi_i} \right)^2, \tag{4.20}
\]

where \((\mu_i, p_\mu), i = 1, \ldots, n - 1\) and \((\phi_j, p_{\phi_j}), j = 1, \ldots, n\) form canonical pairs obeying the conventional Poisson brackets \(\{\mu_i, p_\mu\} = \delta_{ij}, \{\phi_i, p_{\phi_j}\} = \delta_{ij}\) and \(\mu_i^2\) entering the second sum in (4.20) is found from the unit sphere equation \(\sum_{i=1}^{n} \mu_i^2 = 1\).

For \( d = 2n \) the Hamiltonian, which governs the corresponding spherical mechanics, reads

\[
I = \sum_{i,j=1}^{n-1} ((2n - 3)\rho_0^2 \delta_{ij} - \mu_i \mu_j) p_\mu p_{\mu_j} + \sum_{i,j=1}^{n-1} \left( \frac{(2n - 3)\rho_0^2}{\mu_i^2} \delta_{ij} - \frac{(2n - 3)^2 \rho_0^2}{2(n-1)} - \frac{2}{n-1} \right) p_\phi p_{\phi_j} + m^2 \rho_0^2, \tag{4.21}
\]

where \((\mu_i, p_\mu)\) and \((\phi_j, p_{\phi_j}), j = 1, \ldots, n - 1\) form canonical pairs and \(m^2\) is a coupling constant. Note that, as compared to the previous case, the number of the azimuthal coordinates is decreased by one.

Because the azimuthal angular variables \(\phi_i\) are cyclic, it is natural to consider a reduction in which they are discarded. This is achieved by setting in (4.20) and (4.21) the momenta canonically conjugate to \(\phi_i\) to be coupling constants

\[
p_{\phi_i} \rightarrow g_i. \tag{4.22}
\]

Note that, after such a reduction, both (4.20) and (4.21) yield dynamical systems, which contain \((n - 1)\) configuration space degrees of freedom.

Considering the reduction over the cyclic variables and investigating the integrability, we established in [76] that the spherical mechanics corresponding to the \((2n + 1)\)-dimensional black
hole is a maximally superintegrable and exactly solvable system, i.e. it is completely similar to the five-dimensional black hole with the coinciding rotational parameters. In contrast with this case, the spherical mechanics corresponding to the $2n$-dimensional black hole lacks only one constant of the motion to become maximally superintegrability and is not exactly solvable. The solution of its equations of motion is given by elliptic integrals and is similar to that derived for the Kerr background in [64].
4.2 Near horizon metrics

Kerr black hole

The Kerr solution \cite{78} is the stationary axially symmetric solution of the vacuum Einstein equations, which describes the rotating black hole with mass $M$ and angular momentum $J$. It was discovered in 1963 as a solution of the vacuum Einstein equations describing the rotational black holes. Its uniqueness, proven by Carter \cite{79}, as well as the separability of variables of the particle moving in the Kerr background \cite{60} gave to the Kerr solution a special role in General Relativity.

A very particular case of the Kerr solution, when the Cauchy’s and event horizons coincide is called extremal Kerr solution \cite{64}. In this special case the angular momentum $J$ of the Kerr black hole is related with the mass of the Kerr black hole $M$ by the expression $J = \gamma M^2/c$ (in the following formulae we put the gravitational constant $\gamma = 1$ and the speed of light $c = 1$). In 1999 Bardeen and Horowitz derived the near-horizon limit of the extremal Kerr solution and found that the isometry group of the limiting metric is $SO(1,2) \times U(1)$ \cite{80}. They conjectured that the extremal Kerr throat solution might admit a dual conformal theory description in the spirit of AdS/CFT duality. The extensive study of AdS/Kerr duality was initiated almost a decade later in \cite{81} which continues today (see e.g. \cite{82} and refs therein).

It is clear to the moment, that the near-horizon extremal Kerr solution and its generalizations play a distinguished role in supergravity. Particularly, their thermodynamical properties and connection to the string theory allow one to expect that the quantum gravity should be closely related with these objects.

The Kerr solution of the vacuum Einstein equations is defined by the metric \cite{64}

\begin{equation}
\begin{aligned}
ds^2 &= - \left( \frac{\Delta - a^2 \sin^2 \theta}{\rho^2} \right) dt^2 + \frac{\rho^2}{\Delta} dr^2 + \rho^2 d\theta^2 + \\
&\quad + \left( \frac{\Delta^2 - 2 \Delta a^2 \sin^2 \theta}{\rho^2} \right) \sin^2 \theta d\phi^2 - \frac{2a(r^2 + a^2 - \Delta) \sin^2 \theta}{\rho^2} dt d\phi,
\end{aligned}
\end{equation}

\text{67}
where
\[
\Delta = r^2 + a^2 - 2Mr, \quad \rho^2 = r^2 + a^2 \cos^2 \theta, \quad a = \frac{J}{M}.
\] (4.24)

The extremal solution of the Kerr metric corresponds to the choice \( M^2 = J \), so that the event horizon is at \( r = M \). The limiting near-horizon metric is given by the expression \[80\]
\[
ds^2 = \left(1 + \cos^2 \theta \right) \left[ -\frac{r^2}{r_0^2} dt^2 + \frac{r_0^2}{r^2} dr^2 + r_0^2 d\theta^2 \right] + \frac{2r_0^2 \sin^2 \theta}{1 + \cos^2 \theta} \left[ d\varphi + \frac{r}{r_0^2} dt \right]^2, \quad r_0 = \sqrt{2}M.
\] (4.25)

The Kerr metric admits the second rank Killing tensor \[61\], which allows to integrate the geodesic equation for a massive particle in Kerr space-time by quadratures \[60\]. The limiting Killing tensor becomes reducible, in the sense that it can be constructed from the Killing vectors corresponding to the \( SO(2,1) \times U(1) \) isometry group.
4.3 Four-dimensional black holes

Here we will construct the action-angle variables for the angular parts of the following two four-dimensional exactly solvable systems:

- Charged particle moving near the horizon of extremal Reissner-Nordström black hole with magnetic charge
- Particle moving near the horizon of extremal Dilaton-Axion (Clément-Gal’tsov) black hole

The study of this problem not only fills the gap in the paper [59], but also presents its own interest.

Let us reinforce the above mentioned observations on the near-horizon dynamics of particle in the background of extremal Kerr black hole [64]: the use of action-angle variables allowed to find there a critical point $|p_\varphi| = 2mM$ (with $m$ being the mass of the probe particle, $M$ being mass of extremal Kerr black hole), where the trajectories become closed. We will show that there are similar singular points in the dynamics of charged particle moving near the horizons of extremal Reissner-Nordström and Clément-Gal’tsov black holes. They are defined by the relation $p_\varphi = \pm s$, where $s = ep$ for the Reissner-Nordström case (with $e$ being the electric charge of probe particle, and $p$ being magnetic charge of extremal Reissner-Nordström black hole), and $s = e$ for the case of extremal Clément-Gal’tsov black hole (with $e$ being the electric charge of probe particle).

Let us shortly repeat the steps required for the construction of action angle variables of the spherical mechanics 4.5 related to the four-dimensional extremal black hole systems. In this particular case we have a two dimensional system $(\omega_0, I)$,

$$I = L(\theta, p_\theta, p_\varphi) - q(p_\varphi)^2, \quad \omega_0 = dp_\theta \wedge d\theta + dp_\varphi \wedge d\varphi, \quad (4.26)$$

69
To construct the action-angle variables, we should introduce the generating function

\[ S(I, p_\varphi, \theta, \varphi) = p_\varphi \varphi + \int_{I = \text{const}} p_\theta(I, p_\varphi, \theta) d\theta = p_\varphi \varphi + S_0(I, p_\varphi, \theta). \]  

(4.27)

\[ p_\varphi = \text{const} \]

First, we define, by its use, the action variables

\[ I_1(I, p_\varphi) = \frac{1}{2\pi} \oint p_\theta(I, p_\varphi, \theta) d\theta, \quad I_2 = p_\varphi, \]  

(4.28)

Then, interting the first expression we get \( I \) as a function of the action variables: \( I = I(I_1, I_2) \).

Using this expression, we find the corresponding angle variables

\[ \Phi_{1,2} = \frac{\partial S(I_1, I_2), I_2, \theta, \varphi)}{\partial I_{1,2}} \]  

(4.29)
Reissner-Nordström black hole

Here we construct the action-angle variables for the angular part of the conformal mechanics describing the motion of charged particle near horizon of extremal Reissner-Nordström black hole (which defines the electrically and magnetically charged static black hole configuration).

The extremal Reissner-Nordström black hole solution of Einstein–Maxwell equations reads \[21\]:

\[
\begin{align*}
    ds^2 &= -\left(1 - \frac{M}{r}\right)^2 dt^2 + \left(1 - \frac{M}{r}\right)^{-2} dr^2 + r^2 d\Omega^2, \\
    A &= -\frac{q}{r} dt + p \cos \theta d\phi.
\end{align*}
\] (4.30)

Here $M$, $q$, $p$ are the mass, the electric and magnetic charges, respectively, and $d\Omega^2 = d\theta^2 + \sin^2 \theta d\phi^2$ is the standard metric on a sphere. For the extremal solution one has $M = \sqrt{q^2 + p^2}$.

Throughout the paper we use units for which $G = 1$.

The near horizon limit is most easily accessible in isotropic coordinates ($r \to r - M$) which cover the region outside the horizon only

\[
    ds^2 = -\left(1 + \frac{M}{r}\right)^{-2} dt^2 + \left(1 + \frac{M}{r}\right)^{2} (dr^2 + r^2 d\Omega^2).
\] (4.31)

When $r \to 0$ the metric takes the form

\[
    ds^2 = -\left(\frac{r}{M}\right)^{2} dt^2 + \left(\frac{M}{r}\right)^{2} dr^2 + M^2 d\Omega^2,
\] (4.32)

while implementing the limit in the two–form field strength, one finds the background vector field

\[
    A = \frac{q}{M^2} r dt + p \cos \theta d\phi.
\] (4.33)

The last two lines give the Bertotti-Robinson solution of Einstein–Maxwell equations.

Notice that in the literature on the subject it is customary to use other coordinates where the horizon is at $r = \infty$. In particular, the use of these coordinates facilitates the analysis in \[18\].

In this paper we refrain from using such a coordinate system.
From (4.32) it follows that in the near horizon limit the space–time geometry is the product of a two-dimensional sphere of radius $M$ and a two-dimensional pseudo Riemannian space–time with the metric
\[ ds^2 = -\left(\frac{r}{M}\right)^2 dt^2 + \left(\frac{M}{r}\right)^2 dr^2. \] (4.34)

The latter proves to be the metric of $AdS_2$. To summarize, the background geometry is that of the $AdS_2 \times S^2$ space–time with 2–form flux.

Having fixed the background fields, we then consider the action of a relativistic particle on such a background
\[ S = -\int dt \left( m\sqrt{(r/M)^2 - (M/r)^2} - M^2 (\dot{\theta}^2 + \sin^2 \theta \dot{\phi}^2) + eqr/M^2 + ep \cos \theta \dot{\phi} \right). \] (4.35)

Here $m$ and $e$ are the mass and the electric charge of a particle, respectively.

The particle dynamics is most easily analyzed within the Hamiltonian formalism. Introducing the momenta $(p_r, p_\theta, p_\phi)$ canonically conjugate to the configuration space variables $(r, \theta, \phi)$, one finds the Hamiltonian
\[ H = (r/M) \left( \sqrt{m^2 + (r/M)^2 p_r^2 + (1/M)^2 (p_\theta^2 + \sin^{-2} \theta (p_\phi + e \cos \theta)^2)} + eq/M \right), \] (4.36)

which generates time translations. In agreement with the isometries of the background metric one also finds the conserved quantities
\[ K = M^3/r \left( \sqrt{m^2 + (r/M)^2 p_r^2 + (1/M)^2 (p_\theta^2 + \sin^{-2} \theta (p_\phi + e \cos \theta)^2)} - eq/M \right) + t^2 H + 2trp_r, \quad D = tH + rp_r, \] (4.37)

which generate special conformal transformations and dilatations, respectively. Together with the Hamiltonian they form $so(2,1)$ algebra.

From these expressions we immediately get the angular part of our system
\[ I = p_\theta^2 + \frac{(p_\phi + e \cos \theta)^2}{\sin^2 \theta} + (mM)^2 - (eq)^2, \quad \omega = dp_\theta \wedge d\theta + dp_\phi \wedge d\phi. \] (4.38)
It is precisely the spherical Landau problem (Hamiltonian system, describing the motion of the particle on the sphere in the presence of constant magnetic field generated by Dirac monopole), shifted on the constant $I_0 = (mM)^2 - (eq)^2$. Here and through this section we will use the notation

$$s = ep,$$  \hspace{1cm} (4.39)

which is precisely the Dirac’s “monopole number”.

For the construction of action-angle variables of the obtained system, let us introduce the generating function (4.27), where the second term looks as follows

$$S_0(I,p,\varphi,\theta) = \int_{I=\text{const}} d\theta \sqrt{I - (mM)^2 + (eq)^2 - \frac{(p_\varphi + s \cos \theta)^2}{\sin^2 \theta}} =$$

$$= \begin{cases} 
2|s| \arcsin \frac{|s|}{\sqrt{\tilde{I}}} \cot \frac{\varphi}{2} - 2\sqrt{\tilde{I} + s^2} \arctan \frac{\sqrt{\tilde{I} + s^2} \cot \frac{\varphi}{2}}{\sqrt{\tilde{I} - s^2} \cot^2 \frac{\varphi}{2}} & \text{for } p_\varphi = s \\
-2|s| \arcsin \frac{|s|}{\sqrt{\tilde{I}}} \tan \frac{\varphi}{2} + 2\sqrt{\tilde{I} + s^2} \arctan \frac{\sqrt{\tilde{I} + s^2} \tan \frac{\varphi}{2}}{\sqrt{\tilde{I} - s^2} \tan^2 \frac{\varphi}{2}} & \text{for } p_\varphi = -s \\
\sqrt{\tilde{I} + s^2} \left[ 2 \arctan t - \sum_{\pm} \frac{\arctan (1 \pm b)^2 - a^2)}{\sqrt{(1 \pm b)^2 - a^2}} \right] & \text{for } |p_\varphi| \neq |s| \end{cases} \hspace{1cm} (4.40)$$

Here we introduce the notation

$$\tilde{I} = I - (mM)^2 + (eq)^2,$$

$$a^2 = \frac{\tilde{I}^2 - (p_\varphi^2 - s^2) \tilde{I}}{(\tilde{I} + s^2)^2}, \quad b = -\frac{sp_\varphi}{\tilde{I} + s^2},$$

$$t = \frac{a - \sqrt{a^2 - (\cos \theta - b)^2}}{\cos \theta - b}. \hspace{1cm} (4.41)$$

Hence, the equation $p_\varphi = \pm s$ defines critical points, where the system changes its behaviour.

For the non-critical values $p_\varphi \neq \pm s$ we get, by the use of standard methods [1], the following
expressions for the action-angle variables,

\[ I_1 = \sqrt{\mathcal{I}} + s^2 - \frac{|s + p_\varphi| + |s - p_\varphi|}{2}, \]

\[ \Phi_1 = -\arcsin \frac{(\mathcal{I} + s^2) \cos \theta + sp_\varphi}{\mathcal{I}^2 - (p_\varphi^2 - s^2) \mathcal{I}}, \]

\[ I_2 = p_\varphi, \]

\[ \Phi_2 = \varphi + \gamma_1 \Phi_1 + \gamma_2 \arctan \left( \frac{a - (1 - b)t}{\sqrt{(1 - b)^2 - a^2}} \right) + \gamma_3 \arctan \left( \frac{a + (1 + b)t}{\sqrt{(1 + b)^2 - a^2}} \right), \]

where

\[ (\gamma_1, \gamma_2, \gamma_3) = \begin{cases} 
\text{sgn}(I_2)(1, -1, 1) & \text{for } |I_2| > |s| \\
\text{sgn}(s)(0, -1, -1) & \text{for } |I_2| < |s| 
\end{cases} \]

(4.42)

Respectively, the Hamiltonian reads

\[ \mathcal{I} = \left( I_1 + \frac{|s + I_2| + |s - I_2|}{2} \right)^2 + (mM)^2 - (eq)^2 - s^2 = \]

\[ = \begin{cases} 
(I_1 + |I_2|)^2 + (mM)^2 - (eq)^2 - s^2 & \text{for } |I_2| > |s| \\
(I_1 + |s|)^2 + (mM)^2 - (eq)^2 - s^2 & \text{for } |I_2| < |s| 
\end{cases} \]

(4.44)

The effective frequencies \( \Omega_{1,2} = \partial \mathcal{I}/\partial I_{1,2} \) looks as follows

\[ \Omega_1 = \begin{cases} 
2(I_1 + |I_2|) & \text{for } |I_2| > |s| \\
2(I_1 + |s|) & \text{for } |I_2| < |s| 
\end{cases}, \]

\[ \Omega_2 = \begin{cases} 
2(I_1 + |I_2|)\text{sgn}I_2 & \text{for } |I_2| > |s| \\
0 & \text{for } |I_2| < |s| 
\end{cases}. \]

(4.45)

It is seen, that in subcritical regime, \( |I_2| < s \), the frequency \( \Omega_2 \) becomes zero, while frequency \( \Omega_1 \) depends on \( I_1 \) only. In overcritical regime, when \( |I_2| > s \), the frequencies \( \Omega_1 \) and \( \Omega_2 \) coincides modulo to sign: the frequency \( \Omega_2 \) is positive for positive values of \( I_2 \) (which is precisely angular momentum \( p_\varphi \)), and vice versa. This is essentially different from the periodic motion in the
spherical part of the “Kerr particle” observed in [64], where the critical point separated two
critical point, both of which corresponded to the two-dimensional motion, but with opposite sign of
\( \Omega_2 \).

So, in both regimes the trajectories are closed, and the motion is effectively one-dimensional
one. It reflects the existence of the additional constant of motion in the system (4.38), reflecting
the \( so(3) \) invariance of the spherical Landau problem. In other words, it is superintegrable one.
In action-angle variables the additional constant of motion reads \( I_{\text{add}} = \sin(\Phi_1 - \Phi_2) \) (cf. [34, 30]).

Now, let us write down the expressions for action-angle variables at the critical point \( p_{\phi} = \pm s \),

\[
I_1 = 2(\sqrt{\mathcal{I}} + s^2 - |s|), \quad \Phi_1 = \begin{cases} 
-2 \arctan \frac{\sqrt{\mathcal{I} + s^2 \cot^2 \frac{\theta}{2}}}{\sqrt{\mathcal{I} - s^2 \cot^2 \frac{\theta}{2}}} & \text{for } p_{\phi} = s \\
2 \arctan \frac{\sqrt{\mathcal{I} + s^2 \tan^2 \frac{\theta}{2}}}{\sqrt{\mathcal{I} - s^2 \tan^2 \frac{\theta}{2}}} & \text{for } p_{\phi} = -s 
\end{cases} \tag{4.46}
\]

Respectively, the Hamiltonian reads

\[
\mathcal{I} = \left( \frac{I_1}{2} + |s| \right)^2 + (mM)^2 - (eq)^2 - s^2 \tag{4.47}
\]

Notice, that the obtained action variable is not the corresponding limit of (4.42).
Now, let us consider the motion of a particle near the horizon of extremal rotating Clément-Gal’tsov(dilaton–axion) black hole \cite{65}. The conformal generators of this particle system (with mass $m$ and “effective monopole number” $s$, which was refereed in \cite{63, 65} as “effective electric charge” $e$) read \cite{63}

\begin{align*}
H &= r \left( \sqrt{m^2 + (rp_r)^2 + p_\theta^2 + \sin^{-2} \theta [p_\varphi - s \cos \theta]^2} - p_\varphi \right), \\
K &= \frac{1}{r} \left( \sqrt{m^2 + (rp_r)^2 + p_\theta^2 + \sin^{-2} \theta [p_\varphi - s \cos \theta]^2} + p_\varphi \right), \\
D &= rp_r.
\end{align*}

The Casimir of conformal algebra is given by the expression

\begin{equation}
\mathcal{I} = p_\theta^2 + \frac{(p_\varphi \cos \theta - s)^2}{\sin^2 \theta} + m^2.
\end{equation}

The second term in generating function for the action-angle variables (4.27) can be explicitly integrated in elementary functions (its explicit expression could be found, e.g. in Appendix in \cite{3})

\begin{equation}
S_0 = \int_{\mathcal{I}=\text{const}} d\theta \sqrt{\mathcal{I} - m^2 - \frac{(p_\varphi \cos \theta - s)^2}{\sin^2 \theta}} = \\
\begin{cases}
-2|s| \arcsin \frac{|s| \tan \frac{\theta}{2}}{\sqrt{\mathcal{I} - m^2}} + 2\sqrt{\mathcal{I} - m^2 + s^2} \arctan \frac{\sqrt{\mathcal{I} - m^2 + s^2} \tan \frac{\theta}{2}}{\sqrt{\mathcal{I} - m^2 + s^2} \tan^2 \frac{\theta}{2}}, & \text{for } p_\varphi = s \\
2|s| \arcsin \frac{|s| \cot \frac{\theta}{2}}{\sqrt{\mathcal{I} - m^2}} - 2\sqrt{\mathcal{I} - m^2 + s^2} \arctan \frac{\sqrt{\mathcal{I} - m^2 + s^2} \cot \frac{\theta}{2}}{\sqrt{\mathcal{I} - m^2 + s^2} \cot^2 \frac{\theta}{2}}, & \text{for } p_\varphi = -s \\
\sqrt{\mathcal{I} - m^2 + p_\varphi^2} \left[ 2 \arctan t - \sum_{\pm} \frac{\sqrt{(1 \pm b)^2 - a^2}}{(1 \pm b)^2 - a^2} \arctan \frac{(1 \pm b)t \pm a}{\sqrt{(1 \pm b)^2 - a^2}} \right], & \text{for } |p_\varphi| \neq |s|
\end{cases}
\end{equation}

where we introduced the notation

\begin{align}
a^2 &\equiv \frac{(\mathcal{I} - m^2)^2 + (\mathcal{I} - m^2)(p_\varphi^2 - s^2)}{(\mathcal{I} - m^2 + p_\varphi^2)^2}, \\
b &\equiv \frac{sp_\varphi}{\mathcal{I} - m^2 + p_\varphi^2}, \\
t &\equiv \frac{a - \sqrt{a^2 - (\cos \theta - b)^2}}{\cos \theta - b}.
\end{align}

76
Hence, the equation \( p_\varphi = \pm s \) defines critical points, where the system changes its behaviour.

For the non-critical values \( p_\varphi \neq \pm s \) we get, by the use of standard methods \([1]\), the following expressions for the action-angle variables,

\[
I_1 = \sqrt{\mathcal{I} - m^2 + p_\varphi^2} - \frac{|s + p_\varphi| + |s - p_\varphi|}{2},
\]

\[
\Phi_1 = -\arcsin \frac{(\mathcal{I} - m^2 + p_\varphi^2) \cos \theta - sp_\varphi}{\sqrt{(\mathcal{I} - m^2)^2 + (\mathcal{I} - m^2)(p_\varphi^2 - s^2)}} \tag{4.52}
\]

\[
I_2 = p_\varphi,
\]

\[
\Phi_2 = \varphi + \gamma_1 \Phi_1 + \gamma_2 \arctan \left( \frac{a - (1-b)t}{\sqrt{(1-b)^2 - a^2}} \right) + \gamma_3 \arctan \left( \frac{a + (1+b)t}{\sqrt{(1+b)^2 - a^2}} \right) \tag{4.53}
\]

where

\[
(\gamma_1, \gamma_2, \gamma_3) = \begin{cases} 
\text{sgn}(I_2)(1, -1, 1) & \text{for } |I_2| > |s| \\
\text{sgn}(s)(0, 1, 1) & \text{for } |I_2| < |s| 
\end{cases} \tag{4.54}
\]

Respectively, the Hamiltonian reads

\[
\mathcal{I} = \left( I_1 + \frac{|s + I_2| + |I_2 - s|}{2} \right)^2 - I_2^2 + m^2 = \begin{cases} 
(I_1 + |I_2|)^2 - I_2^2 + m^2 & \text{for } |I_2| > |s| \\
(I_1 + |s|)^2 - I_2^2 + m^2 & \text{for } |I_2| < |s| 
\end{cases} \tag{4.55}
\]

In the critical points \( p_\varphi = \pm s \), the action-angle variables read

\[
I_1 = 2(\sqrt{\mathcal{I} - m^2 + s^2} - |s|), \quad \Phi_1 = \begin{cases} 
2 \arctan \frac{\sqrt{\mathcal{I} - m^2 + s^2}\tan \frac{\theta}{2}}{\mathcal{I} - m^2 - s^2\tan \frac{\theta}{2}} & \text{for } p_\varphi = s \\
-2 \arctan \frac{\sqrt{\mathcal{I} - m^2 + s^2}\cot \frac{\theta}{2}}{\mathcal{I} - m^2 - s^2\cot \frac{\theta}{2}} & \text{for } p_\varphi = -s 
\end{cases} \tag{4.56}
\]

Inverting the first expression, we shall get the expression for Hamiltonian

\[
\mathcal{I} = \left( \frac{I_1}{2} + |s| \right)^2 + m^2 - s^2 \tag{4.57}
\]

Let us notice, that the action variable at the critical point is different from the corresponding limit of \(4.52\).
To clarify the meaning of critical point let us calculate the effective frequencies of the system, \( \Omega_{1,2} = \partial I / \partial I_{1,2} \),

\[
\Omega_1 = \begin{cases} 
2(I_1 + |I_2|) & \text{for } |I_2| > |s| \\
2(I_1 + |s|) & \text{for } |I_2| < |s| 
\end{cases}, \\
\Omega_2 = \begin{cases} 
2I_1 \text{sgn} I_2 & \text{for } |I_2| > |s| \\
-2I_2 & \text{for } |I_2| < |s| 
\end{cases}. 
\tag{4.58}
\]

It is seen from this expressions, that in contrast with previous case, the system does not possess the hidden symmetries. The motion is nondegenerated in noncritical regimes. So, in contrast with Reissner-Nordström case, the system is essentially two-dimensional one, and its trajectories are unclosed. The frequencies \( \Omega_1 \) are the same in the both cases, while \( \Omega_2 \) are essentially different. Moreover, frequency \( \Omega_2 \) behaves in essentially different ways in subcritical and overcritical regimes. In the first case it is proportional to \( I_1 \), and in the second case to \( I_2 \).
5 HIGHER-DIMENSIONAL GENERALIZATIONS

5.1 Near horizon metrics

Myers–Perry black hole in \( d = 2n + 1 \)

A vacuum solution of the Einstein equations describing the Myers–Perry black hole in \( d = 2n + 1 \) dimensions for the special case that all \( n \) rotation parameters are equal reads \[83\]

\[
 ds^2 = \frac{\Delta}{U} \left( dt - a \sum_{i=1}^{n} \mu_i^2 d\phi_i \right)^2 - \frac{U}{\Delta} dr^2 - \frac{1}{r^2} \sum_{i=1}^{n} \mu_i^2 \left( adt - (r^2 + a^2) d\phi_i \right)^2 \\
 - (r^2 + a^2) \sum_{i=1}^{n} d\mu_i^2 + \frac{a^2(r^2 + a^2)}{r^2} \sum_{i<j}^{n} \mu_i^2 \mu_j^2 (d\phi_i - d\phi_j)^2, 
\]

(5.1)

\[
 \Delta = \frac{(r^2 + a^2)^n}{r^2} - 2M, \quad U = (r^2 + a^2)^{n-1}, \quad \mu_n^2 = 1 - \sum_{i=1}^{n-1} \mu_i^2, 
\]

where \( M \) stands for the mass and \( a \) is the rotation parameter. In what follows we focus on the extremal solution, for which

\[
 M = \frac{n^n r_0^{2n-2}}{2}, \quad a^2 = (n - 1) r_0^2. 
\]

(5.2)

These conditions follow from the requirement that \( \Delta(r) \) has a double zero at the horizon radius \( r = r_0 \).

The isometry group of (5.1) is \( U(1) \times U(n) \). The first factor corresponds to time translations, while the second factor describes the enhanced symmetry \( U(1)^n \to U(n) \), which occurs if all rotation parameters of the black hole are set equal. In order to make \( U(n) \) explicit, one parametrizes \( n \) spatial two–planes, in which the black hole may rotate, by the coordinates (see, e.g., Ref. \[84\])

\[
 x_i = r \mu_i \cos \phi_i, \quad y_i = r \mu_i \sin \phi_i, 
\]

(5.3)
where \( i = 1, \ldots, n \), and constructs the vector fields

\[
\xi_{ij} = x_i \frac{\partial}{\partial x_j} - x_j \frac{\partial}{\partial x_i} + y_i \frac{\partial}{\partial y_j} - y_j \frac{\partial}{\partial y_i},
\]

\[
\rho_{ij} = x_i \frac{\partial}{\partial y_j} - y_j \frac{\partial}{\partial x_i} + x_j \frac{\partial}{\partial y_i} - y_i \frac{\partial}{\partial x_j}. 
\]

These are antisymmetric and symmetric in their indices, respectively, and obey the structure relations of \( u(n) \).

\[
\begin{align*}
[\xi_{ij}, \xi_{rs}] &= \delta_{jr} \xi_{is} + \delta_{is} \xi_{jr} - \delta_{ir} \xi_{js} - \delta_{js} \xi_{ir}, \\
[\rho_{ij}, \rho_{rs}] &= -\delta_{jr} \xi_{is} - \delta_{is} \xi_{jr} - \delta_{ir} \xi_{js} - \delta_{js} \xi_{ir}, \\
[\xi_{ij}, \rho_{rs}] &= \delta_{jr} \rho_{is} + \delta_{is} \rho_{jr} - \delta_{ir} \rho_{js} - \delta_{js} \rho_{ir}.
\end{align*}
\]

(5.5)

It is straightforward to verify that (5.4) are the Killing vectors of the original black hole metric.

Another way to reveal the \( U(n) \)-symmetry is to introduce the complex coordinates

\[
z_j = r \mu_j e^{i\phi_j}
\]

(5.6)

and rewrite the metric in terms of them. In the complex notation the unitary symmetry is manifest.

In order to construct the near horizon metric, one redefines the coordinates

\[
r \rightarrow r_0 + \epsilon r_0 r, \quad t \rightarrow \frac{nr_0 t}{2(n-1)\epsilon}, \quad \phi_i \rightarrow \phi_i + \frac{r_0 k}{2ae}
\]

(5.7)

and then sends \( \epsilon \) to zero. This yields

\[
ds^2 = r^2 dt^2 - \frac{dr^2}{r^2} - 2n(n-1) \sum_{i=1}^{n} d\mu_i^2 - 2 \sum_{i=1}^{n} \mu_i^2 (rdt + n\sqrt{n-1}d\phi_i)^2 + \\
+ 2n(n-1)^2 \sum_{i<j} \mu_i^2 \mu_j^2 (d\phi_i - d\phi_j)^2, \quad \mu_n^2 = 1 - \sum_{i=1}^{n-1} \mu_i^2.
\]

(5.8)

The conventional structure relations of \( u(n) \) are derived form (5.5) by considering another basis \( E_{ab} = \frac{1}{2}(\xi_{ab} + \rho_{ab}) \), the Casimir elements of \( u(n) \) being \( C_1 = E_{i_1i_1}, C_2 = E_{i_1i_2}E_{i_2i_1}, \ldots, C_n = E_{i_1i_2}E_{i_2i_3} \ldots E_{i_{n-1}i_1} \).
It is straightforward to verify that (5.8) is a vacuum solution of the Einstein equations. The near
horizon metric has a larger symmetry. In addition to $U(1) \times U(n)$ transformations considered
above, the isometry group of (5.8) includes the dilatation

$$t' = t + \lambda t, \quad r' = r - \lambda r,$$

(5.9)

and the special conformal transformation

$$t' = t + (t^2 + \frac{1}{r^2})\sigma, \quad r' = r - 2tr\sigma, \quad \phi'_i = \phi_i - \frac{2}{r\sqrt{n-1}}\sigma,$$

(5.10)

which all together form $SO(2,1) \times U(n)$, the first factor being the conformal group in one
dimension.
Myers–Perry black hole in $d = 2n$

A vacuum solution of the Einstein equations describing the Myers–Perry black hole in $d = 2n$ dimensions for the special case that all $n - 1$ rotation parameters are equal, reads \[\text{(5.11)}\]

\[ds^2 = \frac{\Delta}{U} \left( dt - a \sum_{i=1}^{n-1} \mu_i^2 d\phi_i \right)^2 - \frac{U}{\Delta} dr^2 - \frac{(r^2 + a^2)^{n-2}}{rU} \sum_{i=1}^{n-1} \mu_i^2 (adt - (r^2 + a^2)d\phi_i)^2 - (r^2 + a^2) \sum_{i=1}^{n-1} d\mu_i^2 - r^2 d\mu_n^2 + \frac{a^2(r^2 + a^2)^{n-1}}{rU} \sum_{i<j} \mu_i^2 \mu_j^2 (d\phi_i - d\phi_j)^2, \]

where $M$ is the mass and $a$ is the rotation parameter. As compared to the previous case, the number of the azimuthal coordinates is decreased by one. For the extremal solution $\Delta$ has a double zero at the horizon radius $r = r_0$. In particular, from $\Delta(r_0) = 0$ and $\Delta'(r_0) = 0$ one finds

\[M = \frac{r_0^{2n-3}[2(n-1)]^{n-1}}{2}, \quad a^2 = (2n-3)r_0^2. \quad \text{(5.12)}\]

The isometry group of \[\text{(5.11)}\] includes time translations and the enhanced rotational symmetry $U(1)^{n-1} \to U(n - 1)$, which is a consequence of setting all the rotation parameters equal. The unitary symmetry is manifest in the complex coordinates

\[z_j = \mu_j e^{i\phi_j} = x_j + iy_j. \quad \text{(5.13)}\]

The corresponding Killing vector fields are realized as in Eq. \[\text{(5.4)}\] with $x_i$ and $y_i$ taken from the previous line.

In order to implement the near horizon limit, one redefines the coordinates

\[r \to r_0 + \epsilon r_0 r, \quad t \to \frac{2(n - 1)r_0 t}{(2n - 3)\epsilon}, \quad \phi_i \to \phi_i + \frac{r_0 t}{a \epsilon}. \quad \text{(5.14)}\]
and then sends $\epsilon$ to zero, which yields

$$ds^2 = \rho_0^2 \left( r^2 dt^2 - \frac{dr^2}{r^2} \right) - 2(n-1) \sum_{i=1}^{n-1} d\mu_i^2 - d\mu_n^2 +$$

$$+ \frac{2(n-1)}{\rho_0^2} \sum_{i<j}^{n-1} \mu_i^2 \mu_j^2 (d\phi_i - d\phi_j)^2 - \frac{4}{(2n-3)^2 \rho_0^2} \sum_{i=1}^{n-1} \mu_i^2 (r dt + (n-1)\sqrt{2n-3} d\phi_i)^2, \quad (5.15)$$

$$\rho_0^2 = 1 + \frac{(2n-3)\mu_n^2}{2n-3}, \quad \mu_n^2 = 1 - \sum_{i=1}^{n-1} \mu_i^2.$$

It is straightforward to verify that (5.15) is a vacuum solution of the Einstein equations. Like in $d = 2n+1$, the near horizon metric exhibits additional conformal symmetry, which is realized as in Eqs. (5.9) and (5.10) with the obvious alteration of the special conformal transformation

$$\phi'_i = \phi_i - \frac{2}{r(n-1)\sqrt{2n-3}} \sigma \quad (5.16)$$

acting on the azimuthal angular variables. Thus, for $d = 2n$ the near horizon symmetry is $SO(2,1) \times U(n-1)$. 
5.2 Extremal Myers-Perry black hole in \( d = 2n + 1 \)

For the spherical mechanics (4.20) associated with the extremal rotating black hole in \( d = 2n + 1 \) dimensions the reduction (4.22) yields\(^3\)

\[
I = \sum_{i,j=1}^{n-1} (\delta_{ij} - \mu_i \mu_j) p_i p_j + \sum_{i=1}^{n} \frac{g_i^2}{\mu_i^2}, \quad \mu_n^2 = 1 - \sum_{i=1}^{n-1} \mu_i^2.
\]

(5.17)

Since the first term in (5.17) involves the inverse metric on an \( (n-1) \)-dimensional sphere, the model can be interpreted as a particle moving on \( S^{n-1} \) in the external field.

The analysis of integrability of (5.17) is facilitated in spherical coordinates. Introducing one angle at a time

\[
\mu_n = \cos \theta_{n-1}, \quad \mu_i = x_i \sin \theta_{n-1}, \quad \sum_{i=1}^{n-1} x_i^2 = 1
\]

(5.18)

and computing the metric induced on the sphere \( \sum_{a=1}^{n} d\mu_a^2 \) and its inverse, one can bring (5.17) to the form

\[
I = p_{\theta_{n-1}}^2 + \frac{g_{n}^2}{\cos^2 \theta_{n-1}} + \frac{1}{\sin^2 \theta_{n-1}} \left( \sum_{i,j=1}^{n-2} (\delta_{ij} - x_i x_j) p_i p_j + \sum_{i=1}^{n-1} \frac{g_i^2}{x_i^4} \right),
\]

(5.19)

\[
x_{n-1}^2 = 1 - \sum_{i=1}^{n-2} x_i^2,
\]

where \( p_i \) are momenta canonically conjugate to \( x_i, i = 1, \ldots, n-2 \). Thus, the canonical pair \( (\theta_{n-1}, p_{\theta_{n-1}}) \) is separated, while the expression in braces gives the first integral of the Hamiltonian (5.19). Because its structure is analogous to (5.17), one can proceed along the same lines

\[
x_{n-1} = \cos \theta_{n-2}, \quad x_a = y_a \sin \theta_{n-2}, \quad \sum_{a=1}^{n-2} y_a^2 = 1
\]

(5.20)

until one achieves a complete separation of the variables. The resulting Hamiltonian is a kind of matryoshka doll

\[
I = F_{n-1},
\]

(5.21)

\(^3\)We denote the reduced Hamiltonian by the same letter \( I \). This does not cause confusion, because, from now on, we abandon the parent formulations (4.20) and (4.21).
where $F_{n-1}$ is derived from the recurrence relation

$$F_i = p_{\theta_i}^2 + \frac{g_{i+1}^2}{\cos^2 \theta_i} + \frac{F_{i-1}}{\sin^2 \theta_i},$$  \hspace{1cm} \text{(5.22)}$$

with $i = 1, \ldots, n - 1$ and $F_0 = g_1^2$. The functionally independent integrals of motion in involution $F_i$ ensure the integrability of (5.17). To avoid confusion, let us stress that, given $n$, the Hamiltonian (5.21) describes a system with $(n - 1)$ configuration space degrees of freedom. Note that in a different context this model has been discussed in [84]. Worth mentioning also is that, if a system with the Hamiltonian $F_{i-1}$ has some integrals of motion, these automatically are the integrals of motion of a larger system governed by the Hamiltonian $F_i$. For $n = 2$ Eq. (5.19) reproduces the celebrated Pöschl–Teller model [85].

Although the integrability of (5.17) is obvious in spherical coordinates, the fact that the model is maximally superintegrable is less evident. In order to prove it, we resort to the parent formulation (4.20) and analyze how the reduction (4.22) affects the symmetries (5.4) \footnote{A realization of $U(n)$ in (4.20) is derived from Eq. (5.4) by the standard substitution $\frac{\partial}{\partial \phi_i} \rightarrow p_{\phi_i}, \ \frac{\partial}{\partial \mu_i} \rightarrow p_{\mu_i}$, which links the Killing vectors to the first integrals of the Hamiltonian mechanics. The Hamiltonian (4.20) proves to be a combination of the first two Casimir elements $\xi_{ij}^2 + \rho_{ij}^2$ and $(\rho_{ii})^2$.}. First of all, we notice that $\rho_{ii}$ (no summation over repeated indices) generates rotation in the $i$–th plane. Within the canonical framework it is represented by $\rho_{ii} = 2p_{\phi_i}$. Then the very nature of the reduction mechanism (4.22) suggests that those generators in (5.4), which Poisson commute with $\rho_{ii}$, will be symmetries of the reduced Hamiltonian (5.17). Because (4.20) was constructed from the Casimir elements of $u(n)$, it is straightforward to verify that the combinations (no summation over repeated indices)

$$I_{ij} = \xi_{ij}^2 + \rho_{ij}^2$$  \hspace{1cm} \text{(5.23)}$$

with $i < j$ generate the desired symmetries.

Before we proceed to treat the general case, it proves instructive to illustrate the construction by the examples of $n = 3$ and $n = 4$, which correspond to seven–dimensional and nine–dimensional
black hole configurations. For $n = 3$ the Hamiltonian reads\footnote{Here and in what follows the subscript attached to the Hamiltonian refers to the number of configuration space degrees of freedom in the model.}

$$
I_2 = p_{\theta_2}^2 + \frac{g_1^2}{\cos^2 \theta_2} + \frac{1}{\sin^2 \theta_2} \left( p_{\phi_1}^2 + \frac{g_1^2}{\sin^2 \theta_1} + \frac{g_2^2}{\cos^2 \theta_1} \right). 
$$

(5.24)

In order to construct the integrals of motion, one makes use of (5.3) and (5.4)

$$
\xi_{12} = -p_{\phi_1} \cos \phi_{12} + (p_{\phi_1} \cot \theta_1 + p_{\phi_2} \tan \theta_1) \sin \phi_{12},
$$

$$
\xi_{13} = - (p_{\phi_1} \cos \theta_1 \cot \theta_2 + p_{\phi_2} \sin \theta_1) \cos \phi_{13} + \left( p_{\phi_1} \cot \theta_2 \sin \theta_1 + p_{\phi_3} \sin \theta_1 \tan \theta_2 \right) \sin \phi_{13},
$$

$$
\xi_{23} = (p_{\phi_1} \sin \theta_1 \cot \theta_2 - p_{\phi_2} \cos \theta_1) \cos \phi_{23} + \left( p_{\phi_2} \cot \theta_2 \cos \theta_1 + p_{\phi_3} \cos \theta_1 \tan \theta_2 \right) \sin \phi_{23},
$$

$$
\rho_{12} = p_{\phi_1} \sin \phi_{12} + (p_{\phi_1} \cot \theta_1 + p_{\phi_2} \tan \theta_1) \cos \phi_{12},
$$

$$
\rho_{13} = (p_{\phi_1} \cos \theta_1 \cot \theta_2 + p_{\phi_2} \sin \theta_1) \sin \phi_{13} + \left( p_{\phi_1} \cot \theta_2 \sin \theta_1 + p_{\phi_3} \sin \theta_1 \tan \theta_2 \right) \cos \phi_{13},
$$

$$
\rho_{23} = - (p_{\phi_1} \sin \theta_1 \cot \theta_2 - p_{\phi_2} \cos \theta_1) \sin \phi_{23} + \left( p_{\phi_2} \cot \theta_2 \cos \theta_1 + p_{\phi_3} \cos \theta_1 \tan \theta_2 \right) \cos \phi_{23},
$$

$$
\rho_{11} = 2p_{\phi_1}, \quad \rho_{22} = 2p_{\phi_2}, \quad \rho_{33} = 2p_{\phi_3},
$$

(5.25)

where we abbreviated $\phi_{ij} = \phi_i - \phi_j$, which after implementing the reduction \footnote{Recall that the parent Hamiltonian (4.20) was constructed from the Casimir elements of $u(n)$. Up to a constant, the sum $\sum_{i<j=1}^n I_{ij}$ is what is left after the reduction.} yield

$$
\tilde{I}_{12} = p_{\phi_1}^2 + \frac{g_1^2}{\sin^2 \theta_1} + \frac{g_2^2}{\cos^2 \theta_1},
$$

$$
\tilde{I}_{13} = (p_{\phi_1} \cos \theta_1 \cot \theta_2 + p_{\phi_2} \sin \theta_1)^2 + \left( g_1 \cot \theta_2 \sin \theta_1 + g_3 \sin \theta_1 \tan \theta_2 \right)^2,
$$

$$
\tilde{I}_{23} = (p_{\phi_1} \sin \theta_1 \cot \theta_2 - p_{\phi_2} \cos \theta_1)^2 + \left( g_2 \cot \theta_2 \cos \theta_1 + g_3 \cos \theta_1 \tan \theta_2 \right)^2.
$$

(5.26)

It is straightforward to verify that the vectors $\partial_A \tilde{I}_{ij}$, where $A = (\theta_1, \theta_2, p_{\theta_1}, p_{\theta_2})$ are linearly independent and, hence, the first integrals are functionally independent. Because the Hamiltonian is constructed from $\tilde{I}_{ij}$

$$
I_2 = \tilde{I}_{12} + \tilde{I}_{13} + \tilde{I}_{23} + g_3(g_3 - 2g_1 - 2g_2),
$$

(5.27)
one has three functionally independent integrals of motion for a system with two degrees of freedom and, hence, the model is maximally superintegrable. Note that the algebra formed by $I_{ij}$ is nonlinear. It is convenient to treat the Hamiltonian $I_2$ (with the additive constant $g_3(g_3 - 2g_1 - 2g_2)$ being discarded) and $I_{12}$ as the first integrals in involution, while $I_{23}$ is the additional first integral, which renders the model maximally superintegrable.

The case $n = 4$ is treated likewise. From Eqs. (5.21) and (5.22) one derives the Hamiltonian

$$I_3 = p^2_{\theta_3} + \frac{g_4^2}{\cos^2 \theta_3} + \frac{1}{\sin^2 \theta_3} \left[ p^2_{\theta_2} + \frac{g_3^2}{\cos^2 \theta_2} + \frac{1}{\sin^2 \theta_2} \left( p^2_{\theta_1} + \frac{g_2^2}{\cos^2 \theta_1} + \frac{g_1^2}{\sin^2 \theta_1} \right) \right],$$

(5.28)

while the first integrals prove to be exhausted by those in (5.26) and three more functions

$$\tilde{I}_{14} = \left( p_{\theta_1} \frac{\cos \theta_1 \cot \theta_3}{\sin \theta_2} + p_{\theta_2} \sin \theta_1 \cos \theta_2 \cot \theta_3 + p_{\theta_3} \sin \theta_1 \sin \theta_2 \right)^2 + \left( g_1 \frac{\cot \theta_3}{\sin \theta_1 \sin \theta_2} + g_4 \sin \theta_1 \sin \theta_2 \tan \theta_3 \right)^2,$$

$$\tilde{I}_{24} = \left( p_{\theta_1} \frac{\sin \theta_1 \cot \theta_3}{\sin \theta_2} - p_{\theta_2} \cos \theta_1 \cos \theta_2 \cot \theta_3 - p_{\theta_3} \cos \theta_1 \sin \theta_2 \right)^2 + \left( g_2 \frac{\cot \theta_3}{\cos \theta_1 \sin \theta_2} + g_4 \cos \theta_1 \sin \theta_2 \tan \theta_3 \right)^2,$$

$$\tilde{I}_{34} = \left( p_{\theta_2} \sin \theta_2 \cot \theta_3 - p_{\theta_3} \cos \theta_2 \right)^2 + \left( g_3 \frac{\cot \theta_3}{\cos \theta_2} + g_4 \cos \theta_2 \tan \theta_3 \right)^2.$$  

(5.29)

As in the preceding case, the Hamiltonian is a combination of $\tilde{I}_{ij}$

$$I_3 = \sum_{i<j}^4 \tilde{I}_{ij} + (g_3 - g_4)^2 - 2g_1(g_3 + g_4) - 2g_2(g_3 + g_4).$$

(5.30)

Because for a system with $n$ configuration space degrees of freedom the maximal number of functionally independent integrals of motion is $2n - 1$, the set (5.26) and (5.29) is overcomplete and only five functions prove to be independent.

That for generic $n$ the model is maximally superintegrable can now be proved by induction. For $n = 2$ the systems involves only one configuration space degree of freedom and the Hamiltonian is the only integral of motion. For $n = 3$ we choose $I_2$, $\tilde{I}_{12}$ and $\tilde{I}_{23}$ to be the functionally
independent first integrals. When passing from \( n = 3 \) to \( n = 4 \), the integrals of motion of the former model are automatically the integrals of motion of the latter. To complete the set, we choose \( \mathcal{I}_3 \) and \( \tilde{I}_{34} \). Obviously, this process can be continued to any order. Given a superintegrable system with the Hamiltonian \( \mathcal{H} = \sum_{j=1}^{n-1} \mathcal{I}_j \), \( n - 1 \) configuration space degrees of freedom and \( 2(n-1)-1 \) functionally independent integrals of motion, one introduces one more configuration space degree of freedom and two new integrals of motion \( \mathcal{I}_n \) and \( \tilde{I}_{n,n} \), which all together describe a system with \( n \) configuration space degrees of freedom and \( 2n-1 \) functionally independent integrals of motion.

Let us construct the action–angle variables for the system. Following the standard procedure \[\cite{1}\], one introduces the generating function

\[
S^{\mathrm{odd}}(F_i, |g_i|, \theta_i) = \sum_{i=1}^{n-1} \int p_{\theta_i}(F_1, \ldots, F_{n-1}, \theta_i)d\theta_i,
\]

where \( p_{\theta_i}(F_1, \ldots, F_{n-1}, \theta_i) \) are to be expressed from (5.22). For the action variables one has

\[
I_i = \frac{1}{2\pi} \oint d\theta_i \left[ \sqrt{\frac{F_i - F_{i-1}}{\sin^2 \theta_i}} - \frac{g_{i+1}^2}{\cos^2 \theta_i} \right] = \frac{1}{2} \left( \sqrt{F_i} - \sqrt{F_{i-1}} - |g_{i+1}| \right),
\]

which can be inverted to yield

\[
F_i = \left( 2 \sum_{k=1}^{i} I_k + \sum_{k=i+1}^{n-1} |g_k| \right)^2.
\]

The angle variables are defined by

\[
\Phi_i^{\mathrm{odd}} = \frac{\partial S^{\mathrm{odd}}}{\partial I_i} = \sum_{k=1}^{n-1} \arcsin X_k + 2 \sum_{k=i+1}^{n-1} \arctan Y_k,
\]

where we abbreviated

\[
X_k = \frac{(F_k + F_{k-1} - g_{k+1}^2) - 2F_k \sin^2 \theta_k}{\sqrt{(F_k + F_{k-1} - g_{k+1}^2)^2 - 4F_k g_{k+1}^2}}
\]

\[
Y_k = 2 \left( \frac{F_k + F_{k-1} - g_{k+1}^2}{\sqrt{F_k^2 \sin^2 \theta_k \cos^2 \theta_k - F_{k-1} \cos^2 \theta_k - g_{k+1}^2 \sin^2 \theta_k - 2F_k \sin^2 \theta_k}} \right) \frac{\sqrt{F_k^2 - (F_k + F_{k-1} - g_{k+1}^2)^2}}{\sqrt{F_k^2 - (F_k + F_{k-1} - g_{k+1}^2)^2}}
\]

\[
(5.36)
\]
Being rewritten in the action–angle variables, the Hamiltonian reads

\[ I = \left( 2 \sum_{k=1}^{n-1} I_k + \sum_{k=1}^{n} |g_k| \right)^2, \]  

(5.37)

which coincides with the Hamiltonian of a free particle on an \((n - 1)\)-dimensional sphere up to the shift of the action variables \([30, 31]\). Thus, the only difference with that case is the shift in the range of \(\sum_k I_k\) from \([0, \infty)\) to \([\sum_{k=1}^{n} |g_k|, \infty)\). Thus, the system possesses \(SO(n + 1)\) symmetry and is, obviously, maximally superintegrable.

Let us discuss how hidden constants of the motion can be revealed within the action–angle formulation. Evolution of the angle variables is governed by the equation (see, e.g., Refs. [30, 34])

\[ \frac{d\Phi_{i}^{\text{odd}}}{dt} = 2 \left( 2 \sum_{k=1}^{n-1} I_k + \sum_{k=1}^{n} |g_k| \right). \]  

(5.38)

The expressions \(\cos(\Phi_{i}^{\text{odd}} - \Phi_{j}^{\text{odd}} + \text{const})\) define constants of the motion for any \(i, j = 1, \ldots, n-1\) and only \(n - 2\) of these are functionally independent

\[ G_i = \cos \left( \Phi_{i}^{\text{odd}} - \Phi_{i+1}^{\text{odd}} \right) = \frac{\sqrt{1 - X_i^2(1 - Y_{i+1}^2)} - 2X_iY_{i+1}}{1 + Y_{i+1}^2}, \]  

(5.39)

where \(i = 1, \ldots, n - 2\). Because the \((n - 1)\)-dimensional system has \((2n - 3)\) functionally independent constants of the motion, it is maximally superintegrable. The fact that the Hamiltonian is expressed via the action variables in terms of elementary functions implies also that the system is exactly solvable.
5.3 Extremal Myers-Perry black hole in $d = 2n + 2$

For the spherical mechanics (4.21) associated with the extremal rotating black hole in $d = 2n$ dimensions the reduction (4.22) yields

$$I = \sum_{i,j=1}^{n-1} ((2n-3)\rho_0^2 \delta_{ij} - \mu_i \mu_j) p_i p_j + \sum_{i=1}^{n-1} \frac{(2n-3)\rho_0^2 g_i^2}{\mu_i^2} + \nu \sum_{i=1}^{n-1} \mu_i^2, \quad (5.40)$$

where $\nu$ and $g_i$ are coupling constants and $\rho_0^2$ is given in (4.21).

Like above, the proof of superintegrability of (5.40) is facilitated by introducing the spherical coordinates

$$\mu_i = x_i \sin \theta_{n-1}, \quad \sum_{i=1}^{n-1} x_i^2 = 1 \Rightarrow \sum_{i=1}^{n-1} \mu_i^2 = \sin^2 \theta_{n-1}. \quad (5.41)$$

In order to transform the kinetic term in (5.40), one inverts the metric then computes the line element in spherical coordinates and then inverts it again. This yields

$$I = 2(n-1)\rho_{n-1}^2 + \nu \sin^2 \theta_{n-1} + \left( \frac{2(n-1)}{\sin^2 \theta_{n-1}} - 2n + 3 \right) \left( \sum_{i,j=1}^{n-2} (\delta_{ij} - x_i x_j) p_i p_j + \sum_{i=1}^{n-1} g_i^2 \frac{x_i^2}{x_i^2} \right), \quad (5.42)$$

where $p_i$ are momenta canonically conjugate to $x_i$, $i = 1, \ldots, n - 2$. Beautifully enough, the rightmost factor in (5.42) is the Hamiltonian of a particle on $S^{n-2}$, which was studied in detail in the preceding Section. This sector provides $2(n-2) - 1$ functionally independent integrals of motion, which correlates with the $U(n-1)$ symmetry of the parent formulation (4.21). Because (5.42) involves one more canonical pair $(\theta_{n-1}, p_{\theta_{n-1}})$ and only one extra integral of motion (the Hamiltonian (5.42) itself), the full theory lacks for only one integral of motion to be maximally superintegrable.

Let us construct action–angle variables for the system. In order to simplify the bulky formulae below, from now on we change the notation $n \rightarrow n + 1$, which corresponds to a black hole in $d = 2(n + 1)$ dimensions. To avoid confusion, the corresponding Hamiltonian will be denoted by $I_0$

$$I_0 = 2n \rho_n^2 + \nu \sin^2 \theta_n + \left( \frac{2n}{\sin^2 \theta_n} - 2n + 1 \right) F_{n-1}, \quad (5.43)$$
with $F_{n-1}$ given in (5.22). One starts with the generating function

$$S^{\text{even}} = \sum_{i=1}^{n} \int p_{\theta_i}(\mathcal{I}_0, F_1, \ldots, F_{n-1}, \theta_i) d\theta_i = \int p_{\theta_n}(\mathcal{I}_0, F_{n-1}, \theta_n) d\theta_n + S^{\text{odd}},$$

where $S^{\text{odd}}$ has the structure similar to (5.32), and the expression for $p_{\theta_n}$ is derived from the Hamiltonian $I_0$. The action variables $I_1, \ldots, I_{n-1}$ coincide with those in the odd-dimensional case, while for $I_n$ one gets

$$I_n = \sqrt{-a^+} a^+ F_1 \left( 1, 1, 2, a^+, \frac{1}{a^+} \right),$$

where $F_1$ is Appell’s first hypergeometric function (see e.g. [86]) and

$$a^\pm = 1 - \frac{I_0}{2\nu} - \frac{2n-1}{2\nu} F_{n-1} \pm \sqrt{1 - \left( 1 - \frac{I_0}{2\nu} - \frac{2n-1}{2\nu} F_{n-1} \right)^2 + \frac{I_0}{\nu} - \frac{F_{n-1}}{\nu} - 1.}$$

Inverting this expressions, we would get the Hamiltonian written in terms of the action variables. Unfortunately, this cannot be done in elementary functions. While the system under consideration is integrable, it fails to be exactly solvable.

The angle variable conjugated to $I_n$ reads

$$\Phi^{\text{even}}_n = \frac{\partial I_0}{\partial I_n} \frac{1}{\sqrt{8n\nu a^+}} F \left( \arcsin \sqrt{\frac{a^+}{a^+ - \cos^2 \theta_n} 1 - \frac{a^-}{a^+}} \right),$$

while other $(n-1)$ angle variables are defined by the expressions

$$\Phi^{\text{even}}_i = \Phi^{\text{odd}}_i - A\Pi \left( 1 - \frac{1}{a^+}, \arcsin \sqrt{\frac{a^+}{a^+ - \cos^2 \theta_n} 1 - \frac{a^-}{a^+}} \right) + B F \left( \arcsin \sqrt{\frac{a^+}{a^+ - \cos^2 \theta_n} 1 - \frac{a^-}{a^+}} \right),$$

where $\Phi^{\text{odd}}_i$ were defined in the preceding section, $F(\phi|m)$ is the elliptic integral of the first kind, $\Pi(n; \phi|m)$ is the elliptic integral of the third kind, and we abbreviated

$$A = \sqrt{\frac{8nF_{n-1}}{\nu}} \frac{1}{\sqrt{a^+(a^+ - 1)}}, \quad B = A + \frac{\sqrt{2F_{n-1}}}{\sqrt{8n\nu a^+}} \left( \frac{\partial I_0}{\partial F_{n-1}} + 2n - 1 \right).$$

It follows from (5.45) and (5.46), that the ratio of the effective frequencies $\omega_1 = \partial I / \partial I_n$ and $\omega_2 = \partial I / \partial F_{n-1}$ is not a rational number. Furthermore, it is a function of the action variables.
Hence, although \((\omega_2 \Phi_n - \omega_1 \Phi_i)\) commute with the Hamiltonian \(I_0\), they are not periodic. As a result, using these functions one cannot define additional globally defined constants of the motion (for a related discussions see [34, 30]). All hidden symmetries of the model are thus contained in (5.39). Because the \(n\)-dimensional system has \(n + (n - 2) = 2n - 2\) constants of the motion, it lacks for only one first integral to be maximally superintegrable system.
SUMMARY

Here we recollect the main results of this thesis.

- We have suggested using the action-angle variables for the study of a (quasi)particle in quantum ring. We have presented the action-angle variables for three two-dimensional singular oscillator systems, which play the role of the confinement potential for the quantum ring. The first one is the usual (Euclidean) singular oscillator in constant magnetic field, the other two are spherical generalizations of the first one - singular Higgs oscillator and singular \( CP^1 \) oscillator in constant magnetic field.

- We have suggested a procedure of constructing new integrable systems form the known ones, by adding a radial part to the angular Hamiltonian. Using this method we have constructed a class of integrable generalizations of oscillator and Coulomb systems on \( N \)-dimensional Euclidian space \( R^N \), sphere \( S^N \) and hyperboloid \( H^N \). We have computed the explicit expressions for action-angle variables for systems with oscillator and Coulomb potentials on Euclidean space, on the sphere and on the hyperboloid.

As an example, we have constructed the spherical \( (S^N) \) and pseudospherical \( (H^N) \) generalization of the two-dimensional superintegrable models introduced by Tremblay, Turbiner and Winternitz and by Post and Winternitz. We have demonstrated the superintegrability of these systems and have written down their hidden constants of motion.

- We have developed the methods of study of conformal mechanics, based on separation of the radial and angular parts of the Hamiltonian of the system.

We have studied the angular part as a new Hamiltonian system with finite motion and suggested a method to construct the constants of motion of the new system from the constants of motion of the initial conformal system.

We have illustrated the effectiveness of this method on the example of the rational \( A_3 \) Calogero model and its spherical mechanics (which defines the cuboctahedric Higgs os-
cillator). For the latter we have constructed a complete set of functionally independent constants of motion, proving its superintegrability.

- We have closely explored the conformal mechanics associated with near-horizon motion of massive relativistic particle in the field of extremal black holes in arbitrary dimensions by separating the radial and angular parts of conformal mechanics and studying the angular part using the action-angle variables. We have proved, that by applying a proper canonical transformation one can bring the above mentioned model to the conventional conformal mechanics form. We have written down the explicit expressions of the above mentioned canonical transformation for a large class of extremal black holes.

- We have studied in details the near-horizon motion of massive relativistic particle in the field of extremal Reissner-Nordström black hole with magnetic momentum. We have shown that the angular part of this system is equivalent to the spherical Landau problem, and has a hidden constant of motion. We have found a “critical point” that divides the different phases of effective periodic motion.

We have analysed the near-horizon motion of massive relativistic particle in the field of extremal Clément-Gal’tsov (Dilaton-Axion) black hole. In contrast with Reissner-Nordström case, the angular part of this system does not possess hidden constant of motion. We have found a critical point that divide the phases (both effectively two-dimensional ones) of rotations in opposite directions.

- We have inspected the integrability of spherical mechanics models associated with the near horizon extremal Myers-Perry black hole in arbitrary dimension for the special case that all rotation parameters are equal.

As in the previous cases, we have extracted the spherical part of the initial Hamiltonian and studied it as a new system. We have performed a step-by-step transformation to generalized spherical coordinates, constructing a new constant of motion on every step. We have proved the superintegrability of the new system and demonstrated that the
spherical mechanics associated with the black hole in odd dimensions is maximally superintegrable, while its even-dimensional counterpart lacks for only one constant of the motion to be maximally superintegrable.
ACKNOWLEDGMENTS

It is a pleasure to thank the many people who have knowingly or otherwise helped me in the preparation of this dissertation. I must first mention the name of my Academic supervisor, Professor Armen Nersessian. I owe great deal to him, who has helped me from shaping the idea of this research to getting it to final completion.

I would like to express many thanks to supervisor of my Bachelor thesis and permanent co-author of many papers Professor Tigran Hakobyan for his professional kin eye and readiness to help me.

I am grateful to Professor Merab Gogberashvili from Tbilisi State University, for co-supervising my thesis within the framework of the Regional Training Network in Theoretical Physics, funded by Volkswagenstiftung under contract No 86260.

I express my gratitude to my co-authors, Professor Stefano Bellucci from INFN-Laboratori Nazionali di Frascati, Professor Anton Galajinsky from Tomsk Polytechnic University, Professor Olaf Lechtenfeld from Leibniz Universitat Hannover, and to my co-author and friend Dr. Vahagn Yeghikyan. Most of the results presented in this thesis, have been obtained in collaboration with them. Special thanks to Professor Galajinsky, who constructed near-horizon geometries of higher-dimensional extreme Perry-Myers black holes, and found, in terms of initial coordinates, the explicit expression of hidden constants of motion of the particle moving in these backgrounds.

I am so much grateful to the Authority of the Faculty of Physics of Yerevan State University for providing a stimulating environment for the research.

My special thanks to the people who were always wonderfully helpful in discussing the topic with me during the seminars and assisting in all possible ways. My greatest thanks go to Professors Edvard Chubaryan, Roland Avagyan, Vadim Ohanyan, David Karakhanyan, Hayk Sarkisyan, Gohar Harutyunyan, and all the staff of Academician Gourgen Sahakyan’s Chair
of Theoretical Physics. Discussions with all these people helped me observe the topic from
different angles and shape my ideas.

Last but not least I thank the reviewers of my thesis, Professor Ruben Manvelyan, Professor
Levon Mardoyan and Professor Sergey Krivonos from the Joint Institute for Nuclear Research
(Dubna), who carefully read my thesis and made many useful comments.
