Accuracy of Homology based Coverage Hole Detection for Wireless Sensor Networks on Sphere

Feng Yan, Philippe Martins, Senior Member, IEEE, and Laurent Decreusefond

Abstract—Homology theory has attracted great attention because it can provide novel and powerful solutions to address coverage problems in wireless sensor networks. They usually use an easily computable algebraic object, Rips complex, to detect coverage holes. But Rips complex may miss some coverage holes in some cases. In this paper, we investigate homology-based coverage hole detection for wireless sensor networks on sphere. The situations when Rips complex may miss coverage holes are first presented. Then we choose the proportion of the area of coverage holes missed by Rips complex as a metric to evaluate the accuracy of homology-based coverage hole detection approaches. Three different cases are considered for the computation of accuracy. For each case, closed-form expressions for lower and upper bounds of the accuracy are derived. Simulation results are well consistent with the analytical lower and upper bounds, with maximum differences of 0.5% and 3% respectively. Furthermore, it is shown that the radius of sphere has little impact on the accuracy if it is much larger than communication and sensing radii of each sensor.

Index Terms—Wireless sensor networks, coverage hole, homology.

I. INTRODUCTION

WIRELESS sensor networks (WSNs) have attracted considerable research attention due to their wide potential applications such as battlefield surveillance, environmental monitoring and intrusion detection. Many of these applications require a reliable detection of specified events. Such requirement can be guaranteed only if the target field monitored by a WSN contains no coverage holes, that is to say regions of the domain not monitored by any sensor. Coverage holes can be formed for many reasons, such as random deployment, energy depletion or destruction of sensors. Consequently, it is essential to detect and localize coverage holes in order to ensure the full operability of a WSN.

There is already extensive work on the coverage hole problem in WSNs on 2D plane and 3D space. Some of these work used either precise information about sensor locations [1]–[5] or accurate relative distances between neighbouring sensors [6]–[8] to detect coverage holes. The requirement of precise location or distance information substantially limits their applicability since acquiring such information is either expensive or impractical in many settings. Thus connectivity-based approaches are of great interest for us. In this category, homology-based schemes have received special attention because of its powerfulness for coverage problems in WSNs.

Homology was first introduced by Ghrist and his collaborators in [9]–[11] to address the coverage problems in WSNs. They introduced a combinatorial object, Čech complex, which fully characterizes coverage properties of a WSN (existence and locations of holes). Unfortunately, this object is very difficult to construct even if the precise information about the relative locations of sensors is available. Thus, they introduced another more easily computable complex, Vietoris-Rips complex (we will abbreviate the term to Rips complex in this paper). This complex is constructed with the sole knowledge of the connectivity graph of the network and gives an approximate coverage by simple algebraic calculations. More precisely, Rips complex may miss some special coverage holes. It is thus of paramount importance to analyse the coverage holes missed by Rips complex in order to evaluate the accuracy of homology-based coverage hole detection.

The main contributions of our paper are as follows. First, the relationship between Čech complex and Rips complex in terms of coverage hole on sphere is analysed. Furthermore, it is found that a hole in a Čech complex missed by a Rips complex must be surrounded by a spherical triangle. Based on that, a formal definition of spherical triangular hole is given.

Second, we choose the proportion of the area of spherical triangular holes as a metric to evaluate the accuracy of homology-based coverage hole detection. Such proportion is analysed under a homogeneous setting and it is related to the communication and sensing radii of each sensor. Three cases are considered for the computation of such proportion. For each case, closed-form expressions for lower and upper bounds of the proportion are derived.

Third, extensive simulations are performed to evaluate impacts of communication and sensing radii, radius of sphere on proportion of the area of spherical triangular holes. It is shown that simulation results are well consistent with the analytical lower bound, with a maximum difference of 0.5%, and consistent with the analytical upper bound, with a maximum difference of 3%. Furthermore, simulation results show that the radius of sphere has little impact on the proportion when it is much larger than communication and sensing radii. It further indicates that our analytical results can be applied to more general 3D surfaces.

The rest of the paper is organised as follows. Section II presents the related work. In Section III, the network model and the formal definition of spherical triangular hole are given. Closed-form lower and upper bounds for proportion of the area of spherical triangular holes under three different cases are derived in Section IV. Section V compares simulation results and analytical bounds. Finally, Section VI concludes the paper.
II. RELATED WORK

We present the related work in terms of two aspects: coverage ratio analysis and homology-based coverage hole detection.

First, extensive research has been done to analyze coverage ratio in a WSN on 2D plane or 3D surface. In [12], [13], the fraction of the area covered by sensors was analyzed. In [14], the authors studied how the probability of coverage changes with the sensing radius or the number of sensors. In [15], a point in a plane is defined to be tri-covered if it lies inside a triangle formed by three nodes, and the probability of tri-coverage was analyzed. In [16], the authors propose the surface coverage model and derived the expected coverage ratio under stochastic deployment on 3D surface. In [17], the expected coverage ratio under stochastic deployment on 3D rolling terrains was derived. Nevertheless, none of these research considered spherical triangular holes. We provided some initial results about the proportion of the area of coverage holes missed by Rips complex.

As for homology-based coverage hole detection, De Silva et al. first proposed a centralized algorithm that detects coverage hole via homology in [10]. They constructed the Rips complex corresponding to the communication graph of the network and determined the coverage by verifying whether the first homology group of the Rips complex is trivial. Then the above ideas were first implemented in a distributed way in [19]. It is shown that combinatorial Laplacians are the right tools for distributed computation of homology groups and can be used for decentralized coverage verification. In [20], a gossip-like decentralized algorithm for computation of homology groups was proposed. In [21], a decentralized scheme based on Laplacian flows was proposed to compute a generator of the first homology group. But all these homology-based algorithms do not consider the cases that Rips complex may miss some special coverage holes. In this paper, we describe such cases and analyse the proportion of the area of coverage holes missed by Rips complex.

III. MODELS AND DEFINITIONS

Consider a collection of stationary sensors (also called nodes) deployed randomly on a sphere $S^2$ with radius $R$ according to a homogeneous Poisson point process with intensity $\lambda$. For any two points $p_1$ and $p_2$ on $S^2$, the distance between them $d(p_1, p_2)$ is defined to be the great circle distance, which is the shortest distance between any two points on the surface of a sphere measured along a path on the surface of the sphere. As usual, isotropic radio propagation is assumed. All sensors have the same sensing radius $R_s$ and communication radius $R_c$ on $S^2$. It means for any sensor located at $v$ on $S^2$, any point $p$ on $S^2$ with $d(v, p) \leq R_s$ is within the sensing range of the sensor; and for any two sensors located at $v_i, v_j$ on $S^2$, they can communicate with each other if $d(v_i, v_j) \leq R_c$. In addition, we assume $R_s \ll R, R_c \ll R$.

Before defining the two combinatorial objects, known as Čech complex and Rips complex, it is necessary to give a brief introduction to some tools used in the paper. For further readings, see [22]–[24]. Given a set of points $V$, a $k$-simplex is an unordered set $[v_0, v_1, ..., v_k] \subseteq V$ where $v_i \neq v_j$ for all $i \neq j, k$ is the dimension of this simplex. The faces of this $k$-simplex consist of all $(k-1)$-simplices of the form $[v_0, ..., v_{l-1}, v_{l+1}, ..., v_k]$ for $0 \leq l \leq k$. For example, on a sphere $S^2$, a 0-simplex $[v_0]$ is a vertex, a 1-simplex $[v_0, v_1]$ is the shorter arc of the great circle passing through $v_0$ and $v_1$, a 2-simplex $[v_0, v_1, v_2]$ is a spherical triangle $v_0v_1v_2$ with its interior included, see Figure 1. An abstract simplicial complex is a collection of simplices which is closed with respect to inclusion of faces. A $k$-dimensional abstract simplicial complex $K$ is an abstract simplicial complex where the largest dimension of any simplex in $K$ is $k$.

Fig. 1. 0-, 1- and 2-simplex

Let $V$ denote the set of sensor locations in a WSN on $S^2$ with radius $R$ and $S = \{s_v, v \in V\}$ denote the collection of sensing ranges of these sensors: for a location $v$, $s_v = \{x \in S^2 : d(x, v) \leq R_s\}$. Then Čech complex and Rips complex can be defined as follows.

Definition 1 (Čech complex). Given a finite collection of sensing ranges $\{s_v, v \in V\}$, the Čech complex of the collection, $\tilde{C}(V)$, is the abstract simplicial complex whose $k$-simplices correspond to non-empty intersections of $k + 1$ distinct elements of $\{s_v, v \in V\}$.

Definition 2 (Rips complex). Given a metric space $(S^2, d)$, a finite set of points $V$ on $S^2$ and a fixed radius $\epsilon$, the Rips complex of $V$, $R_\epsilon(V)$, is the abstract simplicial complex whose $k$-simplices correspond to unordered $(k+1)$-tuples of points in $V$ which are pairwise within distance $\epsilon$ of each other.

According to the definitions, the Čech complex and Rips complex of the WSN, respectively denoted by $\tilde{C}_{R_s}(V)$ and $R_{R_c}(V)$, can be constructed as follows: a $k$-simplex $[v_0, v_1, \ldots, v_k]$ belongs to $\tilde{C}_{R_s}(V)$ whenever $\cap_{v_i = 0}^k s_{v_i} \neq \emptyset$ and a $k$-simplex $[v_0, v_1, \ldots, v_k]$ belongs to $R_{R_c}(V)$ whenever $d(v_i, v_m) \leq R_c$ for all $0 \leq i < m \leq k$. In addition, since we consider only coverage holes on the sphere $S^2$, it is sufficient to construct 2-dimensional Čech complex and 2-dimensional Rips complex of the WSN, denoted as $\tilde{C}_{R_s}(V)$ and $R_{R_c}(V)$, respectively.

Figure 2 shows a WSN, its Čech complex and two Rips complexes for two different values of $R_c$. Depending on the relation of $R_s$ and $R_c$, the Rips complex and the Čech complex may be close or rather different. In this example, for $R_c = 2R_s$, the Rips complex sees the hole surrounded by 2, 3, 5, 6 as in the Čech complex whereas it is missed in the Rips complex for $R_c = 2.5R_s$. At the same time, the true coverage hole surrounded by 1, 2, 6 is missed in both Rips complexes.

In fact, as proved in [25], any coverage hole can be found in Čech complex. Furthermore, there are following relations...
between $\hat{\mathcal{C}}^{(2)}_{R_c}(V)$ and $\mathcal{R}_{R_c}^{(2)}(V)$.

**Lemma 1.** Let $V$ denote the set of node locations in a WSN on $S^2$ with radius $R$, all nodes have the same sensing radius $R_s$ and communication radius $R_c$, $R_s < R_c \ll R$, then

$$\mathcal{R}_{R_c}^{(2)}(V) \subset \hat{\mathcal{C}}^{(2)}_{R_c}(V) \subset \mathcal{R}_{2R_c}^{(2)}(V),$$

whenever $R_c \leq R \arccos(3\cos^2(R_s/R) - 1)/2)$ \hfill (1)

**Proof:** See the Appendix.

According to (1), some relationships between Čech complex and Rips complex in terms of coverage hole can be derived as illustrated in the following corollaries.

**Corollary 1.** When $R_c \leq R \arccos(3\cos^2(R_s/R) - 1)/2)$, if there is no hole in $\mathcal{R}_{R_c}^{(2)}(V)$, then there must be no hole in $\hat{\mathcal{C}}^{(2)}_{R_c}(V)$.

**Corollary 2.** When $R_c \geq 2R_s$, if there is a hole in $\mathcal{R}_{R_c}^{(2)}(V)$, there must be a hole in $\hat{\mathcal{C}}^{(2)}_{R_c}(V)$.

**Corollary 3.** When $R \arccos(3\cos^2(R_s/R) - 1)/2) < R_c < 2R_s$, there is no guarantee relation between $\mathcal{R}_{R_c}^{(2)}(V)$ and $\hat{\mathcal{C}}^{(2)}_{R_c}(V)$ in terms of holes.

From the discussions above, a hole in a $\hat{\mathcal{C}}^{(2)}_{R_c}(V)$ not seen in a $\mathcal{R}_{R_c}^{(2)}(V)$ must be bounded by a spherical triangle. Based on this observation, a formal definition of spherical triangular hole is given as follows.

**Definition 3 (Spherical triangular hole).** For a pair of complexes $\hat{\mathcal{C}}^{(2)}_{R_c}(V)$ and $\mathcal{R}_{R_c}^{(2)}(V)$, a spherical triangular hole is an uncovered region bounded by a spherical triangle (2-simplex) which appears in $\mathcal{R}_{R_c}^{(2)}(V)$ but not in $\hat{\mathcal{C}}^{(2)}_{R_c}(V)$.

**IV. Bounds on proportion of spherical triangular holes**

In this section, the conditions under which any point on $S^2$ with radius $R$ is inside a spherical triangular hole are first given. From the discussions in Section III, it is found that the proportion of the area of spherical triangular holes is related to the relation of $R_c$ and $R_s$. Three different cases are considered for the proportion computation. For each case, closed-form expressions for lower and upper bounds of the proportion are derived.

**A. Preliminary**

**Lemma 2.** For any point on $S^2$, it is inside a spherical triangular hole if and only if the following two conditions are satisfied:

1) the great circle distance between the point and its closest node is larger than $R_c$.
2) the point is inside a spherical triangle: the convex hull of three nodes with pairwise great circle distance less than or equal to $R_c$.

**Lemma 3.** If there exists a point $O$ which is inside a spherical triangular hole, then $R_s < R \arccos(1 + 2\cos(R_c/R))/3$.

**Proof:** According to Definition 3, if there is a point $O$ inside a spherical triangular hole, then there exists a 2-simplex $\sigma \in \mathcal{R}_{R_c}^{(2)}(V)$ while $\sigma \notin \hat{\mathcal{C}}^{(2)}_{R_c}(V)$, so $\mathcal{R}_{R_c}^{(2)}(V) \notin \hat{\mathcal{C}}^{(2)}_{R_c}(V)$. According to (1), we have $R_c > R \arccos(3\cos^2(R_s/R) - 1)/2) \Rightarrow R_s < R \arccos(1 + 2\cos(R_c/R))/3$.

**Lemma 4.** Let $O$ be a point inside a spherical triangular hole and $l$ denote the great circle distance between $O$ and its closest neighbour, then $R_s < l \leq R \arccos(1 + 2\cos(R_c/R))/3$.

The proof is similar as that of Lemma 1.

Since we assume nodes are distributed on $S^2$ according to a homogeneous Poisson point process with intensity $\lambda$, any point has the same probability to be inside a spherical triangular hole. This probability in a homogeneous setting is also equal to the proportion of the area of spherical triangular holes.

We use spherical coordinates $(R, \theta, \varphi)$ to denote points on $S^2$ with radius $R$, where $\theta$ is polar angle and $\varphi$ is azimuth angle. We consider the probability of the point $N$ with spherical coordinates $(R, 0, 0)$ being inside a spherical triangular hole. Since the communication radius of each sensor is at most $R_c$, only the nodes within $R_c$ from the point $N$ can contribute to the spherical triangle which bounds a spherical triangular hole containing $N$. Therefore, we only need to consider the Poisson point process constrained on the spherical cap $C(N, R_c)$ which is also a homogeneous Poisson process with intensity $\lambda$, where $C(N, R_c)$ denotes the spherical cap centered at point $N$ and the maximum great circle distance between $N$ and points on the spherical cap is $R_c$. We denote this process as $\Phi$. In addition, $T(x, y, z)$ denotes the property that the point $N$ is inside the spherical triangular hole bounded by the spherical triangle with points $x, y, z$ as vertices. When $n_0, n_1, n_2$ are points of the process $\Phi$, $T(n_0, n_1, n_2)$ is also used to denote the event that the spherical triangle formed by the nodes $n_0, n_1, n_2$ bounds a spherical triangular hole.
containing the point \( N \). In addition, we use \( T'(n_0, n_1, n_2) \) to denote the event that the nodes \( n_0, n_1, n_2 \) can not form a spherical triangle which bounds a spherical triangular hole containing the point \( N \).

Let \( \tau_0 = \tau_0(\Phi) \) be the node in the process \( \Phi \) which is closest to the point \( N \). There are two cases for the point \( N \) to be inside a spherical triangular hole. The first case is that the node \( \tau_0 \) can contribute to a spherical triangle which bounds a spherical triangular hole containing the point \( N \). The second case is that the node \( \tau_0 \) can not contribute to any spherical triangle which bounds a spherical triangular hole containing the point \( N \) but other three nodes can form a spherical triangle which bounds a spherical triangular hole containing the point \( N \). So the probability that the point \( N \) is inside a spherical triangular hole can be defined as

\[
p(\lambda) = P\{N \text{ is inside a spherical triangular hole}\}
\]

\[
= P\{ \bigcup_{\{n_0, n_1, n_2\} \subseteq \Phi} T(n_0, n_1, n_2) \}
\]

\[
= P\{ \bigcup_{\{n_0, n_2\} \subseteq \Phi \setminus \{\tau_0(\Phi)\}} T(\tau_0, n_1, n_2) \}
\]

\[
+ P\{ \bigcup_{\{n_0, \ldots, n_4\} \subseteq \Phi \setminus \{\tau_0(\Phi)\}} T(n_0, n_1, n_2) \mid T'(\tau_0, n_3, n_4) \}
\]

(2)

\[B. \text{ Case } 0 < R_c \leq R \arccos([3 \cos^2(R_2/R) - 1]/2)\]

**Theorem 1.** When \( 0 < R_c \leq R \arccos([3 \cos^2(R_2/R) - 1]/2) \), \( p(\lambda) = 0 \).

\[Proof: \text{ According to (1), when } 0 < R_c \leq R \arccos([3 \cos^2(R_2/R) - 1]/2) \text{, } \mathcal{R}_R(\mathcal{V}) \subset \mathcal{C}_R(\mathcal{V}), \text{ it means that there exists not a spherical triangle which appears in } \mathcal{R}_R(\mathcal{V}) \text{ but not in } \mathcal{C}_R(\mathcal{V}), \text{ so there is no spherical triangular holes which means } p(\lambda) = 0.\]

\[C. \text{ Case } R \arccos([3 \cos^2(R_2/R) - 1]/2) < R_c \leq 2R_2\]

**Theorem 2.** When \( R \arccos([3 \cos^2(R_2/R) - 1]/2) < R_c \leq 2R_2 \), \( p(\lambda) < p(\lambda) < p_0(\lambda), \text{ where} \)

\[
p_0(\lambda) = 2\pi \lambda^2 R^4 \int_{R_2/R}^{\theta_0} \sin \theta_0 d\theta_0 \int_{\pi - \theta_0}^{\pi} d\varphi_0 \int_{\theta_0}^{\theta_1} \sin \theta_1 \]

\[
\times e^{-\lambda|C(N,R\theta_0)|} e^{-\lambda|S^+(\theta_0,\varphi_1)|} (1 - e^{-\lambda|S^-(\theta_0,\theta_1,\varphi_1)|}) \sin \theta_1 d\theta_1.
\]

(3)

\[and\]

\[
p_u(\lambda) = 2\pi \lambda^2 R^4 \int_{R_2/R}^{\theta_0} \sin \theta_0 d\theta_0 \int_{\pi - \theta_0}^{\pi} d\varphi_0 \int_{\theta_0}^{\theta_1} \sin \theta_1 \]

\[
\times e^{-\lambda|C(N,R\theta_0)|} e^{-\lambda|S^+(\theta_0,\varphi_1)|} (1 - e^{-\lambda|S^-(\theta_0,\theta_1,\varphi_1)|}) \sin \theta_1 d\theta_1
\]

\[+ P\{ \bigcup_{\{n_0, \ldots, n_4\} \subseteq \Phi \setminus \{\tau_0(\Phi)\}} T(n_0, n_1, n_2) \mid T'(\tau_0, n_3, n_4) \}
\]

(4)

\[\theta_{0u} = \arccos \left( 1 + 2 \cos(R_c/R) \right) / 3 \]

\[\varphi_m = \arccos \left( \cos(R_c/R) - \cos^2 \theta_0 \right) / (\sin^2 \theta_0) \]

\[\theta_{1u1} = \min \{ \theta_{1u1}, \theta_{1u2} \} \]

\[\theta_{1u2} = \arccos \left( \cos(R_c/R) \right) / \sqrt{1 - \sin^2 \theta_0 \sin^2 (\varphi_1 - \varphi_m)} \]

\[+ \arccos \left( \cos(\varphi_1 - \varphi_m) \tan \theta_0 \right) \]

\[\theta_{1u1} = \arccos \left( \cos(R_c/R) \right) / \sqrt{1 - \sin^2 \theta_0 \sin^2 (\varphi_1 - \varphi_m)} \]

\[+ \arccos \left( \cos(\varphi_1 - \varphi_m) \tan \theta_0 \right) \]

**Proof: We first prove the lower bound. It can be obtained from (2) that**

\[p(\lambda) > P\{ \bigcup_{\{n_1, n_2\} \subseteq \Phi \setminus \{\tau_0(\Phi)\}} T(\tau_0, n_1, n_2) \} \]

So for the lower bound, we only consider the first case that the closest node \( \tau_0 \) must contribute to a spherical triangle which bounds a spherical triangular hole containing the point \( N \).

Using spherical coordinates, we assume the closest node \( \tau_0 \) lies on \( (R, \alpha_0, 0) \) and use \( |S| \) to denote the area of the set \( S \), then we can get the distribution of \( \alpha_0 \) as

\[F_{\alpha_0}(\theta_0) = P(\alpha_0 \leq \theta_0) = 1 - e^{-\lambda|C(N,R\theta_0)|} \]

(5)

since the event \( \alpha_0 > \theta_0 \) means that the spherical cap \( C(N,R\theta_0) \) does not contain any nodes from the process, which is given by the Poisson probability \( e^{-\lambda|C(N,R\theta_0)|} \). Furthermore, \( |C(N,R\theta_0)| \) can be given as

\[|C(N,R\theta_0)| = \int_{\theta_0}^{\theta_0} \int_0^{2\pi} R^2 \sin \theta d\varphi d\theta = 2\pi R^2 (1 - \cos \theta_0) \]

(6)

From (5) and (6), we can get the density of \( \tau_0 \)

\[F_{\alpha_0}(d\theta_0) = 2\pi R^2 \sin \theta_0 e^{-\lambda|C(N,R\theta_0)|} d\theta_0 \]

(7)

The integration range for \( \theta_0 \) can be easily obtained. According to Lemma 4, we have \( R_s < R \theta_0 \leq R \arccos \left(1 + 2 \cos(R_c/R)\right) / 3 \), so \( R_s/R < \theta_0 < \theta_{0u} = R \arccos \left(1 + 2 \cos(R_c/R)\right) / 3 \).

Therefore the probability of the first case can be given as

\[P\{ \bigcup_{\{n_1, n_2\} \subseteq \Phi \setminus \{\tau_0(\Phi)\}} T(\tau_0, n_1, n_2) \}

\[= \int_{R_s/R}^{\theta_{0u}} P\{ \bigcup_{\{n_1, n_2\} \subseteq \Phi \setminus \{\tau_0(\Phi)\}} T((R, \alpha_0, 0), n_1, n_2) \} F_{\alpha_0}(d\theta_0) \]

(8)

where \( \Phi_{\theta_0} \) is the restriction of \( \Phi \) in \( C(N,R_c) \setminus C(N,R\theta_0) \).

Once the node \( \tau_0 \) is determined, the other two nodes must lie in the different half spaces: one in \( H^+ = \mathbb{R}^+ \times (0, \pi/2) \times (\pi, 2\pi) \) and the other in \( H^- = \mathbb{R}^+ \times (0, \pi/2) \times (0, \pi) \). Assume \( n_1 \) lies in \( H^+ \) and \( n_2 \) lies in \( H^- \). Since the great circle distance to \( \tau_0 \) is at most \( R_c \), \( n_1 \) and \( n_2 \) must also lie in the spherical cap \( C(\tau_0, R_c) \). Furthermore, the great circle distance to the
point $N$ is at most $R_2$ and larger than $R_{\alpha_0}$, they should also lie in the area $C(N, R_\alpha) \setminus C(N, R_{\alpha_0})$. Therefore, $n_1$ must lie in $H^+ \cap C(\tau_0, R_2) \cap C(N, R_\alpha) \cap C(N, R_{\alpha_0})$ and $n_2$ must lie in $H^- \cap C(\tau_0, R_2) \cap C(N, R_\alpha) \cap C(N, R_{\alpha_0})$. In addition, considering the great circle distance between $n_1$ and $n_2$ should be at most $R_2$ and the point $N$ should be inside the spherical triangle formed by $\tau_0$, $n_1$ and $n_2$, $n_1$ must lie in the shadow area $A^+ = H^+ \cap C(\tau_0, R_2) \cap C(N, R_\alpha) \cap C(N, R_{\alpha_0}) \cap C(M_2, R_2)$, shown in Figure 3. $M_1$ and $M_2$ are two intersection points between bases of spherical caps $C(N, R_{\alpha_0})$ and $C(\tau_0, R_\alpha)$, such intersection points must exist in this case since $R_2 \leq 2R_\alpha < 2R_{\alpha_0}$.

Ordering the nodes in $A^+$ by increasing azimuth angle $\varphi_1$ so that $\tau_1 = (R, \theta_1, \varphi_1)$ has the smallest azimuth angle $\varphi_1$. And assume the nodes $\tau_0$, $\tau_1$ and another node $\tau_2 \in H^- \cap C(\tau_0, R_{\alpha_0}) \cap C(N, R_\alpha) \cap C(N, R_{\alpha_0})$ can form a spherical triangle which bounds a spherical triangular hole containing the point $N$, then $\tau_2$ must lie to the right of the great circle passing through $\tau_1$ and $N$, denoted by $H^+(\varphi_1)$ which contains all points with azimuth angle $\varphi \in (\varphi_1 - \pi, \varphi_1)$. In addition, the great circle distance to $\tau_1$ is no larger than $R_\alpha$, so the node $\tau_2$ must lie in the region $S^-$, as illustrated in Figure 4.

$$S^-(\tau_0, \tau_1) = S^-(\alpha_0, \theta_1, \varphi_1) = H^- \cap C(\tau_0, R_{\alpha_0}) \cap C(N, R_\alpha) \cap C(N, R_{\alpha_0})$$

Here we need to obtain the density of node $\tau_1$. Considering the way $\tau_1$ was defined, there should be no nodes with a azimuth angle less than $\varphi_1$ in $A^+$, that is to say no nodes are in the region

$$S^+(\tau_0, \tau_1) = S^+(\alpha_0, \varphi_1) = A^+ \cap H^+(\varphi_1)$$

Since the intensity measure of the Poisson point process in spherical coordinates is $\lambda R^2 \sin \theta d\theta d\varphi$, the density $F_{\tau_1}$ of $\tau_1$ can be given as

$$F_{\tau_1}(d\theta_1, d\varphi_1) = \lambda R^2 \sin \theta_1 e^{-\lambda S^+(\alpha_0, \varphi_1)} d\theta_1 d\varphi_1 \quad (9)$$

Then we derive the integration domain $D(\alpha_0)$ with respect to parameters $(\theta_1, \varphi_1)$. Assume the point $M_2$ has the spherical coordinate $(R, \theta_0, \varphi_m)$, $\varphi_m \in (0, \pi)$. Since the great circle distance between $\tau_0$ and $M_2$ is $R_\alpha$, then according to the spherical law of consines, we have $\cos(R_{\alpha}/R) = \cos^2 \theta_0 + \sin^2 \theta_0 \cos \varphi_m \Rightarrow \varphi_m = \arccos[(\cos(R_{\alpha}/R) - \cos^2 \theta_0)/(\sin^2 \theta_0)]$. It can be seen that points $M_1$ and $Q$ have the spherical coordinates $(R, \theta_0, 2\pi - \varphi_m)$ and $(R, \theta_0, 2\varphi_m)$ respectively, where $Q$ is one intersection point between bases of spherical caps $C(N, R_{\alpha_0})$ and $C(M_2, R_2)$. Thus the integration range for $\varphi_1$ is $[2\pi - \varphi_m, 2\varphi_m]$. In addition, assume any point with great circle distance $R_\alpha$ to $\tau_0$ has the spherical coordinate $(R, \theta_1, \varphi_1)$, still using the spherical law of consines, we have $\cos(R_{\alpha}/R) = \cos \theta_0 \cos \theta_1 + \sin \theta_0 \sin \theta_1 \cos \varphi_1 \Rightarrow \theta_1(\varphi_1) = \arccos[\cos(R_{\alpha}/R)\sqrt{1 - \sin^2 \theta_0 \sin^2 \varphi_1}] + \arctan(\cos \varphi_1 \tan \theta_0)$. Similarly, assume any point with great circle distance $R_\alpha$ to $M_2$ has the spherical coordinate $(R, \theta_1', \varphi_1')$, we can obtain $\theta_1'(\varphi_1') = \arccos[\cos(R_{\alpha}/R)\sqrt{1 - \sin^2 \theta_0 \sin^2 (\varphi_1' - \varphi_m)}] + \arctan(\cos \varphi_1' \tan \theta_0)$. Then the integration range for $\theta_1$ is $[\theta_0, \theta_{1u}]$, where $\theta_{1u} = \min\{\theta_{1u1}, \theta_{1u2}\}$, $\theta_{1u1} = \theta_1(\varphi_1)$, $\theta_{1u2} = \theta_1'(\varphi_1)$. Furthermore, $|S^+(\alpha_0, \varphi_1)|$ can be expressed as

$$|S^+(\alpha_0, \varphi_1)| = \int_{2\pi - \varphi_m}^{\varphi_1} \int_{\theta_0}^{\theta_{1u}} R^2 \sin \theta d\theta d\varphi$$

Assume only $\tau_0$, $\tau_1$ and nodes in $S^-(\tau_0, \tau_1)$ can contribute to the spherical triangle which bounds a spherical triangular hole containing the point $N$, we can get a lower bound of the probability that the point $N$ is inside a spherical triangular hole. It is a lower bound because it is possible that $\tau_1$ can not contribute to a spherical triangle which bounds a spherical
triangular hole containing point \( N \), but some other nodes with higher azimuth angles in the area \( A^+ \) can contribute to such a spherical triangle. For example, in Figure 5, if there is no node in \( S^- \) but there are some nodes in \( S'^- \), then \( \tau_1 \) can not contribute to any spherical triangle which bounds a spherical triangular hole containing point \( N \), but \( \tau'_1 \) can form such a spherical triangle with \( \tau_0 \) and another node in \( S'^- \). Based on the assumption, we have

\[
\begin{align*}
\mathbb{P}\{ \bigcup_{(n_1, n_2) \not\in \Phi_{\theta_0}'} T((R, \theta_0, 0), (R, 0, \theta_1, \varphi_1), (n_1, n_2)) \} \\
> \int \int \int \int_{D(\theta_0)} \mathbb{P}\{ \bigcup_{n_2 \notin \Phi_{\theta_0}'} T((R, \theta_0, 0), (R, \theta_1, \varphi_1), (n_2)) \} \, F_{\tau_1}(d\theta_1, d\varphi_1) \\
= \int \int \int_{D(\theta_0)} \mathbb{P}\{ \Phi_{\theta_0}'(S^-(\theta_0, \theta_1, \varphi_1)) > 0 \} \, F_{\tau_1}(d\theta_1, d\varphi_1) \\
= \int \int \int_{D(\theta_0)} (1 - e^{-\lambda |S^-(\theta_0, \theta_1, \varphi_1)|}) \, F_{\tau_1}(d\theta_1, d\varphi_1)
\end{align*}
\]

where \( |S^- (\theta_0, \theta_1, \varphi_1)| \) can be expressed as

\[
|S^- (\theta_0, \theta_1, \varphi_1)| = \int_{\varphi_1}^{\varphi_2} \int_{\theta_0}^{\theta_2u} R^2 \sin \theta_2 \, d\theta_2 \, d\varphi_2
\]

and

\[
\begin{align*}
\varphi_2 &= \varphi_1 - \arccos \frac{\cos(Rc/R) - \cos \theta_1 \cos \theta_0}{\sin \theta_1 \sin \theta_0} \\
\theta_2u &= \min(\theta_1u, \theta_2u) \\
\theta_{2u2} &= \arccos \left[ \cos(R_c/R) \sqrt{1 - \sin^2 \theta_0 \sin^2(\varphi_2 - \varphi_1)} \right] + \arctan(\cos(\varphi_2 - \varphi_1) \tan \theta_1)
\end{align*}
\]

Therefore, from (7), (8), (9) and (10), the lower bound shown in (3) can be derived.

Next we will prove the upper bound. As discussed in Section IV-A, there are two cases for the point \( N \) being inside a spherical triangular hole. As for the second case that the closest node \( \tau_0 \) can not but some other nodes can contribute to a spherical triangle which bounds a spherical triangular hole containing the point \( N \), it is not easy to obtain a closed-form expression for such probability, but we can get it by simulations. Simulation results show that this probability is less than 0.16% whenever \( Rc \leq 3R_s \) with any intensity \( \lambda \). So we still focus on the probability of the first case.

For the lower bound, we only considered the case that \( \tau_1 \) contributes to a spherical triangle which bounds a spherical triangular hole containing point \( N \). For the upper bound, we need to further consider the case that \( \tau_1 \) can not but some other nodes in \( A^- \) can contribute to such a spherical triangle, shown in Figure 5. Assume the node \( \tau'_1 = (R, \theta'_1, \varphi'_1) \) with the second smallest azimuth angle in \( A^- \) can contribute to such a spherical triangle, it means that there is no node in \( S'^-(\alpha_0, \theta_1, \varphi_1) \) but there is at least one node in the region \( S'^-(\alpha_0, \theta_1, \varphi_1, \theta'_1, \varphi'_1) = S'^-(\alpha_0, \theta'_1, \varphi'_1) \setminus S'^-(\alpha_0, \theta_1, \varphi_1) \).

Then the density of the pair \( (\tau_1, \tau'_1) \) is given as

\[
F_{\tau_1, \tau'_1}(d\theta_1, d\varphi_1, d\theta'_1, d\varphi'_1) = \lambda^2 R^4 \sin \theta_1 \sin \theta'_1 e^{-\lambda |S^- (\alpha_0, \varphi)|} d\theta_1 d\varphi_1 d\theta'_1 d\varphi'_1
\]

The probability that \( \tau_1 \) can not but \( \tau'_1 \) can form a spherical triangle which bounds a spherical triangular hole containing point \( N \) with \( \tau_0 \) and another node in \( S'^-(\alpha_0, \theta_1, \varphi_1, \theta'_1, \varphi'_1) \) can be given as

\[
\begin{align*}
\mathbb{P}\{ \bigcup_{(n_3, n_4) \notin \Phi_{\theta_0}'} T((R, \theta_0, 0), (R, \theta_0, 0), (n_3, n_4)) | T'((R, \theta_0, 0), (n_3, n_4)) \}
&= \int \int \int \mathbb{P}\{ \Phi_{\theta_0}'(S^- (\theta_0, \theta_1, \varphi_1)) > 0 \}
\times \mathbb{P}\{ \Phi_{\theta_0}'(S'^-(\theta_0, \theta_1, \varphi_1, \theta'_1, \varphi'_1)) > 0 \}
\times F_{\tau_1, \tau'_1}(d\theta_1, d\varphi_1, d\theta'_1, d\varphi'_1)
\end{align*}
\]

As we can see from Figure 5, as long as \( \tau'_1 \) has a higher polar angle than \( \tau_1 \) has, the sum of \( |S^- (\alpha_0, \theta_1, \varphi_1) \) and \( |S'^-(\alpha_0, \theta_1, \varphi_1, \theta'_1, \varphi'_1) \) will be always smaller than \( |S'^-(\alpha_0, \alpha_0, \varphi)| \).

Therefore we can get from (13)

\[
\begin{align*}
\mathbb{P}\{ \bigcup_{(n_3, n_4) \notin \Phi_{\theta_0}'} T((R, \theta_0, 0), (n_3, n_4)) | T'((R, \theta_0, 0), (n_3, n_4)) \}
&< \int \int \int \left( e^{-\lambda |S^- (\theta_0, \theta_1, \varphi_1)|} - e^{-\lambda |S'^-(\theta_0, \theta_0, \varphi_1)|} \right)
\times F_{\tau_1, \tau'_1}(d\theta_1, d\varphi_1, d\theta'_1, d\varphi'_1)
\end{align*}
\]
Let $S^+(\theta_0, \varphi_1, \varphi'_1) = S^+(\theta_0, \varphi'_1) \setminus S^+(\theta_0, \varphi_1)$, then

$$
\int \int \lambda R^2 \sin \theta'_1 e^{-\lambda |S^+(\theta_0, \varphi_1, \varphi'_1)|} d\theta'_1 d\varphi'_1
= 1 - e^{-\lambda |A^+ \cup S^+(\theta_0, \varphi_1)|} < 1
$$

(15)

It is the complement of the probability that no node is in the area $A^+ \cup S^+(\theta_0, \varphi_1)$.

From (10), (12), (14) and (15), we can obtain

$$
P\{ \bigcup_{n_2 \subseteq \Phi'_{\theta_0} \cap S^-(\tau_1, \tau_1)} T((R, \theta_0, 0), \tau_1, n_2) \}
+ P\{ \bigcup_{(n_3, n_4) \subseteq \Phi'_{\theta_0} \cap S^-(\tau_1, \tau'_1)} T((R, \theta_0, 0), \tau'_1, n_4) \cap T'((R, \theta_0, 0), \tau_1, n_3) \}
< \int \int_{D(\theta_0)} (1 - e^{-\lambda |S^-(\theta_0, \theta_0, \varphi_1)|}) F_{\tau_1}(d\theta_1, d\varphi_1)
$$

(16)

where $|S^-(\theta_0, \theta_0, \varphi_1)|$ has the similar expression as (11).

Similarly, we can further consider the case that neither of $\tau_1$ and $\tau'_1$ can contribute to a spherical triangle which bounds a spherical triangular hole containing point $N$, but other nodes with even higher azimuth angle can contribute to such a spherical triangle. In this way, we can get the same result as (16).

Therefore, it can be derived that

$$
P\{ \bigcup_{\{n_1, n_2\} \subseteq \Phi'_{\theta_0}} T((R, \theta_0, 0), n_1, n_2) \}
< \int \int_{D(\theta_0)} (1 - e^{-\lambda |S^-(\theta_0, \theta_0, \varphi_1)|}) F_{\tau_1}(d\theta_1, d\varphi_1)
$$

(17)

From (2), (7), (8), (12) and (17), the upper bound shown in (4) can be derived.

\section{V. SIMULATIONS AND PERFORMANCE EVALUATION}

In this section, simulation settings are first given. Then simulation results are compared with analytical lower and upper bounds under different settings of $R_s, R_c, R$.

\subsection{A. Simulation settings}

A sphere centered at the origin with radius $R$ is considered in the simulations. The probability of the point with spherical coordinate $(R, 0, 0)$ being inside a spherical triangular hole is computed. Sensors are randomly distributed on the sphere according to a homogeneous Poisson process with intensity $\lambda$. The sensing radius $R_s$ of each node is set to be 10 meters and communication radius $R_c$ is chosen from 20 to 30 meters with interval of 2 meters. Let $\gamma = R_c/R_s$, then $\gamma$ ranges from 2 to 3 with interval of 0.2. In addition, $\lambda$ is selected from 0.001 to 0.020 with interval of 0.001. For each pair of $(\lambda, \gamma)$, $10^7$ simulations are run to check whether the point with spherical coordinate $(R, 0, 0)$ belongs to a spherical triangular hole.

\subsection{B. Impact of $R_s$ and $R_c$}

As illustrated in Section III, $R_s \ll R$ and $R_c \ll R$, here we choose $R = 10R_s$ to analyse the impact of $R_s$ and $R_c$ on the probability of any point being inside a spherical triangular hole. Under this configuration, the probability $p(\lambda)$ obtained
by simulations is presented with the lower and upper bounds in Figure 7(a) and 7(b) respectively.

It can be seen that for any value of $\gamma$, $p(\lambda)$ has a maximum at a threshold value $\lambda_c$ of the intensity. As a matter of fact, for $\lambda \leq \lambda_c$, the number of nodes is small. Consequently the probability of any point being inside a spherical triangular hole is relatively small too. With the increase of $\lambda$, the connectivity between nodes becomes stronger. As a result, the probability of any point being inside a spherical triangular hole increases. However, when the intensity reaches the threshold value, the probability is up to its maximum. $p(\lambda)$ decreases for $\lambda \geq \lambda_c$. The simulations also show that $\lambda_c$ decreases with the increase of $\gamma$.

On the other hand, it can be seen from Figure 7(a) and 7(b) that for a fixed intensity $\lambda$, $p(\lambda)$ increases with the increases of $\gamma$. That is because when $R_s$ is fixed, the larger $R_c$ is, the higher is the probability of each spherical triangle containing a coverage hole.

Furthermore, the maximum probability increases quickly with $\gamma$ ranging from 2.0 to 3.0. These results can also provide some insights for planning of WSNs, which will be discussed in Section V-D.

Finally, it can be found in Figure 7(a) that the probability obtained by simulation is very well consistent with the lower bound. The maximum difference between them is about 0.5%. Figure 7(b) shows that probability obtained by simulation is also consistent with the upper bound. The maximum difference between them is about 3%.

C. Impact of $R$

Although we assume $R_s \ll R$ and $R_c \ll R$, to better understand the impact of $R$ on the probability of any point being inside a spherical triangular hole, we choose $R$ to be $5R_s, 10R_s$ and $100R_s$. In addition, we also want to know the difference of the probability under spherical and 2D planar cases. Therefore, simulation results, lower and upper bounds of the probability under spheres with radii $5R_s, 10R_s, 100R_s$ and 2D plane are shown in Figure 8(a), 8(b) and 8(c) respectively.

It can be seen from Figure 8 that simulations results, lower and upper bounds under spheres with radii $5R_s, 10R_s, 100R_s$ and 2D plane are very close with each other. More precisely, the maximum difference of simulations results under spheres...
with radii $5R_s$ and $10R_s$ is about 0.045%, which is about 0.06% under spheres with radii $5R_s$ and $100R_s$ and is about 0.03% under spheres with radii $10R_s$ and $100R_s$. In addition, the maximum differences of simulation results between 2D planar case and spherical cases with radii $5R_s$, $10R_s$, $100R_s$ are 0.05%, 0.03% and 0.02% respectively. It means the larger the radius of sphere is, the more close are the simulation results under sphere and 2D plane, it is because the larger the radius of sphere is, the more likely of the local of each node on the sphere to be planar.

With respect to lower and upper bounds, it is found that under any two spheres with radii $5R_s$, $10R_s$, $100R_s$, the maximum difference of lower and upper bounds are 0.06% and 0.12% respectively. Furthermore, under spheres with radii $5R_s$, $10R_s$, $100R_s$ and 2D plane, the maximum difference of lower bounds is also 0.06%, and that of upper bounds is also 0.12%. More importantly, under sphere with radius $100R_s$ and 2D plane, the maximum difference of lower bounds is $5 \times 10^{-6}$ and that of upper bounds is $2.5 \times 10^{-5}$. It means the probabilities under cases of sphere with radius $100R_s$ and 2D plane are nearly the same, which is quite logical since when the radius of sphere is much more larger than the sensing radius of any node, the local of any node can be considered to be planar.

It can be further found that under above cases, the maximum differences of simulation results, lower and upper bounds are all so small that they can be neglected. Consequently, it also means that the radius of sphere has little impact on the probability of any point on the sphere to be inside a spherical triangular hole. Our results can thus be extended to more general 3D surfaces.

D. Discussions on applications

In this paper, we only consider spherical triangular holes, for non-spherical triangular holes, we assume they can be detected and covered by additional nodes. Under this assumption, our analytical results can be used for planning of WSNs. For example, a WSN is used to monitor a mountain and the ratio $\gamma = 2$, according to the analytical upper bounds, we can see that the maximum proportion of the area of spherical triangular holes under $\gamma = 2$ is about 0.06 %, which can be neglected. It means that as long as the surface of mountain can be spherically triangulated by nodes, we can say the mountain is covered. But if $\gamma = 3$ and at least 95% of the surface of the mountain should be covered, then it means that the proportion of the area of spherical triangular holes can be at most 5%. From the analytical upper bounds of $\gamma = 3$, it can be seen that when the intensity $\lambda = 0.009$, the upper bound is about 5%, so in order to cover at least 95% of the mountain, the intensity of nodes should be larger than 0.009. Similarly, our results can also be used in the scenarios when using satellite to cover the whole earth.

VI. CONCLUSIONS

This paper studied the accuracy of homology-based coverage hole detection for wireless sensor networks on sphere. First, the situations when Rips complex may miss coverage holes were identified. Then we chose the proportion of the area of coverage holes missed by Rips complex as a metric to evaluate the accuracy. Three different cases were considered to compute the accuracy. For each case, closed-form expressions for lower and upper bounds were derived. Simulation results are well consistent with the derived lower and upper bounds, with maximum differences of 0.5% and 3% respectively. In addition, simulation results also show that the radius of sphere has little impact on the accuracy as long as it is much larger.
than communication and sensing radii of each sensor. This means that our results can be applied to more general 3D surfaces although the results are derived on sphere. This problem will be investigated in our future work.

**APPENDIX**

**PROOF OF LEMMA 1**

*Proof:* The second inclusion is trivial because for any $k$-simplex $[v_0, v_1, \ldots, v_k] \in C_{R_s}(V)$, it means the sensing ranges of these nodes have a common intersection, so the pairwise distance $d(v_i, v_j) \leq 2R_s$ for all $0 \leq i < j \leq k$, which means $[v_0, v_1, \ldots, v_k] \in R_{2R_s}^{(2)}(V)$.

As for the first inclusion, it is clear that $\mathcal{R}_{R_e}^{(2)}(V)$ and $\mathcal{C}_{R_e}(V)$ contain the same 0-simplices. It is also easy to see that all 1-simplices in $R_{R_e}^{(2)}(V)$ must also be in $\mathcal{C}_{R_e}(V)$ since for any 1-simplex $[v_i, v_j]$ with distance $d(v_i, v_j) \leq R_e \leq \arccos([3 \cos^2(R_e/R) - 1]/2) < \arccos(2 \cos^2(R_e/R) - 1) = 2R_s$, it means that the sensing ranges of the two nodes have a common intersection. So we only need to prove that all 2-simplices in $R_{R_e}^{(2)}(V)$ must be in $\mathcal{C}_{R_e}(V)$. It is equivalent to say that for any three nodes with pairwise great circle distance no larger than $R_e$, their sensing ranges must have a common intersection.

Assume a 2-simplex $[v_0, v_1, v_2] \in R_{R_e}^{(2)}(V)$, then the three nodes $v_0, v_1$ and $v_2$ must determine a plane $\alpha$. We consider the spherical cap on $S^2$ cut off by the plane $\alpha$. Since $R_e < R$, the spherical cap must be on a hemisphere. It is easy to see that the intersection of the plane $\alpha$ and sphere $S^2$ is a circle $c$. Let $O_1$ be the center of circle $c$, $O$ be the center of $S^2$, $P$ be the intersection of line $OO_1$ and $S^2$.

Using spherical coordinates, we assume the point $P$ has a spherical coordinate $(R, 0, 0)$. $P$ may be inside $1$ or outside the spherical triangle $v_0v_1v_2$, which is shown in Figure 9(a) and 9(b) respectively.

![Fig. 9. Illustrations of $P$ and spherical triangle $v_0v_1v_2$: (a) $P$ is inside the spherical triangle $v_0v_1v_2$; (b) $P$ is outside the spherical triangle $v_0v_1v_2$.](image)

It can be seen that $P$ has the same great circle distance to $v_0, v_1$ and $v_2$, denoted by $d_p$. If $P$ is inside the spherical triangle $v_0v_1v_2$, as shown in Figure 9(a), then we can prove $d_p \leq R_e$. Since $P$ lying inside the spherical triangle $v_0v_1v_2$ means $\beta + \gamma + \delta = 2\pi$, there must be

\[
\text{one angle no smaller than } 2\pi/3. \text{ Without loss of generality, assume } \beta \geq 2\pi/3. \text{ According to the spherical law of consines, we have } \cos(\beta) = \frac{\cos(d_{01}/R) - \cos(d_{02}/R)}{\sin(d_{01}/R)} \leq -1/2 \Rightarrow \cos(d_{01}/R) \leq [3 \cos^2(R_e/R) - 1]/2. \text{ In addition, } d_{01} \leq R_e \leq R \arccos([3 \cos^2(R_e/R) - 1]/2) \Rightarrow \cos(d_{01}/R) \geq [3 \cos^2(R_e/R) - 1]/2, \text{ and } 0 < d_{01}/R, d_{02}/R < \pi/2, \text{ so we have } [3 \cos^2(R_e/R) - 1]/2 \leq [3 \cos^2(R_e/R) - 1]/2 \Rightarrow d_p \leq R_e, \text{ which means the point } P \text{ is a common intersection of sensing ranges of } v_0, v_1 \text{ and } v_2, \text{ so } [v_0, v_1, v_2] \in C_{R_e}^{(2)}(V). \text{ It means all 2-simplices in } R_{R_e}^{(2)}(V) \text{ must be in } C_{R_e}^{(2)}(V). \text{ Consequently the first inclusion is proved.}
