ABSTRACT

Background: Tuberculosis is an infectious disease cause by the mycobacterium tuberculosis which typically involve lung but can affect other site called extrapulmonary tuberculosis (EPTB). In EPTB lymph node tuberculosis is most common and most severe is tuberculous meningitis. Cartridge based nucleic acid amplification test (CBNAAT) have high sensitivity and perform both respiratory and non-respiratory specimen. The aim of this retrospective study is to find out the proportion of extra pulmonary tuberculosis in hospitalized patient and determine the association of CBNAAT in diagnosis EPTB and Rifampicin resistance.

Methods: This is the retrospective observational study done at Civil Hospital Ahmedabad in between October 2017 to October 2019 among the admitted patient age 1 month to 12 year diagnosed cases of EPTB according to RNTCP guidelines. Data collection done by medical records as indoor case sheets and investigation data from laboratory department.

Results: Incidence of EPTB among the hospitalized children is 1.95% and among total tuberculosis patient is 42.48%. Among 191 suspected EPTB cases 59 confirmed indicate sensitivity of 37.3% and no false positive cases indicate 100% positive predictive value. Sensitivity of CBNAAT was highest in gastric aspirate followed by CSF in present study.

Conclusions: Tuberculosis is more common in male child less than 5-year-old with frequent risk factor is rural residential area, lower socioeconomic class and contact with active cases. In my study is CNS tuberculosis is most common. In my study mortality is higher among 1-to-5-year age group with co morbid condition are SAM and septicemia.

Keywords: EPTB, CBNAAT, RNTCP, TB lymphadenitis, CNS tuberculosis

INTRODUCTION

Global tuberculosis (TB) 2018 Report suggest that In India average 2.2 lakh children become ill with TB each year (22% Of global TB burden) with slightly higher burden among males. Pulmonary TB is the most common form in Tuberculosis in children but the extra pulmonary TB forms a larger proportion than in adults.1

Tuberculosis is an infectious disease which is cause by the Mycobacterium tuberculosis which typically involve the lung (Pulmonary TB) but can affect other site called extra pulmonary tuberculosis. In extra pulmonary tuberculosis lymph node tuberculosis is most common in form of EPTB and most severe form in EPTB is tuberculous meningitis (TBM).Worldwide extra pulmonary tuberculosis accounts for 25% of all TB cases and even higher percentage in HIV infected individual and children.2

The major challenge in diagnosis of EPTB is that frequently atypical presentation, low bacillary load, lack of access to health care because live in vulnerable and poor community.
The conventional Mycobacterium tuberculosis detection technique based on microscopic examination of acid-fast bacilli is relatively insensitive. CBNAAT/Gene Expert MTB/RIF have been the game changer as they have far high sensitivity than smear almost reaches to culture and perform both respiratory and non-respiratory specimen. CBNAAT is real time PCR technique diagnosis of TB and detection of rifampicin resistance conferring mutation within 2 hours.

CBNAAT sensitivity and specificity in sputum is around 98% and 99% for smear positive patient and 72% for smear negative culture positive patient and for GA have been 68% and 99% respectively.3,4

**Aims and objectives**

To study the incidence of extra pulmonary tuberculosis in hospitalized patients to determine the association of CBNAAT in diagnosis extra pulmonary tuberculosis and rifampicin resistance.

**METHODS**

The study was a retrospective, conducted at tertiary level hospital at pediatrics department Civil Hospital Ahmedabad Gujarat in between October 2017 to October 2019. Out of 191 patients 158 patients met the criteria of RNTCP CRS (composite reference standard) which include smear microscopy, clinical finding at time of presentation and investigation. Study included patients admitted age group from 1 month to 12 years with suspected as presumptive case of extra pulmonary tuberculosis according to RNTCP GUIDE were included and diagnosed outside private and government sector.

Study excluded patients take treatment OPD based and isolated pulmonary tuberculosis.

Data collection done by detailed history with complete clinical and physical examination. Family history with close contact and BCG vaccination and socioeconomic status of children classified according to modified Kuppuswamy Classification. The nutritional status assessed and classified according to IAP classification and BMI according to age.

Software used for data analysis was Microsoft Excel. RNTCP guideline applied for diagnosed extra pulmonary tuberculosis. Relevant investigation done with special reference regarding CBNAAT was done. All children tested for HIV.

All patient treated as per RNTCP Guideline 2019. In suspected extra pulmonary tuberculosis patient sample collected under aseptic precaution and sent to examine for Gene Expert at RNTCP lab at state TB Division Centre Ahmedabad.

**RESULTS**

In my study total number of patients diagnosed with TB among total number of patients admitted during the study period (10468) were 481 suggestive of incidence is 4.59%, in which patients detected with EPTB were only 191 (1.95%).

| TB skin (scrofuloderma)           | 02                    | 1.04              |                           |
| TB osteomyelitis                  | 04                    | 2.09%             | 4% 4%                     |
| Genitourinary tuberculosis        | 01                    | 0.5               |                           |

Global TB report 2018 reports that in India, Annual incidence of Tuberculosis in 199 per 1 lakh population which results in 2.2 lakh cases every year (22% of global TB burden). 15-20% these cases are of EPTB. Approximately 10% the total cases reported to RNTCP are from children <14 years of age.

Anil et al and Virani et al have also observed similar risk factors comparable with present study.

ICMR survey 2005 states prevalence of disease is equal in both rural and urban whereas Chadha et al observed TB infection rate is higher in urban areas (2.2%) than in rural areas (1.3%).

CNS tuberculosis was the most common form of EPTB observed in 44.4%. In study of Sheth et al, TB lymphadenitis (78%) was the most common form of EPTB.

Lower sensitivity could be due to either small sample, inadequate sample collection, improper transport and delay in processing.

Out of total 191 patients, 158 were CRS positive, among which 59 were CBNAAT positive (true positive cases), 99 were CBNAAT negative (false negative cases). 33 patients does not match CRS criteria and were also CBNAAT negative (Empirically AKT started) (true negative).

Table 3: Analysis of CBNAAT results in EPTB samples.

| Tubercular cases     | Positive Cases | Tortilo et al 2012 (%) | Avashia et al 2016 (%) |
|----------------------|----------------|------------------------|------------------------|
| Gastric aspirate     | 53             | 32.97                  | 97.3                   |
| Sputum               | 8              | 17.75                  | 88                     |
| CSF(n=85)            | 26             | 30.5                   | 85.7                   |
| Ascitic fluid(n=15)  | 2              | 13.3                   | 50                     |
| Pleural fluid(n=29)  | 3              | 11.5                   | 44.4                   |
| Lymph node(n=20)     | 3              | 15                     | 88.3                   |
| Total sample 355     | 95             | 26.7                   | 81.3                   |

Table 4: Calculation of indices for CBNAAT.

| CRS +ve | CRS -ve | Total |
|---------|---------|-------|
| CBNAAT +ve | 59      | 59    |
| CBNAAT -ve | 99      | 132   |
| Total    | 158     | 191   |

Sensitivity and specificity of CBNAAT in sputum sample is around 98% and 99% in smear positive whereas both are around 72% in smear negative but culture positive patients. Sensitivity and specificity have been 68% and 99% respectively (RNTCP pediatric guidelines 2019).

Currently, WHO estimated incidence of Rifampicin resistance and MDR TB in INDIA is estimated to be around 147000. This translates to be around 11 patients per 100000 population annually as per the Global TB Report, WHO 2018.

According to Global TB report 2018 In India TB mortality ranges from 30-35 /1 lakh population and children’s account for 10-15% among cases. The TB
mortality rate is falling at about 3% per year with the overall reduction of 42% in the period from 2000-2017.1

Table 8: Analysis of MDR TB patients.

| MDR patients profile | Cases (n=8) |
|----------------------|-------------|
| Prevalence among EPTB| 8 (4.1%)    |
| HIV co-infection     | 2           |
| SAM                  | 3           |
| Defaulter            | 3           |
| Treatment failure    | 2           |
| Contact with MDR TB known case | 6 |
| CBNAAT positive      | 3           |
| Mortality            | 3 (37.5%)   |

According to Global TB report 2018 estimated burden of MDR/RR cases were 5.58 lakh in world and 1.35 lakh in India.

Among cases of MDR TB 8.5% were estimated to have XDR TB. Three countries accounted for almost half of the world cases of MDR/RR TB: India (24%), China (13%) and Russian federation (10%) (Global TB report 2019).

DISCUSSION

Incidence of TB among in hospitalized children was 4.59%. Incidence of EPTB was 1.95% which contribute up to 39.7% all pediatric TB patients. Male to female ratio is 1.27. Among them 72.7% of children were less than 5 year of age.In various study, Sheth et al and Virani et al also has male predominant.8,5

Rural residential area (66.4%), lower socio-economic class (61.7%) and contact with active TB (44.5%) were the most frequent risk factor. Severe nutritional anemia (43.9%) and severe acute malnutrition (30.3%) were the most common co morbid condition. Israni et al and Virani et al have also observed similar risk factors comparable with present study.5,6 Fever is most common constitutional symptom (80.1%). Pallor (48.6%) and generalised lymphadenopathy (30.8%) were the most common generalised signs. Also in comparative study, fever is common symptoms (72.3% in Israni et al and 97% in Virani et al) followed by cough cold and weight loss.5,6

CNS TB is most common form of EPTB observed in this study (44.4%). In Vimlesh et al, cervical lymphadenopathy (78%) is common in EPTB.8

Figure 1: Calculation for indices for CBNAAT.

Figure 2: Rifampicin resistance detected by CBNAAT.

International Journal of Contemporary Pediatrics | December 2021 | Vol 8 | Issue 12 | Page 1950
Out of 191 patients 25.1% show positive CXR finding in form of effusion (16.2%) followed by consolidation (16.2%). In neuro-imaging hydrocephalus was most common abnormality (74%). MT positive in 28.2%.

Overall positivity of ZN stain in various body fluid around 4% only. Sensitivity of CBNAAT was highest in Gastric aspirate (32.97%) followed by CSF (30.5%) in present study. Sensitivity of gene expert for plurural fluid, ascitic fluid and lymph node is 11.5%, 13.3% and 15% respectively. Among 158 EPTB cases 59 were CBNAAT confirmed indicate sensitivity of 37.3% and no false positive cases indicates 100% positive predictive value. Possitivity of CBNAAT was significantly higher as compared to smear examination in all specimen. Table 5 suggest comparison of various study with CBNAAT indices.

Rifampicin resistance was 5%. Adverse effect of antitubercular drugs were seen in 25.6%. Similar as in Hillemann et al study rifampicin resistance was noted in 5.79% and in Avashia et al was 5.40%10,11. Acute life threatening complication like cardiac tamponade and intestinal perforation were observed.

Overall mortality rate of EPTB in present study was 19.8% with highest among CNS TB (32.9%) followed by disseminated TB (26.9%), pleural TB (7.6%) and abdominal Koch (3.6%).

In present study we are not estimated total incidence of EPTB as OPD based treated and other than study hospital treated patients are not included. Also, in present study excluded the pulmonary tuberculosis cases so that CBNAAT sensitivity and specificity and also rifampicin resistance detection by Gene Xpert cannot be estimated overall.

CONCLUSION

Tuberculosis is more common in male child less than 5-year-old with most frequent high-risk factor is rural residential area, lower socioeconomic class and contact with active TB patient. In general TB Lymphadenitis is most common type of EPTB but in my study is CNS tuberculosis is most common. In my study mortality is higher among 1-to-5-year age group with most co morbidity condition are SAM and septicemia. Rifampicin resistance observed was 5%.
