Aim: To assess whether combining measurements obtained from carotid ultrasonography in addition to the age, creatinine, and ejection fraction (ACEF) score would improve the predictive ability of outcome in patients with acute coronary syndrome (ACS).

Methods: We examined 264 patients with ACS (194 men; mean age: 68±11 years) who underwent percutaneous coronary intervention. The carotid plaque score (cPS) and intima–media thickness (cIMT) were determined by carotid ultrasonography. The modified ACEF score was calculated using the following formula: (age/left ventricular ejection fraction) +1 point for every 10 mL/min reduction in creatinine clearance below 60 mL/min per 1.73 m². The endpoint of this study was major adverse cardiovascular and cerebrovascular events (MACEs), defined as all-cause death, myocardial infarction, stroke, and target vessel revascularization.

Results: During the median 4-year follow-up, there were 121 incidents of MACEs. Multivariate Cox proportional hazard regression analysis revealed that cPS ≥ 9.8 (hazard ratio [HR], 1.52; 95% confidence interval [CI], 1.01–2.31) and ACEF score ≥ 1.20 (HR, 1.62; 95% CI, 1.11–2.39) were significantly associated with MACEs, whereas cIMT was not. When the new combined risk score was calculated by multiplying the cPS by the modified ACEF score, the freedom from MACEs at 5 years was 71% and 31% for the lower and higher scores, respectively (p<0.001). The area under the receiver-operating characteristic curve for MACEs for the ACEF score, cPS, and combined risk score were 0.65, 0.66, and 0.71, respectively (p<0.05).

Conclusion: The cPS offers an incremental predictive value when combined to the simple ACEF score in ACS.

Key words: Acute coronary syndrome, Carotid ultrasonography, Risk stratification

Introduction

Although the patient prognosis after acute coronary syndrome (ACS) has improved since the introduction of primary percutaneous coronary intervention (PCI), as well as statin and antithrombotic therapy, risk stratification in these patients remains one of the major challenges for physicians. Age, ejection fraction, and renal function have been identified as powerful predictors of ACS in patients after myocardial infarction. Under these conditions, age, creatinine, and ejection fraction (ACEF) score has been reported as a simple and useful clinical tool for predicting outcome in patients with ACS; however, this clinical risk model does not contain anatomical characteristics that reflect the severity of coronary artery disease and subsequent outcome.

Non-invasive determination of carotid intima-media thickness (cIMT) using high-resolution B-mode ultrasonography has been reported in the diagnosis of subclinical carotid atherosclerosis as both a surrogate marker of coronary atherosclerosis and as a predictor...
During the study period, 90 patients with ACS who did not undergo examination of carotid ultrasonography were excluded. Finally, 264 patients were included for analysis. The median duration from the date of PCI to carotid ultrasonography was 9 days (interquartile range: 5 to 16 days). Our study complied with the Declaration of Helsinki and was approved by the local ethics committee with respect to the use of the clinical data.

Definitions

We defined ACS as ST-segment elevated myocardial infarction, non-ST-segment elevated myocardial infarction, or unstable angina pectoris. Myocardial infarction was defined as an increase in serum creatine kinase of 2 times the upper limit of the normal range with elevated muscle-brain fraction. Patients with ST-segment elevated myocardial infarction exhibited ST-segment elevation of >1 mm on 2 or more contiguous leads. Patients with non-ST-segment elevated myocardial infarction exhibited elevated cardiac enzymes, as noted above, without ST-segment elevation on the ECG. Unstable angina pectoris was defined by the following criteria: presence of typical chest discomfort lasting at least 5 min and occurring within 96 h of (or during) hospital admission, and having an unstable pattern of pain, consisting of either resting pain, new onset, severe or frequent angina, or accelerating angina.

Aim

The aim of this study was to assess the incremental prognostic value of cPS and cIMT in patients with ACS.

Methods

Study Population

This was a single center retrospective study. From November 2006 to May 2015, 354 consecutive patients with ACS who underwent PCI were analyzed. All PCI procedures were performed using standard techniques.
Clinical Carotid Plaque Score in ACS

Table 1. Baseline clinical characteristics

| Variable                  | All (n = 264) | cPS (n = 133) | cIMT (n = 122) |
|---------------------------|--------------|--------------|----------------|
| Age, years                | 68 ± 11      | 71 ± 9       | 64 ± 12        |
| Male gender, n (%)        | 194 (73)     | 100 (75)     | 94 (72)        |
| Clinical presentation     |              |              | 0.53           |
| STEMI, n (%)              | 126 (48)     | 61 (46)      | 65 (50)        |
| NSTEMI, n (%)             | 43 (16)      | 23 (17)      | 20 (15)        |
| UAP, n (%)                | 95 (36)      | 49 (37)      | 46 (35)        |
| Hypertension, n (%)       | 181 (69)     | 101 (76)     | 80 (61)        |
| Diabetes mellitus, n (%)  | 101 (38)     | 59 (44)      | 42 (32)        |
| Dyslipidemia, n (%)       | 114 (43)     | 63 (47)      | 51 (39)        |
| Current smoker, n (%)     | 115 (44)     | 59 (44)      | 56 (43)        |
| Previous MI, n (%)        | 27 (10)      | 15 (11)      | 12 (9)         |
| Previous stroke, n (%)    | 35 (13)      | 26 (20)      | 9 (7)          |
| CrCL (mL/min)             | 71 ± 40      | 61 ± 34      | 82 ± 42        |
| Left ventricular EF (%)   | 58 ± 14      | 56 ± 14      | 59 ± 13        |
| Medication during hospital stay |          |              |                |
| ACE inhibitor or ARB, n (%)| 212 (80)     | 108 (81)     | 104 (79)       |
| β-blocker, n (%)          | 144 (55)     | 77 (58)      | 67 (51)        |
| Statin, n (%)             | 223 (84)     | 110 (83)     | 113 (86)       |

Values are expressed as n (%) or mean ± standard deviation.
ACE, angiotensin-converting enzyme; ARB, angiotensin receptor blocker; CrCL, creatinine clearance; cIMT, carotid intima-media thickness; cPS, carotid plaque score; EF, ejection fraction; MI, myocardial infarction; STEMI, ST-segment elevated myocardial infarction; NSTEMI, Non-ST-segment elevated myocardial infarction; UAP, unstable angina pectoris.

The presence of coronary artery stenosis was defined as a lumen diameter stenosis ≥ 50% in a major coronary artery. Each patient was classified into one of the following groups based on the numbers of diseased vessels: 1-vessel disease, 2-vessel disease, 3-vessel disease (patients with disease in 3 vessels or left main trunk disease). Multivessel disease was defined as ≥ 50% luminal narrowing in more than 2-vessels or in the left main trunk. Hypertension was defined as a blood pressure ≥ 140/90 mmHg or requiring treatment with antihypertensive medications. Diabetes mellitus was defined as HbA1c ≥ 6.5%, plasma glucose ≥ 200 mg/dL, or requiring treatment with insulin or hypoglycemic agents. Dyslipidemia was defined as a serum total cholesterol concentration ≥ 220 mg/dL, a low-density lipoprotein-cholesterol concentration ≥ 140 mg/dL, or currently requiring treatment with lipid-lowering therapy. Standard transthoracic M-mode and 2-dimensional echocardiographic studies were performed within a week after experiencing an ACS. Left ventricular ejection fraction was calculated by the Teichholz method and by the modified Simpson’s method when left ventricular dilatation or a regional reduction of the left ventricular wall motion occurred.

The ACEF score was computed as follows: (age/12 + left ventricular ejection fraction +1 if serum creatinine value was >2 mg/dL). The modified ACEF score was calculated using the following formula: (age/12 + left ventricular ejection fraction +1 point for every 10 mL/min reduction in creatinine clearance below 60 mL/min per 1.73 m2 (up to a maximum of 6 points). Creatinine clearance was calculated using the Cockcroft–Gault equation. In all patients, peripheral venous blood samples for laboratory analysis were drawn at the time of presentation before the patients were transferred to the catheter laboratory.

Assessment of Carotid Ultrasonography
Carotid ultrasonography parameters were measured using ultrasound system (Apio, Toshiba Medical Systems, Tokyo, Japan) with a 7.5-MHz transducer, by trained sonographers who were blinded to the clinical data. The cIMT was recorded during the examination, as described previously. In brief, cIMT from the right and left side was measured from the far wall; the location of which was identified as the vertical distance from the leading edge of the first to the second echogenic line. Three independent cIMT determinations were measured in the walls at the site of greatest thickness of each common carotid artery, and these

Values are expressed as n (%) or mean ± standard deviation.

cIMT, carotid intima-media thickness; cPS, carotid plaque score; PCI, percutaneous coronary intervention; TIMI, Thrombolysis In Myocardial Infarction.

Comparisons between quantitative variables were performed with Student’s t-test. Categorical variables were compared using the Chi-squared test. Multivariate analysis of independent predictors of adverse outcome was performed using the Cox proportional hazard regression model. Variables with p < 0.05 on univariate analysis were selected for multivariate analysis in consideration of potential confounding variables. Continuous variables were dichotomized for the median in the multivariate model. We compared Kaplan–Meier estimates of endpoints using log-rank test. We performed receiver operating characteristic analysis and calculated the area under the receiver operator characteristic curve to estimate the predictive performance for MACEs. The area under the receiver operator characteristic curve was compared according to the method of Delong et al. Probability values of < 0.05 were considered statistically significant. Statistical analyses were performed using JMP pro Version 12 (SAS institute, Cary, NC, USA).

Results

First, we dichotomized patients into two groups, according to the median values of the cPS and cIMT.
The mean patient age was 68 \pm 11 years; 194 (73\%) were male (Table 1). The angiographic and procedural characteristics are presented in Table 2. In coronary angiography, multivessel disease was observed in 154 patients (58\%). As shown in Fig. 2, diseased coronary arteries increased significantly with increasing cPS and cIMT.

Table 3. Clinical outcome after PCI

|                  | All (n = 264) | cPS | P value | cIMT | P value |
|------------------|---------------|-----|---------|------|---------|
|                  |               | Higher (\(\geq 9.8\)) | Lower (\(< 9.8\)) |       | Higher (\(\geq 0.8\) mm) | Lower (\(< 0.8\) mm) |       |
| All-cause death  | 37 (14)       | 31 (23) | 6 (5) | \(< 0.001\) | 30 (21) | 7 (6) | \(< 0.001\) |
| Cardiovascular death | 24 (9)   | 20 (15) | 4 (3) | \(< 0.001\) | 19 (13) | 5 (4) | \(< 0.05\) |
| Myocardial infarction | 13 (5) | 6 (5) | 7 (5) | 0.75 | 5 (4) | 8 (7) | 0.26 |
| Definite stent thrombosis | 6 (2) | 4 (3) | 2 (2) | 0.42 | 3 (2) | 3 (2) | 0.85 |
| Stroke           | 17 (6)        | 12 (9) | 5 (4) | 0.08 | 12 (8) | 5 (4) | 0.14 |
| Target vessel revascularization | 76 (29) | 43 (32) | 33 (25) | 0.20 | 44 (31) | 32 (26) | 0.39 |
| MACEs            | 121 (46)      | 77 (58) | 44 (34) | \(< 0.001\) | 77 (54) | 44 (36) | \(< 0.05\) |

Values are expressed as n (%). cIMT, carotid intima-media thickness; cPS, carotid plaque score; MACEs, major adverse cardiovascular and cerebrovascular events; PCI, percutaneous coronary intervention.

The mean patient age was 68 ± 11 years; 194 (73\%) were male (Table 1). The angiographic and procedural characteristics are presented in Table 2. In coronary angiography, multivessel disease was observed in 154 patients (58\%). As shown in Fig. 2, diseased coronary arteries increased significantly with increasing cPS and cIMT.

The median duration of follow-up for the survivors was 4.1 years (interquartile range: 2.1 to 6.4 years). Complete 1-, 2-, and 4-year follow-up information was obtained for 87\%, 80\%, and 59\% of all patients, respectively. During follow-up, there were 121 incidents of MACEs. Outcomes of selected endpoints are shown in Table 3. We performed Cox proportional hazard regression analyses to identify predictors of MACEs (Table 4). On multivariate analysis (Table 4, model A), an ACEF score of \(\geq 1.20\) (hazard ratio [HR], 1.62; 95\% confidence interval [CI], 1.11–2.39) and cPS of \(\geq 9.8\) (HR, 1.52; 95\% CI, 1.01–2.31) were significantly related to MACEs. However, cIMT was no longer a significant factor for MACEs in multivariate analysis (HR, 1.27; 95\% CI, 0.84–1.94). On the other hand, when the analysis was conducted by entering the variable of multivessel disease (Table 4, model B), the statistical significance of cPS was attenuated (HR, 1.22; 95\% CI, 0.80–1.88). In the present study, we
developed a new combined risk scoring system (clinical cPS). The clinical cPS was calculated by multiplying the cPS by the modified ACEF score. Interestingly, clinical cPS was found to be significantly associated with MACEs, even after adjustment for multivessel disease (Table 4, model C: HR, 1.78; 95% CI, 1.18–2.75).

Freedom from MACEs at 5 years was 64% and 32% in the patients with lower and higher ACEF scores, respectively (Fig. 3A). Similarly, freedom from MACEs at 5 years was 61% and 39% in patients with lower and higher cPS, respectively (Fig. 3B). Furthermore, stratification of patients based on the median of the clinical cPS exhibited significantly different estimates for 5-year freedom from MACEs for the lower and higher risk groups: 71% and 31%, respectively (Fig. 3C). The area under the curve for the probability of MACEs for clinical cPS was much higher than that for the ACEF score and cPS alone (Fig. 4). The prognostic performances of the ACEF score, cPS, and clinical cPS compared with traditional risk factors are shown in Supplementary Table 1.

Table 4. Univariate and multivariate predictors of MACEs

| Univariate | Multivariate (Model A) | Multivariate (Model B) | Multivariate (Model C) |
|------------|------------------------|------------------------|------------------------|
|            | HR (95% CI)            | P value                | HR (95% CI)            | P value                | HR (95% CI)            | P value                |

Discussion

This study provided the following important new findings: (1) both cPS and cIMT reflect the extents of coronary artery disease in patients with ACS; (2) cPS, but not cIMT, was a major predictor of MACEs in ACS; (3) the combination of cPS as an anatomical characteristic to the ACEF score, which is a simple clinical risk score, improved the prognostic ability in patients with ACS who underwent PCI. This is the first study to demonstrate the prognostic utility of cPS in patients with ACS. Furthermore, we demonstrated the importance of combining risk assessment by incorporating anatomical characteristics, as assessed by carotid ultrasonography, and the ACEF score, which is comprised of simple clinical characteristics.

Although several investigators have examined the predictive value of cIMT or other metrics obtained from carotid ultrasound in primary prevention\textsuperscript{13, 14}, the prognostic ability of cIMT in patients with established atherosclerotic vascular disease remains controversial\textsuperscript{30-32}. The measurements obtained from carotid ultrasonography appear to be derived from similar components. However, progression of atheromatous plaques usually occurs at sites of low shear stress such as the bifurcation in the proximal internal carotid artery\textsuperscript{33}, which is of interest in calculating the cPS, thus contributing to the difference in performance in the detection of disease severity compared with cIMT. A recent study demonstrated a stronger association between cPS and the occurrence of cardiovascular events compared with cIMT in patients with hypertension\textsuperscript{34}.

Given the significant relationship between cPS and

![Fig. 3. Kaplan–Meier time-to-event curves for MACEs](image)

Kaplan–Meier time-to-event curves were stratified across the median of (A) ACEF score, (B) cPS, and (C) clinical cPS for freedom from MACEs. The numbers of patients at risk at each time point are indicated below the graph. ACEF, age, creatinine, and ejection fraction; cPS, carotid plaque score; MACEs, major adverse cardiovascular and cerebrovascular events.

* $p < 0.05$ vs. ACEF score; $\ddagger p < 0.05$ vs. cPS. ACEF, age, creatinine, and ejection fraction; AUC, area under the receiver operator characteristic curve; CI, confidence interval; cPS, carotid plaque score.

the incidence of cardiovascular outcomes, it is important to consider whether cPS offers incremental information beyond the known risk factors. Although the coexistence of peripheral artery disease has been reported as a more diffuse and complex atherosclerotic phenotype in patients undergoing PCI\textsuperscript{35, 36}, few data
exist regarding potential improvement for risk stratification in evaluating subclinical carotid atherosclerosis over known risk factors in patients with coronary artery disease. In this respect, cPS is shown to be a promising factor as an anatomical characteristic that could refine risk assessment when combined with the clinical risk score. Although the incorporation of an angiographic scoring system was successful in improving the prognostic ability of the clinical risk score, the combined risk score requires both an invasive imaging modality and clinical characteristics; thus, risk assessment may only be performed after coronary angiography. Approaches of risk assessment by combining anatomical characteristics obtained using non-invasive imaging and a clinical risk score might extend to the patients considering coronary angiography. Furthermore, in the present study, an improvement in the ability of the clinical risk score to predict MACEs could be achieved by the combined risk score, although the clinical utility of the combined risk score appeared controversial for predicting a wide spectrum of adverse outcomes. Thus, the assessment of subclinical carotid atherosclerosis using cPS may contribute to compensatory strategies for coronary angiographic risk scoring system in patients requiring coronary revascularization.

The present study has several limitations to consider. First, this was a retrospective study with a small sample size. In addition, although carotid ultrasonography was always performed to identify subclinical carotid atherosclerosis as part of our standard practice, many patients without carotid ultrasonography findings were excluded. Those patients who died as a result of ACS before carotid ultrasonography were not included in this study. Furthermore, our study consisted entirely of Japanese patients with ACS and, therefore, some caution should be taken when extending our findings to other cohorts. Despite these limitations, the present study could clearly show the importance of estimating subclinical carotid atherosclerosis with respect to predicting outcomes in ACS patients. Second, due to the very long enrolment period, significant differences in treatment strategies could exist over time. However, all patients in the present study underwent similar procedures such as coronary intervention. Third, statin intensity and combinations of antihypertensive drugs were different in this study population. Therefore, we could not take into account the association between the medical treatment and subsequent outcome. It is possible that regression of carotid atherosclerosis with drug administration reflects the prognostic benefit. Finally, we did not assess the Framingham Risk Score, which is used as a reference risk model, when incorporating anatomical characteristics from a non-invasive imaging modality, because it remains unknown whether this risk assessment is applicable to patients after myocardial infarction.

Conclusion

This is the first study to demonstrate the prognostic utility of cPS in patients with ACS. Furthermore, the cPS is a promising factor as an anatomical characteristic that could refine risk assessment through incorporation into a simple clinical risk score. Approaches of risk assessment by combining anatomical characteristics obtained using non-invasive imaging and a clinical risk score warrant further investigation in a large prospective trial.

Acknowledgments

We express special thanks to the staff of the clinical laboratory for their technical assistance in this study.
