Abstract

A method for highly sensitive and rapid detection of Pseudomonas aeruginosa, based on magnetic enrichment and magnetic separation, is described in this paper. The magnetic nanoparticles (MNPs) were applied to adsorb genome DNA after the sample was lysed. The DNA binding MNPs were directly subjected to polymerase chain reaction (PCR) to amplify gyrB specific sequence of Pseudomonas aeruginosa. The biotin labeled PCR products were detected by chemiluminescence when they were successively incubated with the probes-modified MNPs and alkaline phosphatase (ALP) labeled streptavidin (SA). Agarose gel electrophoresis analyses approved the method of in situ PCR to be highly reliable. The factors which could affect the chemiluminescence were studied in detail. The results showed that the MNPs of 400 nm in diameter are beneficial to the detection. The sequence length and the binding site of the probe with a target sequence have obvious effects on the detection. The optimal concentration of the probes, hybridization temperature and hybridization time were 10 μM, 60 °C and 60 mins, respectively. The method of in situ PCR based on MNPs can greatly improve the utilization rate of the DNA template ultimately enhancing the detection sensitivity. Experiment results proved that the primer and probe had high specificity, and Pseudomonas aeruginosa was successfully detected with detection limits as low as 10 cfu/mL by this method, while the detection of a single Pseudomonas aeruginosa can also be achieved.

Key words: Pseudomonas aeruginosa; Magnetic Enrichment; gyrB; In Situ PCR; Chemiluminescence.

Introduction

Nanotechnology has made rapid development in the past decades, opening new doors of its applications in various fields. The magnetic nanoparticles (MNPs) possess high surface area and they can easily be controlled under the external magnetic field, which emphasizes their potential use in the detection of biological signals [1-4]. For possessing many advantages such as high sensitivity, high specificity, low background, and the ease for quantitative analysis, etc., chemiluminescence is broadly applied in bioa-
The combined use of magnetic particles and chemiluminescence technology for the development of efficient biosensors for clinical purposes is an emerging trend [5-7].

*Pseudomonas aeruginosa* is one of the most extensive and serious problems in nosocomial infection which can infect wounds, foster otitis media and cause pneumonia, cystic fibrosis, sepsis, and other diseases [8-10]. *Pseudomonas aeruginosa* infection is the main reason of septicemia for patients who receive organ transplants [11]. The study by Van der Waaij's showed that 10 to 100 cells of *Pseudomonas aeruginosa* can lead to gut colonization in patients admitted in intensive care units and immunosuppressed [12]. It is also a primary cause of morbidity and mortality in patients with cystic fibrosis (CF), and early antibiotic treatment is crucial [9,13-16]. Therefore, the development of rapid and sensitive technique for early detection of *Pseudomonas aeruginosa* is very important for effective treatment of those diseases.

In this paper, we have concocted a simple method of *in situ* PCR based on MNPs. From the Fig. 1, the DNA binding Fe₃O₄@SiO₂ MNPs were directly added into the polymerase chain reaction (PCR) system to amplify *gyrB* specific sequence of *Pseudomonas aeruginosa*, which can improve both the utilization rate of the DNA template and detection sensitivity. dTTP was partly replaced with biotin-labeled-dUTP. The carboxyl-modified MNPs were conjugated with amino-modified probes by incubation, and the probes-modified MNPs were used to capture the specific PCR products. These complexes were bonded with alkaline phosphatase (ALP) through the special coupling function between biotin and streptavidin. Furthermore, the chemiluminescent signal was detected by adding AMPPD which was the substrate reagent of ALP. Different primers and probes, based on *ecfx* gene and *gyrB* gene, were devised to detect *Pseudomonas aeruginosa* in order to study the effects of the product length and probe location on the chemiluminescent signal intensity (Fig. 2).
Materials and Methods

Materials

*Pseudomonas aeruginosa* strain (ATCC27853) was purchased from Huankai Microbial. Sci. & Tech. Co. Ltd. *Salmonella enteritidis, Staphylococcus aureus, Shigella dysenteriae,* and *Escherichia coli* were kindly donated by Dr. Ru Zhang of Hunan Institute of Engineering. The oligonucleotides were synthesized and HPLC purified by the Sangon Company (Table 1). 3-(2’-spiroadamantane)-4-methoxy-4-(3’-phosphoryloxy) phenyl-1,2-dioxetane (AMPPD) was purchased from the Biochem-ZX (China). Taq DNA polymerase and other polymerase chain reaction (PCR) reagents were obtained from ShangHai Biocolor BioScience Technology Company (China). Streptavidin-modified alkaline phosphatase (SA-AP) and PEG-4000 were ordered from the Sangon Company (China). The biotin-11-dUTP was purchased from the Fermentas (USA). Other unnamed reagents were domestic analytical reagents. The chemiluminescent intensity was detected using a multi-function micro hole plate reading machine Victor X3 (Perkin Elmer, USA). The PCR amplifier used in this experiment was ABI9700 (Applied Biosystems, USA).

Preparation of Fe₃O₄ MNPs and Fe₃O₄@SiO₂ MNPs

Fe₃O₄ nanoparticles were prepared by the solvothermal method. 2.03 g of FeCl₃ 6H₂O, 2 g of PEG-4000 and 4 g of NaAc were dissolved in ethylene glycol. The solution was placed in a reaction kettle and allowed to react for 12 h at 180 °C. The obtained precipitate was washed with deionized water 3 times. The obtained nanoparticles were dispersed in 150 mL solution of ethanol/water (4:1) with the help of an ultrasonic. 3 mL of tetraethoxysilane (TEOS) and 4 mL of ammonia were added into the mixture and then the obtained mixture was stirred for 3 hours. Finally, Fe₃O₄@SiO₂ MNPs were magnetically separated from the reactant mixture by applying an external magnetic field and washed. The amino-modification of Fe₃O₄@SiO₂ MNPs was performed as follows. 150 mg of Fe₃O₄@SiO₂ MNPs were separated by the external magnetic field and dispersed in 30 mL of ethanol/water (199:1) solution by the ultrasonic, and then 60 μL of 3-aminopropyl triethoxysilane (APTES) was added into this mixture. The solution was stirred for 7 h at room temperature. The product was separated from the reactant mixture by the external magnetic field, then washed with N,N-dimethylformamide (DMF) for 5 times. The amino-modified MNPs were dispersed in DMF to a concentration of 5 mg/mL. For carboxyl-modification, 15 mL of amino-modified MNPs solution prepared as above was dropped into equal volume of succinic anhydride solution; the mixture was stirred at 20 °C for 24 h. 7.5 mL of carboxyl-modified MNPs was then acquired by magnetic separation after washing with DI water for 3 times [17-21].

Bacterial Culture

*Pseudomonas aeruginosa, Salmonella enteritidis, Staphylococcus aureus, Shigella dysenteriae* and *Escherichia coli* were grown in a LB broth separately. The bacteria were cultured for 24 h in an incubator at 37 °C, shaking at 180 rpm. The pathogens were inactivated for 48 h by 0.5 % of formaldehyde solution.

The Method of *Pseudomonas aeruginosa* Genomic DNA Extraction and in situ PCR Based on MNPs

100 µL of *Pseudomonas aeruginosa* sample, 20 µL of protease K and 100 µL of lysis solution were mixed in a 1.5 mL sterile centrifugal tube; the mixture was
incubated for 20 min at 56 °C. 400 μg of Fe3O4@SiO2 MNPs were dispersed in 300 μL of binding buffer after lysis, the sample of Pseudomonas aeruginosa was added into the binding buffer. After 5 minutes, MNPs were separated from the mixture under an external magnetic field and cleaned twice. Taq DNA polymerase buffer, MgCl2, primer, dNTPs, sterile water and Taq DNA polymerase were successively added into the PCR tube and mixed with the Fe3O4@SiO2 MNPs bound with genomic DNA. PCR was conducted under the following thermocycling conditions: 95 °C for 5 min, followed by 35 cycles of 94 °C for 40 sec, 60 °C for 30 sec and 72 °C for 30 sec. A final extension step was continued for another 7 min at 72 °C. A tube containing the reaction mixture and sterile water was included in all reactions as a negative control. The PCR products were analysed by electrophoresis (1.5 % agarose gel) [22-24].

**Detection of Pseudomonas aeruginosa Based on Chemiluminescence and Magnetic Separation**

The probes was attached onto the surface of carboxyl-modified MNPs according to covalent binding [24]. 90 μL of 10 μmol/L amino-modified probes diluted with pH 6.0 25 mmol/L MES and 60 μL of 5 mg/mL 1-Ethyl-3-(3-dimethyllaminopropyl) carbodiie hydrochlide (EDC) were mixed with 4.5 mg carboxyl-modified MNPs, incubated for 4 h at 4 °C, and then the probes-modified MNPs were washed with pH 7.4 50 mmol/L Tris-HCl buffer for 4 times. At last the probes-modified MNPs were dispersed in 150 μL of PBS buffer. Per mg MNPs could bond to 120 pmol of probes if the reaction is completed. Li’s method was followed for the detection of specific gyrB products with some slight modifications [22]. 10 μL of probes-modified MNPs (10 mg/mL) were put into a PCR tube, then the supernatant was abandoned after magnetic separation. A 10 μL hybridization solution, 19.5 μL of deionized water and 1 μL gyrB PCR products (10 μL gyrB PCR products were used for sensitivity detection) were added in to the PCR tube. Universal primer PCR products were used as negative control and deionized water in place of the gyrB PCR products as a blank control. The mixture was hybridized at 60 °C for 1 hour, then it was washed for 3 min with 60 μL 2×SSC and cleaning solution (50 mM Tris, 0.15 M NaCl), respectively. The supernatant was abandoned after magnetic separation. The hybrid products were blocked for 30 min by cleaning solution containing 0.25 % of bovine serum albumin (BSA), then were incubated with 10 μL of ALP-SA for 30 min. Furthermore, the MNPs were cleaned twice with cleaning solution. Finally, the chemiluminescent intensity were detected by adding 100 μL of 0.25 mM AMPPD, which was the substrate reagent of AP. Each process was repeated 3 times. The response of chemiluminescence was studied for different concentration of MNPs, different concentration of probes, different hybridization temperatures and different hybrid times.

**Specificity and Sensitivity Test**

The specificity of gyrB primer and probe to Pseudomonas aeruginosa was tested using Salmonella enteritidis, Staphylococcus aureus, Shigella dysenteriae and Escherichia coli, acting as controls. The Pseudomonas aeruginosa was inactivated for 48 hour in 0.5 % formaldehyde, and bacteria were calculated by plate cultivation which is a classical method, 5 readings were recorded each time. The bacterial concentration was diluted to 10 cfu/mL, 100 cfu/mL and 1000 cfu/mL. 100 μL of the above samples were used in every test. Each experiment or treatment was repeated 5 times.

**Data Analysis**

All of the data were expressed as mean ± SD (Standard Deviations). Student’s t-test was used for comparing the chosen level of statistical significance. The data analysis was made using SPSS 13.0 software.

**Results and Discussion**

**Genomic DNA Extraction and In Situ PCR Based on MNPs**

Because of the needs for nucleic acid automated testing and the characteristics of MNPs to help achieving the objective of automation, the genomic DNA extraction technology has rapidly improved in recent years [25]. Many researchers have explored the potential use of different magnetic nanoparticles for nucleic acid extraction, as well as the improvement of the extraction process [26-28]. However, the studies on the direct use of MNPs combined with genome DNA in in situ PCR are still rare. The automated testing of pathogens will be more convenient and the detection will be more sensitive if an in situ PCR based on the DNA binding MNPs can be developed. In this paper, we have described a method of genomic DNA enrichment based on the Fe3O4@SiO2 MNPs and an in situ PCR which featured the direct use of DNA bound at the surface of MNPs as a DNA template. The in situ PCR is based on the purification of genomic DNA acquired by enrichment of Fe3O4@SiO2 MNPs (Shown in Fig. 3A) and the ability of deionized water to elute the genomic DNA from Fe3O4@SiO2 MNPs at 65 °C. In clinical samples, the quantity of the pathogenic bacteria is usually very low. The detection results may

http://www.thno.org
present a false negative if the utilization of DNA templates is too low. Most DNA templates (Which bonded with Fe₃O₄@SiO₂ MNPs) were used for amplification in in situ PCR, therefore, theoretically, its sensitivity should be better than traditional PCR which usually uses few DNA templates. The results were shown in Fig. 3B-C, demonstrating our method can amplify sufficient PCR products for detection, and the efficiency of amplification is greater than the traditional PCR.

**The Detection of Pseudomonas aeruginosa Based on Chemiluminescence and Magnetic Separation**

AMPPD is a safe and stable chemiluminescence reagent acting as the substrate for ALP [29]. In this study, the carboxyl-modified MNPs were conjugated with amino-modified gyrB probes or amino-modified ecfx probes and then applied for the detection of *Pseudomonas aeruginosa*. The biotin-dUTP-labeled DNA fragments were amplified by in situ PCR. After the probes-modified MNPs were hybridized with gyrB gene fragments, SA-ALP was added. A universal bacterial primer pair was used as negative control. The chemiluminescent intensity was detected by adding AMPPD as the substrate.

Fig. 4A indicates that the chemiluminescent intensity of the sample was very strong in comparison with the control. The chemiluminescent intensity reached maximum after 30~40 mins, and then became stable. The MNPs with a diameter of 400 nm performed better than the smaller ones for detection of gyrB gene fragments of *Pseudomonas aeruginosa*. The reason is that bigger MNPs have a higher recovery rate and less steric hindrance. Different primers and probes were devised to detect *Pseudomonas aeruginosa* based on ecfx gene and gyrB gene. The short ecfx sequences and gyrB probes, complementary with the upstream sequence of targets, gave higher chemiluminescent intensity than the long ecfx sequence probes complementary with the middle sequence of the target (Fig. 2 and Fig. 4B). Owing to its shorter length, the short ecfx sequence had higher efficiency than gyrB sequence. Therefore, the sequence length and the binding site of probe clearly have effects on the detection of *Pseudomonas aeruginosa* since they are important factors of hybridization. The gyrB sequence was chosen in the following study because the specificity of the short ecfx sequence was very poor.

In order to obtain the optimal assay conditions, the effects of different factors on the detection of *Pseudomonas aeruginosa* were studied. The results shown in Fig. 5 indicates that the optimal concentration of probes is 10 μM/L, the optimal hybridization temperature is 60 °C, and the optimal hybridization time is 60 mins.

Control-2: the *ecfx* probes that captured PCR products of bacterial universal gene.

The Test of Specificity and Sensitivity

The specificity was largely determined by primer and probe choice. Qin et al studied the specificity of *gyrB* gene primer and probe used in this study, and no unspecific amplification was found [30-32]. The specificity of this method for the detection of *Pseudomonas aeruginosa* was tested, using *Salmonella enteritidis*, *Staphylococcus aureus*, *Shigella dysenteriae* and *Escherichia coli* as controls. As shown in Fig. 6A, the primer and probe of *gyrB* had high specificity.

For clinical samples, the sensitivity of a test for detecting pathogens is very important [33]. Usually, the sensitivity can be influenced by many factors, such as the sampling procedure, the DNA-extraction method or the PCR procedure [13,34]. In this paper, *in situ* PCR based on MNPs was introduced greatly improving detection sensitivity. In addition, the nucleic acid signal was further amplified since the PCR products were labeled with ALP which produced a chemiluminescent signal when reacting with AMPPD.

To test the sensitivity of the system for detecting gyrB of Pseudomonas aeruginosa, the Pseudomonas aeruginosa samples were diluted to different concentration, the results are presented in Fig. 6B. It was clearly shown that the chemiluminescent intensity was different than that of the control (P<0.01 versus control) even if the concentration of Pseudomonas aeruginosa is about 10 cfu/mL. Indeed, only 100 μL of Pseudomonas aeri-

**Conclusion**

The development of highly sensitive techniques for early detection of Pseudomonas aeruginosa is an important consideration of medical research [51,52]. Herein, we introduced an in situ PCR based on MNPs and a method of detection based on chemiluminescence and magnetic separation. The parameters for detection were optimized in this method. Finally, a highly sensitive and rapid detection method for Pseudomonas aeruginosa based on magnetic enrichment and magnetic separation has been developed with detection limits as low as about 10 cfu/mL, while the detection of a single Pseudomonas aeruginosa is also recognized. Automation of pathogen detection is a developing trend. The DNA enrichment and in situ PCR based on MNPs can simplify the process of detection, making automation more convenient.
