Abstract Voltage-gated Na\textsuperscript{+} channels (VGSCs) are heteromeric membrane protein complexes containing pore-forming \(\alpha\) subunits and smaller, non-pore-forming \(\beta\) subunits. VGSCs are classically expressed in excitable cells, including neurons and muscle cells, where they mediate action potential firing, neurite outgrowth, pathfinding, and migration. VGSCs are also expressed in metastatic cells from a number of cancers. The Na\textsubscript{v}1.5 \(\alpha\) subunit (encoded by SCN5A) is expressed in breast cancer (BCa) cell lines, where it enhances migration and invasion. We studied the expression of SCN5A in BCa array data, and tested the effect of the VGSC-blocking anticonvulsant phenytoin (5,5-diphenylhydantoin) on Na\textsuperscript{+} current, migration, and invasion in BCa cells. SCN5A was up-regulated in BCa samples in several datasets, and was more highly expressed in samples from patients who had a recurrence, metastasis, or died within 5 years. SCN5A was also overexpressed as an outlier in a subset of samples, and associated with increased odds of developing metastasis. Phenytoin inhibited transient and persistent Na\textsuperscript{+} current recorded from strongly metastatic MDA-MB-231 cells, and this effect was more potent at depolarized holding voltages. It may thus be an effective VGSC-blocking drug in cancer cells, which typically have depolarized membrane potentials. At a concentration within the therapeutic range used to treat epilepsy, phenytoin significantly inhibited the migration and invasion of MDA-MB-231 cells, but had no effect on weakly metastatic MCF-7 cells, which do not express Na\textsuperscript{+} currents. We conclude that phenytoin suppresses Na\textsuperscript{+} current in VGSC-expressing metastatic BCa cells, thus inhibiting VGSC-dependent migration and invasion. Together, our data support the hypothesis that SCN5A is up-regulated in BCa, favoring an invasive/metastatic phenotype. We therefore propose that repurposing existing VGSC-blocking therapeutic drugs should be further investigated as a potential new strategy to improve patient outcomes in metastatic BCa.

**Introduction**

Breast cancer (BCa) is the most common cancer in women, and the leading cause of female cancer-related deaths worldwide [1]. Metastasis is the main cause of mortality and is therefore a critical therapeutic target [2]. Treatment options currently available to patients with metastatic BCa are largely limited to palliation [3]. Thus, there is an urgent need to identify new molecular targets and adjuvant therapies with curative intent.

Voltage-gated Na⁺ channels (VGSCs) are heteromeric membrane protein complexes composed of one pore-forming α subunit and smaller β subunits [4]. Inward flow of Na⁺ through VGSCs is responsible for the depolarizing phase of action potentials in neurons and muscle cells [5]. There are nine α subunits (Na₁.1–Na₁.9) and four β subunits (β₁–β₄) [4]. The β subunits contain an extracellular immunoglobulin loop [6]. While they do not form the ion conducting pore, they modulate channel gating, and are members of the immunoglobulin superfamily of cell adhesion molecules (CAMs) [7]. VGSCs play a key role in organogenesis of the developing central nervous system [8]. VGSC α and β subunits function within complexes in neurons to regulate electrical excitability, neurite outgrowth, pathfinding, and migration [9–11].

VGSCs are widely expressed in metastatic cells from a number of cancers, including BCa (reviewed in [8]). For example, SCN5A (encoding Na₁.5), SCN8A (encoding Na₁.6), and SCN9A (encoding Na₁.7) mRNAs have been detected in BCa cell lines [12]. Of these, a neonatal splice variant of SCN5A is most abundant, and its mRNA is ~1,800-fold higher in strongly metastatic MDA-MB-231 cells than weakly metastatic MCF-7 cells [12]. Na⁺ currents have been recorded in MDA-MB-231 cells, but are absent in weakly metastatic MCF-7 cells [12, 13]. Neonatal SCN5A mRNA expression in BCa biopsies correlates with occurrence of lymph node metastasis [12]. Suppression of Na₁.5 in MDA-MB-231 cells, either with the pore-blocking tetrodotoxin (TTX), function-blocking antibodies, or with siRNA, inhibits cellular behaviors associated with metastasis, including detachment, migration, galvanotaxis, and invasion [12–15]. Na⁺ current carried by Na₁.5 enhances the cells' invasiveness by promoting cysteine cathepsin activity in caveolae [16, 17]. In contrast to Na₁.5, the VGSC β1 subunit functions as a CAM in BCa cells, enhancing adhesion [18]. Thus, VGSC α and β subunits appear to play dynamic roles in regulating cell adhesion, migration, and invasion in BCa.

Phenytoin (5,5-diphenylhydantoin), a class 1b antiepileptic drug, is a potent blocker of VGSCs (IC₅₀ ~ 10 µM) [19, 20]. It also inhibits delayed rectifier human Ether-a-go-go-related gene (HERG) K⁺ channels at significantly higher concentrations (IC₅₀ > 300 µM) [21]. The affinity of VGSCs for phenytoin is increased when they are in their inactivated state, following sustained membrane depolarization or high frequency channel activation, e.g., during action potential firing in neurons [20]. Phenytoin inhibits prostate-specific antigen (PSA) and interleukin-6 (IL-6) secretion, and migration in prostate cancer cells [22, 23]. It also suppresses endocytosis in small cell lung cancer cells [20, 24]. However, the effect of phenytoin on VGSC currents and metastatic cell behavior in BCa cells is unknown.

Our aims here were to (1) study the expression of SCN5A in published BCa array data and (2) assess the effect of phenytoin on Na⁺ current, migration, and invasion in BCa cells. We demonstrate that SCN5A is up-regulated in BCa samples in several datasets, and associates with poor prognosis. In addition, phenytoin inhibits Na⁺ current, migration, and invasion in metastatic BCa cells in vitro. We propose that VGSCs may be a promising target for therapeutic intervention in BCa using existing VGSC-inhibiting drugs. Furthermore, phenytoin, as a widely used FDA-approved oral anticonvulsant, should be further studied as a potential, cost-effective, new treatment approach.

**Methods**

*In silico analysis*

SCN5A expression in BCa microarrays was studied using the web-based Oncomine database, as described previously [25–27]. Normalization and statistical analysis were performed in Oncomine using the standard settings: for each array, data were log₂-transformed, median centered, and standard deviation normalized to one [25]. Fold changes <1.3-fold were not considered significant because such small changes are often not reproducible by quantitative PCR validation [28–30]. Cancer outlier profile analysis (COPA) was used to evaluate SCN5A outlier expression in a subset of BCa samples [31]. Outlier expression was defined as being in the top 10 % of COPA scores at any of three percentile cutoffs (75th, 90th, and 95th). Where
applicable, REMARK reporting criteria have been used [32]. Patients, specimen characteristics and assay methods are detailed in the reference cited for each dataset, and at www.oncomine.org.

Cell culture

MCF-7 and MDA-MB-231 cells were grown in Dulbecco’s modified eagle medium supplemented with 5% fetal bovine serum and 4 mM L-glutamine [12]. Cells were confirmed to be mycoplasma-free by 4’,6-diamidino-2-phenylindole (DAPI) method [33]. Molecular identity was confirmed by short tandem repeat analysis [34].

Immunocytochemistry, confocal microscopy, and image analysis

Immunocytochemistry and confocal microscopy were performed as in Refs. [9, 10]. Samples were labeled with a monoclonal pan-VGSC α subunit antibody (1:100; Sigma), polyclonal anti-β1 antibody (1:2,000) [35] or polyclonal anti-GM130 antibody (1:1,500; Proteintech), Alexa Fluor-conjugated phalloidin (1:40; Molecular Probes), and DAPI. Images were processed and analyzed using ImageJ software (NIH). The intensity profiles of VGSC α subunit and phalloidin were determined using the “straight line profile” function drawn across lamellipodia into the cell body, as in Refs. [36, 37]. For both channels, peak signal intensity in lamellipodia (defined as the peak in phalloidin labeling) was expressed as a ratio of the mean signal intensity 5–10 μm inside the plasma membrane. Measurements (3 per cell) were taken from ≥12 cells per line.

Electrophysiology

The whole-cell patch clamp technique was used to record membrane Na+ currents from cells grown on glass cover-slips [18]. Voltage-clamp recordings were made using a Multiclamp 700B amplifier (Molecular Devices) compensating for series resistance by 40–60%. Currents were digitized using a Digidata 1440A interface (Molecular Devices), low-pass filtered at 10 kHz, sampled at 50 kHz, and analyzed using pCLAMP 10.3 software (Molecular Devices). Linear components of leak were subtracted using a P/6 protocol [38]. Data manipulation and curve fitting were performed as before [9].

Pharmacology

Phenytoin sodium salt (Sigma) was prepared as a 180 mM stock dissolved in 75 mM NaOH. It was frozen in aliquots, then thawed and diluted in culture medium to 5–200 μM, as required. Control cells were treated with the final working concentration of NaOH (2–83 μM). In assays that exceeded 24 h, treatments were replaced daily.

Viability

The cytotoxicity of phenytoin was determined using a trypan blue exclusion assay [39]. Cells (5 × 10⁴) were plated in 35 mm dishes. The next day, dishes were treated each with phenytoin or vehicle. After 24 h, the number of live versus dead cells was determined from 20 fields of view per dish. Results were compiled from three experimental repeats.

Proliferation

Cells (3 × 10⁴ per well) were seeded in 12-well plates. The following day, triplicate wells were treated each with phenytoin or vehicle for 24 h. The number of cells per well was determined using the colorimetric 3-[4,5-dimethylthiazol-2-yl]-2,5-diphenyltetrazolium bromide (MTT) assay [40]. Results were compiled as the mean of three repeats.

Motility

Cellular motility was determined using a wound healing assay, as described previously [23]. Cells (2 × 10⁵) were seeded in 35 mm dishes. The following day, three wounds were made per dish using a P1000 pipette tip. Dishes were rinsed once in fresh medium, and wound widths were immediately measured (W₀) using an inverted microscope with graticule at 45 fixed points per dish (pre-labeled on the underside of the dish with a pen). Dishes were then treated with phenytoin or vehicle for 24 h and the same sites were subsequently re-measured (Wₜ). For each site, a migration index (MI) was calculated as MI = 1 – (Wₜ/W₀). Means were compiled from three repeat experiments, giving at least 135 data points for analysis.

Invasion

Cell culture inserts for 24-well plates, with 8 μm pores, were coated with extracellular matrix gel (Sigma). Cells (5 × 10⁵/ml) were plated in triplicate in a 0.1–1% fetal bovine serum chemotactic gradient and incubated with phenytoin (50 μM) or vehicle for 48 h. The number of invaded cells was determined using the MTT assay [12, 40]. Results were compiled as the mean of three repeats.

Data analysis

Data are presented as mean and SEM unless stated otherwise. Statistical analysis was performed using GraphPad Prism 5.0d. Normal distribution was determined using
D’Agostino–Pearson omnibus test. Pairwise statistical significance was determined with t tests, or Mann–Whitney tests. Multiple comparisons were made using ANOVA and Tukey post hoc tests, or Kruskal–Wallis with Dunn’s tests, as appropriate. P values computed by Oncomine were corrected for multiple comparisons by Bonferroni method [25]. Predictive value of SCN5A was assessed using receiver operating characteristic (ROC) curves. Kaplan–Meier curves for overall survival were compared by log-rank tests. Percent survival and hazard ratios are presented with 95% confidence intervals. Results were considered significant at \( P < 0.05 \) (*).

**Results**

SCN5A is expressed in patient BCa samples and is predictive of poor prognosis

Na\(_{1,5}\) (in its neonatal splice form) is present in BCa biopsies, correlating with lymph node metastasis [12]. Na\(_{1,5}\) is also expressed in MDA-MB-231 cells, where it potentiates invasion and migration [12, 13, 15]. In order to extend these observations to clinically relevant datasets, we used the Oncomine database to compare the expression of SCN5A in normal breast and BCa samples across multiple microarrays [25]. SCN5A was expressed at significantly higher levels in BCa (including ductal carcinoma in situ, and invasive, ductal and metastatic BCa), compared with normal breast tissue, in three out of seven datasets for which differential data were available [1.5-fold, \( P < 0.001 \), [41] and The Cancer Genome Atlas (TCGA) dataset \(^1\); and 3.6-fold, \( P < 0.05 \) [42] (Fig. 1a)]. There was no relationship between SCN5A expression and estrogen receptor (ER), progesterone receptor (PR), or human epidermal growth factor 2 (HER2) status (Table 1).

We next studied the prognostic value of SCN5A expression. SCN5A was more highly expressed in tumor samples from patients who subsequently developed metastases than from those who did not within 1 year (\( P < 0.05 \)), 3 years (\( P < 0.01 \)), and 5 years (\( P < 0.01 \)) [43]. However, the up-regulation of SCN5A (1.3-fold) was at the limit of significance [28–30]. Nonetheless, ROC analysis revealed that SCN5A expression was effective at predicting metastasis [area under the curve (AUC) = 0.63 ± 0.06; \( P < 0.05 \); Fig. 1b]. SCN5A was more highly expressed in those who experienced recurrence within 5 years than from those who did not (4.1-fold; \( P < 0.05 \); Fig. 1c [44]). In addition, SCN5A expression was higher in patients who were dead at 5 years (3.6-fold, \( P < 0.05 \), Fig. 1d; TCGA dataset). High SCN5A expression (cut-off at 60th percentile) associated with reduced survival (overall survival at 60 months: 45.4 % [25.3–63.5] for “low” SCN5A expression, and 18.5 % [4.3–40.0] for “high” SCN5A expression; hazard ratio = 2.1 [0.93–4.84]), although this was not quite statistically significant (\( P = 0.07 \); log-rank test; Fig. 1e [45]).

We next used COPA in Oncomine to investigate whether SCN5A, similar to other heterogeneously activated oncogenes [31], was expressed as an outlier. An outlier profile occurs when a gene is highly expressed in a fraction of samples in the total population. SCN5A was overexpressed in the top 10% of outliers at the 75th, 90th, and 95th percentiles, across five datasets (mean COPA score: 12.4 ± 4.3; Fig. 2a; Table 2). SCN5A overexpression as an outlier (cut-off at 90th percentile) in the primary tumor was associated with developing metastasis within 5 years [odds ratio = 3.2 (1.1–9.4); \( P < 0.05 \); Fig. 2b] [43]. In summary, SCN5A expression is higher in BCa than normal breast across several datasets in Oncomine, and is higher in BCa samples from patients who developed metastasis, recurrence, or who died within 5 years. Furthermore, SCN5A is overexpressed as an outlier in a subset of samples, and associates with increased odds of developing metastasis.

VGSC \( \alpha \) and \( \beta \) subunits are expressed in BCa cell lines

Strongly metastatic MDA-MB-231 cells express significantly more neonatal Na\(_{1,5}\) protein than weakly metastatic MCF-7 cells [12]. By contrast, \( \beta 1 \) is more highly expressed in MCF-7 cells than MDA-MB-231 cells [18]. Here, we studied the subcellular distribution of VGSC \( \alpha \) and \( \beta 1 \) subunits in MDA-MB-231 and MCF-7 cells by confocal immunocytochemistry. Given that \( \beta 1 \) can modulate Na\(^+\) current carried by Na\(_{1,5}\) [18], and that \( \beta 1 \)-mediated process extension in neurons requires Na\(^+\) current [9], we hypothesized that \( \alpha \) and \( \beta 1 \) subunits colocalize at the plasma membrane of BCa cells, as in neurons [9]. We used a pan-specific \( \alpha \) subunit antibody, which will detect not only Na\(_{1,5}\) but also Na\(_{1,6}\) and Na\(_{1,7}\), which have also been detected in these cell lines at mRNA level [12]. We found that in both MCF-7 and MDA-MB-231 cells, \( \alpha \) subunits were expressed throughout the cytoplasm, and on perinuclear internal membranes, colocalizing with \( \beta 1 \) and the Golgi marker GM130 (Fig. 3a, b, arrowheads). This pattern of expression is consistent with previous reports from us and other groups showing perinuclear VGSC expression inside neurons, HEK-293, and cancer cells [15, 17, 36, 46, 47]. Importantly, \( \alpha \) and \( \beta 1 \) were also colocalized along lamellipodia, defined by phalloidin labeling of F-actin (Fig. 3a, arrows). Line profiles drawn across lamellipodia revealed that \( \alpha \) subunits were highly expressed at the lamellipodial plasma membrane of MDA-MB-231 cells, colocalizing with a peak in phalloidin

\(^1\) http://tcga-data.nci.nih.gov/tcga/.
staining, but less so in MCF-7 cells (Fig. 3c, d). The ratio of lamellipodial/cell body staining was significantly higher in MDA-MB-231 than MCF-7 cells ($P < 0.001$; Fig. 3e). This suggests that $\alpha$ subunits are more highly expressed at the lamellipodia of MDA-MB-231 cells than MCF-7 cells. Given that the neonatal Nav1.5 splice variant is more highly expressed in MDA-MB-231 cells than MCF-7 cells [12], the $\alpha$ subunit immunoactivity in MCF-7 cells may represent other variant(s) of Na$^+$v1.5 that have impaired conduction [48], or other subtypes, e.g., Na$^+$v1.6 or Na$^+$v1.7 [12]. In summary, the arrangement of $\alpha$ subunits and $\beta$1 at lamellipodia is consistent with their functioning within complexes in these regions to regulate adhesion and migration.

Phenytoin inhibits Na$^+$ currents in MDA-MB-231 cells

In order to explore the therapeutic potential of Na$^+$v1.5 expression in BCa, we next tested the effect of a widely used VGSC-blocking anticonvulsant drug, phenytoin (50 μM), on Na$^+$ current in BCa cells, using whole-cell patch clamp recording. This concentration is within the serum therapeutic range used in clinical settings for treatment of epilepsy (10–20 μg/ml) [49]. The inhibition of neuronal VGSCs, e.g., Na$^+$v1.2, by phenytoin is well established [20]. However, the effect of phenytoin on Na$^+$v1.5-mediated Na$^+$ current in BCa cells has not been investigated. Consistent with previous reports [12, 13], we did not detect any voltage-activated Na$^+$ currents in

Breast Cancer Res Treat (2012) 134:603–615
weakly metastatic MCF-7 cells (n = 10 cells recorded; Fig. 4a, upper trace). We therefore focused our electro-physiological analysis on MDA-MB-231 cells, which express robust Na\(^{+}\) currents [15].

We first studied the tonic block of Na\(^{+}\) current, which arises from low-affinity binding of phenytoin to VGSCs in their resting state. Following step depolarization of MDA-MB-231 cells to −10 mV, the VGSCs opened, resulting in a “transient” inward Na\(^{+}\) current that decayed toward baseline within a few milliseconds due to VGSCs rapidly entering the inactivated state (Fig. 4a, lower trace). The VGSC inactivation was incomplete, and a small steady-state “persistent” Na\(^{+}\) current (approximately 5% of the transient peak) continued to flow until the end of the depolarizing step (Fig. 4a). Perfusion of phenytoin (50 \(\mu\)M) onto cells during the recording significantly and reversibly reduced the amplitude of the transient and persistent Na\(^{+}\) currents (Fig. 4a).

When cells were depolarized to −10 mV from a holding potential of −120 mV, the transient current was inhibited by 43.3 ± 5.4% (P < 0.001; Fig. 4b; Table 3). Similarly, the persistent current (measured as mean inward current between 45 and 50 ms following depolarization) was inhibited by 42.4 ± 8.0% (P < 0.05; Fig. 4b; Table 3). The tonic block following depolarization to −10 mV from a less negative holding potential of −80 mV was considerably larger: transient current was inhibited by 79.9 ± 2.2%, and persistent current was inhibited by 49.1 ± 7.4% (P < 0.001; Fig. 4c; Table 3).

Phenytoin also caused a hyperpolarizing shift in the voltage-dependence of steady-state inactivation, shifting the voltage at which half the channels were inactivated (\(V_{1/2}\)) from −79.0 ± 2.0 mV to −104.4 ± 4.8 mV (P < 0.001; Fig. 4d; Table 3).

We next studied the use-dependent block of Na\(^{+}\) current by phenytoin. Repeated depolarization from −120 to 0 mV, at a frequency of 50 Hz, caused a rapid decline in current amplitude that reached a plateau of 84.2% of initial current after the fourth pulse (Fig. 4e). In the presence of phenytoin, the decline in current reached a plateau of 80.6% after the fifth pulse (Fig. 4e). Thus, phenytoin...
caused a small increase in the use-dependent rundown of Na\(^+\) current in MDA-MB-231 cells.

Phenytoin caused a tonic inhibition of transient and persistent Na\(^+\) current in MDA-MB-231 cells, which was larger at more depolarized holding potentials. This dependence of tonic block on holding potential has been reported previously, e.g., [20, 50], and is due to phenytoin having a higher affinity for channels in the inactivated than the resting state. Consistent with previous reports, the resting membrane potential of MDA-MB-231 cells was $-20.3 \pm 0.9 \text{ mV}$ ($n = 5$) [12]. At this voltage, the majority of VGSCs are likely to be in the inactivated state, thus phenytoin would likely be a highly potent blocker of the remaining persistent Na\(^+\) current.

Phenytoin inhibits migration and invasion of BCa cells

The VGSC blocker TTX inhibits detachment, migration, galvanotaxis, and invasion of MDA-MB-231 cells [12–15]. TTX has no effect on these behaviors in cell lines that do not express VGSC-mediated Na\(^+\) currents, including MCF-7 cells [12, 13]. We therefore hypothesized that phenytoin would inhibit migration and invasion of MDA-MB-231 cells, but not MCF-7 cells. We first tested whether phenytoin was cytotoxic.

**a** MCF-7 and MDA-MB-231 cells labeled with pan-VGSC \(\alpha\) subunit and \(\beta1\) antibodies (magenta and green, respectively), phalloidin to label actin cytoskeleton (red), and DAPI to label nucleus (blue). 

**b** MCF-7 and MDA-MB-231 cells labeled with pan-VGSC \(\alpha\) subunit antibody (magenta) and GM130 antibody (Golgi marker; green), phalloidin (red), and DAPI (blue). Arrows indicate co-expression of \(\alpha\) and \(\beta1\) at the cell edge. Arrowheads indicate perinuclear expression of \(\alpha\) and \(\beta1\), colocalizing with GM130 (b). Intensity profiles (normalized to maximum signal) for pan-VGSC \(\alpha\) subunit and phalloidin across representative lamellipodia indicated by lines in (a) are shown for MCF-7 (c) and MDA-MB-231 (d) cells. 

**e** VGSC \(\alpha\) subunit intensity in lamellipodia relative to internal signal, for MCF-7 and MDA-MB-231 cells. Data are mean ± SEM ($n \geq 36$). ***P < 0.001.
Incubation with phenytoin (5–200 μM) for 24 h had no effect on viability of MCF-7 or MDA-MB-231 cells in a trypan blue exclusion assay (P = 0.93 and 0.67, respectively; Fig. 5a). Similarly, phenytoin had no effect on the proliferation of MCF-7 or MDA-MB-231 cells (P = 0.98 and 0.73, respectively; Fig. 5b).

We next tested the effect of phenytoin on migration in a wound heal assay. Phenytoin (5–200 μM; 24 h) had no effect on the migration of MCF-7 cells (P = 0.41), but significantly reduced the migration of MDA-MB-231 cells by 27.3 ± 1.9 % at 50 μM, and 37.2 ± 1.8 % at 200 μM (P < 0.001; Fig. 6a, b). Similarly, phenytoin (50 μM;
48 h) had no effect on the invasion of MCF-7 cells ($P = 0.99$), but significantly reduced the invasion of MDA-MB-231 cells by $27.1 \pm 3.1\%$ ($P < 0.05$; Fig. 6c). In conclusion, phenytoin significantly inhibited the migration and invasion of MDA-MB-231 cells, which express functional VGSCs.

### Discussion

The expression of VGSCs in electrically excitable cells, and their importance as therapeutic targets in excitability-related disorders, e.g., epilepsy, has been long established [19]. However, it is only more recently that their importance in cancer has begun to be identified [8]. SCN5A/Na,1.5 is expressed, predominantly in its neonatal splice form, in MDA-MB-231 cells, which are triple negative for ER/PR/HER2 [12]. Neonatal Na,1.5 is expressed in cells of epithelial origin in BCa biopsies, but is absent in normal breast [12]. We found several studies in Oncomine in which SCN5A was up-regulated in BCa compared with normal tissue. However, there was no relationship between SCN5A expression and ER/PR/HER2 status in these datasets. SCN5A expression has been reported in other cancers, including lymphoma [51], neuroblastoma [52], colorectal [53], lung [24], and ovarian cancers [54]. In addition, other VGSC subtypes have been reported in melanoma [55], mesothelioma [56], cervical [57, 58], lung [24], ovarian [54], and prostate cancers [59, 60].

SCN5A was more highly expressed in samples from patients who had a recurrence, metastasis, or died within 5 years. SCN5A expression as an outlier also associated with metastasis. These findings agree with a previous report correlating neonatal SCN5A variant mRNA in BCa biopsies with lymph node metastasis [12]. The microarray probes used in the studies in Oncomine do not distinguish between neonatal and adult SCN5A splice variants. However, the neonatal splice variant is predominant in MDA-MB-231 cells and in BCa biopsies in which both variants were studied [12, 15]. In conclusion, our data support the notion that SCN5A is up-regulated in BCa, and may be a marker for poor prognosis.

Blocking Na$^+$ current carried by Na,1.5 in MDA-MB-231 cells with TTX, siRNA, or antibodies, inhibits migration, galvanotaxis, and invasion, and enhances adhesion [12–15]. Similarly, blocking Na$^+$ current suppresses these behaviors in cell lines from other cancers (reviewed in [8]). VGSCs are expressed at lamellipodia of MDA-MB-231 and MCF-7 cells, consistent with VGSCs functioning within these regions to regulate adhesion, migration, and invasion. Importantly, the lamellipodial/cell body z subunit expression ratio is higher in MDA-MB-231 cells than MCF-7 cells, consistent with z subunits regulating migration and invasion in the former, rather than the latter cell line. It is possible that MCF-7 cells also express other VGSC z subunit variants that have impaired conduction [48]. Thus, in addition to being a

### Table 3 Effect of phenytoin on Na$^+$ current parameters in MDA-MB-231 cells

| Parameter                  | Control          | Phenytoin (50 μM) |
|----------------------------|------------------|-------------------|
| Tonic block, $V_m = \text{-}120 \text{ mV}$ |                  |                   |

marker for metastatic BCa, Nav1.5 may be a useful therapeutic target for slowing disease progression and/or metastasis.

A number of VGSC-targeting drugs are used to treat other diseases, e.g., epilepsy [19]. Several of these drugs, including phenytoin, bind preferentially to VGSCs that are inactivated [20, 50]. VGSCs typically inactivate within a few milliseconds of opening following depolarization, and remain in that state until the membrane repolarizes [5]. Several subtypes, including Na\(_{\text{a}1.5}\), do not inactivate completely, and continue to carry a small steady-state persistent Na\(^+\) current at depolarized potentials [61, 62]. Cancer cells typically have a more depolarized membrane potential than normal epithelial cells, or terminally differentiated excitable cells, e.g., neurons [63]. Thus, it is the persistent component of Na\(^+\) current that is likely to be predominant in BCa cells, potentiating invasion and migration. Phenytoin significantly inhibited both transient and persistent Na\(^+\) currents in MDA-MB-231 cells. Importantly, the tonic block was greater at more depolarized holding voltages, suggesting that phenytoin may be a highly effective VGSC blocker in depolarized cancer cells. This is the first report of phenytoin inhibiting Na\(^+\) current in cancer cells, and agrees with the effect of this drug on VGSCs in other cells, e.g., [20, 50].

Our electrophysiological data suggest that phenytoin may be a useful therapeutic agent for blocking Na\(^+\) current in BCa cells. Na\(^+\) current enhances invasion by promoting cysteine cathepsin activity in caveolae [16, 17], and Na\(_{\text{a}1.5}\) has been proposed to be a key regulator of invasion-controlling genes [53]. We found that phenytoin significantly inhibited migration and invasion in MDA-MB-231 cells expressing Na\(^+\) currents by \(\sim 30\%\). This is equivalent to the effect of blocking VGSCs using TTX, siRNA, or antibodies, reported previously [12, 13, 15]. Phenytoin had no effect on the migration or invasion of MCF-7 cells, which do not express Na\(^+\) currents. Phenytoin also had no effect on the proliferation of either cell line, consistent with previous reports indicating that VGSCs regulate cell migration and invasion, but not proliferation [8]. Phenytoin has been shown to inhibit HERG channels at significantly higher concentrations (IC\(_{50}\) for HERG > 300 \(\mu\)M, vs. IC\(_{50}\) for VGSC \(\sim 10\) \(\mu\)M) [19, 21]. MCF-7 cells express outward K\(^+\) currents, although the channel has not yet been identified [12, 17]. In contrast, MDA-MB-231 cells do not express any voltage-dependent K\(^+\) (e.g., HERG) currents [12, 17]. Together, these data suggest that phenytoin (50, 200 \(\mu\)M) inhibited VGSC-dependent migration and invasion in MDA-MB-231 cells by suppressing Na\(^+\) current, rather than inhibiting another target, e.g., HERG channels.

The concentration of phenytoin that inhibits Na\(^+\) current, migration, and invasion (50 \(\mu\)M) is within the serum therapeutic range used in clinical settings for treatment of epilepsy [49]. Our data suggest that repurposing phenytoin

---

Fig. 6 Effect of phenytoin on migration and invasion. a Representative images of MCF-7 and MDA-MB-231 cells in a wound healing assay at 0 h, and 24 h following treatment with phenytoin (5, 50, 200 \(\mu\)M) or vehicle. b Migration of MCF-7 and MDA-MB-231 cells treated with phenytoin (5, 50, 200 \(\mu\)M) or vehicle for 24 h in wound healing assay, normalized to control (n = 135 measurements per condition). c Invasion of MCF-7 and MDA-MB-231 cells ± phenytoin (50 \(\mu\)M) for 48 h, normalized to control (n = 9). Data are mean ± SEM. **p < 0.01; ***p < 0.001.
to BCa warrants further study as a potential new treatment. However, it is possible that the effect of phenytoin on BCa in vivo may be more complex, given that VGSCs are expressed on a multitude of cell types, and this would require further investigation [8, 64, 65]. Another FDA-approved VGSC-blocking drug, riluzole, which also inhibits metabotropic glutamate receptors, has shown promise in treating melanomas, and reduces BCa tumor volume in mice [66, 67]. Use of VGSC-blocking local anesthetics during radical prostatectomy surgery is associated with substantially reduced recurrence and metastasis [68]. In conclusion, a growing body of evidence supports the notion that VGSCs may be useful therapeutic targets in cancer.

Our data support the hypothesis that SCN5A is up-regulated in BCa, and plays a role in metastasis. In agreement with previous reports [12, 53], SCN5A expression may be an important event in progression toward metastasis. Together with other studies [12, 13, 15, 53], this study suggests that Na+1.5-mediated Na+ current favors an invasive phenotype. We therefore propose that using VGSC-blocking drugs, in particular those that target persistent Na+ current, should be considered for further study as a potential strategy to improve patient outcomes in metastatic BCa.
