SOME SHARP NORM ESTIMATES IN THE SUBSPACE PERTURBATION PROBLEM

ALEXANDER K. MOTOVILOV AND ALEXEI V. SELIN

ABSTRACT. We discuss the spectral subspace perturbation problem for a self-adjoint operator. Assuming that the convex hull of a part of its spectrum does not intersect the remainder of the spectrum, we establish an a priori sharp bound on variation of the corresponding spectral subspace under off-diagonal perturbations. This bound represents a new, a priori, \( \tan \Theta \) Theorem. We also extend the Davis–Kahan \( \tan 2\Theta \) Theorem to the case of some unbounded perturbations.

1. INTRODUCTION

Assume that the spectrum of a self-adjoint operator \( A \) on a Hilbert space \( \mathcal{H} \) consists of two disjoint components \( \sigma_- \) and \( \sigma_+ \), i.e. \( \text{spec}(A) = \sigma_- \cup \sigma_+ \) and

\[
d = \text{dist}(\sigma_-, \sigma_+) > 0. \tag{1.1}
\]

Then \( \mathcal{H} \) is decomposed into the orthogonal sum \( \mathcal{H} = \mathcal{H}^- \oplus \mathcal{H}^+ \) of the spectral subspaces \( \mathcal{H}_\pm = \text{Ran} E_A(\sigma_\pm) \) where \( E_A(\delta) \) denotes the spectral projection of \( A \) associated with a Borel set \( \delta \subset \mathbb{R} \). It is well known (see, e.g., [19, §135]) that sufficiently small self-adjoint perturbation \( V \) of \( A \) does not close the gaps between the sets \( \sigma_- \) and \( \sigma_+ \) which allows one to think of the corresponding disjoint spectral components \( \sigma'_- \) and \( \sigma'_+ \) of the perturbed operator \( L = A + V \) as a result of the perturbation of the spectral sets \( \sigma_- \) and \( \sigma_+ \), respectively. Moreover, the decomposition \( \mathcal{H} = \mathcal{H}'_- \oplus \mathcal{H}'_+ \) with \( \mathcal{H}'_\pm = \text{Ran} E_L(\sigma'_\pm) \) is continuous in \( V \) in the sense that the projections \( E_L(\sigma'_\pm) \) converge to \( E_A(\sigma_\pm) \) in the operator norm topology as \( \|V\| \to 0 \).

Given a mutual disposition of the spectral components \( \sigma_\pm \) of the operator \( A \), the problem of perturbation theory is to study variation of these components and the corresponding spectral subspaces under the perturbation \( V \). In particular, the questions of interest are as follows (see [13], [16]):

(i) Under what (sharp) condition on \( \|V\| \) do the gaps between the sets \( \sigma_- \) and \( \sigma_+ \) remain open, i.e. \( \text{dist}(\sigma'_-, \sigma'_+) > 0 \)?

(ii) Having established this condition, can one ensure that it implies inequality

\[
\|E_L(\sigma'_-) - E_A(\sigma_-)\| < 1? \tag{1.2}
\]

(Surely, \( \|E_L(\sigma'_+) - E_A(\sigma_+)\| < 1 \) does.)
In general, answer to the question (i) is well known: the gaps between \( \sigma_- \) and \( \sigma_+ \) remain open if
\[
\|V\| < \frac{d}{2}.
\]
Among all perturbations of the operator \( A \) we distinguish the ones that are off-diagonal with respect to the decomposition \( \mathcal{J} = \text{Ran} E_A(\sigma_-) \oplus \text{Ran} E_A(\sigma_+) \), i.e., the perturbations that anticommute with the difference
\[
J = E_A(\sigma_+) - E_A(\sigma_-)
\]
of the spectral projections \( E_A(\sigma_+) \) and \( E_A(\sigma_-) \). If one restricts oneself to perturbations \( V \) of this class then inequality \( \text{dist}(\sigma'_-, \sigma'_+) > 0 \) is ensured by the weaker condition
\[
\|V\| < \frac{\sqrt{3}}{2} \frac{d}{2}
\]
proven in [16, Theorem 1]. Similarly to (1.3), condition (1.5) is sharp.

For a review of the known answers to the question (ii) we refer to [13] in case of the general bounded perturbations and to [16] in case of the off-diagonal ones. Notice that complete answers to the question (ii) were found only under certain additional assumptions on the mutual disposition of the sets \( \sigma_- \) and \( \sigma_+ \). It is still an open problem whether or not the corresponding conditions (1.3) and (1.5) imply (1.2) under the only assumption (1.1).

In the present paper we are concerned with the off-diagonal perturbations and restrict ourselves to two particular mutual dispositions of the spectral sets \( \sigma_- \) and \( \sigma_+ \). The first one corresponds to the case where the sets \( \sigma_- \) and \( \sigma_+ \) are subordinated, say
\[
\sup \sigma_- < \inf \sigma_+.
\]
The second case under consideration corresponds to a disposition with one of the sets \( \sigma_- \) and \( \sigma_+ \) lying in a (finite) gap of the other set, say
\[
\sigma_+ \cap \text{conv}(\sigma_-) = \emptyset,
\]
where \( \text{conv}(\sigma) \) denotes the convex hull of a set \( \sigma \subset \mathbb{R} \).

In both these cases the perturbed spectral sets \( \sigma'_- \) and \( \sigma'_+ \) are known to remain disjoint under requirements on \( \|V\| \) much weaker than that of (1.5).

In particular, if (1.6) holds then for any bounded off-diagonal perturbation \( V \) the interval \( (\sup \sigma_-, \inf \sigma_+) \) is in the resolvent set of the perturbed operator \( L = A + V \), and thus \( \sigma'_- \subset (-\infty, \sup \sigma_-] \) and \( \sigma'_+ \subset [\inf \sigma_+, +\infty) \) (see [2], [8]; cf. [15]). Moreover, in this case the following norm estimate holds [8]
\[
\|E_L(\sigma'_-) - E_A(\sigma_-)\| \leq \sin\left(\frac{1}{2} \arctan \frac{2\|V\|}{d}\right) < \frac{\sqrt{2}}{2}.
\]
This (sharp) bound on the difference of the spectral projection \( E_L(\sigma'_-) \) and \( E_A(\sigma_-) \) is known as the Davis–Kahan \( \tan 2\Theta \) Theorem since it can be written in the equivalent form \( \|\tan 2\Theta\| \leq \frac{\|V\|}{d} \) where \( \Theta \) is the operator angle between the subspaces \( \mathcal{J}_- ' \) and \( \mathcal{J}_- \) (or between the subspaces \( \mathcal{J}_+ ' \) and \( \mathcal{J}_+ \)). For definition of the operator angle between two subspaces see, e.g., [14].
Our first principal result is an extension of the tan 2Θ Theorem that holds not only for bounded but also for some unbounded off-diagonal perturbations $V$.

**Theorem 1.** Given a self-adjoint operator $A$ on the Hilbert space $\mathcal{H}$ assume that 

$$\text{spec}(A) = \sigma_- \cup \sigma_+ \text{ and } \sup \sigma_- < \inf \sigma_+.$$ 

Suppose that a symmetric operator $V$ on $\mathcal{H}$ with $\text{Dom}(V) \supset \text{Dom}(A)$ is off-diagonal with respect to the decomposition $\mathcal{H} = \text{Ran} E_A(\sigma_-) \oplus \text{Ran} E_A(\sigma_+)$ and the closure

$L = A + V$ of the sum $A + V$ with $\text{Dom}(A + V) = \text{Dom}(A)$ is a self-adjoint operator.

Then the spectrum of $L$ consists of two subordinated components $\sigma'_-$ and $\sigma'_+$ such that

$$\sigma'_- \subset (-\infty, \sup \sigma_-], \quad \sigma'_+ \subset [\inf \sigma_+, +\infty),$$

and the following inequality holds

$$\|E_L(\sigma'_-) - E_A(\sigma_-)\| \leq \sin \left( \frac{1}{2} \arctan \kappa \right), \quad (1.8)$$

where

$$\kappa = \inf_{\sup \sigma_- < \mu < \inf \sigma_+} \sup_{x \in \text{Dom}(A), \|x\| = 1} \frac{|\langle x, JV x \rangle|}{\langle x, A - \mu \rangle}$$

with $J$ given by (1.4).

Notice that throughout the paper we adopt the natural convention that

$$\arctan(+\infty) = \pi/2.$$ 

In particular, under this convention inequality (1.8) for $\kappa = +\infty$ reads

$$\|E_L(\sigma'_-) - E_A(\sigma_-)\| \leq \frac{\sqrt{2}}{2}.$$ 

By Remark 4.6 (iii) below the estimate (1.8) is sharp.

Theorem 1 is a corollary to a more general statement (Theorem 4.4) that is valid even in the case where $\sup \sigma_- = \inf \sigma_+$. In its turn, the Davis-Kahan tan 2Θ Theorem (Theorem 4.7) appears to be a simple corollary to Theorem 1.

We also remark that for a class of unbounded off-diagonal perturbations studied in [1] (cf. [11], [18]) the rough estimate $\|E_L(\sigma'_-) - E_A(\sigma_-)\| \leq \frac{\sqrt{2}}{2}$ can be proven by combining [1, Theorem 5.3] and [17, Theorem 5.6]. Example 4.5 to Theorem 1 shows that estimate (1.8) may hold (even with finite $\kappa$) for unbounded perturbations that do not fit the assumptions of [1].

As regards the spectral disposition (1.7), it has been proven in [16] (see also [15]) that the gaps between $\sigma_-$ and $\sigma_+$ remain open and the bound (1.2) holds if the perturbation $V$ satisfies condition

$$\|V\| < \sqrt{2}d.$$ 

Moreover, under this condition by [15] Theorems 1 (i) and 3.2] the following inclusions hold:

$$\sigma'_+ \subset \mathbb{R}\setminus \Delta \text{ and } \sigma'_- \subset [\inf \sigma_- - \delta_-, \sup \sigma_+ + \delta_+], \quad (1.9)$$

where $\Delta = (\alpha, \beta), \alpha < \beta$, stands for the finite gap in the set $\sigma_+$ that contains $\sigma_-$ and

$$
\delta_- = \|V\| \tan \left( \frac{1}{2} \arctan \frac{2\|V\|}{\beta - \inf \sigma_-} \right) < \inf \sigma_- - \alpha, \quad (1.10)
$$

$$
\delta_+ = \|V\| \tan \left( \frac{1}{2} \arctan \frac{2\|V\|}{\sup \sigma_- - \alpha} \right) < \beta - \sup \sigma_- . \quad (1.11)
$$

The only known sharp bound [16, Theorem 2.4] (see also [15, Theorem 2]) for the norm of the difference $E_{A+V}(\sigma') - E_A(\sigma_-)$ involves the distance from the initial spectral set $\sigma_+$ to the perturbed spectral set $\sigma'_+$, and thus this bound is an a posteriori estimate.

Our second principal result just adds an a priori sharp bound for the norm $\|E_{A+V}(\sigma') - E_A(\sigma_-)\|$ in the case where (1.7) holds and $\|V\| < d$.

**Theorem 2.** Given a self-adjoint operator $A$ on the Hilbert space $H$ assume that

$\text{spec}(A) = \sigma_- \cup \sigma_+, \quad \text{dist}(\sigma_+, \sigma_-) = d > 0, \quad \text{and} \quad \sigma_+ \cap \text{conv}(\sigma_-) = \emptyset$.

Let $V$ be a bounded self-adjoint operator on $H$ off-diagonal with respect to the decomposition $H = \text{Ran}E_A(\sigma_-) \oplus \text{Ran}E_A(\sigma_+)$. Assume in addition that

$$
\|V\| < d. \quad (1.12)
$$

Then

$$
\|E_L(\sigma') - E_A(\sigma_-)\| \leq \sin \left( \arctan \frac{\|V\|}{d} \right) = \frac{\|V\|}{\sqrt{d^2 + \|V\|^2}}, \quad (1.13)
$$

where $L = A + V$ with $\text{Dom}(L) = \text{Dom}(A)$.

**Remark 3.** Estimate (1.13) can be equivalently written in the form

$$
\|\tan \Theta\| \leq \frac{\|V\|}{d}, \quad (1.14)
$$

where $\Theta$ is the operator angle between the subspaces $\text{Ran}E_A(\sigma_-)$ and $\text{Ran}E_L(\sigma_-)$. Thus, Theorem 2 may be called the a priori $\tan \Theta$ Theorem. It adds a new item to the list of fundamental estimates on the norm of the difference of spectral projections known as $\sin \Theta, \sin 2\Theta, \tan 2\Theta$ Theorems (from [7, 8]) and a posteriori $\tan \Theta$ Theorems (from [8, 15]).

We perform the proofs of both Theorems [1] and [2] by constructing the direct rotation [6] from the subspace $\text{Ran}E_A(\sigma_-)$ to the subspace $\text{Ran}E_L(\sigma_-)$.

Recall that the direct rotation $U$ from a closed subspace $\mathcal{M}$ of a Hilbert space $H$ to a closed subspace $\mathcal{N} \subset H$ with $\dim(\mathcal{M} \cap \mathcal{N}^\perp) = \dim(\mathcal{M}^\perp \cap \mathcal{N})$ is a unitary operator on $H$ mapping $\mathcal{M}$ onto $\mathcal{N}$ and being such that for any other unitary $W$ on $H$ with $\text{Ran}W|_{\mathcal{M}} = \mathcal{N}$ the following inequality holds: $\|I - U\| \leq \|I - W\|$ where $I$ is the identity operator on $H$. That is, the direct rotation is closer (in the operator norm topology) to the identity operator than any other unitary operator on $H$ mapping $\mathcal{M}$ onto $\mathcal{N}$. The norm of the difference between the corresponding orthogonal projections onto $\mathcal{M}$ and $\mathcal{N}$ is completely determined by location of $\text{spec}(U)$ on the unit circumference.
We extract information on the spectrum of the direct rotation from the subspace \( \text{Ran } E_\sigma \) to the subspace \( \text{Ran } E_{\sigma'} \) by using the following auxiliary result which, we think, is of independent interest.

**Theorem 4.** Let \( T \) be a closed densely defined operator on a Hilbert space \( \mathcal{H} \) with the polar decomposition \( T = W|T| \). Assume that \( G \) is a bounded operator on \( \mathcal{H} \) such that both \( GT \) and \( G^*T^* \) are accretive (resp. strictly accretive). Then the products \( GW \) and \( WG \) are also accretive (resp. strictly accretive) operators.

Notice that in this theorem and below an operator \( T \) on the Hilbert space \( \mathcal{H} \) is called accretive (resp. strictly accretive) if
\[
\text{Re}\langle x, Tx \rangle \geq 0 \quad \text{(resp. \( \text{Re}\langle x, Tx \rangle > 0 \)) for any } x \in \text{Dom}(T), \| x \| = 1.
\]

We also adopt the convention that the partial isometry \( W \) in the polar decomposition \( T = W|T| \) is extended to \( \text{Ker}(T) \) by
\[
W|_{\text{Ker}(T)} = 0.
\]
In this way the isometry \( W \) is uniquely defined on the whole space \( \mathcal{H} \) (see, e.g., [12, §VI.7.2]).

A convenient way to construct the direct rotation between two closed subspaces of a Hilbert space is rendered by using a pair of self-adjoint involutions associated with these subspaces. Although the relative geometry of two subspaces is studied in great detail (see, e.g., [10], [12], [19]), for convenience of the reader we give in Section 2 a short but self-contained exposition of the subject reformulating some results in terms of a pair of involutions.

The remaining part of the article is organized as follows. Section 3 contains a proof of Theorem 4. The principal result of this section is Theorem 3.4 that allows one to compare two involutions one of which is associated with a self-adjoint operator. Theorem 1 and several other related statements are proven in Section 4. Section 5 contains a proof of Theorem 2. Notice that Theorem 2 appears to be a corollary to a more general statement (Theorem 5.3) proven under a weaker than (1.12) but more detail assumption (5.3) involving the length of the finite gap in \( \sigma_+ \) that contains the other spectral set \( \sigma_- \).

We conclude the introduction with description of some more notations used throughout the paper. The identity operator on any Hilbert space \( \mathcal{H} \) is denoted by \( I \). Given a linear operator \( T \) on \( \mathcal{H} \), by \( \mathcal{W}(T) \) we denote its numerical range,
\[
\mathcal{W}(T) = \{ \lambda \in \mathbb{C} | \lambda = \langle x, Tx \rangle \text{ for some } x \in \text{Dom}(T), \| x \| = 1 \}.
\]

We use the standard concepts of commuting and anticommuting operators dealing only with the case where at least one of the operators involved is bounded (see, e.g., [5, §3.1.1]). Assuming that \( S \) and \( T \) are operators on \( \mathcal{H} \) suppose that the operator \( S \) is bounded. We say that the operators \( S \) and \( T \) commute (resp. anticommute) and write \( S \sim T \) or \( T \sim S \) (resp. \( S \prec T \) or \( T \prec S \)) if \( ST \subset TS \) (resp. \( ST \subset -TS \)).

2. A PAIR OF INVOLUTIONS

2.1. An involution. We start with recalling the concept of a (self-adjoint) involution on a Hilbert space. This concept is a main tool we use in the present paper.
Notice that in the theory of spaces with indefinite metric the involutions are often called canonical symmetries (see, e.g., [4]).

**Definition 2.1.** A linear operator $J$ on the Hilbert space $H$ is called an **involution** if

$$J^* = J \quad \text{and} \quad J^2 = I. \quad (2.1)$$

In particular, if $P^-$ and $P^+ = I - P^-$ are two complementary orthogonal projections on $H$ then the differences $P^+ - P^-$ and $P^- - P^+$ are involutions.

By definition, any involution $J$ is a self-adjoint operator. In fact, it is also a unitary operator since (2.1) yields

$$J^{-1} = J^*.$$

Hence $\text{spec}(J) = \{-1, 1\}$ and the spectral decomposition of $J$ reads

$$J = \int_{\mathbb{R}} \lambda E_J(d\lambda) = E_J(\{+1\}) - E_J(\{-1\}),$$

which implies that any involution on $H$ is the difference between two complementary orthogonal projections. Obviously, the projections $E_J(\{\pm 1\})$ are equal to

$$E_J(\{+1\}) = \frac{1}{2}(I + J) \quad \text{and} \quad E_J(\{-1\}) = \frac{1}{2}(I - J). \quad (2.2)$$

**Definition 2.2.** Let $J$ be an involution on the Hilbert space $H$. The subspaces

$$H^- = \text{Ran } E_J(\{-1\}) \quad \text{and} \quad H^+ = \text{Ran } E_J(\{+1\}) \quad (2.3)$$

are called the **negative** and **positive** subspaces of the involution $J$, respectively. The decomposition

$$H = H^- \oplus H^+ \quad (2.4)$$

of $H$ into the orthogonal sum of the subspaces (2.3) is said to be **associated** with $J$.

Recall that a linear operator $A$ on $H$ is called diagonal with respect to decomposition (2.4) if the subspace $H^-$ (and hence the subspace $H^+$) reduces $A$. A linear operator $V$ on $H$ is said to be off-diagonal with respect to decomposition (2.4) if

$$H^- \cap \text{Dom}(V) = \text{Ran } P^-|_{\text{Dom}(V)}, \quad H^+ \cap \text{Dom}(V) = \text{Ran } P^+|_{\text{Dom}(V)},$$

where $P^-$ and $P^+$ are orthogonal projections onto $H^-$ and $H^+$, respectively, and

$$\text{Ran } V|_{H^- \cap \text{Dom}(V)} \subset H^+, \quad \text{Ran } V|_{H^+ \cap \text{Dom}(V)} \subset H^- \quad (2.5)$$

A criterion for an operator on $H$ to be diagonal or off-diagonal with respect to the orthogonal decomposition of $H$ associated with an involution $J$ can be formulated in terms of a commutation relation between this operator and $J$.

**Lemma 2.3.** A linear operator $A$ on the Hilbert space $H$ is diagonal with respect to the orthogonal decomposition of $H$ associated with an involution $J$ if and only if $J\sim A$.

**Proof.** This assertion is an immediate corollary to [5, Theorem 1 in §3.6]. \(\square\)

**Lemma 2.4.** A linear operator $V$ on the Hilbert space $H$ is off-diagonal with respect to the orthogonal decomposition of $H$ associated with an involution $J$ if and only if $J\sim V$. 

Proof. “Only if part.” Assume that \( V \) is off-diagonal with respect to an orthogonal decomposition of \( J \) associated with \( J \). Let \( P^\pm = E_I(P^\pm) \). Then \( J = P^+ - P^- \) and \( P^+ + P^- = I \). By the hypothesis one infers that \( P^\pm x \in \text{Dom}(V) \) for any \( x \in \text{Dom}(V) \). Hence \( x \in \text{Dom}(V) \) implies \( Jx \in \text{Dom}(V) \). Moreover, for any \( x \in \text{Dom}(V) \) the following chain of equalities holds

\[
VJx = VP^+x - VP^-x \\
= P^-VP^+x - P^+VP^-x \\
= P^-V(P^+ + P^-)x - P^+V(P^+ + P^-)x \\
= (P^- - P^+)Vx \\
= -JVx,
\]

since \( P^+VP^+x = P^-VP^-x = 0 \) (cf. (2.5)). Thus \( J \sim V \).

“If part.” Suppose that \( J \sim V \) which means that (i) \( x \in \text{Dom}(V) \) implies \( Jx \in \text{Dom}(V) \) and (ii) \( VJx = -JVx \) for all \( x \in \text{Dom}(V) \). Let \( \tilde{J} = \text{Ran} E_I(P^\pm) \). Condition (i) and equalities (2.2) imply that \( E_I(P^\pm)x \in \text{Dom}(V) \) whenever \( x \in \text{Dom}(V) \). Therefore it follows from condition (ii) that if \( x_- \in \tilde{J}_- \cap \text{Dom}(V) \), then \( Vx_- = -VJx_- = JVx_- \). Hence \( Vx_- \in \tilde{J}_+ \) for all \( x_- \in \tilde{J}_- \cap \text{Dom}(V) \). In a similar way one verifies that \( Vx_+ \in \tilde{J}_- \) for all \( x_+ \in \tilde{J}_+ \cap \text{Dom}(V) \). Hence \( V \) is off-diagonal with respect to the decomposition of \( \tilde{J} \) associated with \( J \), which completes the proof.

\[ \square \]

Remark 2.5. Operators that are diagonal or off-diagonal with respect to the decomposition (2.4) are often written in the block operator matrix form,

\[
A = \begin{pmatrix} A_- & 0 \\ 0 & A_+ \end{pmatrix}, \quad V = \begin{pmatrix} 0 & V_+ \\ V_- & 0 \end{pmatrix},
\]

where \( A_\pm \) are the parts of the diagonal operator \( A \) in \( \tilde{J}_\pm \), and \( V_\pm \) are the corresponding restrictions of the off-diagonal operator \( V \) to \( \tilde{J}_\pm \),

\[
A_\pm = A|_{\text{Dom}(A) \cap \tilde{J}_\pm}, \quad V_\pm = V|_{\text{Dom}(V) \cap \tilde{J}_\pm}.
\]

In particular, if both \( A \) and \( V \) are closed operators and, in addition, \( V \) is bounded, then the closed operator \( L = A + V \) with \( \text{Dom}(L) = \text{Dom}(A) \) admits the block operator matrix representation

\[
L = \begin{pmatrix} A_- & V_+ \\ V_- & A_+ \end{pmatrix}. \tag{2.6}
\]

In this case

\[
A = \frac{1}{2}(L + JLJ), \quad V = \frac{1}{2}(L - JLJ),
\]

where \( J \) is the involution that corresponds to the decomposition (2.4).

Notice that the study of invariant subspaces for block operator matrices of the form (2.4) is closely related to the question concerning existence of solutions to the associated operator Riccati equations (see, e.g., [3] and references therein).
2.2. **Involutions in the acute case.** Recall that two closed subspaces $\mathcal{M}$ and $\mathcal{N}$ of a Hilbert space $\mathcal{H}$ are said to be in the acute case if
\[ \mathcal{M} \cap \mathcal{N}^\perp = \{0\} \quad \text{and} \quad \mathcal{M}^\perp \cap \mathcal{N} = \{0\}. \]
To formulate the notion of the acute case in terms of the corresponding involutions we adopt the following definition.

**Definition 2.6.** Involutions $J$ and $J'$ on the Hilbert space $\mathcal{H}$ are said to be in the acute case if
\[ \text{Ker}(I + J'J) = \{0\}. \]

**Remark 2.7.** By inspection, $\text{Ker}(I + J'J) = \text{Ker}(I + JJ')$ which means that this definition is symmetric with respect to the entries $J$ and $J'$.

**Lemma 2.8.** If involutions $J$ and $J'$ are in the acute case and $J \sim J'$, then $J = J'$.

**Proof.** Taking into account the self-adjointness of both $J$ and $J'$, the hypothesis $JJ' = J'J$ implies that the unitary operator $J'J$ is self-adjoint. Hence $\text{spec}(J'J) \subset \{-1, 1\}$. Then from the assumption that $J$ and $J'$ are in the acute case it follows that $-1 \not\in \text{spec}(J'J)$. This yields $J'J = I$ and hence $J = J'$.

Some criteria for a pair of involutions $J$ and $J'$ to be in the acute case are presented in Lemma 2.9 below. In particular, this lemma justifies Definition 2.6 stating that $J$ and $J'$ are in the acute case if and only if their negative (resp. positive) subspaces are in the acute case.

One of the criteria in Lemma 2.9 involves the numerical range $\mathcal{W}(J'J)$ of the product $J'J$. Since $J'J$ is a unitary operator, its numerical range is a subset of the unit disc $\{\lambda \in \mathbb{C} \mid |\lambda| \leq 1\}$. Equalities $J'J = J(J'J)J = J(J'J)^{-1}$ imply that the products $J'J$ and $JJ'$ are unitarily equivalent. Hence $\mathcal{W}(J'J) = \mathcal{W}(JJ')$. By $JJ' = (JJ')^*$ this means that the numerical range of $J'J$ is symmetric with respect to the real axis.

**Lemma 2.9.** Let $J$ and $J'$ be two involutions on the Hilbert space $\mathcal{H}$. Assume that $\mathcal{H}_\pm = \text{Ran} E_{\mathbb{P}}(\{\pm 1\})$ and $\mathcal{H}'_\pm = \text{Ran} E_{\mathbb{P}'}(\{\pm 1\})$. The following four statements are equivalent:

1. $\mathcal{H}_- \cap \mathcal{H}'_+ = \{0\}$ and $\mathcal{H}_+ \cap \mathcal{H}'_- = \{0\}$,
2. $\text{Ker}(I + J'J) = \{0\}$,
3. $\|\lambda J'Jx\| < \|x\|$ for all $x \in \mathcal{H}_\pm$, $x \neq 0$,
4. $-1 \not\in \mathcal{W}(J'J)$.

**Proof.** We prove the implications $(i) \Rightarrow (ii) \Rightarrow (iii) \Rightarrow (iv) \Rightarrow (i)$.

$(i) \Rightarrow (ii)$. We prove this implication by contradiction. Suppose that $\text{Ker}(I + J'J) \neq \{0\}$ and $x \in \text{Ker}(I + J'J)$ is a non-zero vector. Representing this vector as $x = x_+ + x_-$ with $x_- \in \mathcal{H}_-$ and $x_+ \in \mathcal{H}_+$ one obtains $(I + J'J)x = (I - J')x_- + (I + J')x_+$ and hence
\[ (I - J')x_- + (I + J')x_+ = 0 \quad (2.7) \]
since $(I + J'J)x = 0$. Applying $(I - J')$ to both parts of (2.7) gives $(I - J')^2 x_- = 0$ and thus $J'x_- = x_-$. Therefore $x_-$ is an eigenvector of the operator $J'$ corresponding...
to the eigenvalue $+1$ which means $x_- \in \mathcal{S}_- \cap \mathcal{S}'_+$. In a similar way, by applying $(I + J')$ to both parts of (2.7), one concludes that $J'x_+ = -x_+$ and hence $x_+ \in \mathcal{S}_+ \cap \mathcal{S}'_-$. Then it follows from condition (i) that $x_- = x_+ = 0$ and thus $x = 0$ which contradicts the assumption.

(ii) $\Rightarrow$ (iii). It follows from condition (ii) that $\| (I + J')x \| > 0$ for any non-zero $x \in \mathcal{S}$. Then by taking into account the identities

$$\|(J - J')x\|^2 + \|(J + J')x\|^2 = 4\|x\|^2$$

and

$$\|(J + J')x\| = \|J'(J' + J)x\| = \|(I + J'J)x\|$$

one easily concludes that (ii) implies (iii).

(iii) $\Rightarrow$ (iv). By inspection

$$\|x\|^2 + \text{Re} \langle x, J'Jx \rangle = \frac{1}{2} \left\{ 4\|x\|^2 - \|(J - J')x\|^2 \right\}.$$ 

Hence (iii) implies

$$\|x\|^2 + \text{Re} \langle x, J'Jx \rangle > 0 \quad \text{for any non-zero } x \in \mathcal{S}.$$ 

In particular, this means that $\text{Re} \langle x, J'Jx \rangle > -1$ for any $x \in \mathcal{S}$ such that $\|x\| = 1$ and therefore $-1 \notin \mathcal{W}(J'J)$.

(iv) $\Rightarrow$ (i). Suppose that at least one of the subspaces $\mathcal{S}_- \cap \mathcal{S}'_+$ and $\mathcal{S}_+ \cap \mathcal{S}'_-$ is non-trivial. Pick up vectors $x_- \in \mathcal{S}_- \cap \mathcal{S}'_+$ and $x_+ \in \mathcal{S}_+ \cap \mathcal{S}'_-$ such that at least one of them is non-zero. Clearly, $J'J(x_- + x_+) = J'(-x_- + x_+) = -(x_- + x_+)$ which means that $-1$ is an eigenvalue of the operator $J'J$ and thus $-1 \notin \mathcal{W}(J'J)$. This contradicts the assumption (iv) and thus proves the implication. \hfill \Box

Remark 2.10. Making use of relationship (2.2) between an involution and its spectral projections yields

$$P^+ - P^- = P^- - P'^- = \frac{J' - J}{2},$$

where $P^\pm = E_J(\{\pm 1\})$ and $P'^\pm = E_{J'}(\{\pm 1\})$.

Corollary 2.11. If

$$\|P'^- - P^-\| < 1 \quad \text{or} \quad \|P'^+ - P^+\| < 1$$

holds then the involutions $J$ and $J'$ are in the acute case. Hence, the negative (resp. positive) subspaces of $J$ and $J'$ are also in the acute case.

2.3. The direct rotation. Let $J$ and $J'$ be involutions on $\mathcal{S}$. Assume that $\mathcal{S}_-$ and $\mathcal{S}_+$ are the negative and positive subspaces of $J$, respectively. Similarly, assume that $\mathcal{S}'_-$ and $\mathcal{S}'_+$ are the negative and positive subspaces of $J'$. It is well known (see, e.g., [6, Theorem 3.1]) that if

$$\dim(\mathcal{S}_- \cap \mathcal{S}'_+) = \dim(\mathcal{S}_+ \cap \mathcal{S}'_-), \quad (2.8)$$

then there exists a unitary operator $W$ on $\mathcal{S}$ mapping $\mathcal{S}_-$ onto $\mathcal{S}'_-$ and $\mathcal{S}_+$ onto $\mathcal{S}'_+$. Clearly, $W$ satisfies the commutation relation

$$J'W = WJ. \quad (2.9)$$
In particular, by Lemma 2.9 such a unitary $W$ exists if $J$ and $J'$ are in the acute case. The canonical choice of the unitary mapping of one subspace in the Hilbert space onto another, the so-called direct rotation, was suggested by C. Davis in [6] and T. Kato in [12, Sections I.4.6 and I.6.8]. The idea of this choice goes back yet to B. Sz.-Nagy (see [19, §105]). We adopt the following definition of the direct rotation.

**Definition 2.12.** Let $J$ and $J'$ be involutions on the Hilbert space $H$. A unitary operator $U$ on $H$ is called the direct rotation from $J$ to $J'$ if

$$(i) \quad J'U = UJ, \quad (ii) \quad U^2 = J'J, \quad (iii) \quad \text{Re} \ U \geq 0.$$  \quad (2.10)

**Remark 2.13.** The spectrum of any direct rotation is a subset of the unit circumference lying in the closed right half-plane symmetrically with respect to the real axis. To see this, observe that equalities $(i)$ and $(ii)$ imply $U^* = JUJ$ by taking into account that $U$ is a unitary operator. Hence the operator $U$ is unitary equivalent to its adjoint and thus the spectrum of $U$ is symmetric with respect to the real axis. From $(iii)$ it follows that this spectrum is a subset of the half-plane $\{z \in \mathbb{C} \mid \text{Re} \ z \geq 0\}$. To complete the proof of the statement it only remains to recall that the spectrum of any unitary operator lies on the unit circumference.

We give a short proof of the existence and uniqueness of the direct rotation for the instance where the corresponding involutions are in the acute case. For a different proof of this fact see [8, Propositions 3.1 and 3.3].

**Theorem 2.14.** If involutions $J$ and $J'$ are in the acute case then there is a unique direct rotation from $J$ to $J'$.

**Proof.** We divide the proof into two parts. In the first part we prove the existence of a direct rotation from $J$ to $J'$. The uniqueness of the direct rotation is proven in the second part.

(Existence.) Set $T = I + J'J$. One easily verifies that $T$ is a normal operator. By hypothesis

$$\text{Ker}(T) = \text{Ker}(T^*) = \{0\}$$  \quad (2.11)

taking into account Remark 2.7. Hence the the isometry $U$ in the polar decomposition

$$T = U \abs{T} = \abs{T} U,$$  \quad (2.12)

is a unitary operator (see [19, §110]).

By inspection

$$J'T = TJ$$  \quad (2.13)

and thus

$$J\abs{T}^2 = JT^*T = T^*J'T = T^*TJ = \abs{T}^2 J,$$

$$J'\abs{T}^2 = J'TT^* = TT^*J' = \abs{T}^2 J'.$$

Hence $J \sim \abs{T}$ and $J' \sim \abs{T}$. Then (2.12) and (2.13) yield $\abs{T}(J'U - UJ) = 0$, which implies that

$$J'U = UJ$$  \quad (2.14)
since \( \ker(|T|) = \ker(T) = \{0\} \). Observing that \( J'JT^* = T \), by the same reasoning one obtains \( |T|(U - J'JU^*) = 0 \). Hence \( U = J'JU^* \) and thus

\[
U^2 = J'J. \tag{2.15}
\]

Finally, \( T + T^* = |T|^2 \) and \( T + T^* = |T|(U + U^*) \) imply \( |T|(U + U^* - |T|) = 0 \). Therefore

\[
\Re U = \frac{1}{2}|T| \geq 0. \tag{2.16}
\]

Comparing (2.14), (2.15), and (2.16) with (2.10), one concludes that \( U \) is the direct rotation from \( J \) to \( J' \).

(Uniqueness.) Suppose that \( U' \) is another unitary operator such that \( U'^2 = U^2 \) and \( \Re U' \geq 0 \). By inspection,

\[
(\Re U')^2 = \frac{1}{2} \left( I + \Re(U'^2) \right) = \frac{1}{2} \left( I + \Re(U^2) \right) = (\Re U)^2.
\]

Then it follows from the uniqueness of the positive square root of a positive operator that \( \Re U = \Re U' \). In addition, the requirement \( \Im(U^2) = \Im(U'^2) \) implies \( \Re U(\Im U - \Im U') = 0 \) which means that \( \Im U = \Im U' \) since \( \ker(\Re U) = \ker(|T|) = \{0\} \) by combining (2.11) and (2.16). Thus \( U' = \Re U + i\Im U = U \), completing the proof. \( \square \)

Remark 2.15. In the nonacute case the direct rotation exists if and only if (2.8) holds (see [8, Proposition 3.2]). If it exists, it is not unique.

To specify location of the spectrum of a unitary operator on the unit circumference we introduce the notion of the spectral angle.

Definition 2.16. Let \( W \) be a unitary operator. The number

\[
\varphi(W) = \sup_{z \in \text{spec}(W)} |\arg z|, \quad \arg z \in (-\pi, \pi],
\]

is called the spectral angle of \( W \).

Remark 2.17. \( \varphi(W^*) = \varphi(W) \).

Remark 2.18. The (self-adjoint) operator angle between two closed subspaces in a Hilbert space is expressed through the direct rotation \( U \) from one of these subspaces to the other one by \( \Theta = \arccos(\Re U) \) (see [8, Eq. (1.18)]). Hence \( \varphi(U) \) is nothing but the spectral radius of the corresponding operator angle \( \Theta \).

The next statement shows that the spectral angle \( \varphi(W) \) is a quantity that characterizes the distinction of the unitary operator \( W \) from the identity operator.

Lemma 2.19. Let \( W \) be a unitary operator. Then

\[
\|I - W\| = 2 \sin \left( \frac{\varphi(W)}{2} \right). \tag{2.17}
\]
Proof. Observe that $I - W$ is a normal operator. Then by using the spectral mapping theorem one concludes that the following chain of equalities holds:

\[ \|I - W\| = \sup_{\lambda \in \text{spec}(I - W)} |\lambda| \]
\[ = \sup_{z \in \text{spec}(W)} |1 - z| \]
\[ = \sup_{z \in \text{spec}(W)} 2\sin\left(\frac{|\arg z|}{2}\right) \]
\[ = 2\sin\left(\frac{1}{2} \sup_{z \in \text{spec}(W)} |\arg z| \right) \]
\[ = 2\sin\left(\frac{\vartheta(W)}{2}\right), \]

where $\arg z \in (-\pi, \pi]$. \hfill \Box

Remark 2.20. If $U$ is the direct rotation from an involution $J$ to an involution $J'$ then it possesses the extremal property

\[ \vartheta(U) \leq \vartheta(W), \]

where $W$ is any other unitary operator satisfying (2.9). This can be easily seen from (2.17) by using [6, Theorem 7.1] which states that $\|I - U\| \leq \|I - W\|$.

Remark 2.21. Again assume that $U$ is the direct rotation from an involution $J$ to an involution $J'$. Then by (2.10) the spectral mapping theorem implies

\[ 0 \leq \vartheta(U) \leq \frac{\pi}{2} \quad \text{and} \quad \vartheta(U) = \frac{1}{2} \vartheta(J'J). \quad (2.18) \]

Since $\|J' - J\| = \|I - J'J\|$, by (2.17) it follows from (2.18) that

\[ \|J' - J\| = 2\sin\left(\frac{\vartheta(J'J)}{2}\right) = 2\sin \vartheta(U). \]

Hence by Remark 2.10

\[ \|P^{+} - P^{+}\| = \|P^{-} - P^{-}\| = \sin \vartheta(U), \quad (2.19) \]

where $P^{\pm} = E_{J}(\{\pm 1\})$ and $P^{\pm} = E_{f}(\{\pm 1\})$.

In the proof of the next lemma we will use the following notation. Assume that $\mathcal{S}$ is a subset of the complex plane. Then $e^{i\varphi} \mathcal{S}$ denotes the result of rotation of $\mathcal{S}$ by the angle $\varphi \subset (-\pi, \pi]$ around the origin, that is,

\[ e^{i\varphi} \mathcal{S} = \{z \in \mathbb{C} \mid z = e^{i\varphi} \zeta \text{ for some } \zeta \in \mathcal{S}\}. \]

Lemma 2.22. Let $W_{1}$ and $W_{2}$ be two unitary operators on the Hilbert space $\mathcal{H}$. Then

\[ |\vartheta(W_{1}) - \vartheta(W_{2})| \leq \vartheta(W_{2}W_{1}) \leq \vartheta(W_{1}) + \vartheta(W_{2}). \quad (2.20) \]
Indeed, if since by the Schwartz inequality

\[ \vartheta(W_2W_1) \leq \vartheta(W_1) + \vartheta(W_2) \]  

(2.21)

Denote by \( \vartheta_1 \), \( \vartheta_2 \) and \( \vartheta_3 \) the spectral angles of \( W_1 \), \( W_2 \), and \( W_2 W_1 \), respectively. The case \( \vartheta_1 + \vartheta_2 \geq \pi \) is trivial since \( \vartheta_3 \leq \pi \) by Definition 2.16. If \( \vartheta_1 + \vartheta_2 < \pi \), we prove (2.21) by contradiction. Suppose that the opposite inequality holds, that is,

\[ \vartheta_3 > \vartheta_1 + \vartheta_2. \]

Then there is a number \( \varphi \in (-\pi, \pi) \) such that \( e^{i\varphi} \in \sigma(W_2 W_1) \)

\[ \vartheta_1 + \vartheta_2 < |\varphi| \leq \pi. \]  

(2.22)

Since \( W_2 W_1 \) is a normal (unitary) operator, there exists a sequence of vectors \( x_n \in \mathfrak{H}, \ n = 1, 2, ... \), such that

\[ \|x_n\| = 1 \quad \text{and} \quad \|W_2 W_1 x_n - e^{i\varphi} x_n\| \to 0, \quad n \to \infty. \]  

(2.23)

Indeed, if \( e^{i\varphi} \) is an eigenvalue of \( W_2 W_1 \), to satisfy (2.23) one simply takes \( x_n = x_\varphi \), \( n = 1, 2, ... \), where \( x_\varphi \) is a normalized eigenvector of \( W_2 W_1 \) corresponding to the eigenvalue \( e^{i\varphi} \), i.e. \( W_2 W_1 x_\varphi = e^{i\varphi} x_\varphi \). Otherwise such a sequence exists by the Weyl criterion for the essential spectrum.

Let \( z_{1,n} = (x_n, W_1 x_n) \) and \( z_{2,n} = (x_n, W_2^* x_n) \). Clearly, (2.23) yields

\[ |z_{1,n} - e^{i\varphi} z_{2,n}| \to 0, \quad n \to \infty, \]  

(2.24)

since by the Schwartz inequality

\[ |z_{1,n} - e^{i\varphi} z_{2,n}| = |\langle x_n, W_1 x_n - e^{i\varphi} W_2^* x_n \rangle| \]

\[ \leq \|W_1 x_n - e^{i\varphi} W_2^* x_n\| = \|W_2 W_1 x_n - e^{i\varphi} x_n\|. \]

Taking into account that \( z_{1,n} \subset \mathcal{H}(W_1) \) and \( z_{2,n} \subset \mathcal{H}(W_2) \), from (2.24) one concludes that

\[ \text{dist}(\mathcal{H}(W_1), e^{i\varphi} \mathcal{H}(W_2^*)) = 0. \]  

(2.25)

Meanwhile, if \( W \) is a unitary operator with the spectral angle \( \vartheta \), the spectral theorem implies

\[ \mathcal{H}(W) \subset \mathfrak{S}_\vartheta \quad \text{and} \quad \mathcal{H}(W^*) \subset \mathfrak{S}_\vartheta, \]

where

\[ \mathfrak{S}_\vartheta = \{ z \in \mathbb{C} \mid \Re z \geq \cos \vartheta \quad \text{and} \quad |z| \leq 1 \} \]

is a segment of the closed unit disc centered at the origin. Therefore, \( \mathcal{H}(W_1) \subset \mathfrak{S}_{\vartheta_1} \) and \( \mathcal{H}(W_2) \subset \mathfrak{S}_{\vartheta_2} \). Obviously, \( e^{i\varphi} \mathcal{H}(W_2^*) \subset e^{i\varphi} \mathfrak{S}_{\vartheta_2} \) and hence

\[ \text{dist}(\mathcal{H}(W_1), e^{i\varphi} \mathcal{H}(W_2^*)) \geq \text{dist}(\mathfrak{S}_{\vartheta_1}, e^{i\varphi} \mathfrak{S}_{\vartheta_2}). \]  

(2.26)

One easily verifies by inspection that under the assumption (2.22)

\[ \text{dist}(\mathfrak{S}_{\vartheta_1}, e^{i\varphi} \mathfrak{S}_{\vartheta_2}) = 2 \sin \left( \frac{\varphi - \vartheta_1 - \vartheta_2}{2} \right) \sin \left( \frac{\varphi + \vartheta_2 - \vartheta_1}{2} \right) > 0 \]

and thus by (2.26)

\[ \text{dist}(\mathcal{H}(W_1), e^{i\varphi} \mathcal{H}(W_2^*)) > 0 \]

which contradicts (2.25). This completes the proof of (2.21).
By Remark 2.17, inequality (2.21) implies
\[ \vartheta(W_2) = \vartheta(W_2 W_1 W_1^*) \leq \vartheta(W_2 W_1) + \vartheta(W_1) \]  
(2.27)
\[ \vartheta(W_1) = \vartheta(W_2^* W_2 W_1) \leq \vartheta(W_2^*) + \vartheta(W_2 W_1) = \vartheta(W_2) + \vartheta(W_2 W_1). \]  
(2.28)
Combining (2.27) and (2.28) yields the left inequality in (2.20). The proof is complete. \(\square\)

Remark 2.23. Setting \(W_1 = e^{i\vartheta_1}I\) and \(W_2 = e^{i\vartheta_2}I\) with \(\vartheta_1, \vartheta_2\) appropriate reals, one verifies that both inequalities of (2.20) are sharp.

3. A PROPERTY OF THE POLAR DECOMPOSITION

In this section we give a proof of Theorem 4. We also derive corollaries to this theorem for the case where one of the operators involved is self-adjoint and the other one is related to an involution.

We start with an auxiliary result.

Lemma 3.1. Let \(A\) be a positive operator on the Hilbert space \(\mathcal{H}\). Suppose that \(x, y \in \mathcal{H}\) are such that
\[ \text{Re} \langle x, A(A^2 + \alpha)^{-1}y \rangle > 0 \quad (\geq 0) \quad \text{for any} \quad \alpha > 0. \]  
(3.1)
Then
\[ \text{Re} \langle x, Qy \rangle > 0 \quad (\geq 0), \]  
(3.2)
where \(Q\) is the orthogonal projection onto \(\text{Ker}(A)^\perp\).

Proof. By the spectral theorem
\[ \text{Re} \langle x, A(A^2 + \eta^2)^{-1}y \rangle = \int_{\mathbb{R}} \frac{\lambda m(d\lambda)}{\lambda^2 + \eta^2} = \int_{(0, +\infty)} \frac{\lambda m(d\lambda)}{\lambda^2 + \eta^2}, \quad 0 \neq \eta \in \mathbb{R}, \]
where for any Borel set \(\delta \subset \mathbb{R}\) the Lebesgue–Stieltjes measure \(m(\delta)\) reads
\[ m(\delta) = \text{Re} \langle x, E_A(\delta)y \rangle. \]
Hence for any \(\varepsilon > 0\)
\[ \int_{\varepsilon}^{1/\varepsilon} d\eta \text{ Re} \langle x, A(A^2 + \eta^2)^{-1}y \rangle = \int_{\varepsilon}^{1/\varepsilon} \frac{\lambda m(d\lambda)}{\lambda^2 + \eta^2} = \int_{(0, +\infty)} m(d\lambda) \int_{\varepsilon}^{1/\varepsilon} \frac{\lambda d\eta}{\lambda^2 + \eta^2} \]
by the Fubini theorem. Therefore
\[ \int_{\varepsilon}^{1/\varepsilon} d\eta \text{ Re} \langle x, A(A^2 + \eta^2)^{-1}y \rangle = \int_{(0, +\infty)} m(d\lambda) \left[ \arctan \left( \frac{1}{\lambda \varepsilon} \right) - \arctan \left( \frac{\varepsilon}{\lambda} \right) \right]. \]  
(3.3)
From (3.3) one immediately infers that
\[
\lim_{\epsilon \downarrow 0} \frac{1}{\epsilon} \int d\eta \Re \langle x, A^2 + \eta^2 \rangle^{-1} y = \frac{\pi}{2} m((0, +\infty)).
\] (3.4)

Notice that \(m((0, +\infty)) = \Re \langle x, Qy \rangle\) since \(Q = E_A((0, +\infty))\). Hence (3.4) yields
\[
\Re \langle x, Qy \rangle = \lim_{\epsilon \downarrow 0} \frac{1}{\epsilon} \int d\eta \Re \langle x, A^2 + \eta^2 \rangle^{-1} y).
\] (3.5)

Clearly, by (3.5) inequalities (3.2) follow directly from the corresponding assumptions (3.1). The proof is complete. □

With Lemma 3.1 we are ready to prove Theorem 4.

Proof of Theorem 4. Assume first that the operators \(GT\) and \(G^*T^*\) are both accretive. To prove that \(GW\) is also an accretive operator, pick up arbitrary \(\alpha > 0\) and \(x \in \mathcal{H}\) and set
\[
g = (T^*T + \alpha)^{-1} x.
\] (3.6)

Taking into account that \(g \in \text{Dom}(T)\), introduce
\[
h = Tg = T(T^*T + \alpha)^{-1} x.
\] (3.7)

Clearly, \(h \in \text{Dom}(T^*)\) and
\[
x = \alpha g + T^*h.
\] (3.8)

By using (3.6), (3.7), and (3.8) it is easy to verify that the following chain of equalities holds
\[
\Re \langle W^*G^*x, |T|(\|T\|^2 + \alpha)^{-1} x \rangle = \Re \langle G^*x, W|T|g \rangle
\]
\[
= \Re \langle G^*x, Tg \rangle
\]
\[
= \Re \langle x, Gh \rangle
\]
\[
= \Re \langle \alpha g + T^*h, Gh \rangle
\]
\[
= \alpha \Re \langle g, Gh \rangle + \Re \langle Gh, T^*h \rangle
\]
\[
= \alpha \Re \langle g, GTg \rangle + \Re \langle h, G^*T^*h \rangle.
\] (3.9)

Since by hypothesis both \(GT\) and \(G^*T^*\) are accretive, (3.9) implies that
\[
\Re \langle W^*G^*x, |T|(\|T\|^2 + \alpha)^{-1} x \rangle \geq 0 \text{ for any } \alpha > 0 \text{ and } x \in \mathcal{H},
\]
and hence by Lemma 3.1
\[
\Re \langle W^*G^*x, Qx \rangle = \Re \langle x, GWQx \rangle \geq 0,
\]
where \(Q\) is the orthogonal projection onto \(\text{Ker}(|T|)\). According to the convention (1.15) we have \(\text{Ker}(|T|) = \text{Ker}(T) = \text{Ker}(W)\). Then one concludes that \(WQ = W\) and hence
\[
\Re \langle x, GWx \rangle \geq 0 \text{ for all } x \in \mathcal{H},
\]
which proves that the operator \(GW\) is accretive.
Further, assume that $GT$ and $G^*T^*$ are both strictly accretive operators. In particular, this implies that
\begin{equation}
\text{Ker}(T) = \text{Ker}(|T|) = \{0\}.
\end{equation}
In this case if $x \neq 0$ then neither $g$ nor $h$ defined in (3.6) and (3.7) can be zero vectors. Indeed, the equality $g = 0$ implies $h = Tg = 0$ and hence by (3.8) it contradicts the assumption $x \neq 0$. Independently, the equality $h = 0$ yields $g \in \text{Ker}(T)$ by taking into account (3.7). Then $x \in \text{Ker}(T)$ since $x = \alpha g$ by (3.8). This is again a contradiction because of (3.10).

Therefore if $x \neq 0$ and $\alpha > 0$ then necessarily $g \neq 0$, $h \neq 0$. Hence by (3.9) now we have the strict inequality
\begin{equation}
\text{Re} \langle W^*G^*x, |T|^2 + \alpha \rangle x > 0.
\end{equation}
Then by taking into account (3.10) Lemma 3.1 proves the strict accretiveness of the operator $GW$.

The accretiveness (resp., the strict accretiveness) of the operator $WG$ can be proven in a similar way. \hfill \square

Now assume that $T$ is a self-adjoint operator on the Hilbert space $\mathcal{H}$ and $\text{Ker}(T) = \{0\}$. Then the isometry $J'$ in the polar decomposition
\begin{equation}
T = J'|T|
\end{equation}
is an involution that reads
\begin{equation}
J' = E_T((0, +\infty)) - E_T((-\infty, 0)).
\end{equation}
Clearly, the negative and positive subspaces of this involution coincide with the corresponding spectral subspaces of $T$:
\begin{equation}
\mathcal{H}_- = \text{Ran} E_T((-\infty, 0)) \quad \text{and} \quad \mathcal{H}_+ = \text{Ran} E_T((0, +\infty)).
\end{equation}
Below we will show that in some cases Theorem 4 allows one to determine the spectral angle of the product $J'J$ where $J$ is another involution on $\mathcal{H}$. The norm of the difference between the orthogonal projections onto the corresponding positive (or negative) subspaces of $J'$ and $J$ is then easily computed by using (2.19).

We study the following two cases.

**Hypothesis 3.2.** Let $J$ be an involution on the Hilbert space $\mathcal{H}$. Assume that $T$ is a self-adjoint operator on $\mathcal{H}$ such that

(a) $\text{Ker}(T) = \{0\}$ and the product $JT$ is accretive

or

(b) the product $JT$ is strictly accretive.

Obviously, if the assumption (b) holds then the assumption (a) holds, too. Therefore, both (a) and (b) assume that $\text{Ker}(T) = \{0\}$. Hence any of these two assumptions implies that the isometry $J'$ in the polar decomposition (3.11) of $T$ is an involution.

To describe the accretive operators in some more detail we introduce the following definition.
**Definition 3.3.** Let $S$ be an accretive operator on the Hilbert space $\mathcal{H}$. Then the finite or infinite number

$$k(S) = \sup_{z \in \mathcal{W}(S) \setminus \{0\}} \frac{|\text{Im} z|}{\text{Re} z}$$

is called the *sector bound* of $S$.

Clearly, if $k(S)$ is finite then $S$ is a sectorial operator (see [12, §V.3.10]) with vertex 0 and semi-angle $\theta = \arctan k(S)$.

Main result of this section is the following

**Theorem 3.4.** Assume Hypothesis 3.2 (a). Let $T = J^* |T|$ be the polar decomposition of $T$. Then the involutions $J'$ and $J$ are in the acute case, and

$$\vartheta(U) \leq \frac{1}{2} \arctan k(JT) \quad \left( \leq \frac{\pi}{4} \right),$$

(3.12)

where $U$ is the direct rotation from $J$ to $J'$.

**Proof.** Since $JT$ is accretive and $T = J^* |T|$, it follows from Theorem 4 that the operator $J'J$ is also accretive. Hence $-1 \notin \mathcal{W}(J'J)$ and thus by Lemma 2.9 the involutions $J$ and $J'$ are in the acute case.

If $k(JT) = 0$ then $\mathcal{W}(JT)$ is a subset of the real axis which means that $JT$ is a symmetric operator. This implies $J \sim T$ since $T$ is self-adjoint. Hence $J' \sim J$ (see, e.g., [12, Lemma VI.2.37]) and thus $J = J'$ by Lemma 2.8. In this case estimate (3.12) is trivial since $\vartheta(U) = 0$.

Further, assume that $k(JT) > 0$. Set

$$\varphi = \frac{\pi}{2} - \arctan k(JT), \quad \varphi \in [0, \pi/2),$$

and observe that the operators $GT$ and $G^* T^*$ with $G = e^{i\varphi} J$ are both accretive. Then by Theorem 4 one concludes that the products $e^{i\varphi} J'J$ and $e^{-i\varphi} J'J$ are also accretive operators. Hence $\mathcal{W}(J'J)$ is a subset of the closed sector

$$\left\{ z \in \mathbb{C} \mid |\text{arg} z| \leq \frac{\pi}{2} - \varphi \right\}.$$

Then from the inclusion $\text{spec}(J'J) \subset \overline{\mathcal{W}(J'J)}$ it follows that the spectral angle of the unitary operator $J'J$ satisfies

$$\vartheta(J'J) \leq \arctan k(JT).$$

(3.13)

Now (3.12) follows immediately from (3.13) and (2.18), completing the proof. \(\square\)

In the two following statements we present some uniqueness results concerning the involution $J'$ referred to in Theorem 3.4

**Theorem 3.5.** Assume Hypothesis 3.2 (a). Let $J'$ be an involution on $\mathcal{H}$ such that

(i) $J'$ and $J$ are in the acute case,  
(ii) $J' \sim T$, and  
(iii) $J' \neq J'$,

where $J'$ is the involution in the polar decomposition of $T$. Then

$$\vartheta(U) \geq \frac{\pi}{2} - \frac{1}{2} \arctan k(JT) \quad \left( \geq \frac{\pi}{4} \right),$$

(3.14)

where $U$ is the direct rotation from $J$ to $J'$. 
Theorem 3.6. Assume Hypothesis 3.2 (b). Let $T = J'T$ be the polar decomposition of $T$. Then $J'$ is a unique involution on $\mathcal{H}$ such that

(i) $J$ and $J'$ are in the acute case, (ii) $J' \sim T$, and (iii) $\vartheta(U) \leq \frac{\pi}{4}$,

where $U$ is the direct rotation from $J$ to $J'$.

Proof of Theorem 3.3. For a proof by contradiction suppose that instead of (3.14) the opposite inequality holds. Then by (2.18) in Remark 2.21 we have

\[ \vartheta(JJ') < \pi - \arctan k(JT). \]  

(3.15)

Similarly, Theorem 3.4 yields

\[ \vartheta(JJ') \leq \arctan k(JT). \]  

(3.16)

By (3.15) and (3.16) Lemma 2.22 implies that

\[ \vartheta(JJ') = \vartheta((\tilde{J}J)(JJ')) \leq \vartheta(JJ) + \vartheta(JJ') < \pi. \]

In particular, this means that $-1 \notin \text{spec}(\tilde{J}J')$ which proves that the involutions $J'$ and $\tilde{J}'$ are in the acute case.

By hypothesis $\tilde{J}$ commutes with $T$ and $J'$ is the isometry in the polar decomposition of $T$. Hence [12] Lemma VI.2.37 implies $\tilde{J} \sim J'$. Then from Lemma 2.8 it follows that $\tilde{J} = J'$ which contradicts the assumption (iii). Therefore $\vartheta(U)$ satisfies (3.14) completing the proof. \hfill \Box

Proof of Theorem 3.6. Arguing by contradiction, suppose that there is an involution $\tilde{J}$ distinct from $J'$ and such that conditions (i)–(iii) are satisfied. In particular, this implies that $\vartheta(JJ) \leq \pi/2$ and hence

\[ \Re \langle x, JJ'x \rangle \geq 0 \quad \text{for all} \quad x \in \mathcal{H}. \]

Since $JT$ is strictly accretive and $T = J'|T|$, by Theorem 4 the operator $JJ'$ is also strictly accretive, that is,

\[ \Re \langle x, JJ'x \rangle > 0 \quad \text{for all} \quad x \in \mathcal{H}, \quad x \neq 0. \]

Therefore,

\[ \Re \langle x, JJ'x \rangle + \Re \langle x, JJ'x \rangle > 0 \quad \text{for all} \quad x \in \mathcal{H}, \quad x \neq 0. \]  

(3.17)

Now assume that there is $y \in \text{Ker}(I + JJ')$ such that $y \neq 0$. Then applying $\tilde{J}$ to both parts of the equality $y + JJ'y = 0$ yields $J'y + J'y = 0$. Hence

\[ \Re \langle y, JJ'y \rangle + \Re \langle y, JJ'y \rangle = 0, \]

and it follows from (3.17) that $y = 0$. This proves that $\text{Ker}(I + JJ') = \{0\}$, i.e. the involutions $\tilde{J}$ and $J'$ are in the acute case.

Clearly, $\tilde{J} \sim J'$ since by hypothesis $\tilde{J}$ commutes with $T$ and $J'$ is the isometry in the polar decomposition of $T$ (see [12] Lemma VI.2.37). Hence, by Lemma 2.8 $\tilde{J} = J'$ which contradicts the assumption that $\tilde{J}$ is distinct from $J'$.

The proof is complete. \hfill \Box
4. An Extension of the Davis-Kahan \(\tan 2\Theta\) Theorem.

**Proof of Theorem 1**

Throughout this section we adopt the following hypothesis.

**Hypothesis 4.1.** Given a self-adjoint operator \(A\) on the Hilbert space \(\mathcal{H}\) assume that
\[
\text{Ker}(A - \mu) = \{0\} \quad \text{for some} \quad \mu \in \mathbb{R}. \tag{4.1}
\]

Let \(V\) be a symmetric operator on \(\mathcal{H}\) such that
\[
(i) \quad \text{Dom}(A) \subset \text{Dom}(V),
\]
\[
(ii) \quad V \prec J \quad \text{where} \quad J = E_A((\mu, +\infty)) - E_A((-\infty, \mu)),
\]
and
\[
(iii) \quad \text{the closure} \quad L = \overline{L_0} \quad \text{of the operator} \quad L_0 = A + V \quad \text{with} \quad \text{Dom}(L_0) = \text{Dom}(A) \quad \text{is a self-adjoint operator}.
\]

Under this hypothesis the product \(J(L - \mu)\) appears to be a strictly accretive operator. Moreover, the sector bound \(k(J(L - \mu))\) admits an explicit description in terms of the perturbation \(V\).

**Lemma 4.2.** Assume Hypothesis 4.1. Then \(J(L - \mu)\) is a strictly accretive operator and
\[
k(J(L - \mu)) = \sup_{x \in \text{Dom}(A), \|x\| = 1} \frac{|\langle x, JV x \rangle|}{\langle x, |A - \mu|x \rangle}. \tag{4.2}
\]

**Proof.** Obviously, under Hypothesis 4.1
\[
J(A - \mu) = |A - \mu| > 0.
\]

Hence by items (ii) and (iii) of this hypothesis
\[
\text{Re} \langle x, J(A + V - \mu)x \rangle = \langle x, |A - \mu|x \rangle \quad \text{for all} \quad x \in \text{Dom}(A). \tag{4.3}
\]

Pick up an arbitrary \(y \in \text{Dom}(L)\). By the assumption (iii) it follows that there exists a sequence of vectors \(y_n \in \text{Dom}(A)\) such that \(y_n \to y\) and \(L_0y_n \to Ly\) as \(n \to \infty\), and thus
\[
\text{Re} \langle y_n, J(L_0 - \mu)y_n \rangle \to \text{Re} \langle y, J(L - \mu)y \rangle \quad \text{as} \quad n \to \infty. \tag{4.4}
\]

Then (4.3) and (4.4) imply \(\text{Re} \langle y, J(L - \mu)y \rangle \geq 0\). Moreover, \(y \in \text{Ker}(|A - \mu|) \subset \text{Dom}(A)\) whenever \(\text{Re} \langle y, J(L - \mu)y \rangle = 0\). Taking into account that \(\text{Ker}(|A - \mu|) = \text{Ker}(A - \mu) = \{0\}\), one infers that
\[
\text{Re} \langle y, J(L - \mu)y \rangle > 0 \quad \text{for all non-zero} \quad y \in \text{Dom}(L),
\]
which means that the operator \(J(L - \mu)\) is strictly accretive.

Now observe that
\[
k(J(L - \mu)) \geq \kappa, \tag{4.5}
\]
where
\[
\kappa = \sup_{x \in \text{Dom}(A), \|x\| = 1} \frac{|\langle x, JV x \rangle|}{\langle x, |A - \mu|x \rangle}. \tag{4.6}
\]
Indeed,
\[
k(J(L - \mu)) = \sup_{x \in \text{Dom}(L), \|x\| = 1} \frac{|\text{Im}\langle x, J(L - \mu)x \rangle|}{\text{Re}\langle x, J(L - \mu)x \rangle}
\]

\[
\geq \sup_{x \in \text{Dom}(A), \|x\| = 1} \frac{|\text{Im}\langle x, J(A + V - \mu)x \rangle|}{\text{Re}\langle x, J(A + V - \mu)x \rangle}
\]

since by Hypothesis 4.1(iii) \text{Dom}(A) \subset \text{Dom}(L) and \(L|_{\text{Dom}(A)} = A + V\). Then (4.5) holds by (4.3) since Hypothesis 4.1(ii) implies
\[
|\text{Im}\langle x, J(L_0 - \mu)x \rangle| \leq \kappa \text{Re}\langle x, J(L_0 - \mu)x \rangle \text{ for any } x \in \text{Dom}(L_0) = \text{Dom}(A).
\]

Since \(L\) is the closure of \(L_0\), by continuity of the inner product the same inequality holds for \(L\), that is,
\[
|\text{Im}\langle x, J(L - \mu)x \rangle| \leq \kappa \text{Re}\langle x, J(L - \mu)x \rangle \text{ for any } x \in \text{Dom}(L).
\]

In particular, this means that
\[
\sup_{x \in \text{Dom}(L), \|x\| = 1} \frac{|\text{Im}\langle x, J(L - \mu)x \rangle|}{\text{Re}\langle x, J(L - \mu)x \rangle} = k(J(L - \mu)) \leq \kappa. \tag{4.8}
\]

Now combining (4.5), (4.6), and (4.8) completes the proof. \(\square\)

**Remark 4.3.** Since \(J(L - \mu)\) is a strictly accretive operator, the isometry \(J'\) in the polar decomposition \(L - \mu = J'|L - \mu|\) is an involution. Clearly, it reads
\[
J' = E_L((\mu, +\infty)) - E_L((-\infty, \mu)).
\]

**Theorem 4.4.** Assume Hypothesis 4.1. Let \(L - \mu = J'|L - \mu|\) be the polar decomposition of \(L - \mu\). Then the involutions \(J\) and \(J'\) are in the acute case, and
\[
\vartheta(U) \leq \frac{1}{2} \arctan \left( \sup_{x \in \text{Dom}(A), \|x\| = 1} \frac{|\langle x, JVx \rangle|}{\langle x, |A - \mu|x \rangle} \right) \left( \leq \frac{\pi}{4} \right), \tag{4.9}
\]

where \(U\) is the direct rotation from \(J\) to \(J'\). Moreover, \(J'\) is a unique involution on \(\mathcal{H}\) with the properties

(i) \(J'\) and \(J\) are in the acute case, (ii) \(J' \sim L\), and (iii) \(\vartheta(U) \leq \frac{\pi}{4}\). \tag{4.10}

The spectral angle of the direct rotation \(\tilde{U}\) from \(J\) to any other involution \(\overline{J}'\) distinct from \(J'\) and satisfying (i) and (ii) is bounded from below as follows
\[
\vartheta(\tilde{U}) \geq \frac{\pi}{2} - \frac{1}{2} \arctan \left( \sup_{x \in \text{Dom}(A), \|x\| = 1} \frac{|\langle x, JVx \rangle|}{\langle x, |A - \mu|x \rangle} \right) \left( \geq \frac{\pi}{4} \right). \tag{4.11}
\]
Proof. The operators $J$ and $T = L - \mu$ satisfy Hypothesis 3.2 (b) (and hence, Hypothesis 3.2 (a)). Then the assertion is proven simply by combining Theorems 3.4, 3.5 and 3.6 with Lemma 4.2.

With Theorem 4.4, one can easily prove Theorem 1.

Proof of Theorem 1. Pick up arbitrary $\mu, \nu \in (\sup \sigma_-, \inf \sigma_+)$, $\mu < \nu$. Clearly, Hypothesis 4.1 holds for both $\mu$ and $\nu$ with the same involution $J = \mathbb{E}_A(\sigma_+) - \mathbb{E}_A(\sigma_-)$. By Remark 4.3, the isometries $J_\mu'$ and $J'_\nu$ in the polar decompositions $L - \mu = J_\mu' |L - \mu|$ and $L - \nu = J'_\nu |L - \nu|$ are involutions. By Theorem 4.4, the involutions $J$ and $J'_\mu$ are in the acute case, $J_\mu' \preceq L$, and $\vartheta(U_\mu) \leq \pi/4$ where $U_\mu$ is the direct rotation from $J$ to $J'_\mu$. The same holds for $J'_\nu$ and the corresponding direct rotation $U_\nu$ from $J$ to $J'_\nu$. Therefore, (4.10) is satisfied for both $J' = J'_\mu$ and $J' = J'_\nu$. Hence, Theorem 4.4 implies $J'_\mu = J'_\nu$ which by Remark 4.3 yields $E_L((\mu, \nu)) = 0$. Since $\mu, \nu \in (\sup \sigma_-, \inf \sigma_+)$ are arbitrary, one then concludes that $E_L((\sup \sigma_-, \inf \sigma_+)) = 0$, and thus the interval $(\sup \sigma_-, \inf \sigma_+)$ belongs to the resolvent set of $L$. Hence,

$$J'_\mu = \mathbb{E}_L(\sigma_+) - \mathbb{E}_L(\sigma_-) \quad \text{for all} \quad \mu \in (\sup \sigma_-, \inf \sigma_+),$$

where $\sigma'_-$ and $\sigma'_+$ are the parts of the spectrum of $L$ in the intervals $(-\infty, \sup \sigma_-]$ and $[\inf \sigma_+, +\infty)$, respectively. Since $J'_\mu$ does not depend on $\mu \in (\sup \sigma_-, \inf \sigma_+)$, the direct rotation $U_\mu$ does not, too. Then estimate (4.9) of Theorem 4.4 yields

$$\tan 2\vartheta(U) \leq \inf_{\sup \sigma_- < \mu < \inf \sigma_+} \sup_{x \in \text{Dom}(A)} \frac{|\langle x, JVx \rangle|}{\langle x, |A - \mu| x \rangle},$$

(4.12)

where $U$ is the direct rotation from the involution $\mathbb{E}_A(\sigma_+) - \mathbb{E}_A(\sigma_-)$ to the involution $\mathbb{E}_L(\sigma'_+) - \mathbb{E}_L(\sigma'_-)$. Now inequality (4.12) proves the bound (1.8) by taking into account (2.19) in Remark 2.21. The proof is complete.

Example 4.5. Let $\mathcal{D}_a = \mathbb{R} \setminus (-a, a)$ for some $a \geq 0$. Given $x \geq 0$ assume that $A$ and $V$ are operators on the Hilbert space $\mathcal{H}_a = L^2(\mathcal{D}_a)$ defined by

$$\langle Ax \rangle(t) = |t|x(-t), \quad \langle Vx \rangle(t) = x(t), \quad t \in \mathcal{D}_a.$$  

$$\text{Dom}(A) = \text{Dom}(V) = \{ x \in \mathcal{H}_a \mid \int_{\mathcal{D}_a} t^2|x(t)|^2dt < +\infty \}. \quad (4.13)$$

Both $A$ and $L = A + V$ are self-adjoint operators. The spectrum of the operator $A$ is purely absolutely continuous. For $a > 0$ it consists of the two disjoint components $\sigma_- = (-\infty, -a]$ and $\sigma_+ = [a, +\infty)$ and for $a = 0$ it covers the whole real axis. Obviously, the isometry $J$ in the polar decomposition $A = J|A|$ is the parity operator, $(Jx)(t) = x(-t), x \in \mathcal{H}_a$, and the absolute value of $A$ is given by $(|A|x)(t) = |t|x(t), x \in \text{Dom}(A)$. Clearly, $J$ is an involution on $\mathcal{H}_a$ such that $J \sim A$ and $J \sim V$. Therefore, for $a > 0$ (resp. for $a = 0$) the operators $A$ and $V$ satisfy the hypothesis of Theorem 1 (resp. the hypothesis of Theorem 4.4 for $\mu = 0$).

Our analysis of the subspace perturbation problem involving $A$ and $V$ given by (4.13) is divided into three parts below.
(i) For any \( x \in \text{Dom}(A) \), \( \|x\| = 1 \), we have

\[
|\langle x, JVx \rangle| = \left| \int_{\mathbb{R}} x'(t)x(-t)dt \right|
\]

\[
\leq \kappa \int_{\mathbb{R}} |t|x(t)x(-t)|dt
\]

\[
\leq \kappa \int_{\mathbb{R}} |t||x(-t)|^2 + |x(t)|^2 dt
\]

\[
= \kappa \int_{\mathbb{R}} |t||x(t)|^2 dt
\]

\[
= \kappa \langle x, |A|x \rangle,
\]

Moreover, if \( x \in \text{Dom}(A) \) is such that \( x(-t) = \text{sign}(t)x(t) \) then inequalities in (4.14) turn into equalities. Hence, by taking this into account, (4.14) implies

\[
\sup_{x \in \text{Dom}(A), \|x\| = 1} \frac{|\langle x, JVx \rangle|}{\langle x, |A|x \rangle} = \kappa.
\]

An explicit evaluation of the involution \( J' = E_L((+\infty, 0)) - E_L((-\infty, 0)) \) by using the polar decomposition \( L = J'|L| \) yields

\[
(J'Jx)(t) = \frac{1}{\sqrt{1 + \kappa^2}} x(t) + \text{sign}(t) \frac{\kappa}{\sqrt{1 + \kappa^2}} x(-t).
\]

From (4.16) it follows by inspection that the spectrum of the unitary operator \( J'J \) consists of the two mutually conjugate eigenvalues,

\[
\text{spec}(J'J) = \left\{ \frac{1 - i\kappa}{\sqrt{1 + \kappa^2}}, \frac{1 + i\kappa}{\sqrt{1 + \kappa^2}} \right\}.
\]

This implies that \( \vartheta(J'J) = \arctan \kappa \) and then the spectral angle of the direct rotation \( U \) from \( J \) to \( J' \) is equal to \( \vartheta(U) = \frac{1}{2} \arctan \kappa \). Combining this with (4.15) yields that in the case under consideration

\[
\vartheta(U) = \frac{1}{2} \arctan \left( \sup_{x \in \text{Dom}(A), \|x\| = 1} \frac{|\langle x, JVx \rangle|}{\langle x, |A|x \rangle} \right) \quad \text{for any} \quad a \geq 0.
\]

(ii) Now set \( J' = -J' \). Clearly, \( \vartheta(J'J) = \pi - \vartheta(J'J) \) and thus the spectral angle of the direct rotation \( \tilde{U} \) from \( J \) to \( J' \) reads

\[
\vartheta(\tilde{U}) = \frac{\pi}{2} - \frac{1}{2} \arctan \left( \sup_{x \in \text{Dom}(A), \|x\| = 1} \frac{|\langle x, JVx \rangle|}{\langle x, |A|x \rangle} \right).
\]

Notice that the involution \( J' \) commutes with \( L \) since \( J' \) does. By (4.16) it follows that \( \text{Ker}(I - J'J) = \{0\} \) whenever \( \kappa \neq 0 \). Hence \( \text{Ker}(I + J'J) = \{0\} \) whenever \( \kappa \neq 0 \) which means that for \( \kappa > 0 \) the involutions \( J \) and \( J' \) are in the acute case.
(iii) For $a > 0$ we have

$$\inf_{|\mu| < a} \sup_{x \in \text{Dom}(A), \|x\| = 1} \frac{|\langle x, JV x \rangle|}{\langle x, |A - \mu|x \rangle} \leq \sup_{x \in \text{Dom}(A), \|x\| = 1} \frac{|\langle x, JV x \rangle|}{\langle x, |A|x \rangle}.$$  \hfill (4.19)

Since $\sin \vartheta(U) = \|E_L((-\infty,-a]) - E_A((-\infty,-a])\|$, by Theorem 1 the strict inequality in (4.19) implies

$$\vartheta(U) < \frac{1}{2} \arctan \left( \sup_{x \in \text{Dom}(A), \|x\| = 1} \frac{|\langle x, JV x \rangle|}{\langle x, |A|x \rangle} \right),$$

which contradicts (4.17). Hence only the equality sign in (4.19) is allowed and thus

$$\inf_{|\mu| < a} \sup_{x \in \text{Dom}(A), \|x\| = 1} \frac{|\langle x, JV x \rangle|}{\langle x, |A - \mu|x \rangle} = \sup_{x \in \text{Dom}(A), \|x\| = 1} \frac{|\langle x, JV x \rangle|}{\langle x, |A|x \rangle}.$$  \hfill (4.20)

**Remark 4.6.** Example 4.5 shows the following.

(i) Estimate (4.9) of Theorem 4.4 is sharp. This is proven by equality (4.17).

(ii) Estimate (4.11) of the same theorem is sharp. This is proven by equality (4.18).

(iii) Estimate (1.8) of Theorem 1 is sharp. This is proven by combining equalities (4.17) and (4.20).

The celebrated sharp estimate for the operator angle between the spectral subspaces $\text{Ran} E_A(\sigma_-)$ and $\text{Ran} E_A(\sigma'_-) \cup \text{Ran} E_A(\sigma'_+)$ known as the Davis-Kahan tan$2\Theta$ Theorem [8] (cf. [17]) appears to be a simple corollary to Theorem 1.

**Theorem 4.7** (The Davis–Kahan tan$2\Theta$ Theorem). Given a self-adjoint operator $A$ on the Hilbert space $\mathcal{H}$ assume that

$$\text{spec}(A) = \sigma_- \cup \sigma_+, \quad d = \text{dist}(\sigma_-, \sigma_+) > 0, \quad \text{and} \quad \sup \sigma_- < \inf \sigma_+.$$  

Suppose that a bounded self-adjoint operator $V$ on $\mathcal{H}$ is off-diagonal with respect to the decomposition $\mathcal{H} = \text{Ran} E_A(\sigma_-) \oplus \text{Ran} E_A(\sigma_+)$. Then the spectrum of $L = A + V$ consists of two disjoint components $\sigma'_-$ and $\sigma'_+$ such that

$$\sigma'_- \subset (-\infty, \sup \sigma_-] \quad \text{and} \quad \sigma'_+ \subset [\inf \sigma_+, +\infty),$$

and

$$\|E_L(\sigma'_-) - E_A(\sigma_-)\| \leq \sin \left( \frac{1}{2} \arctan \frac{2\|V\|}{d} \right).$$  \hfill (4.21)
Proof. Hypothesis of Theorem \[4.21\] is satisfied and thus we only need to prove the estimate \(4.21\). Set \(\mu_0 = \frac{1}{2}(\sup \sigma_+ + \inf \sigma_-)\). Clearly, \[
\inf_{\sup \sigma_- < \mu < \inf \sigma_+} \sup_{x \in \text{Dom}(A), \|x\| = 1} \frac{|\langle x, J\nu x \rangle|}{(x, |A - \mu|x)} \leq \sup_{x \in \text{Dom}(A), \|x\| = 1} \frac{|\langle x, J\nu x \rangle|}{(x, |A - \mu_0|x)} \leq \sup_{x \in \text{Dom}(A), \|x\| = 1} \frac{\|\nu\|}{(x, |A - \mu_0|x)} \leq \frac{2\|\nu\|}{d},
\]
which immediately implies \(4.21\) by taking into account \(1.8\). \(\square\)

5. PROOF OF THEOREM 2

In the proof of the main result of this section we will use some auxiliary statements. We start with the following lemma.

Lemma 5.1. Let \(T\) be a densely defined operator on a Hilbert space \(\mathcal{H}\) with \(\dim(\mathcal{H}) \geq n\) for some \(n \in \mathbb{N}\). Assume that \(t(x, y)\) is a sesquilinear form on \(\mathcal{H}\) such that \(\text{Dom}(T) \subset \text{Dom}(t)\) and \(t(x, y) = \langle x, Ty \rangle\) for any \(x, y \in \text{Dom}(T)\).

Suppose that there are orthogonal projections \(P_i \neq 0, i = 1, 2, \ldots, n\), on \(\mathcal{H}\) with the properties \(P_i P_j = 0\) if \(i \neq j\), \(\sum_{i=1}^{n} P_i = I\), and \(P_i x \in \text{Dom}(t)\) whenever \(x \in \text{Dom}(t)\).

Let \(\mathcal{E}\) be a set of ordered \(n\)-element orthonormal systems in \(\mathcal{H}\) defined by

\[\mathcal{E} = \{\{e_i\}_{i=1}^{n} \subset \text{Dom}(t) \mid e_i \in \text{Ran} P_i \text{ and } \|e_i\| = 1 \text{ for all } i = 1, 2, \ldots, n\}.\]

Then \(\mathcal{W}(T) \subset \bigcup_{e \in \mathcal{E}} \mathcal{W}(t^e)\), \(\text{(5.1)}\) where for any \(e \in \mathcal{E}\) the \(n \times n\) matrix \(t^e\) is given by \(t^e_{ij} = t(e_i, e_j)\) with \(e_i, e_j \in e\), \(i, j = 1, 2, \ldots, n\).

If, in addition, \(\text{Dom}(t) = \text{Dom}(T)\) then \(\mathcal{W}(T) = \bigcup_{e \in \mathcal{E}} \mathcal{W}(t^e)\). \(\text{(5.2)}\)

Proof. By hypothesis \(\text{Dom}(T) = \mathcal{H}\) and hence \(\text{Dom}(t) = \mathcal{H}\), too. Therefore there exists \(y \in \text{Dom}(t)\) such that \(P_i y \neq 0\) for all \(i = 1, 2, \ldots, n\). Set \(e_i = \frac{P_i y}{\|P_i y\|}\). Taking into account that by hypothesis \(P_i y \in \text{Dom}(t)\) and thus \(e_i \in \text{Dom}(t), i = 1, 2, \ldots, n\), one concludes that \(\{e_i\}_{i=1}^{n} \in \mathcal{E}\). Hence, the set \(\mathcal{E}\) is non-empty.
Assume that $z \in \mathcal{W}(T)$. Then there exists $x \in \text{Dom}(T)$ such that $\langle x, Tx \rangle = z$ and $\|x\| = 1$. Pick up an arbitrary $f = \{f_i\}_{i=1}^{n} \in \mathcal{E}$ and define the orthonormal system $g = \{g_i\}_{i=1}^{n}$ by

$$g_i = \begin{cases} \frac{P_i x}{\|P_i x\|}, & \|P_i x\| \neq 0, \\ f_i, & \|P_i x\| = 0. \end{cases}$$

Obviously, $g \in \mathcal{E}$ and

$$\sum_{i,j=1}^{n} t(g_i, g_j) \|P_i x\| \|P_j x\| = \langle x, Tx \rangle = z,$$

which implies $z \in \mathcal{W}(t^h)$ since $\sum_{i=1}^{n} \|P_i x\|^2 = \|x\|^2 = 1$. This proves the inclusion (5.1).

To prove the converse inclusion in the case where $\text{Dom}(t) = \text{Dom}(T)$, pick up an arbitrary $h = \{h_i\}_{i=1}^{n} \in \mathcal{E}$ and assume that $z \in \mathcal{W}(h^b)$. Then there are $\alpha_i \in \mathbb{C}$, $i = 1, 2, \ldots, n$, such that

$$z = \sum_{i,j=1}^{n} t(h_i, h_j) \alpha_i \alpha_j, \quad \sum_{i=1}^{n} |\alpha_i|^2 = 1.$$

Set $x = \sum_{i=1}^{n} \alpha_i h_i$. Clearly, $\|x\| = 1$ and $x \in \text{Dom}(t) = \text{Dom}(T)$. Hence $z = t(x, x) = \langle Tx, x \rangle$. This yields $z \in \mathcal{W}(T)$ and hence $\mathcal{W}(h^b) \subset \mathcal{W}(T)$. One then concludes that

$$\bigcup_{e \in \mathcal{E}} \mathcal{W}(e^b) \subset \mathcal{W}(T)$$

and hence (5.2) holds, completing the proof. \hfill \Box

The next simple result on the numerical range of a $2 \times 2$ numerical matrix is well known (see, e.g., [9, Lemma 1.1-1]).

**Lemma 5.2.** Given numbers $\alpha > 0$, $\beta > 0$, and $\gamma \in \mathbb{C}$ let $M$ be a $2 \times 2$ matrix of the form

$$M = \begin{pmatrix} \alpha & -\gamma \\ \gamma & \beta \end{pmatrix}.$$ 

The matrix $M$ is strictly accretive and its sector bound reads

$$k(M) = \frac{|\gamma|}{\sqrt{\alpha \beta}}.$$ 

The numerical range $\mathcal{W}(M)$ is a (possibly degenerate) elliptical disc with foci at the eigenvalues of $M$.

Now we are in a position to prove the main statement of the section. We only recall that by a finite gap of a closed set $\sigma \subset \mathbb{R}$ one understands an open finite interval on the real axis that does not intersect this set but both its ends belong to $\sigma$. 
Theorem 5.3. Given a self-adjoint operator $A$ on the Hilbert space $\mathcal{H}$ assume that 
\[ \text{spec}(A) = \sigma_- \cup \sigma_+, \quad \text{dist}(\sigma_+, \sigma_-) = d > 0, \quad \text{and} \quad \sigma_- \subset \Delta, \]
where $\Delta = (\alpha, \beta)$, $\alpha < \beta$, is a finite gap of $\sigma_+$. Assume in addition that $V$ is a bounded self-adjoint operator on $\mathcal{H}$ anticommuting with $J = E_A(\sigma_+) - E_A(\sigma_-)$ and such that 
\[ \|V\| < \sqrt{d(\Delta - d)}, \]
where $|\Delta| = \beta - \alpha$ denotes the length of the gap $\Delta$. Then the spectrum of $L = A + V$ consists of two disjoint components $\sigma'_-$ and $\sigma'_+$ such that inclusions (1.9) hold with $\delta \pm$ given by (1.10), (1.11) and the involutions $J$ and $J' = E_L(\sigma'_+) - E_L(\sigma'_-)$ are in the acute case. The spectral angle of the direct rotation $U$ from $J$ to $J'$ satisfies the bound 
\[ \vartheta(U) \leq \frac{1}{2} \arctan \kappa(\|V\|) \left( \leq \frac{\pi}{4} \right), \]
where the function $\kappa(v)$ is defined for $0 \leq v < \sqrt{d(\Delta - d)}$ by 
\[ \kappa(v) = \begin{cases} 
\frac{2v}{d} & \text{if } v \leq \sqrt{\frac{d}{2}(\frac{|\Delta|}{2} - d)} , \\
\frac{v|\Delta|}{2} + \sqrt{d(\Delta - d)\left[\left(\frac{|\Delta|}{2} - d\right)^2 + v^2\right]} & \text{if } v > \sqrt{\frac{d}{2}(\frac{|\Delta|}{2} - d)} .
\end{cases} \]
Moreover, $J'$ is a unique involution on $\mathcal{H}$ with the properties 
(ii) $J'$ and $J$ are in the acute case, (ii) $J' \sim L$, and (iii) $\vartheta(U) \leq \frac{\pi}{4}$.

The spectral angle of the direct rotation $\bar{U}$ from $J$ to any involution $\bar{J}'$ distinct from $J'$ and satisfying (i) and (ii) is bounded from below as follows 
\[ \vartheta(\bar{U}) \geq \frac{\pi}{2} - \frac{1}{2} \arctan(\|V\|). \]

Proof. Recall that inclusions (1.9) with $\delta_\pm$ given by (1.10), (1.11) follow from [18, Theorems 1 (i) and 3.2]. In the proof of the remaining statements one may assume without loss of generality that the gap $\Delta$ is centered at the point zero. Under this assumption we set 
\[ \alpha = -b \quad \text{and} \quad \beta = b \quad \text{with} \quad b = \frac{|\Delta|}{2}. \]

Then 
\[ \sigma_+ \subset \mathbb{R} \setminus (-b, b) \quad \text{and} \quad \sigma_- \subset [-a, a], \]
where 
\[ a = \frac{|\Delta|}{2} - d, \quad 0 \leq a < b. \]

For $\alpha, \beta$ given by (5.7), inclusions (1.9) imply that the intervals $(-b, -a')$ and $(a', b)$ with 
\[ a' = a + \|V\| \tan \left( \frac{1}{2} \arctan \frac{2\|V\|}{a + b} \right) < b \]

are disjoint and 
\[ d(\|V\|) = \|V\| > \sqrt{d(\|V\| - d)}, \]
where 
\[ |\Delta| = \beta - \alpha \]
denotes the length of the gap. The spectral angle of the direct rotation $U$ from $J$ to $J'$ satisfies the bound 
\[ \vartheta(U) \leq \frac{1}{2} \arctan \kappa(\|V\|) \left( \leq \frac{\pi}{4} \right), \]
where the function $\kappa(v)$ is defined for $0 \leq v < \sqrt{d(\|V\| - d)}$ by 
\[ \kappa(v) = \begin{cases} 
\frac{2v}{d} & \text{if } v \leq \sqrt{\frac{d}{2}(\frac{|\Delta|}{2} - d) - v^2} , \\
\frac{v|\Delta|}{2} + \sqrt{d(\|V\| - d)\left[\left(\frac{|\Delta|}{2} - d\right)^2 + v^2\right]} & \text{if } v > \sqrt{\frac{d}{2}(\frac{|\Delta|}{2} - d) - v^2} .
\end{cases} \]

Moreover, $J'$ is a unique involution on $\mathcal{H}$ with the properties 
(i) $J'$ and $J$ are in the acute case, (ii) $J' \sim L$, and (iii) $\vartheta(U) \leq \frac{\pi}{4}$.

The spectral angle of the direct rotation $\bar{U}$ from $J$ to any involution $\bar{J}'$ distinct from $J'$ and satisfying (i) and (ii) is bounded from below as follows 
\[ \vartheta(\bar{U}) \geq \frac{\pi}{2} - \frac{1}{2} \arctan(\|V\|). \]
are in the resolvent set of $L$. Hence the interval $(a^2, b^2)$ lies in the resolvent set of $L^2$. Taking into account (5.8) one verifies by inspection that $a^2 \leq a^2 + \|V\|^2 < b^2$. Therefore, the interval $(a^2 + \|V\|^2, b^2)$ belongs to the resolvent set of $L^2$ and the spectral projections $E_{L^2-\mu}((\infty, 0))$ and $E_{L^2-\mu}((0, \infty))$ do not depend on
\[ \mu \in (a^2 + \|V\|^2, b^2). \] (5.9)

Moreover,
\[ E_{L^2-\mu}((\infty, 0)) = E_L(\sigma'_+), \quad E_{L^2-\mu}((0, \infty)) = E_L(\sigma'_+), \]
and hence
\[ E_{L^2-\mu}((0, \infty)) - E_{L^2-\mu}((\infty, 0)) = J'. \] (5.10)

Now for any $\mu$ satisfying (5.9) set
\[ T_\mu = J(L^2 - \mu), \quad \text{Dom}(T_\mu) = \text{Dom}(L^2), \] (5.11)
and
\[ t_\mu(x, y) = (LJx, Ly) - \mu (x, Jy), \quad x, y \in \text{Dom}(t_\mu) = \text{Dom}(L). \] (5.12)

Clearly, $\text{Dom}(T_\mu) \subset \text{Dom}(t_\mu)$ and $t_\mu(x, y) = (x, Jt_\mu y)$ for any $x, y \in \text{Dom}(T_\mu)$. Further, introduce the set $\mathcal{E}$ of ordered orthonormal two-element systems in $\mathcal{H}$ by
\[ \mathcal{E} = \{ \{e_-, e_+\} \subset \text{Dom}(t_\mu) \mid e_\pm \in \mathcal{H}_\pm, \quad \|e_\pm\| = 1 \}. \]

Then by Lemma 5.1
\[ \mathcal{W}(T_\mu) \subset \bigcup_{\mathcal{E}} \mathcal{W}(t_\mu^e), \] (5.13)
where $t_\mu^e$ are $2 \times 2$ matrices given by
\[ t_\mu^e = \begin{pmatrix} t_\mu(e_-, e-) & t_\mu(e_-, e+) \\ t_\mu(e_+, e-) & t_\mu(e_+, e+) \end{pmatrix}, \quad \mathcal{E} = \{e_-, e_+\} \in \mathcal{E}. \]

By taking into account that $A \prec J$ and $V \prec J$, one observes
\[ t_\mu^e = \begin{pmatrix} \mu - \|Ae_+\|^2 - \|Ve_-\|^2 & \langle Ae_+, Ve_- \rangle + \langle Ve_+, Ae_- \rangle \\ \langle Ae_+, Ve_- \rangle + \langle Ve_+, Ae_- \rangle & \|Ae_+\|^2 + \|Ve_-\|^2 - \mu \end{pmatrix}. \] (5.14)

From (5.8) it follows that for $\{e_-, e_+\} \in \mathcal{E}$
\[ \|Ae_+\| \leq a \quad \text{and} \quad \|Ae_+\| \geq b. \] (5.15)

Hence, under the assumption (5.9) by Lemma 5.2 it follows from (5.14) and (5.15) that for all $e \in \mathcal{E}$ the numerical ranges $\mathcal{W}(t_\mu^e)$ are elliptical discs that lie in the open right half-plane $\{z \in \mathbb{C} \mid \text{Re} z > 0\}$. Then (5.13) implies that the numerical range $\mathcal{W}(T_\mu)$ also lies in the open right half-plane, that is, the operator $T_\mu$ is strictly accretive. Now taking into account (5.10) and (5.11), Theorem 3.4 yields that the involution $J$ and $J'$ are in the acute case. Moreover, for the direct rotation $U$ from $J$ to $J'$ the following inequality holds
\[ \vartheta(U) \leq \frac{1}{2} \arctan k(T_\mu), \] (5.16)
Remark 5.4. Notice that in the case where the operator $A$ is bounded, the estimate $\|E_{\lambda}(\sigma_-') - E_A(\sigma_-')\| < \frac{\sqrt{2}}{2}$ (or equivalently $\vartheta(U) < \pi/4$) may be obtained by combining [15, Theorem 1 (ii)] and [17, Theorem 5.6].
Theorem 2 is an immediate corollary to Theorem 5.3.

Proof of Theorem 2. Let $\Delta$ again denote the finite gap of the set $\sigma_+$ that contains $\sigma_-$. Obviously, $|\Delta| \geq 2d$ and thus $\|V\| < d \leq \sqrt{d(|\Delta|-d)}$. By Theorem 5.3 one concludes that

$$\|E_L(\sigma^+_-) - E_A(\sigma^-_+)\| \leq \sin\left(\frac{1}{2} \arctan \kappa(\|V\|)\right)$$

with $\kappa(v)$ given by (5.5). Observing that for $0 \leq v < d$

$$\kappa(v) \leq \frac{2vd}{d^2-v^2} = \tan\left(2\arctan\frac{v}{d}\right)$$

completes the proof. □

Example 5.5. Let $A$ be a self-adjoint operator on $\mathcal{H} = \mathbb{C}^4$ defined by

$$A = \text{diag}\{-b, -a, a, b\}, \quad 0 \leq a < b.$$ 

Divide the spectrum of $A$ into the two disjoint sets $\sigma_- = \{-a, a\}$ and $\sigma_+ = \{-b, b\}$. Clearly, $d = \text{dist}(\sigma_-, \sigma_+) = b-a > 0$. The interval $\Delta = (-b, b)$ appears to be the gap of the set $\sigma_+$ containing the set $\sigma_-$. The involution $J = E_A(\sigma_+) - E_A(\sigma_-)$ reads

$$J = \text{diag}\{+1, -1, -1, +1\}.$$

Assume that $V$ is a $4 \times 4$ matrix of the form

$$V = \begin{pmatrix} 0 & v_1 & v_2 & 0 \\
v_1 & 0 & 0 & v_2 \\
v_2 & 0 & 0 & v_1 \\
0 & v_2 & v_1 & 0 \end{pmatrix}, \quad (5.23)$$

where $v_1, v_2 \geq 0$. By inspection, $V$ anticommutes with $J$ and $\|V\| = v_1 + v_2$. The involution $J' = E_L(\mathbb{R} \setminus \Delta) - E_L(\Delta)$ is computed explicitly as soon as the eigenvectors of the $4 \times 4$ matrix $L = A + V$ are found. Under the assumption that (5.3) holds, that is, for $\|V\|^2 < b^2 - a^2$, the explicit evaluation of the spectral angle of the direct rotation $U$ from $J$ to $J'$ results in

$$\vartheta(U) = \frac{1}{2} \arctan\left(\frac{2a(v_1 - v_2) + 2b\|V\|}{b^2 - a^2 - \|V\|^2 + (v_1 - v_2)^2}\right).$$

Taking into account that the value of $v_1 - v_2$ for different matrices (5.23) with the same norm $\|V\|$ runs through the interval $[-\|V\|, \|V\|]$, one easily verifies that the maximal possible value $\vartheta_{\max}$ of $\vartheta(U)$ is equal to

$$\vartheta_{\max} = \frac{1}{2} \arctan \kappa(\|V\|), \quad (5.24)$$

with $\kappa(v)$ given by (5.5). In particular, if $a = 0$ then

$$\vartheta_{\max} = \arctan\left(\frac{\|V\|}{d}\right). \quad (5.25)$$

Remark 5.6. Example 5.5 shows the following.

(i) Estimate (5.4) of Theorem 5.3 is sharp. This is proven by equality (5.24).
Estimate (1.13) of Theorem 2 is also sharp. This is proven by equality (5.25).

Remark 5.7. We conjecture that estimate (1.13) of Theorem 2 also holds for 

\[ d \leq \| V \| < \sqrt{2}d. \]
