Axion and axion-like particle models are typically affected by a strong fine-tuning problem in conceiving the electroweak and the Peccei-Quinn breaking scales. Within the context of the Minimal Linear σ Model, axion-like particle constructions are identified where this hierarchy problem is solved, accounting for a TeV Peccei-Quinn breaking scale and a pseudoscalar particle with a mass larger than 10 MeV. Potential signatures at colliders and B-factories are discussed.

I. INTRODUCTION

A suggestive mechanism to protect the Higgs mass from radiative corrections arises when the Higgs field belongs to the Nambu Goldstone Boson (GB) sector of a model equipped with a global symmetry $G$ spontaneously broken, by an unknown strongly interacting dynamics, to a subgroup $H$. In the Composite Higgs (CH) framework, the Standard Model (SM) GBs and the Higgs field parametrise some of the coset $G/H$ coordinates and are forced to be strictly massless [1–4]. The gauging of the SM symmetries and the introduction of fermionic Yukawa couplings introduce an explicit breaking of $G$, leading to a non-vanishing mass term for the Higgs and to the spontaneous breaking of the electroweak (EW) symmetry.

The minimal CH model (MCHM) [5], is based on the symmetric coset $G/H = SO(5)/SO(4)$. Extended constructions have been presented in Refs. [6, 7]. CH models are typically written in the language of effective field theories, parametrising the lack of knowledge of the strongly interacting sector with a large set of unknown coefficients. This description is consequently valid only up to a scale $A_s$, where strong dynamics resonances are supposed to appear. The Minimal Linear σ-Model (MLσM) [8–11] is, instead, a renormalisable model that represents a convenient and well-defined framework that, at need, by integrating out the extra scalar degree of freedom (dof) $\sigma$, matches the usual effective non-linear MCHM [5, 12–14] Lagrangian, or the more general Higgs Effective Field Theory Lagrangian [15–37]. Following the treatment of Ref. [10], the symmetry content of the MLσM consists of a global $SO(5)$ spontaneously broken to $SO(4)$ when the scalar $SO(5)$ quintuplet $\phi$, containing the SM EW doublet Higgs $H$ and the EW singlet $\sigma$, acquires a non-vanishing vacuum expectation value (VEV) $f_\sigma$, assumed to be at the TeV scale in order to solve the Higgs naturalness problem. Moreover, non-vanishing masses for the SM fermions originate through the partial-compositeness mechanism [38, 39], by adding bilinear ($SO(5)$ explicit breaking) operators between the SM and exotic fermions. Finally, the symmetry sector is customarily enlarged by an extra $U(1)_X$ symmetry to correctly account for the SM hypercharge assignment. By extending the MLσM spectrum with an additional complex scalar field $s$, singlet under SM and $SO(5)$ symmetries, and by supplementing it with an additional global Abelian symmetry à la Peccei-Quinn (PQ) [40], $U(1)_\text{PQ}$, an axion or an axion-like particle (ALP) can also be introduced. Such a framework has been dubbed Axion-MLσM (AMLσM) [41, 42].

The tree-level renormalisable scalar potential associated to the AMLσM, describing the spontaneous $SO(5)/SO(4)$ and PQ symmetry breaking, reads [42]

$$V(\phi, s) = \lambda_\phi (\phi^T \phi - f_\phi^2)^2 + \lambda_s (2s^* s - f_s^2)^2 + 2\lambda_{s\phi} (s^* s) (\phi^T \phi) + \ldots,$$

where $\lambda_\phi$, $\lambda_s$ and $\lambda_{s\phi}$ are dimensionless parameters, $f_\phi$ and $f_s$ the $SO(5)$ and $U(1)_\text{PQ}$ symmetry breaking scales, and the dots stand for all possible $SO(5)$ and/or PQ explicit breaking terms necessary to guarantee the EW symmetry breaking, a viable SM spectrum and the renormalisability of the model.

It is customary to parametrise the complex scalar singlet $s$, in the PQ symmetry broken phase, with an exponential notation,

$$s = \frac{v_s + r}{\sqrt{2}} e^{i\theta} a/f_a,$$

with $r$ the radial component field and $a$ the pseudoscalar field, to be identified with the axion or ALP dof. The
axion (or ALP) decay constant $f_a \equiv \langle r \rangle \equiv \nu_r$ is typically of the order of the QCD axion scale $f_R$, and may undergo strong constraints arising from the experimental limits on the pseudoscalar coupling to photons. In the case of a being the QCD axion, with mass $m_a < 10$ eV, the bound\(^1\) on the scale $f_a$ is [50–52]

$$f_a \gtrsim |g_{a\gamma\gamma}| \times 10^7 \text{GeV}, \quad (3)$$

where $g_{a\gamma\gamma}$ is the adimensional effective coupling of the axion to two photons and depends on the fermionic spectrum and on the PQ charge assignment considered. For masses $10$ eV $< m_a < 0.1$ GeV the constraints become even stronger [53].

The bound in Eq. (3) strongly crashes with the requirement of a natural EW scale. Indeed, as explicitly shown in Ref. [42], either the coupling $\lambda_{so}$ in Eq. (1) is unnaturally set to 0, or the ”effective” $SO(5)/SO(4)$ breaking scale, labelled $f_{R}$, runs to the highest scale, $f_{R} \approx f_a \approx f_s$, reintroducing a strong fine-tuning between the EW and the CH scale, $\xi = v^2/f_{R}^2 \ll 1$. This suggests that the AMLσM framework is ”natural” only if $f_s$, and therefore $f_a$, are at the TeV scale.

To escape the constraint in Eq. (3), two approaches can be outlined. The first is still to rely on the QCD axion paradigm, as the solution to the strong CP problem: in this case a specific (ad hoc) choice of the PQ charges can be identified such that the $a\gamma\gamma$ coupling is vanishing [54] and consequently the astrophysical constraints are automatically evaded. The second approach consists in abandoning, partially or completely, the QCD ansatz and considering, instead, an ALP particle: then the inverse proportionality relation between the QCD axion mass and its decay constant does not need to be enforced anymore and a mass larger than 0.1 GeV can be achieved, relaxing the astrophysics bounds on the $a\gamma\gamma$ coupling, $f_a \gtrsim |g_{a\gamma\gamma}|$ GeV.

In Ref. [42], a minimal ALP scenario in the AMLσM framework has been considered, assuming that the PQ dynamics does not intervene in the explicit breaking of the $SO(5)$ symmetry, i.e. the two scales $f$ and $f_s$ are independent. The scale $f$ can be taken in the TeV range and the phenomenology associated to the $SO(5)/SO(4)$ sector turns out to be very similar to the one described in the original MLσM in Ref. [10]: the scale $f_s$, and therefore $f_a$, can also be taken in the TeV range, opening the possibility to test this model both at colliders and at B-factories. Moreover, no fine-tuning between the two scales $f$ and $f_s$ is necessary in this model.

\(^{1}\) A recent analysis [43] shows a preferred region of the parameter space $g_{a\gamma\gamma} \times g_{aee}$, being the latter the effective coupling of the axion with two electrons. When interpreted in terms of the DFSZ [44, 45] or KSVZ [46, 47] axion models, the best fit point is in the border of the perturbative unitarity of the Yukawas, while the fit is inconclusive at more than $2\sigma$. This region will be tested by future ARIADNE [48] and IAXO [49] experiments.

In this letter, the mechanisms behind the PQ and the $SO(5)$ symmetry breaking are instead identified assuming $f_s = f$ around the TeV scale (the possibility of $f_s \approx f$ has already been considered in Ref. [41], where however only the QCD axion scenario has been investigated, with $f_s \approx f \gg$ TeV). This is obtained by substituting the scales appearing in the $SO(5)$ explicit breaking terms with the singlet scalar $s$: once this field develops a VEV, these terms break $SO(5)$ spontaneously and not explicitly, thus linking $f$ with $f_s$. In this context, where $SO(5)$ is dynamically broken, alternative constructions with respect to the ALP solution considered in Ref. [42] can be considered. Moreover, as shown in Sect. IV, these AMLσM realisations can be testable at colliders and flavour factories.

In Sec. II the introduction of an ALP in the MLσM is reviewed, while in Sec. III viable, natural and minimal models are identified. The associated phenomenology is discussed in Sec. IV and final remarks are deferred to Sec. V. In the App. A, the ALP Lagrangian is reported with the explicit expression for the ALP-gauge boson couplings.

II. INTRODUCING $U(1)_{\text{PQ}}$ IN THE MLσM

The AMLσM [41, 42] is characterised by the global symmetry $SO(5) \times U(1)_X \times U(1)_{\text{PQ}}$. The spectrum includes the SM gauge bosons, the $SO(5)$ scalar quintuplet $\phi$, the complex scalar $s$, the third family SM fermions and four exotic fermions, two $SO(5)$ quintuplets $\psi(\')$ and two $SO(5)$ singlets $\chi(\')$. Only the exotic fields transform under $U(1)_X$, with the unprimed (primed) fields having a charge $+2/3$ ($−1/3$) respectively. The SM hypercharge $Y$ is given by the following combination between the generators of $SU(2)_R \subset SO(5)$ and $U(1)_X$:

$$Y = \Sigma_{R}^{(3)} X. \quad (4)$$

The decomposition of the exotic fermions and their transformation properties under the SM gauge symmetry can be found in Tab. I.

| $SO(5) \times U(1)_X$ $SU(3)_C \times SU(2)_L \times U(1)_Y$ | $Q_{em}$ |
|-----------------|----------|
| $\psi$ $(5,2/3)$ $K = (3,2,7/6)$ | $5/3, 2/3$ |
| | $Q = (3,2,1/6)$ | $2/3, −1/3$ |
| | $T_5 = (3,1,2/3)$ | $2/3$ |
| $\chi$ $(1,2/3)$ $T_1 = (3,1,2/3)$ | $2/3$ |
| $\psi'$ $(5,−1/3)$ $Q' = (3,2,1/6)$ | $2/3, −1/3$ |
| | $K' = (3,2,−5/6)$ | $−1/3, −4/3$ |
| | $B_5 = (3,1,−1/3)$ | $−1/3$ |
| $\chi'$ $(1,−1/3)$ $B_1 = (3,1,−1/3)$ | $−1/3$ |

Table I. Decomposition of the exotic fermions and their transformation properties under the SM gauge symmetry.
Generalising the notation of Ref. [41, 42], the SO(5) \times U(1)_X invariant Lagrangian containing the fermionic interactions can be written as follows:

\begin{align*}
L &= i \bar{q}_L i \mathcal{D} q_L + i \bar{t}_R i \mathcal{D} t_R + \bar{b}_R i \mathcal{D} b_R + \bar{q}_L i \mathcal{D} M_3 \psi + \bar{\chi} \left[ i \mathcal{D} - M_1 \right] \chi + \bar{\psi'} \left[ i \mathcal{D} - M_5' \right] \psi' + \bar{\chi} \left[ i \mathcal{D} - M_1' \right] \chi' \\
&- \left[ y_1 \bar{\psi}_L \phi R + y_2 \bar{\psi}_R \phi \chi L + z_1 \bar{\chi} \chi L s + z_5 \bar{\psi}_L \psi s + z_5 \bar{\psi}_L \psi L s^* + \right. \\
&\quad + \left( \Lambda_1 + k_1 s + \tilde{k}_1 s^* \right) (\bar{\psi}_L \Delta_2 \chi_5) \psi' + \left( \Lambda_2 + k_2 s + \tilde{k}_2 s^* \right) \bar{\psi}_L (\Delta_2 \chi_1 t_R) + \left( \Lambda_3 + k_3 s + \tilde{k}_3 s^* \right) \bar{\chi}_L t_R + h.c. \left] + \right. \\
&- \left[ y'_1 \bar{\psi}_L \phi' R + y'_2 \bar{\psi}_R \phi' \chi L + z'_1 \bar{\chi} \chi L s + z'_5 \bar{\psi}_L \psi s + z'_5 \bar{\psi}_L \psi L s^* + \right. \\
&\quad + \left( \Lambda'_1 + k'_1 s + \tilde{k}'_1 s^* \right) (\bar{\psi}_L \Delta_2' \chi_5) \psi' + \left( \Lambda'_2 + k'_2 s + \tilde{k}'_2 s^* \right) \bar{\psi}_L (\Delta_2' \chi_1 b_R) + \left( \Lambda'_3 + k'_3 s + \tilde{k}'_3 s^* \right) \bar{\chi}_L b_R + h.c. \right].
\end{align*}

The first line contains the kinetic terms for all the fermions plus the direct mass terms, \( M_1^{[1,5]} \), of the exotic fields. The second and third lines refer to the top sector. The terms proportional to \( y_i \) are SO(5) invariant Yukawa terms between exotic fermions and the scalar quintet. The ones proportional to \( z_i \) and \( \tilde{z}_i \) are Yukawa-type interactions, between the exotic fermions and the SO(5) singlet scalar, which contribute to the exotic fermion masses once the PQ symmetry breaking occurs. In the third line the partial compositeness operators linking the exotic fermions and the top quark are included, needed for providing a non-vanishing top mass. The first two terms, which are proportional to \( \Delta_{i x j} \), explicitly break the SO(5) symmetry, while the last one is, instead, SO(5) preserving. The \( \Delta_{i x j} \) quantities play the role of spurions [55–59] for the SO(5) \times U(1)_X symmetry. Finally the last two lines refer to the bottom sector and all the previous comments on the unprimed terms apply to their primed counterparts as well.

With the exotic fermions acquiring masses larger than the EW scale, a fermionic Seesaw mechanism provides the masses for the SM fermions [4, 38, 39, 60–67]: the Leading Order (LO) contribution reads:

\begin{equation}
\begin{aligned}
m_t &= \frac{y_1 \Lambda_1(v_r) \Lambda_3(v_r) v_h}{M_1(v_r) M_5(v_r) - y_1 y_2 (v_h^2 + v_\sigma^2)} + \\
&\quad - \frac{y_1 y_2 \Lambda_1(v_r) \Lambda_2(v_r) v_h v_\sigma}{M_1(v_r) M_5(v_r) - y_1 y_2 M_5(v_r) (v_h^2 + v_\sigma^2)},
\end{aligned}
\end{equation}

where \( v_h, v_\sigma \) and \( v_r \) are the VEVs of the physical field \( h \), \( \sigma \) and \( r \), satisfying to \( v_h^2 + v_\sigma^2 = f^2 \), and the functions of \( v_r \) are defined as

\begin{equation}
\begin{aligned}
\Lambda_i(v_r) &\equiv \Lambda_i + (k_i + \tilde{k}_i) v_r, \\
M_i(v_r) &\equiv M_i + (z_i + \tilde{z}_i) v_r.
\end{aligned}
\end{equation}

Similar expressions hold for the bottom sector too.

A general comment has to be highlighted. In the Lagrangian in Eq. (5) and in the expressions for the SM fermion masses above, not all the terms can actually be present at the same time. Depending on the specific choice of the PQ charges, several terms are simply forbidden: in particular only one term among those proportional to \( \Lambda_i \), to \( k_i \) and to \( \tilde{k}_i \) is allowed for a given PQ charge assignment; a similar observation holds for the terms proportional to \( M_i \), \( z_i \) and \( \tilde{z}_i \).

Once the fermionic Lagrangian is fully determined, the computation of the 1-loop contributions to the scalar potential is straightforward: the Coleman-Weinberg (CW) formula [68] allows to extract the divergences generated at 1-loop with internal fermion and gauge boson lines. This aspect has been described in details in Ref. [10, 42] for the MLσM without and with the presence of the PQ symmetry. In general, several divergent contributions arise at one loop that cannot be re-absorbed in the tree-level SO(5) invariant scalar potential in Eq. (1). In consequence, to have a renormalisable Lagrangian, consistent with a viable EW symmetry breaking, the corresponding terms need to be added to the tree-level scalar potential. As two is the minimum number of explicit SO(5) breaking terms needed to have a viable EW breaking sector, constructions with only two extra parameters in Eq. (1) have been dubbed “minimal”.

III. VIABLE, NATURAL & MINIMAL AMLσM

A proper model should be viable, natural and minimal. In order to construct an AMLσM satisfying these three features, the following guiding conditions are required: i) third generation SM fermion masses are generated at LO and therefore the expression in Eq. (6) must not vanish; ii) no large hierarchy is present between the SO(5) and \( U(1)_{\text{PQ}} \) breaking scales; iii) the model depends on the minimal possible number of parameters.

In order to identify the PQ charge assignments compatible with these three requirements, it is useful to introduce the following five PQ charges differences: for the top sector,

\begin{equation}
\begin{aligned}
\Delta_{y_1} &\equiv n_{v_L} - n_{\chi_R}, \\
\Delta_{\Lambda_1} &\equiv n_{q_L} - n_{\psi_R}, \\
\Delta_{\chi} &\equiv n_{\chi_L} - n_{\chi_R}, \\
\Delta_{\psi} &\equiv n_{\psi_L} - n_{\psi_R}.
\end{aligned}
\end{equation}
Similar quantities can be defined for the bottom sector by replacing the unprimed fields with the primed ones.

Condition i) is satisfied by requiring that none among $y_1$, $\Lambda_1(v_r), \Lambda_3(v_r)$, $M_1(v_r)$ and $M_3(v_r)$ is vanishing. Alternative possibilities with non-vanishing $\Delta_2(v_r)$ turn out to be non-minimal. In terms of the quantities defined above, this corresponds to

$$\Delta_{y_1} = 0, \quad \Delta_{\Lambda_1} = \{0, \pm n_s\}, \quad \Delta_{\Lambda_3} = \{0, \pm n_s\}, \quad \Delta_\chi = \{0, \pm n_s\}, \quad \Delta_\psi = \{0, \pm n_s\}.$$  

Whenever one of these quantities vanishes, the corresponding allowed term in the Lagrangian is the constant one: i.e. $y_1$, $\Lambda_1$ and $M_1$. On the other hand, if any of the charge differences is equal to $-n_s$ ($+n_s$), the corresponding term, allowed in the Lagrangian, is proportional to $s$ ($s^*$). As an example, $\Delta_\chi = 0$ indicates that $\chi_L$ and $\chi_R$ transform under $U(1)_{PQ}$ with the same charge and therefore the term $M_1\chi_L\chi_L$ is invariant under $U(1)_{PQ}$ and should be kept in the Lagrangian. If, instead, $\Delta_\psi = -n_s$, then the $z_2\chi_L\chi_L$ term is the invariant one. There are $3^4 = 81$ possible different configurations compatible with condition i) for a single fermion sector, while any value different from 0 or $\pm n_s$ leads to vanishing SM fermion masses.

The naturalness requirement, condition ii), is satisfied only if all the scales in the Lagrangian, except for $M_1$ and $\Delta_3$, are in the TeV range. The $SO(5)$ and $U(1)_{PQ}$ breaking scales $f$ and $f_s$ need to satisfy this condition in order to avoid large fine-tunings in the tree-level scalar potential, as discussed in the Introduction. For the other quantities, such as $M_3$, $\Lambda_1$ and $\Lambda_2$, the reason resides in the fact that they correct the scalar potential parameters at one-loop (see Ref. [42] for details). If these parameters are much larger than the TeV, large fine-tunings would be necessary in order to guarantee a viable EW VEV. $M_1$ and $\Delta_3$ evade this condition because they do not enter the EW contributions: as already pointed out in Ref. [41], they only need to satisfy $\Delta_3/M_1 \sim 1$ in order to provide a viable value for the mass of third generation SM quarks – see Eq. (6) – assuming natural Yukawa couplings $y_i$.

The minimality condition iii) only concerns the number of parameters that enter the scalar potential once considering the 1-loop contributions. Two divergent terms, proportional to $h^2$ and $h^4$, arise from the CW potential induced by the gauge bosons: these divergences are independent of the specific PQ charge assignment and therefore the corresponding terms necessarily enter the final scalar potential. Minimal constructions are those where the fermionic CW potential does not introduce any additional divergence that cannot be absorbed by a re-definition of the parameters in Eq. (1) or of $h^2$ or $h^4$, as discussed in Ref. [42].

Out of the 81 possible AML$\sigma$M constructions, only seven satisfy to all three conditions and they are listed in Tab. II, defined by the PQ charges of the fermion fields, written as a function of the charge $n_s$ of the PQ scalar field. In the same table, the parameters entering the Lagrangian are explicitly reported. On the right side, the corresponding values for $\Delta_\psi$, $\Delta_\chi$ and $\Delta_t$ are listed.

| $M_1$ | $n_{\psi_L} = n_{\psi_R} = n_{\chi_L} = n_{\chi_R} = n_{q_L} = n_{q_R} = 2n_s$ | $y_1$ | $y_2$ | $\Lambda_1$ | $k_1$ | $k_3$ | $z_1$ | $M_5$ | $z_5$ | $\Delta_\psi$ | $\Delta_\chi$ | $\Delta_t$ | $\Delta_b$ |
|-------|-------------------------------------------------------------------|-------|-------|------------|-------|-------|-------|-------|-------|----------|----------|----------|--------|
| $M_2$ | $n_{\psi_L} = n_{\psi_R} = n_{\chi_L} = n_{\chi_R} = n_{q_L} = n_{q_R} = n_{q_L} = n_{q_R} = 2n_s$ | ✓     | ✓     | ✓         | ✓     | ✓     | ✓     | ✓     | ✓     | 0 $n_s$  | $-2n_s$  | $0 n_s$  | $-2n_s$ |
| $M_3$ | $n_{\psi_L} = n_{\psi_R} = n_{\chi_L} = n_{\chi_R} = n_{q_L} = n_{q_R} = 2n_s = n_{q_L} = n_{q_R} = 2n_s$ | ✓     | ✓     | ✓         | ✓     | ✓     | ✓     | ✓     | ✓     | 0 $n_s$  | $-3n_s$  | $0 n_s$  | $-3n_s$ |

Table II. List of the viable, natural and minimal AML$\sigma$M realizations, defined by the conditions on the PQ charges of the fermion fields written in terms of the charge $n_s$ of the PQ scalar field. The constants allowed in the Lagrangian are indicated with “✓”, while all the remaining Lagrangian parameters that are not listed in this table are not allowed for symmetry reasons. On the right side, the corresponding values for $\Delta_\psi$, $\Delta_\chi$ and $\Delta_t$ are listed.
$\Delta_s = \Delta_b$, while $M^a_7$ for the opposite charge case, where $\Delta_\psi = -\Delta_\psi$, $\Delta_\chi = -\Delta_\chi$, and $\Delta_t = -\Delta_b$. The explicit charge assignment for each model can be read in Tab. V.

The scalar potential associated to all the models listed in Tab. II has already been studied in Ref. [42], together with the phenomenology associated to the exotic fermions and scalar fields. As a consequence, the next section will only focus on the ALP phenomenology.

### IV. THE ALP PHENOMENOLOGY

Performing fermion field redefinitions, the Lagrangian in Eq. (5) can be rewritten such that the axion or ALP has only derivative couplings with fermions. In particular, these models predict that the axion or ALP couples to both top and bottom quarks: these interactions can be written as

$$\mathcal{L}_a = - c_{a\psi}\psi' \frac{\partial a}{\partial f_a} \gamma^\mu \gamma_5 \psi', \quad (11)$$

where the couplings $c_{a\psi'}$ depend on the specific model considered and can be read in Tab. III.

| $c_{\text{eff}}$ | $c_{\text{abh}}$ |
|------------------|------------------|
| $M^a_1$         | $2n_s$           |
| $M^a_1$         | $2n_s$           |
| $M^a_2$         | $3n_s$           |
| $M^a_2$         | $3n_s$           |
| $M^a_3$         | $4n_s$           |
| $M^a_3$         | $4n_s$           |
| $M^a_4$         | $3n_s$           |
| $M^a_4$         | $3n_s$           |
| $M^a_5$         | $2n_s$           |
| $M^a_5$         | $2n_s$           |
| $M^a_6$         | $n_s$            |
| $M^a_6$         | $n_s$            |
| $M^a_7$         | $n_s$            |
| $M^a_7$         | $n_s$            |

Table III. Values of the coefficients $c_{a\psi'}$ in terms of the charge $n_s$ for the top and bottom quarks.

Moreover, at the quantum level, the derivative of the axial current is non-vanishing, giving rise to the following effective axion-gauge boson couplings: in the physical basis for the gauge bosons,

$$\delta \mathcal{L}_a^{\text{eff}} = - \frac{\alpha_s}{8\pi} c_{aGG} \frac{a}{f_a} \frac{a}{Z} \frac{a}{G^\mu_\nu} - \frac{\alpha_m}{8\pi} c_{a\gamma\gamma} \frac{a}{f_a} \frac{a}{F^\mu_\nu} + \frac{\alpha_m}{8\pi} c_{aZZ} \frac{a}{f_a} \frac{a}{Z^\mu_\nu} - \frac{\alpha_m}{8\pi} c_{a\gamma Z} \frac{a}{f_a} \frac{a}{F^\mu_\nu} + \frac{\alpha_m}{8\pi} c_{aWW} \frac{a}{f_a} \frac{a}{W^+^\mu_\nu} \frac{a}{\tilde{W}^-} ,$$

where $X^\mu_\nu = \epsilon^{\mu\nu\rho\sigma} X_{\rho\sigma}/2$ and the convention $\epsilon_{1230} = +1$ is used. The mass independent anomaly contributions to the coefficients $c_{ai}$ are explicitly reported in App. A2, in terms of the PQ fermionic charges, while in Tab. IV the anomalous coefficients for the seven models summarised in Tab. II are listed.\(^2\) These coefficients include the contributions of all the fermions that do couple with $a$.

| $c_{aGG}$ | $c_{a\gamma\gamma}$ | $c_{aZZ}$ | $c_{a\gamma Z}$ | $c_{aWW}$ |
|------------|-------------------|-----------|-----------------|------------|
| $M^a_1$    | $-2n_s$           | $-\frac{27}{20} n_s$ | $-\frac{3n_s}{20} \sigma_0$ | $\frac{3}{2} n_s \theta - \frac{6n_s}{20} \theta_0$ | $-\frac{6n_s}{20} \theta_0$ |
| $M^a_2$    | $-4n_s$           | $-\frac{3}{20} n_s$ | $-\frac{3n_s}{20} \sigma_0$ | $\frac{3}{2} n_s \theta - \frac{6n_s}{20} \theta_0$ | $-\frac{6n_s}{20} \theta_0$ |
| $M^a_3$    | $0$               | $-4n_s$   | $-\frac{3}{20} n_s$ | $\frac{3}{2} n_s \theta - \frac{6n_s}{20} \theta_0$ | $-\frac{6n_s}{20} \theta_0$ |
| $M^a_4$    | $6n_s$            | $\frac{92}{5} n_s$ | $\frac{92}{5} n_s \sigma_0$ | $-\frac{12n_s}{5} \theta + \frac{12n_s}{5} \theta_0$ | $\frac{12n_s}{5} \theta_0$ |
| $M^a_5$    | $0$               | $6n_s$    | $\frac{92}{5} n_s \sigma_0$ | $-\frac{12n_s}{5} \theta + \frac{12n_s}{5} \theta_0$ | $\frac{12n_s}{5} \theta_0$ |
| $M^a_6$    | $8n_s$            | $\frac{12n_s}{5} \sigma_0$ | $\frac{12n_s}{5} n_s \sigma_0$ | $-\frac{12n_s}{5} \theta + \frac{12n_s}{5} \theta_0$ | $\frac{12n_s}{5} \theta_0$ |
| $M^a_7$    | $0$               | $0$       | $\frac{2n_s \sigma_0}{3}$ | $-\frac{3n_s \theta - \frac{6n_s}{20} \theta_0}{20} \theta_0$ | $-\frac{6n_s}{20} \theta_0$ |

Table IV. Values of the coefficients $c_{ai}$ in terms of the charges $n_s$, $\theta$ and $\theta_0$ for the tangent and the sine of the Weinberg angle respectively.

It is now possible to discuss the phenomenological features of the seven AMLR models presented. Firstly, all models, but $M^a_7$, have a non-vanishing coupling between the ALP and two photons. As a consequence, the strong bound present on this coupling - reported in Eq. (3) - translates into a constraint on the scale $f_a$ that should be much larger than the EW scale, introducing a strong Hierarchy problem in the scalar potential (tree and loop level [69]). In order to avoid this fine-tuning problem, $m_a \gtrsim 0.1$ GeV has to be considered for all the models $M^a_{6,7}$. As a drawback, none of these ALP models provide a solution to the Strong CP problem: such a large mass would correspond to an explicit breaking of the shift symmetry, perturbing the QCD potential and preventing the classical solution of the QCD axion models [40, 44–47, 70, 71].

On the other hand, having $f_a$ in the TeV region opens the possibility of direct searches of ALP signatures at present and future experimental facilities [42, 52, 72].

\(^2\) Only one generation of SM fermions has been considered here, consistently with the formulation of the AMLR model in the previous section. Once extending this study to the realistic case of three generations, the values reported in Tab. IV has to be modified: for example, assuming that the same charges will be adopted for all the fermion generations, the numerical values in the table would have to be multiplied by a factor 3.
ALP with mass $m_a \sim 1$ GeV will be considered in the following as an illustration.

For an ALP with a mass in the GeV region several constraints are present on its couplings to gauge bosons. Assuming that the ALP does not decay within the detector and therefore is treated as missing energy in data analyses, there are bounds from collider searches. In particular LEP data [73, 74] has been used to constrain ALP coupling to two photons [75] once the axion is produced through a virtual photon: the corresponding bound on the scale $f_a$ reads

$$\frac{f_a}{|c_{a\gamma\gamma}|} \gtrsim 1 \text{ GeV}. \quad (13)$$

This bound may be improved by two order of magnitudes with dedicated analyses based on data from BaBar and from Belle-II [75–77]. Moreover, a similar sensitivity may be obtained considering the $\Upsilon(nS) \rightarrow \gamma + \text{inv.}$ decay [77, 78].

Studies on mono-$W$ and mono-$Z$ present LHC data [79] lead to

$$\frac{f_a}{|c_{aWW}|} \gtrsim 0.7 \text{ GeV}, \quad \frac{f_a}{|c_{aZZ}|} \gtrsim 1.4 \text{ GeV}, \quad (14)$$

while LEP data [73, 74] on the radiative $Z$ decays has been used to infer a bound on $a\gamma Z$ one [77]:

$$\frac{f_a}{|c_{a\gamma Z}|} \gtrsim 18 \text{ GeV}. \quad (15)$$

Future LHC sensitivity prospects on mono-$W$ and mono-$Z$ considering an integrated luminosity of 3000 fb$^{-1}$ improve the first two bounds of an order of magnitude [79].

On the other side, rare meson decays provide strong constraints on the ALP coupling to two $W$'s. In the case of an invisible ALP, the most stringent bounds arise from Belle limits on $B(B \rightarrow K\nu\bar{\nu})$ [80]. By assuming that only $c_{aWW}$ contributes, it leads to

$$\frac{f_a}{|c_{aWW}|} \gtrsim 10 \text{ GeV}. \quad (16)$$

Belle-II expected sensitivity improves this bound of approximately one order of magnitude [76, 81].

Finally, considering the ALP coupling to top and bottom quarks, $B$ and $\Upsilon$ decays provide interesting bounds. Once considering that $B^+ \rightarrow K^+ a$ proceeds only via a loop diagram containing the $c_{att}$ coupling, the bound that can be extracted from Belle data [80] for $m_a \approx 1$ GeV reads [82]

$$\frac{f_a}{|c_{att}|} \gtrsim 200 \text{ TeV}, \quad (17)$$

while Belle-II may improve this bound of a factor of 5. In general, both $c_{aWW}$ and $c_{att}$ contribute to this decay and may exist part of the parameter space where a cancellation take place, relaxing the bounds in Eqs. (16) and (17). As discussed in Ref. [82], this cancellation is possible only if both $c_{aWW}$ and $c_{att}$ are loop-induced: this is not the case in the models discussed here, where $c_{att}$ is at tree-level.

Finally, data from BaBar [83, 84] and Belle [85] on $\Upsilon(nS) \rightarrow \gamma + \text{inv.}$ put bounds on $f_a/|c_{abb}|$, but they are sub-dominant with respect to the previous bound from $B$ decays, reaching a sensitivity of a few TeV [78]: for $10 \text{ keV} \lesssim m_a \lesssim 5$ GeV,

$$\frac{f_a}{|c_{abb}|} \gtrsim 2.5 \text{ TeV}, \quad (18)$$

Also for $\Upsilon(nS) \rightarrow \gamma + \text{inv.}$, in general, the branching ratio would depend on both $c_{abb}$ and $c_{a\gamma\gamma}$: however, in the models considered here, $c_{a\gamma\gamma}$ is weighed by loop factors and then its contribution is negligible with respect to the one proportional to $c_{abb}$ (for the generic analysis see Ref. [78]). For heavier ALPs, there are only very weak bounds from colliders or B-factories, that would allow $f_a/|c_{abb}|$ to be in the TeV range. On the other side, for lighter masses, $m_a \lesssim 10$ keV, much stronger bounds from stellar cooling data [86] are obtained:

$$\frac{f_a}{|c_{att}|} \gtrsim 1.2 \times 10^6 \text{ TeV} \quad \text{for the top} \quad (19)$$

$$\frac{f_a}{|c_{abb}|} \gtrsim 6.1 \times 10^2 \text{ TeV} \quad \text{for the bottom}. \quad (15)$$

These constraints have been derived translating the existing bounds on axion coupling to electrons into constraints on the axion emission occurring via a top or bottom loop.

When the ALP decays within the detector, other observables need to be considered. Focussing on the radiative ALP decay, LEP data [73, 74] on the radiative $Z$ decays can again be used to infer a bound on $a\gamma Z$ coupling [77]:

$$\frac{f_a}{|c_{a\gamma Z}|} \gtrsim 1.8 \text{ GeV}, \quad (20)$$

under the assumption that $B(a \rightarrow \gamma\gamma) = 1$. These bounds may be improved by two order of magnitude with dedicated analyses both at B-factories and at LHC [75–77].

Although $a$ decays dominantly into photons in the models considered here ($c_{a\gamma\gamma} > c_{agg}$), the coupling with gluons can provide interesting phenomenology and can be bounded considering the BaBar results on the branching ratio of $\Upsilon(2s,3s) \rightarrow \gamma a(\rightarrow jj)$ [87]: for $m_a = 1$ GeV,

$$\frac{f_a}{|c_{agg}|} \gtrsim 80 \text{ GeV}. \quad (21)$$

This bound is expected to reach values of 0.2 TeV at Belle-II [88].
Finally, considering the ALP coupling with bottom quarks, data on \(b \to s q\) or \(b \to sq\bar{q}\) from CLEO collaboration \cite{89} allows to put bound on \(f_a/|c_{ab}|\) \cite{90}: for \(0.4 \text{ GeV} \lesssim m_a \lesssim 4.8 \text{ GeV},\)

\[
\frac{f_a}{|c_{ab}|} \gtrsim 2 \text{ TeV}.
\] (22)

On the other side, \(B^{\pm} \to K^{\pm} a(\to 2\gamma)\) decay, that could be studied at Belle-II, may be extremely useful to improve on these bound and will work as a test for the models presented here. Assuming that Belle-II reached a sensitivity of \(10^{-6}\) on \(B(B \to K \gamma \gamma)\), strong bound can be inferred to \(aWW\) and \(att\) couplings: values of \(f_a\) as large as \(|c_{aWW}| \times 60 \text{ GeV} \) and \(|c_{att}| \times 300 \text{ TeV}\) could be probed.

To understand which bounds apply to the models listed above, the ALP decay length must be considered. It is generically given by \cite{79}

\[
d \sim 10^{-2} \left(\frac{\text{GeV}}{m_a}\right)^4 \left(\frac{f_a}{\text{TeV}}\right)^2 \left(\frac{|p_a|}{\text{GeV}}\right).
\] (23)

For an ALP of \(m_a \sim 1 \text{ GeV}, f_a \sim 1 \text{ TeV}\) and typical momentum \(|p_a| \sim 100 \text{ GeV},\) the traveling distance before decaying into two photons (the dominant channel as \(|c_{a\gamma\gamma}| \gg |c_{agg}|\)) is around \(1/c_{a\gamma\gamma}^2 \text{ m},\) that is in the interval \(1 \text{ mm} \sim 0.1 \text{ m}\) for \(n_s = 1,\) depending on the specific value of \(c_{a\gamma\gamma}\) reported in Tab. IV. Therefore, all the ALPs described in the models \(M_{1-6}^\pm\) decay within the detector and the bounds in Eqs. (20)–(22) apply. The models \(M_{7-8}^\pm\) instead, predict vanishing ALP couplings with both photons and gluons and therefore these ALPs are stable at tree level for masses up to \(\sim 10 \text{ GeV}\): for these models the bounds in Eqs. (13)–(18) apply.

Considering the explicit values of the axion coupling, taking \(n_s = 1,\) the strongest bounds on \(f_a\) for each model \(M_{1-6}^\pm\) read as follow:

\[
\begin{align*}
M_1^\pm & \to f_a \gtrsim 4 \text{ TeV}, & M_2^\pm & \to f_a \gtrsim 6 \text{ TeV}, \\
M_3^\pm & \to f_a \gtrsim 8 \text{ TeV}, & M_4^\pm & \to f_a \gtrsim 6 \text{ TeV}, \\
M_5^\pm & \to f_a \gtrsim 4 \text{ TeV}, & M_6^\pm & \to f_a \gtrsim 2 \text{ TeV}.
\end{align*}
\] (24)

For all these cases, \(f_a\) can be in the TeV range, where the \(SO(5)\) breaking mechanism is expected to occur.

On the other side, to summarise the most relevant constraints for \(M_7^\pm\), the plots in Fig. 1 are shown. As can be seen, pretty strong constraints are present for \(m_a \lesssim 4.8 \text{ GeV};\) in this case, \(f_a \gtrsim 200 \text{ TeV}\) and therefore a mild tuning is present in the scalar potential of the models \(M_7^\pm\). For masses larger than this value, but up to \(10 \text{ GeV}\) the constraints are milder and \(f_a \sim \mathcal{O}(1) \text{ TeV},\) avoiding any tuning in the scalar potential.

Finally, it is possible to comment \textit{a posteriori} on the assumed value for \(m_a\). In ALP models, corrections to the QCD potential are expected to be present such that the inverse proportionality between \(m_a\) and \(f_a\) gets broken: this is achieved with breaking terms at least of the order of \(\Lambda_{QCD} \approx 100 \text{ MeV}.\) As a consequence, the ALP mass is expected to be of the same order of these breaking terms and then larger than \(\sim 0.1 \text{ GeV}.\) On the order side, the ALP Lagrangian is written as an expansion in inverse powers of \(f_a,\) and for the EFT description to be meaningful, the ALP should be lighter than \(f_a.\) The benchmark scenario of \(m_a = 1 \text{ GeV}\) enters in this range of values.

\section{Conclusions}

The strong bounds on axion/ALP couplings to photons and electrons imply very high values for the PQ breaking scale \(f_a.\) This represents the origin of a hierarchy problem present in most of the axion models: the quartic coupling in the potential between the Higgs field and
the complex scalar field, associated to the axion, can be hardly ever prevented by symmetry arguments. As a consequence, avoiding fine-tuning among parameters, any other energy scale tends to be close to $f_a$. The AMLσM is a well defined and renormalisable framework where to address this problem. To delimitate the landscape of possible PQ charge assignments, three criteria have been imposed: i) third generation SM fermion masses are generated at LO; ii) the $SO(5)$ and $U(1)_{PQ}$ breaking scales coincide; iii) the model depends on the minimal possible number of parameters. Seven possible scenarios have been identified.

For ALPs with masses larger than 10 MeV, the aforementioned astrophysical bounds on couplings to photons and electrons are avoided. For concreteness, a mass of 1 GeV has been considered. This value is within the expected range of values for an ALP, that naturally has a mass larger than $\Lambda_{QCD}$ but smaller then $f_a$. In six of the models, the ALP decays within the detector and the most relevant bounds come from CLEO: they can be translated into constraints of the scale of the ALP, $f_a \gtrsim 2 \div 8$ TeV. For the seventh model, the ALP does not decay and the strongest constraints arise from $B^+ \rightarrow K^+ a$ decay: in this case, for ALP with masses up to ~4.5 GeV, $f_a = f \sim 200$ TeV, while for larger masses up to ~10 GeV much weaker bounds are present and $f_a = f \sim O(1)$ TeV. Therefore, in all the realisations presented, the PQ and $SO(5)$ breaking scales can satisfy to $f_a = f \approx O(1)$ TeV and then these models have the possibilities to be tested soon both at colliders and at Belle-II (the only exception is $M_\pm^7$ and for ALP masses up to ~4.8 GeV). In conclusion, these are testable and natural AMLσM, free from any fine-tuning in the scalar potential, and where the typical hierarchy problem that affects axion and ALP models is avoided.

Appendix A: Axion Lagrangian

The axion or ALP Lagrangian in the basis where axion-fermion couplings are only derivative is given by

$$\mathcal{L}_a = -\frac{\partial_\mu a}{2f_a} \left[ \Delta_\psi \bar{\psi} \gamma^\mu \psi + \Delta_\chi \bar{\chi} \gamma^\mu \chi + \Delta_\psi' \bar{\psi}' \gamma^\mu \psi' + \Delta_\chi' \bar{\chi}' \gamma^\mu \chi' + \Delta_t \bar{t} \gamma^\mu t + \Delta_b \bar{b} \gamma^\mu b \right]. \quad (A1)$$

The axion or ALP couplings with gauge bosons arise due to the anomalous nature of the PQ symmetry. They can
be read out in the following effective Lagrangian that encodes the traditional 1-loop contributions of all the fermions:

\[
\delta \mathcal{L}_{\text{eff}} \geq -\frac{\alpha_s}{8\pi} \left[ 5 (\Delta_\psi + \Delta_\psi') + \Delta_\chi + \Delta_\chi' + \Delta_\ell + \Delta_b \right] G_{\mu\nu} \tilde{G}^{\mu\nu} + \\
- \frac{\alpha_{em}}{8\pi} \left[ 6 \Delta_\psi \left( 1 + 2 (Y^2_K + \frac{1}{2} Y_{T_3}^2) + 6 \Delta_\psi' \left( 1 + 2 (Y^2_K' + \frac{1}{2} Y_{T_3}^2) + Y_{B_3}^2 \right) + 6 (\Delta_\chi Y_{T_1}^2 + \Delta_\chi' Y_{B_1}^2) + 6 (\Delta_\ell Y_{T_1}^2 + \Delta_b Y_{B_1}^2) \right] F_{\mu\nu} \tilde{F}^{\mu\nu} + \\
- \frac{\alpha_{em}}{8\pi} \left[ \frac{6}{\sin^2 \theta_W} \left( 2 (\Delta_\psi + \Delta_\psi') + \frac{\Delta_\ell + \Delta_b}{4} \right) W_{\mu\nu} \tilde{W}^{-\mu\nu} + \\
- \frac{\alpha_{em}}{8\pi} \left[ 6 \Delta_\psi \left( \frac{1}{\tan^2 \theta_W} + \tan^2 \theta_W \left( 2 (Y^2_K + \frac{1}{2} Y_{T_3}^2) + Y_{B_3}^2 \right) \right) + 6 \Delta_\chi \tan^2 \theta_W Y_{T_1}^2 + \\
+ 6 \Delta_\psi' \left( \frac{1}{\tan^2 \theta_W} + \tan^2 \theta_W \left( 2 (Y^2_K' + \frac{1}{2} Y_{T_3}^2) + Y_{B_3}^2 \right) \right) + 6 \Delta_\chi' \tan^2 \theta_W Y_{B_1}^2 + \\
+ \frac{3}{4} \frac{\Delta_\ell + \Delta_b}{\tan^2 \theta_W} \left( 1 + \tan^2 \theta_W \right) + 6 \tan^2 \theta_W \left( \Delta_\chi Y_{T_1}^2 + \Delta_b Y_{B_1}^2 \right) \right] Z_{\mu\nu} \tilde{Z}^{\mu\nu} + \\
- \frac{\alpha_{em}}{8\pi} \left[ 12 \Delta_\psi \left( \frac{1}{\tan \theta_W} - \tan \theta_W \left( 2 (Y^2_K + \frac{1}{2} Y_{T_3}^2) \right) \right) - 12 \tan \theta_W \Delta_\chi Y_{T_1}^2 + \\
+ 12 \Delta_\psi' \left( \frac{1}{\tan \theta_W} - \tan \theta_W \left( 2 (Y^2_K' + \frac{1}{2} Y_{T_3}^2) + Y_{B_3}^2 \right) \right) - 12 \tan \theta_W \Delta_\chi' Y_{B_1}^2 + \\
+ 3 \frac{\Delta_\ell + \Delta_b}{2} \left( \frac{1}{\tan \theta_W} + \tan \theta_W \right) - 12 \tan \theta_W \left( \Delta_\chi Y_{T_1}^2 + \Delta_b Y_{B_1}^2 \right) \right] F_{\mu\nu} \tilde{F}^{\mu\nu}.
\]

(A2)

In the previous expression, \( \Delta_\ell \) are defined in Eqs. (8), (9) and (10), while \( n_f \) is the PQ charge of the generic field \( f \) that are reported for simplicity in Tab. V.

| \( M_i \) | \( n_\psi = n_\chi = n_\nu = n_\chi' = n_\nu' = n_\chi'' = n_\nu'' = n_\gamma = n_\beta = n_\gamma' = n_\beta' = n_\gamma'' = n_\beta'' = n_\eta = n_\zeta = n_\theta = n_\delta = n_\epsilon = n_\zeta' = n_\zeta'' = n_\zeta''' = n_\zeta'''' = n_\zeta''''' = n_\zeta'''''' = n_\zeta''''''' = n_\zeta'''''''' = n_\zeta''''''''' = n_\zeta''''''''''' = n_\zeta'''''''''' = n_\zeta'''''''''''' = n_\zeta'''''''''''''' = n_\zeta'''''''''''''''' = n_\zeta'''''''''''''''''' = n_\zeta'''''''''''''''''''' = n_\zeta'''''''''''''''''''''' = n_\zeta'''''''''''''''''''''''' = n_\zeta'''''''''''''''''''''''''' = n_\zeta'''''''''''''''''''''''''''' = n_\zeta'''''''''''''''''''''''''''''' = n_\zeta'''''''''''''''''''''''''''''''' = n_\zeta'''''''''''''''''''''''''''''''''' = n_\zeta'''''''''''''''''''''''''''''''''''' = n_\zeta'''''''''''''''''''''''''''''''''''''' = n_\zeta'''''''''''''''''''''''''''''''''''''''' = n_\zeta'''''''''''''''''''''''''''''''''''''''''' = n_\zeta'''''''''''''''''''''''''''''''''''''''''''' = n_\zeta'''''''''''''''''''''''''''''''''''''''''''''' = n_\zeta'''''''''''''''''''''''''''''''''''''''''''''''' = n_\zeta'''''''''''''''''''''''''''''''''''''''''''''''''' = n_\zeta'''''''''''''''''''''''''''''''''''''''''''''''''''' = n_\zeta'''''''''''''''''''''''''''''''''''''''''''''''''''''' = n_\zeta'''''''''''''''''''''''''''''''''''''''''''''''''''''''' = n_\zeta'''''''''''''''''''''''''''''''''''''''''''''''''''''''''' = n_\zeta'''''''''''''''''''''''''''''''''''''''''''''''''''''''''''' = n_\zeta'''''''''''''''''''''''''''''''''''''''''''''''''''''''''''''' = n_\zeta'''''''''''''''''''''''''''''''''''''''''''''''''''''''''''''''' = n_\zeta'''''''''''''''''''''''''''''''''''''''''''''''''''''''''''''''''' = n_\z_|
