Abstract

IL-21 is a type-I cytokine that has pleiotropic immuno-modulatory effects. Primarily produced by activated T cells including NKT and T<sub>FH</sub> cells, IL-21 plays a pivotal role in promoting T<sub>FH</sub> differentiation through poorly understood cellular and molecular mechanisms. Here, employing a mouse model of influenza A virus (IAV) infection, we demonstrate that IL-21, initially produced by NKT cells, promotes T<sub>FH</sub> differentiation by promoting the migration of late activator antigen presenting cell (LAPC), a recently identified T<sub>FH</sub> inducer, from the infected lungs into the draining lymph nodes (dLN). LAPC migration from IAV-infected lungs into the dLN is CXCR3-CXCL9 dependent. IL-21-induced TNF-α production by conventional T cells is critical to stimulate CXCL9 expression by DCs in the dLN, which supports LAPC migration into the dLN and ultimately facilitates T<sub>FH</sub> differentiation. Our results reveal a previously unappreciated mechanism for IL-21 modulation of T<sub>FH</sub> responses during respiratory virus infection.

Introduction

Following infection with pathogenic microorganisms, the encounter of B cells with their cognate specific Ag in secondary lymphoid organs triggers B cell activation, proliferation and differentiation ultimately resulting in germinal center (GC) formation within B cell follicles. The GC response is particularly pronounced due to the inflammatory stimulus produced by the invading microorganisms. GC B cell responses and GC formation is largely T cell dependent. Hallmarks of the GC response include BcR affinity maturation, plasma cell differentiation and the generation of memory B cells. Hence, the GC response not only contributes to pathogen clearance but also plays a pivotal role in preventing subsequent infections with the infecting microorganism [1–5]. T<sub>FH</sub> T cells are recently recognized as a distinct CD4<sup>+</sup> T cell subset defined as PD1<sup>+</sup>ICOSL<sup>+</sup>ICOS receptor on the activated CD4<sup>+</sup> T cells [6–10].

The factors controlling T<sub>FH</sub> differentiation are not as yet fully understood, and multiple cell types and molecules have been implicated in this process [4,6]. IL-21 was initially proposed as a key soluble factor driving the differentiation of Ag-primed CD4<sup>+</sup> T cells along the T<sub>FH</sub> lineage pathway [8,11], and is now recognized as promoting an optimal T<sub>FH</sub> response [12,13]. However, the mechanism(s) by which IL-21 optimizes the T<sub>FH</sub> response has not yet been clearly defined.

Recently, we have identified a novel immune cell population in virus infected murine lungs with migratory properties and antigen presenting capacity, the late activator antigen presenting cell (LAPC) [14]. The mPDCA1<sup>+</sup>CD11c<sup>+</sup>B220<sup>+</sup>TcrR<sup>+</sup> LAPCs initiate their migration out of the IAV-infected lungs into the draining lymph nodes relatively late in the course of infection (i.e., between 6–12 days post-infection (d.p.i.) via CXCR3-CXCL9 dependent chemotactic pathway. In the dLN, LAPCs promote T<sub>FH</sub> differentiation of Ag-activated CD4<sup>+</sup> T cells by display of ICOSL and engagement of ICOS receptor on the activated CD4<sup>+</sup> T cells [14–16]. In this report we demonstrate that IL-21, initially produced by NKT cells, promotes optimal T<sub>FH</sub> differentiation by augmenting CXCR3-CXCL9 dependent LAPC migration into the dLN during influenza A virus (IAV) infection. IL-21-induced TNF-α production by conventional T cells is critical to stimulate CXCL9 expression by DCs in the dLN, which supports LAPC...
mice were then infected with A/PR/8/34 IAV. Determined by FACS-analysis and the successfully reconstituted Taconic farms and bred in house.

In vivo

For OT-II T cell transfer into CD45.1+ mice, lethally irradiated (1,100 rads) CD45.1+ wild type B6 mice and reconstituted the irradiated mice with CD45.1+ wild type BM (2×10^6) cells) mixed with CD45.2+ il-21r-/- BM (2×10^6). After 8 weeks, using PBMC the reconstitution efficiency was determined by FACS-analysis and the successfully reconstituted mice were then infected with A/PR/8/34 IAV.

Quantitative RT-PCR

dLN cell suspensions were prepared as described [14,15]. DCs were isolated from FACS (Reflection HAPS 2) to examine cxf-9 expression. mRNA isolation, reverse transcription and real-time PCR were performed as previously described [19]. Data were generated with the comparative threshold cycle method, by normalizing to hypoxanthine phosphoribosyltransferase (hprt). The sequences of primers used in the studies are available on request.

Bone marrow chimeras

To generate mixed bone marrow (BM) chimeras containing wild type (CD45.1+) and il-21r-/- (CD45.2+) BM in a 1:1 ratio, we lethally irradiated (1,100 rads) CD45.1+ wild type B6 mice and reconstituted the irradiated mice with CD45.1+ wild type BM (2×10^6 cells) mixed with CD45.2+ il-21r-/- BM (2×10^6). After 8 weeks, using PBMC the reconstitution efficiency was determined by FACS-analysis and the successfully reconstituted mice were then infected with A/PR/8/34 IAV.

In vivo migration assay

Both B6 and il-21r-/- mice were anesthetized as described above and infected by i.n. instillation with 50 µl PBS containing 0.05 LD_{50} A/PR/8/34 virus. On day 5 p.i., mice received 50 µl of sterile PBS, and anti-TNF-α blocking mAb (200 µg/day/mouse) from 4 d.p.i. till 7 d.p.i. At 8 d.p.i., the levels of CXCL9 expression in DCs, LAPCs and CD45.2+ Thy1.2+CD8+ mice. Isolated day 5 in vivo virus activated OT-II cells were ex vivo co-cultured with day 8 LAPCs for additional 24 hrs to assess T_FH differentiation by FACS-analysis.

Cell sorting

For ex vivo co-culture experiments, recipients of transferred OT-II T-cells or wild type mice were infected with A/WSN/ OVA-II influenza. Different cell populations from the dLN were sorted by FACS (Reflection HAPS 2) based on the following markers at either 5 or 8 d.p.i.: OT-II cells, CD45.2+Thy1.2+CD4+; LAPCs, mPDCA-1+CD11c+ B220+TcRβ+. For cxd-9 qPCR, DCs (CD11c+TcRβ+) were sorted from the dLN of A/PR/8/34 IAV infected wild type mice at 6 d.p.i. For ilf-2 qPCR, both wild type (CD45.1+) and il-21r-/- (CD45.2+) T cells (CD4 and CD8 T) were sorted by FACS from the dLN of A/PR/8/34 IAV-infected mixed BM chimera mice at 6 d.p.i. (CD45.1+Thy1.2+CD4+, CD45.2+Thy1.2+CD4+, CD45.1+Thy1.2+CD8+, CD45.2+Thy1.2+CD8+). For in vivo adoptive transfer experiments, non-TFH total T cells (Thy1.2+CXCRI5+) were isolated by FACS from the dLN of A/PR/8/34 IAV-infected wild type or ilf-2-/- mice at 6 d.p.i. and adoptively transferred by the i.v. route (2×10^6cells/mouse) into 6 d.p.i. A/PR/8/34 IAV-infected recipient ilf-2-/- mice.

Antibodies and FACS-analysis

All antibodies were purchased from BD Biosciences or eBioscience (unless otherwise stated): CD4 (L3T4), CD8a (53-67), CD11c (HL3), CD45.1 (A20), CD45.2 (104), CD90.2 (30-H12), B220/CD45R (RA3-6B2), NK1.1 (PK136), TCR-β (H57-597), IL-21 (FA21), CXCXR5 (2G8), PD-1 (RMP1-30), ICOS-L (HK5.3), TNF-α (MP6-XT22) and CXCL9 (MIG-2F5). mPDCA-1 mAb (JF05-1C2.4.1) was purchased from Miltenyi Biotec. A CXCXR3 specific mAb was obtained from both R&D Systems (220083) and Biolegend (CXCXR3-173). mTNF-α mAb (XT3.11) were purchased from BioXcell for in vivo mTNF-α blocking experiments. Flow cytometry was performed on FACS-Canto with optimal compensation set for six-color staining. The data were analyzed using FlowJo software (Tree Star, Inc.). All cytokine (IL-21 and TNF-α) and chemokine (CXCL9) expressions by dLN-derived cells were measured directly ex vivo without further in vitro re-stimulation.

In vivo TNF-α blocking experiments

To examine the role of TNF-α in LAPC-mediated T_FH differentiation, in vivo TNF-α blocking experiments were performed. Brieﬂy, B6 mice infected with 0.05LD_{50} A/PR/8/34 virus were treated (i.p.) daily with either isotype control Abs (Rat IgG) or mTNF-α blocking mAb (200 µg/day/mouse) from 4 d.p.i. till 7 d.p.i. At 8 d.p.i, the levels of CXCL9 expression in DCs, LAPCs and CD45.2+Thy1.2+CD8+ mice. Isolated day 5 in vivo virus activated OT-II cells were ex vivo co-cultured with day 8 LAPCs for additional 24 hrs to assess T_FH differentiation by FACS-analysis.

IAV-specific antibody ELISA

BAL fluid was collected from IAV-infected mice on 8 d.p.i. by intra-tracheal instillation of 500 µl of sterile PBS, and anti-influenza antibody responses in the BAL fluid were measured by ELISA. Brieﬂy, wells of 96-well plates were coated overnight at room temperature with 50 µl of either A/PR/8 or B/Lee influenza virus. The plates were washed twice with PBS supplemented with 0.05% Tween-20 (PBST) and incubated with 50 µl of 2% BSA in PBST for 1 hr at room temperature. After washing the plates with PBST, 50 µl of diluted BAL fluid was added to each well and incubated for 2 hrs at room temperature.
Bound antibodies were detected by the incubation of horseradish peroxidase (HRP)-conjugated anti-mouse IgM (1:10,000; SouthernBiotech) or total IgG (1:10,000; SouthernBiotech) antibodies. After 1 hr, the plates were washed with PBST, and 100 μl of 3,3′,5,5′-tetramethylbenzidine (TMB) substrate solution (Sigma-Aldrich) was added into each well and incubated for a further 30 minutes. The enzyme reaction was stopped by adding 100 μl of 2N H2SO4 and O.D. values were determined at 450 nm using a plate reader (Bio-TEK).

Statistical analysis

Unless otherwise noted, an unpaired two-tailed Student’s t-test was used to compare two treatment groups. Groups larger than two were analyzed with one-way ANOVA (Tukey’s post-test). These statistical analyses were performed using Prism 3 software (for Macintosh; GraphPad Software, Inc.). Data are mean ± s.e.m. A p value of <0.05 was considered to be statistically significant.

Results

IL-21 can promote T FH differentiation in CD4+ T cells lacking an IL-21 receptor

To characterize T follicular helper cell response to primary IAV infection at a mucosal tissue i.e. the respiratory tract, we examined the kinetics of generation and accumulation of T FH T cells in the draining mediastinal lymph nodes (dLN) of C57BL/6 mice intranasally (i.n.) infected with a sub-lethal dose (0.05LD50) of A/PR/8/34 virus. The generation of T FH T cells (i.e. CD4+PD1+CXCR5+Thy1.2+) was monitored in the dLN by FACS-analysis. As previously shown in BALB/c mice [16], in the uninfected mice the number of T FH cells was negligible. T FH cells were first detected at 6 d.p.i. and showed the accumulation (absolute number) of T FH cell in the dLN was maximum at 12 d.p.i. (Fig. 1a). The kinetics of T FH expansion and contraction do differ modestly from that reported by Boyd et al. [20]. The most likely explanation for this difference is the virus infectious dose since Boyd et al. used 0.1 LD50 A/PR/8/34 virus.

To examine whether IL-21 is necessary for optimal T FH differentiation in IAV infection, we evaluated the generation/accumulation of T FH T cells in the draining mediastinal lymph nodes (dLN) of C57BL/6 mice intranasally (i.n.) infected with a sub-lethal dose (0.05LD50) of A/PR/8/34 virus. The generation of T FH T cells (i.e. CD4+PD1+CXCR5+Thy1.2+) was monitored in the dLN by FACS-analysis. As previously shown in BALB/c mice [16], in the uninfected mice the number of T FH cells was negligible. T FH cells were first detected at 6 d.p.i. and showed the accumulation (absolute number) of T FH cell in the dLN was maximum at 12 d.p.i. (Fig. 1a). The kinetics of T FH expansion and contraction do differ modestly from that reported by Boyd et al. [20]. The most likely explanation for this difference is the virus infectious dose since Boyd et al. used 0.1 LD50 A/PR/8/34 virus.

IL-21 can promote T FH differentiation in CD4+ T cells lacking an IL-21 receptor

To characterize T follicular helper cell response to primary IAV infection at a mucosal tissue i.e. the respiratory tract, we examined the kinetics of generation and accumulation of T FH T cells in the draining mediastinal lymph nodes (dLN) of C57BL/6 mice intranasally (i.n.) infected with a sub-lethal dose (0.05LD50) of A/PR/8/34 virus. The generation of T FH T cells (i.e. CD4+PD1+CXCR5+Thy1.2+) was monitored in the dLN by FACS-analysis. T FH cells were first detected at 6 d.p.i. and showed the accumulation (absolute number) of T FH cell in the dLN was maximum at 12 d.p.i. (Fig. 1a). The kinetics of T FH expansion and contraction do differ modestly from that reported by Boyd et al. [20]. The most likely explanation for this difference is the virus infectious dose since Boyd et al. used 0.1 LD50 A/PR/8/34 virus.

The tempo of IL-21 production in the dLN of IAV-infected mice correlates with LAPC accumulation at this site

To further investigate the underlying mechanism accounting for the contribution of IL-21 to T FH differentiation, we next examined the kinetics of IL-21 expression in the dLN of A/PR/8/34 virus infected C57BL/6 mice. Time course studies revealed that expression of IL-21 both at the gene and protein level is first detected at 6 d.p.i. and keep increasing until 12 d.p.i., in keeping with the kinetics of T FH accumulation in the dLN of IAV-infected mice (Fig. 1a). 

IL-21 production is regulated by TNF-Alpha

Recently, we have identified a novel migratory immune cell type, LAPC, in the respiratory track of IAV-infected mice [14]. LAPCs unlike conventional APCs such as respiratory dendritic cells (DCs) migrate from the infected lung tissue into the dLN late, i.e. starting at 6 d.p.i. during IAV infection and have been demonstrated to promote the differentiation of Ag-primed activated CD4+ T cells along the T FH differentiation pathway [14–16]. As with IL-21 production, the kinetics of LAPC accumulation in the dLN directly parallels T FH accumulation in the dLN (Fig. 1a). 

IL-21 receptor signaling modulates LAPC migration from lung tissue into the dLN of IAV-infected mice

Since in the mixed bone marrow (BM) chimera the absence of the IL-21R on the responding anti-viral CD4+ T cells did not diminish the generation of CD4+ T FH T cells in the dLN but the kinetics of IL-21 expression paralleled with LAPC accumulation in the dLN, we considered the possibility of IL-21 expression and...
IL-21 can promote T$_{FH}$ differentiation in CD4$^+$ T cells lacking an IL-21 receptor. CS7BL/6 (WT) (n = 51), il-21r$^{-/-}$ (n = 9) and il-21$^{-/-}$ mice (n = 9) were infected intranasally (i.n.) with a sub-lethal dose (0.05 LD$_{50}$) of A/PR/8/34 virus, as described in the Materials and Methods. (a) The kinetics of T$_{FH}$ accumulation in the dLNs of B6 mice was monitored by flow cytometric (FACS) analysis. The data are presented as absolute.
LAPC migration might be linked. To examine the contribution of IL-21 in the migration of LAPCs from IAV-infected lungs into the dLN, we next evaluated the migration of LAPCs following in vivo FITC-Dextran administration and uptake of this fluorescent marker by LAPCs in IAV-infected wild type and il-21r−/− mice. Interestingly, il-21r−/− mice showed significantly diminished FITC positive LAPC accumulation in the dLN at 6 d.p.i. compared to wild type mice (Fig. 3a). Although we cannot formally exclude the possibility that the diminished accumulation of FITC positive LAPC from il-21r−/− mice in the dLN at day 5–6 p.i reflects defective uptake of FITC-dextran in the lung by LAPC deficient in IL-21R signaling, diminished LAPC accumulation in the dLN of both il-21r−/− and il-21r−/− mice in terms of absolute LAPC numbers suggests that IL-21/IL-21R signaling plays a pivotal role in the migration of LAPCs from IAV-infected lungs into the dLN (Fig. 3b). Since NKT cells are the initial primary source of IL-21 in the dLN of IAV-infected mice (Fig. 2d and 2e), the mice lacking NKT cells (cd-1d−/−) showed significantly diminished LAPC accumulation in the dLNs comparable to that of il-21r−/− mice at 8 d.p.i. (Fig. 3b).

To determine if the deficit in LAPC migration in mice deficient in the IL-21 receptor was attributable to a defect in the expression of this receptor by LAPC, we constructed mixed bone marrow (BM) chimeras in which mice were reconstituted with a one-to-one mixture of BM from CD45.1+ il-21r−/− and CD45.2+ il-21r−/− mice. Eight weeks after BM reconstitution, mice were infected with IAV and at 8 d.p.i. the frequency of wild type (CD45.1+) and il-21r−/− (CD45.2+) LAPCs in the dLN were determined (Fig. 3c). Notably, at 8 d.p.i. the ratio of wild type (CD45.1+) to il-21r−/− (CD45.2+) LAPCs was comparable and equivalent to that of total dLN cells. These results suggest that IL-21 modulates LAPC migration from infected lung tissue into the dLN independently of IL-21R signaling in LAPCs.

We recently reported that ICOS-L expression by LAPC and the engagement of ICOS on CD4+ T cells is required for LAPC to promote T FH differentiation [16]. We therefore wanted to determine whether IL-21 not only affects LAPC migration into the dLN but also directly enhances the capacity of LAPC to facilitate T FH differentiation by up-regulating ICOS-L expression on LAPC. We found, however, that LAPCs isolated from the dLN of il-21r−/− mice showed comparable level of ICOS-L expression to that of LAPCs from wild type mice (Fig. 3d). To further evaluate the impact of IL-21 signaling on the ability of LAPCs to support T FH differentiation, LAPC were isolated from IAV infected il-21r−/− mice and co-cultured with activated CD4+ T cells. Briefly, OVA-specific TCR transgenic CD4+ OT-II T cells were isolated from naive CD45.2+ OT-II mice and transferred by the intra-venous (i.v.) route into CD45.1+ C57BL/6 mice. 24hrs later, mice were sub-lethally infected i.n. with the recombinant IAV A/WSN/OVA-II virus which expresses the OVA epitope recognized by OT-II cells. At 5 d.p.i., that is the time p.i. when the majority (>95%) of transferred OT-II T cells displayed an activated (CD44hi or CD62Llo) phenotype but did not as yet express the characteristic T FH phenotype (PD1hiCXCR5+) [14,16], in vivo activated IAV specific OT-II T cells were isolated from the dLN. These activated CD4+ T cells were placed in short-term (24 hrs) culture with LAPCs isolated from the dLN of OT-II T cells infected wild type or il-21r−/− mice. LAPC driven T FH differentiation of the OT-II T cells was monitored by flow cytometry. As shown in figure 3e, LAPCs isolated from il-21r−/− mice were comparable to their wild type counterparts in promoting T FH differentiation of Ag-primed CD4+T cells. This result further suggests that IL-21 does not modulate intrinsic capacity of LAPC to support T FH differentiation.

IL-21 enhances CXCL9 expression by DCs in the dLN of IAV-infected mice by an IL-21R independent mechanism

LAPC in the IAV-infected lungs express CXCR3 and the migration of the cells from the lungs into the dLN is CXCL9 dependent [16]. Since IL-21 promotes LAPCs migration into the dLN, we questioned whether CXCR3 and/or CXCL9 expression was regulated by IL-21 receptor signaling during IAV infection. We observed that at the peak of LAPC accumulation in the infected lungs i.e. 6 d.p.i. when the IAV initiate migration into the dLN [14], LAPC isolated from the lungs of infected wild type and il-21r−/− mice expressed CXCR3 at comparable levels (Fig. 4a). By contrast, the expression of CXCL9 in the 6 d.p.i. dLN, which is largely restricted to CD455 cells primarily DCs (Fig. 4b and [16]), is substantially decreased in DCs from the dLN of infected il-21r−/− mice (Fig. 4c and 4d). Importantly, compared to wild type DC, CXCL9 expression was increased in DC isolated from 6 d.p.i. dLN of infected il-21r−/− mice (Fig. 4d). IAV-infected cd-1d−/− mice, deficient for the initial primary source of IL-21, NKT cell, also showed significantly diminished expression of CXCL9 in DCs comparable to that of il-21r−/− mice (Fig. 4d). Of note, the gene encoding cxcl-10, another CXCR3 ligand, was not expressed in the dLN of wild type mice during the course of IAV infection (unpublished data).

To directly address the impact of IL-21 signaling in dLN DCs on CXCL9 expression by these cells, we employed the CD45.1+ il-21r−/− and CD45.2+ il-21r−/− mixed bone marrow (BM) chimera strategy described above (Fig. 3). After BM reconstitution, mice were infected with IAV and at 6 d.p.i. the CXCL9 expression levels by wild type (CD45.1+) and il-21r−/− (CD45.2+) DCs in the dLN were determined by FACS-analysis (Fig. 4e). We found that at 6 d.p.i. the CXCL9 expression by wild type (CD45.1+) and il-21r−/− (CD45.2+) DCs were comparable. This finding suggests that IL-21 regulates CXCL9 production by DCs through a mechanism independent of IL-21R signaling in the chemokine producing dLN DCs.

IL-21 enhances TNF-α production by T cells in the dLN of IAV-infected mice

IL-21 can modulate a variety of the immunoregulatory functions including IL21R signaling dependent up-regulation of TNF-α production by immune cells notably activated T cells...
IL-21 Modulates LAPC Migration via TNF-Alpha

Figure 2. IL-21 expression and LAPC accumulation in the dLN of IAV-infected mice exhibit comparable kinematics. The tempo of IL-21 expression was examined by both (a) qPCR and (b) FACS-analysis in the dLNs of A/PR/8/34 virus infected C57BL/6 mice (n = 32). Representative data from three independent experiments are shown. (c) At 6 d.p.i., IL-21 expression was examined by FACS-analysis in each gated population isolated from the dLNs of C57BL/6 mice using IAV-infected cd1d-/- mice (n = 6) as a negative control for live lymphocytes based on FSC/SSC profile (B cells: B220+ CD11c Thy1.2; CD4 T cells: CD4+Thy1.2; CD8 T cells: CD8b+Thy1.2; NKT cells: NK1.1+Tcrβ+CD1d+PD-1+CXCR5+; NK cells: NK1.1+Tcrβ+DCs: CD11c+Thy1.2+). For CD1d-tetramer and Tfnr marker (PD-1 and CXCR5) staining, either unloaded CD1d-tetramers, isotype control Abs (Rat IgG2b:RG2b) or secondary Abs (streptavidin-APC:st-APC) has been used as negative controls for each subset and absolute cell numbers (Fig. 5b). To further demonstrate the capability to enhance the expression of a variety of chemokines including CXCL9 [26–28], TNF-α was well recognized as a critical regulator for immune and inflammatory cell migration into tissues through its capacity to enhance the expression of a variety of chemokines including CXCL9 [29-31]. It was therefore of interest to determine whether TNF-α was expressed in the dLN of IAV-infected mice at 6 d.p.i. and also to identify the cell type(s) producing TNF-α. This analysis revealed that TNF-α production in the dLN, analyzed by intracellular cytokine staining directly ex vivo, was restricted primarily to conventional T-cells (7.6% of total T cells) and to a lesser extent to NKT cells (5% of total NKT cells) (Fig. 5a). However, in terms of absolute cell number T cells are predominant producers for TNF-α in the dLN at 6 d.p.i. Both CD4+ and CD8+ T cells in the 6 d.p.i. dLN expressed TNF-α (i.e. ~7–8% of the respective T-cells subset) (Fig. 5b). It is also noteworthy that the T-cells from the corresponding dLN of IAV-infected il-21-/- mice exhibited a significantly diminished protein expression of TNF-α compared to infected wild type mice both in terms of the percentage of each subset and absolute cell numbers (Fig. 5b). To further confirm the contribution of IL-21R signaling in TNF-α expression by IAV-activated T cells, mixed BM chimeras containing wild type (CD45.1+) and il-21ra-/- (CD45.2+) BM in a 1:1 ratio were generated. After 8 weeks, the successfully reconstituted mice were infected with A/PR/8/34 IAV. Since TNF-α expression can be regulated both pre-and post-transcriptionally, on 6 d.p.i. both wild type (CD45.1+) and il-21ra-/- (CD45.2+) T cells (both CD4 and CD8 T cells) were isolated from the dLN by FACS and ilf-α gene expression in sorted T cells was determined by qPCR. As shown in figure 5c, il-21ra-/- T cells (both CD4 and CD8 T cells) exhibited significantly higher TNF-α gene expression compared to WT-T cells (Fig. 5c). Of note, IL-21 deficiency had no impact on TNF-α production by NKT cells in the 6 d.p.i. dLN of il-21-/- mice (data not shown). However, since NKT cells are the initial primary source of IL-21 in the 6 d.p.i. dLN, IAV-infected cd1d-/- mice exhibited significantly diminished expression of TNF-α in conventional T cells compared to wild type mice at 6 d.p.i. (Fig. 5d). Finally, these data all together suggest that IL-21, initially produced by NKT cells, promotes TNF-α production by conventional T cells via IL-21R stimulation in the dLN of IAV-infected mice.

TNF-α produced by T cells promotes CXCL9-mediated LAPC migration into the dLN and subsequent Tfh differentiation during IAV infection

In view of the above results it was of interest first to determine if TNF-α influenced the production of CXCL9 by DCs in the dLN and thereby the migration of LAPC from the infected lungs to the dLN and subsequent Tfh cell accumulation. To this end IAV-infected mice were treated by i.p. with either mTNF-α neutralizing mAbs (XT3.11) or isotype control Abs (Rat IgG) over time frame including the initial migration of LAPC into the dLN i.e. between 4 d.p.i and 7 d.p.i. (Fig. 6a). The level of CXCL9 expression by dLN DCs was evaluated directly ex vivo 24 hrs later by flow cytometric analysis. In vivo neutralization of TNF-α resulted in a significant decrease in CXCL9 production by DCs (Fig. 6b). In parallel with the decrease in CXCL9 expression, we observed that the accumulation of both LAPC and Tfh cells in the dLN were significantly diminished in the IAV-infected mice following TNF-α neutralization as reflected in both the absolute numbers of these two cell types and their percentage within the dLN (Fig. 6c). Next, we examined whether IAV-infected tnf-α-/- mice displayed a phenotype comparable to that of mice in which TNF-α was neutralized in vivo by neutralizing mTNF-α mAb administration and whether the transfer of TNF-α producing T cells into tnf-α-/- mice could rescue the phenotype of these mice (Fig. 7a). Indeed, compared to wild type mice IAV-infected tnf-α-/- mice showed significantly diminished CXCL9 expression in DCs (Fig. 7b). The accumulation of both LAPC and Tfh cells in the dLN were also significantly diminished in the IAV-infected tnf-α-/- mice (Fig. 7c). Finally, the adoptive transfer of TNF-α producing non-Tfh total T cells [Thy1.2+CXCR5+] isolated from the dLNs of IAV-infected wild type mice at 6 d.p.i. (D6 WT-T, Fig. 5a) could rescue CXCL9 expression by DCs in tnf-α-/- mice. In addition, LAPC and Tfh accumulation in the dLNs were restored in tnf-α-/- mice following transfer of WT-T cells to levels comparable to that of IAV-infected wild type mice (Fig. 7b and 7c). However, the adoptive transfer of il21ra-/- T cells, which exhibit significantly diminished TNF-α expression compared to WT-T cells (Fig. 5c), could not rescue the phenotype in Tfh accumulation of tnf-α-/- mice (data not shown). Of note, by the repeated experiments, in which the donor wild type CD4 T cells (CD45.1+) were distinguished from recipient tnf-α-/- CD4 T cells (CD45.2+), we confirmed that the rescue of phenotype in Tfh accumulation of WT-T cell supplemented tnf-α-/- mice was due to the differentiation of recipient tnf-α-/- CD4 T cells into Tfh cells by the help from donor WT-T cells but not solely reflect Tfh differentiation from transferred donor WT-T cells (data not shown). Collectively, these results suggest that IL-21-induced TNF-α production from conventional T cells enhances Tfh differentiation in part at least via modulating CXCR3-CXCL9 dependent LAPC migration into the dLN during IAV infection.
IL-21 modulates LAPC migration from lung tissue into the dLN of IAV-infected mice. (a) C57BL/6 (WT) (n = 12) and il-21r α−/− mice (n = 6) were infected with IAV, followed by FITC-Dextran administration i.n. on 5 d.p.i. 24 hrs later cells were isolated from the dLNs and the extent of LAPCs migration was determined by FACS-analysis. Numbers indicate the percentage of FITC+ cells within the LAPC population. Data representative of two independent experiments are shown. (b) At 8 d.p.i, LAPC accumulation in the dLNs was examined by FACS-analysis in C57BL/6 (WT) (n = 15), il-21r α−/− (n = 15), il21r α−/− (n = 15) and cd-1d−/− mice (n = 6). The data are presented as both a percentage of lineage i.e. TcRβ B220− cells and absolute LAPC numbers (mean ± s.e.m) and were analyzed by Student’s t test. Representative data of five independent experiments.
are shown. (c) The effect of IL-21R signaling on LAPC migration into the dLN was evaluated in mixed BM chimera containing wild type (CD45.1⁺) and il-21r⁻⁻ (CD45.2⁺) BM in a 1:1 ratio as described in the Materials and Methods. At 8 wks post reconstitution, mice (n = 7) were infected with A/PR/8/34 virus. At 8 d.p.i., the percentage of wild type (CD45.1⁺) and il-21r⁻⁻ (CD45.2⁺) LAPCs among total LAPCs (mPDCA1⁺CD11c⁺B220⁺TCrβ⁺) was determined in the dLN by FACS-analysis. Representative images of three independent experiments are shown. (d) Both C57BL/6 (n = 6) and il-21r⁻⁻ mice (n = 6) were infected with 0.05 LD₅₀ of A/PR/8/34 virus. At 8 d.p.i., ICOSL expression on LAPCs isolated from the dLN of C57BL/6 and il-21r⁻⁻ mice was examined by FACS-analysis. The gray histogram represents isotype control Ab staining for ICOS-L. Representative data from two independent experiments are shown. (e) In vivo Ag primed OT-II cells (DST) were generated as described in the Materials and Methods. FACS-sorted 5 d.p.i. OT-II cells (5 x 10⁵ cells/well) (DST) were incubated with LAPCs (mPDCA1⁺CD11c⁺B220⁺TCrβ⁺) (2.5 x 10⁶ cells/well) isolated from the dLN of A/WSN/OVA-II virus infected either C57BL/6 (wt) (n = 9) and il-21r⁻⁻ (ko) mice (n = 18) at 8 d.p.i. 24 hrs after ex vivo co-culture, T₅₀⁺, differentiation (PD-1 and CXCR5 expression) in the OT-II (CD45.2⁺Thy1.2⁺CD4⁺) T-cells was evaluated by FACS-analysis. Representative data of three independent experiments are shown.

Discussion

IL-21, first identified as a product of activated human T cells, is a pleiotropic cytokine which has diverse effects on the immune response through its ability to modulate the activity of many immune cell types [23–25]. Primarily produced by activated CD4⁺ T cell (in particular, T FH effector cells), IL-21 regulates B cell responses within the B cell follicular germinal center (GC) [25]. NK T cells are an additional potential major source of IL-21 and produce even higher level of this cytokine than activated conventional CD4⁺ T cells when appropriately stimulated [22]. As a result of engagement of IL-21R on CD₄⁺ T cell receptor complex, IL-21 promotes the survival and proliferation, as well as cytokine and chemokine production by multiple immune cell types including macrophages, B, T, NK and NKT cells [24].

Although CD4⁺ T FH effector cells are the predominant cell type producing IL-21 during the germinal center response in the dLN, in this model of respiratory virus infection, we find that NK T cells likely are a major source of IL-21 during the early phase of CD4⁺ T FH effector cell differentiation and GC formation in the dLN. Our unpublished data suggested that there is minimal IL-21 release or expression into the IAV infected lungs before day 3–6 post infection. Indeed, at later stage of infection IL-21 was present in the lung mostly derived from IAV-specific CD4⁺ T cells entering the infected lungs from the dLN. The stimulus for IL-21 production by the NK T cells responding to IAV infection in the dLN is not as yet defined. NK T cells have been reported to produce IL-21 following antigen receptor engagement or following stimulation by TLR ligands [17,22,25]. Since the A/PR/8/34 IAV strain employed in this analysis does not efficiently replicate in the dLN of infected mice, IL-21 production as a result of stimulation of TLR on NK T cells by IAV-derivd TLR ligands generated in the dLN seems unlikely. The more likely possibility is that IL-21 is produced by NK T cells following TCR-engagement in response to recognition of lipid moieties released from IAV infected cells.

IL-21 was also initially proposed as an important T cell-derived soluble factor regulating T FH differentiation through engagement of the IL-21R on recently activated CD4⁺ T cells prior to lineage commitment [8,11,13]. Subsequent reports [12,32] including our findings herein demonstrating a reduced (by ~ 50%) T FH response in the dLN of IAV-infected il-21r⁻⁻ mice (Fig. 1b) further substantiates the contribution of IL-21 to T FH differentiation. However, it was unclear whether IL-21 acts directly on naive/ recently activated CD4⁺ T cells to drive T FH differentiation [4,6,12]. Indeed, our analysis of T FH responses in mixed BM chimeric mice indicates that when evaluated in the presence of IL-21 R signaling competent T cells IL-21R deficient responding CD4⁺ T cells are fully capable of undergoing T FH differentiation (Fig. 1c). Therefore, during pulmonary IAV infection at least, there is no intrinsic signal delivered by IL-21 to the responding CD4⁺ T cells in the dLN which is required to program the cells along the T FH differentiation pathway.

Our results suggest a novel and heretofore underappreciated role of IL-21 in regulating T FH differentiation that is through the production of TNF-α. IL-21 either alone or in concert with other cytokines (i.e. IL-7 or IL-15) has been demonstrated to promote T FH-α production most notably from responding T cells [26–28]. We observed that during IAV infection that the absence of TNF-α resulted in a markedly diminished T FH response (Fig. 6c and 7c). In addition, the major source of TNF-α in the responding dLN were T cells whose production of this cytokine required IL-21 and the expression of the IL-21R by the responding T-cells as defective signaling through the IL-21R resulted in significantly decreased TNF-α production by the T-cells (Fig. 5a, 5b and unpublished data).

TNF-α has been demonstrated to play a central role in stimulating chemokine expression at sites of inflammation including CXCL9, which is a strong chemotactic stimulus for mononuclear cells [29–31,33–35]. We observed during IAV infection, that DCs are the major source of CXCL9 in the dLN (Fig. 4b) [16]. Of note, the absence of TNF-α mediated stimulation significantly but not completely diminished CXCL9 production by DCs isolated from the dLN of IAV-infected mice (Fig. 6b and 7b). This incomplete inhibition of CXCL9 expression may due to an effect of other soluble factors present in the dLN which are capable of regulating CXCL9 expression in the dLN, most notably, IFN-α [34,35]. CXCL9 production by the dLN DCs was also significantly decreased in IAV-infected IL-21 or IL-21R deficient mice (Fig. 4c and 4d). However, in our mixed BM chimera study the absence of IL-21R expression on the dLN DC resulted in a markedly diminished T FH response (Fig. 6c and 7c). Of note, the absence of TNF-α in the responding dLN was not due to an effect of other soluble factors present in the dLN but rather the absence of IL-21R expression on DCs. These results suggest that the impact of IL-21/IL21R signaling on CXCL9 production by DCs is dependent on the presence of IL-21 R signaling in these cells as suggested that the impact of IL-21R signaling on CXCL9 production by the dLN DC was indirect (Fig. 4e), is, through the effect of IL-21 on TNF-α production. Even though we cannot rule out the possibility that TNF-α works synergistically with IFN-α in the dLN to induce CXCL9 expression from DCs [34,35], it is unlikely that IL-21 also modulates IFN-α expression since both il-21⁻⁻ and il-21r⁻⁻ mice showed no difference in IFN-α gene expression in the dLN post-IAV infection (unpublished data).

We believe that the likely link between IL-21/IL-21R signaling, TNF-α production and T FH differentiation is via LAPC. This antigen presenting cell type picks up viral antigen in the IAV-infected lungs, migrate from the lungs into the dLN late in the infection cycle (i.e. between 6 and 12 d.p.i.) where these cells facilitate T FH differentiation of Ag-activated CD4⁺ T cells. We recently reported that the migration of LAPC into the inflamed dLN is largely CXCR3-CXCL9 dependent [16]. In the current report we find that both IAV infected il-21⁻⁻ and il-21r⁻⁻ mice showed significantly diminished (~ 60–70%) LAPC migration/accumulation into the dLN (Fig. 3a and 3b) and concomitantly a decreased T FH response following IAV infection in spite of normal CXCR3 expression by the LAPC from the IL-21/IL-21R
IL-21 enhances CXCL9 expression in IL-21R deficient dLN DCs following IAV infection. 

(a) C57BL/6 (WT) (n = 6) and il-21r<sup>a</sup><sup>2</sup>/<sup>2</sup> mice (n = 6) were infected with 0.05 LD<sub>50</sub> of A/PR/8/34 virus. At 6 d.p.i., CXCR3 expression on LAPCs isolated from the lungs of these mice was analyzed by FACS-analysis. The gray histogram represents isotype control Ab staining for CXCR3. Representative data from two independent experiments are shown. 

(b) CXCL9 expression on prominent mononuclear cell subsets was examined by FACS-analysis in each gated population (B cells: CD45.2<sup>+</sup>B220<sup>+</sup>CD11c<sup>2</sup>Thy1.2<sup>2</sup>; T cells: CD45.2<sup>+</sup>Thy1.2<sup>+</sup>B220<sup>2</sup>; DCs: CD45.2<sup>+</sup>CD11c<sup>2</sup>Thy1.2<sup>2</sup>; NK/NKT cells: CD45.2<sup>+</sup>NK1.1<sup>+</sup>) isolated from the dLNs of 6 d.p.i. C57BL/6 mice (n = 9). The gray histogram represents isotype control Ab staining for CXCL9. Representative data from three independent experiments are shown. 

(c & d) C57BL/6 (WT) (n = 12), il-21r<sup>a</sup><sup>2</sup>/<sup>2</sup>(n = 12), il-21<sup>2</sup>/<sup>2</sup>(n = 6) and cd-1d<sup>2</sup>/<sup>2</sup> mice (n = 6) were infected with A/PR/8/34 virus. (c) At 6 d.p.i., DCs were isolated by FACS-sorting from the dLNs of both C57BL/6 (WT) and il-21r<sup>a</sup><sup>2</sup>/<sup>2</sup> mice. Cxcl9 gene expression in these isolated DCs was evaluated by qPCR. Representative data from two independent experiments are shown. (d) The expression level of CXCL9 in DCs was also examined by FACS-analysis in dLN-derived DCs isolated from 6 d.p.i. C57BL/6 (WT), il-21r<sup>a</sup><sup>2</sup>/<sup>2</sup>, il-21<sup>2</sup>/<sup>2</sup> and cd-1d<sup>2</sup>/<sup>2</sup> mice. Representative data from two independent experiments are shown. 

(e) To examine whether IL-21 modulates CXCL9 production from DCs via IL-21R signaling in DCs, mixed BM chimera mice established using wild type (CD45.1<sup>+</sup>) and il-21r<sup>a</sup><sup>2</sup>/<sup>2</sup>(CD45.2<sup>+</sup>) BM in a 1:1 ratio were generated as described in the Materials and Methods. At 8 wks after reconstitution, mice (n = 7) were infected with A/PR/8/34 virus. At 6 d.p.i., the expression level of CXCL9 in DCs was compared in the dLNs by FACS-analysis. Representative images of two independent experiments are shown.

Figure 4. IL-21 enhances CXCL9 expression in IL-21R deficient dLN DCs following IAV infection.
Figure 5. IL-21 stimulates TNF-α production by T cells in the dLN of IAV-infected mice. (a) C57BL/6 (n = 6) mice were infected with 0.05 LD₅₀ of A/PR/8/34 virus. At 6 d.p.i., mTNF-α expression in gated lymphoid (B (B220⁺Thy1.2⁻), T (B220⁻Thy1.2⁺)), NKT (NK1.1⁺TcRb⁺CD1d⁺) and non-lymphocytes (B220⁻Thy1.2⁻) cell types isolated from the dLNs was examined by FACS-analysis. The data are representative from two independent
signal defective IAV-infected mice (Fig. 1b and 4a). Most important, the absence of TNF-α mediated stimulation in vivo during IAV infection, like defective IL-21/IL-21R signaling, resulted in both decreased LAPC migration into the dLN and in a diminished TFH response (Fig. 6c and 7c). IL-21 also modulates B cell response which contributes to the maintenance of TFH response [6]. Although B cells are poor inducers for initial TFH differentiation [16], we cannot rule out the possibility that at the maintenance phase of TFH response during IAV infection (after 9–10 d.p.i.) IL-21, predominantly produced by TFH cells, may also contribute to TFH maintenance via modulating B cells. Although IL-21, TNF-α and CD1d are implicated in anti-IAV TFH/GC-B cell response, we found that deficiency in IL-21 or IL-21R has no effect on virus clearance or recovery from IAV infection in C57BL/6 background (unpublished data). Also, as we reported cd-1d deficiency does impact on IL–5 production during IAV infection but does not affect virus clearance or recovery from IAV infection in BALB/c background [36].

In conclusion, in this report we have identified a novel mechanism, by which IL21 promotes optimal TFH responses in pulmonary virus infection. Our results suggest that during IAV infection IL-21 produced in the dLN early in infection i.e. 5–6 d.p.i. (most likely by NKT cells in the dLN) stimulates TNF-α production by CD4 and CD8 T cells responding to infection in the dLN. The TNF-α stimuli enhances CXCL9 production by dLN resident DCs which in turn acts as a chemotactic stimulus to experiments and presented as percent mTNF-α+ cells in the particular cell type. (b & d) C57BL/6 (WT) (n = 9), il-21−/− (n = 9) and cd-1d−/− mice (n = 6) were infected with 0.05 LD₅₀ of A/PR/8/34 virus. At 6 d.p.i., mTNF-α expression in CD4+ T (CD4+Thy1.2+), CD8+ T (CD8α+Thy1.2+) and total T cells (Thy1.2) isolated from the dLNs of infected mice was examined by FACS-analysis. The data are presented as both percent of mTNF-α+ cells within the T-cells subset and absolute number of mTNF-α+ cells (mean ± s.e.m.). The data were analyzed using Student’s t test. Representative data from three independent experiments are shown. (c) Mixed BM chimeras containing wild type (CD45.1+) and il-21ra−/− (CD45.2+) BM in a 1:1 ratio were generated. After 8 weeks, the successfully reconstituted mice were infected with A/PR/8/34 IAV. On 6 d.p.i. both wild type (CD45.1+) and il-21ra−/− (CD45.2+) T cells (both CD4 and CD8 T cells) were isolated from the dLN by FACS (CD45.1+Thy1.2+CD4+, CD45.2+Thy1.2+CD4+, CD45.1+Thy1.2+CD8+, CD45.2+Thy1.2+CD8+) and m-TNF gene expression in sorted T cells was determined by qPCR. The data were analyzed using Student’s t test. Representative data from two independent experiments are shown.

Figure 6. TNF-α promotes CXCL9-mediated LAPC migration into the dLN and subsequent TFH differentiation during IAV infection. (a) C57BL/6 (WT) (n = 12) mice were infected with 0.05 LD₅₀ of A/PR/8/34 virus. From 4 d.p.i. thru 7 d.p.i. mice were treated (i.p.) with either isotype control Abs (Rat IgG) or αmTNF-α blocking mAb (XT3.11) (200 mg/day/mouse). At 8 d.p.i., (b) the expression level of CXCL9 was examined in DCs by FACS-analysis. (c) The extend of LAPC accumulation and TFH differentiation in the dLN of infected mice following control Ab or αmTNF-α blocking Ab treatment were likewise evaluated by FACS-analysis. The data are presented as both percent population and absolute numbers (mean ± s.e.m.) and were analyzed by Student’s t test. Representative data from two independent experiments are shown.

doi:10.1371/journal.pone.0105872.g006
promote LAPC migration into the dLN. As a result of the increased accumulation of LAPC, this antigen presenting cell can facilitate optimal differentiation of Ag-activated responding CD4+ T cells in the dLN into T_{FH} cells.
