Abstract

In the present work we carry out a systematic study of the renormalization properties of the integral equation that determines the momentum evolution of the effective gluon mass. A detailed, all-order analysis of the complete kernel appearing in this particular equation reveals that the renormalization procedure may be accomplished through the sole use of ingredients known from the standard perturbative treatment of the theory, with no additional assumptions. However, the subtle interplay of terms operating at the level of the exact equation gets distorted by the approximations usually employed when evaluating the aforementioned kernel. This fact is reflected in the form of the obtained solutions, whose deviations from the correct behavior are best quantified by resorting to appropriately defined renormalization-group invariant quantities. This analysis, in turn, provides a solid guiding principle for improving the form of the kernel, and furnishes a well-defined criterion for discriminating between various possibilities. Certain renormalization-group inspired Ansätze for the kernel are then proposed, and their numerical implications are explored in detail. One of the solutions obtained fulfills the theoretical expectations to a high degree of accuracy, yielding a gluon mass that is positive-definite throughout the entire range of physical momenta, and displays in the ultraviolet the so-called “power-law” running, in agreement with standard arguments based on the operator product expansion. Some of the technical difficulties thwarting a more rigorous determination of the kernel are discussed, and possible future directions are briefly mentioned.

I. INTRODUCTION

A recent development in the ongoing study of the basic QCD Green’s functions within the nonperturbative framework of the Schwinger-Dyson equations (SDEs) \[1–18\] is the derivation of the particular integral equation that governs the momentum evolution of the effective gluon mass \[19–22\]. As has been argued in a series of works \[23–26\], the generation of such a mass offers a natural and self-consistent explanation for the infrared finiteness of the (Landau gauge) gluon propagator and ghost dressing function \[11, 19, 20, 27, 28\], established in large-volume lattice simulations, both in \(SU(2)\) \[29\] and in \(SU(3)\) \[30–33\].

The systematic scrutiny of this equation could eventually place the gluon mass generation on an equal conceptual footing as the more familiar phenomenon of constituent quark mass generation \[1, 34–38\]. In order to reach an equivalent level of understanding, however, several theoretical tasks need be carried out. In particular, one of the main unresolved issues in this context is the proper renormalization of this homogeneous integral equation. The renormalization procedure, in turn, may impose crucial restrictions on the form of its kernel, which, even though is formally known, for all practical purposes must undergo approximations and modelling \[21\].

In the present work we study in detail the general renormalization procedure, and, most importantly, the properties of the mass equation, and its corresponding solutions, under the renormalization group (RG). This is a rather technical endeavor, whose main field-theoretic points may be summarized as follows.

To begin with, it is important to recognize that the renormalization of the mass equation, as well as the gluon mass itself, is accomplished entirely by means of the same renormalization constants familiar from the perturbative treatment of Yang-Mills theories, namely those associated with the gluon and ghost propagators, and the various interaction vertices \[39\]. The deeper field-theoretic reasons for this fact may be traced back to the intricate dynamical mechanism that generates this effective mass; specifically, the formation of non-perturbative massless bound states \[40–44\], which act as would-be Goldstone bosons, trigger the well-known Schwinger mechanism \[45, 46\], without ever modifying the original Lagrangian. In addition, a crucial identity enforces the total annihilation of any potential quadratic divergence, related to seagull-type integrals \[47\]. As a result, no bare gluon mass needs be introduced at any stage; this is absolutely essential, since a term of the type \(m_0^2 A_\mu^2\) is for-
bidden by the local gauge invariance of the Yang-Mills Lagrangian [10, 19].

Furthermore, it is clear that the correct implementation of the aforementioned renormalization procedure relies crucially on the precise properties of the kernel of the mass equation under the RG. If the kernel is treated at the formal level, these properties are automatically enforced, as a direct consequence of the corresponding RG properties of the basic ingredients that build it up. However, the kernel is expressed in terms of a complicated diagrammatic expansion, which, for all practical purposes, must be truncated, and further simplified or approximated [21]. As a result, the exact RG properties of the kernel may be compromised; this flaw, in turn, will make its way into the solutions obtained from the corresponding mass equation. Thus, depending on the quality of the approximations employed for the kernel, the corresponding gluon masses will encode their formal RG properties with variable degrees of accuracy.

The quantitative study of the situation described above may be best accomplished by using RG invariant (RGI) quantities, which, by construction, maintain the same form before and after renormalization, and are independent of the value of the renormalization point \( \mu \), used to implement the various subtractions [19, 27]. In particular, an RGI gluon mass may be defined, and then subsequently constructed from the solutions of the mass equation, for any given Ansatz for the kernel, and for several different values of \( \mu \). Then, the amount by which the resulting quantity departs from the perfect \( \mu \)-independence can serve as a discriminant of the various possible Ansätze for the kernel.

The article is organized as follows. In Section II we introduce the relevant notation, define the basic renormalization constants, and discuss in detail the particularities of the gluon mass and its renormalization. In Section III we carry out the full renormalization of the gluon mass equation, and explore its properties under the RG. Then, in Section IV we study the tensorial structure of the main unknown ingredient that composes the kernel, and determine how its various form factors affect the infrared behavior of the mass equation. In Section V we outline the procedure for estimating the discrepancies from the correct RG behavior induced by the various approximations to the kernel. This procedure is then applied to the original version of the mass equation, and considerable deviations are found. In Section VI we present two RG-inspired improvements of the kernel, which, a priori, seem to capture more faithfully its formal RG properties, and determine the corresponding departures of the new solutions from the ideal \( \mu \)-independence. This study reveals a significant improvement, in accordance
with the initial expectation. The asymptotic behavior of one of these “improved” solutions is further analyzed, suggesting a possible connection with general arguments originating from the operator product expansion (OPE) \[48–50\]. Finally, in Section VII we present our discussion and conclusions.

II. RENORMALIZATION AND THE GLUON MASS

In this section we set up the notation, and introduce the field theoretic relations and concepts necessary for carrying out the renormalization of the gluon mass equation, and for exploring its properties under the RG.

A. General renormalization relations

In the Landau gauge, the full gluon propagator (quenched or unquenched) assumes the general form

\[ i\Delta_{\mu\nu}(q) = -i\Delta(q^2)P_{\mu\nu}(q); \quad P_{\mu\nu}(q) = g_{\mu\nu} - q_{\mu}q_{\nu}/q^2. \] (2.1)

At any finite order in perturbation theory, the scalar cofactor \(\Delta(q^2)\) is conveniently parametrized in terms of the inverse gluon dressing function, \(J(q^2)\),

\[ \Delta^{-1}(q^2) = q^2J(q^2). \] (2.2)

In addition, the full ghost propagator, \(D(q^2)\), is usually parameterized in terms of the corresponding ghost dressing function, \(F(q^2)\), according to

\[ D(q^2) = \frac{F(q^2)}{q^2}. \] (2.3)

We will now consider the combination of the pinch technique (PT) \[19, 51–55\] with the background field method (BFM) \[56\], known as the PT-BFM scheme \[10, 57, 58\]. Within the PT-BFM formalism, the natural separation of the gluonic field into a “quantum” (\(Q\)) and a “background” (\(B\)) part, gives rise to an increase in the type of possible Green’s functions that one may consider \[56\]. In particular, three types of gluon propagator make their appearance: (\(i\)) the conventional gluon propagator (two quantum gluons entering, \(QQ\)), denoted (as above) by \(\Delta(q^2)\); (\(ii\)) the background gluon propagator (two background gluons entering, \(BB\)), indicated by \(\tilde{\Delta}(q^2)\); and (\(iii\)) the mixed background-quantum gluon propagator (one background and one quantum gluons entering, \(BQ\)), denoted by \(\tilde{\Delta}(q^2)\).
The conversion between quantum and background two-point functions is achieved through the so-called background-quantum identities (BQIs) [59, 60]. For instance, $\hat{\Delta}$ and $\Delta$, as well as their corresponding components, are related by

$$O(q^2) = (1 + G(q^2))^2 O(q^2); \quad O = \Delta^{-1}, \ J, \ m^2,$$

$$\hat{O}(q^2) = (1 + G(q^2))O(q^2). \quad (2.4)$$

The function $G(q^2)$ represents the $g_{\mu\nu}$ component of a special Green’s function, $\Lambda_{\mu\nu}(q)$, typical of the PT-BFM framework [55], i.e., $\Lambda_{\mu\nu}(q) = G(q^2)g_{\mu\nu} + L(q^2)q_{\mu}q_{\nu}/q^2$; for various field-theoretic properties of the above functions, see [61] and references therein. Here it should suffice to mention that, for practical purposes, one often uses the approximate (but rather accurate) relation

$$1 + G(q^2) \approx F^{-1}(q^2), \quad (2.5)$$

which becomes exact in the deep IR [27, 61–63].

At any finite order in perturbation theory, the renormalization of the pure Yang-Mills theory proceeds through the standard redefinition of the bare fundamental fields, gluon $A^a_\mu(x)$, and ghost $c^a_\mu(x)$, and the bare gauge coupling, $g_0$; specifically, the corresponding renormalized quantities, $A^a_\mu(x)$, $c^a_\mu(x)$, and $g_R$, are given by

$$A^a_\mu(x) = Z_A^{-1/2}A^a_\mu(x), \quad c^a_\mu(x) = Z_c^{-1/2}c^0_\mu(x); \quad g_R = Z_g^{-1}g_0. \quad (2.6)$$

Then the associated two point functions are renormalized as

$$\Delta_R(q^2) = Z_A^{-1}\Delta_0(q^2); \quad D_R(q^2) = Z_c^{-1}D_0(q^2), \quad (2.7)$$

or, equivalently,

$$J_R(q^2) = Z_A J_0(q^2); \quad F_R(q^2) = Z_c^{-1}F_0(q^2). \quad (2.8)$$

Similarly, the renormalization constants of the three fundamental Yang-Mills vertices (gluon-ghost, three-gluon, and four-gluon vertices) are defined as [64]

$$\Gamma^\mu_R = Z_1 \Gamma^\mu_0; \quad \Gamma^{\mu\alpha\beta}_R = Z_3 \Gamma^{\mu\alpha\beta}_0; \quad \Gamma^{\mu\alpha\beta\nu}_R = Z_4 \Gamma^{\mu\alpha\beta\nu}_0. \quad (2.9)$$

The standard Slavnov-Taylor identities (STIs) of the theory enforce a set of important relations on the various renormalization constants [64], namely

$$Z_g = Z_1 Z_A^{-1/2} Z_c^{-1} = Z_3 Z_A^{-3/2} = Z_4^{1/2} Z_A^{-1}, \quad (2.10)$$
which will be used extensively in Section III.

In the BFM one introduces, in addition, the wave-function renormalization constant $\tilde{Z}_A$, associated with the background gluon $B$. Then, $\tilde{\Delta}(q^2)$ renormalizes according to

$$\tilde{\Delta}(q^2) = \tilde{Z}_A^{-1}\Delta_0(q^2).$$

(2.11)

Due to the Abelian Ward Identities (WIs) of the BFM, $Z_g$ and $\tilde{Z}_A$ are related by the fundamental QED-like relation [56]

$$Z_g = \tilde{Z}_A^{-1/2}.$$  

(2.12)

Finally, the renormalization relation for $G(q^2)$ reads [61]

$$1 + G_R(q^2) = Z_G[1 + G_0(q^2)],$$

(2.13)

where, due to Eqs. (2.4) and (2.12), $Z_G = \tilde{Z}_A^{1/2}Z_A^{-1/2} = Z_g^{-1}Z_A^{-1/2}$. 

B. Gluon mass renormalization

Nonperturbatively, the dynamical generation of an effective gluon mass accounts for the infrared finiteness of the (Landau gauge) gluon propagator, observed in a variety of large-volume lattice simulations [29–32]. To describe this behavior, the parametrization in Eq. (2.2) is modified according to (Minkowski space) [20]

$$\Delta^{-1}(q^2) = q^2J(q^2) - m^2(q^2),$$

(2.14)

with $m^2(0) \neq 0$. In addition, the generation of the aforementioned mass explains also, in a natural way, the corresponding saturation of the ghost dressing function, $F(q^2)$ [4, 11]. Moreover, both $\tilde{\Delta}(q^2)$ and $\tilde{\Delta}(q^2)$ are also infrared finite, and must be parametrized in a way exactly analogous to that of $\Delta(q^2)$ in Eq. (2.14), namely in terms of $\tilde{J}(q^2)$, $\tilde{m}^2(q^2)$, and $\tilde{J}(q^2)$, $\tilde{m}^2(q^2)$, respectively [21].

It is important to emphasize that the generation of a gluon mass does not interfere, in any way, with the renormalization of the theory, which proceeds exactly as before. In particular, the following main points must be stressed:

(i) The Lagrangian of the Yang-Mills theory (or that of QCD) is never altered; the generation of the gluon mass takes place dynamically, without violating any of the underlying
symmetries. In particular, no bare gluon mass is introduced, since a term of the type $m_0^2 A^2_\mu$ is forbidden by the local gauge invariance.

However, although no such term is ab-initio introduced, the possible appearance of the so-called “seagull” divergences at later stages of the analysis could force its emergence. Such divergences are produced by integrals of the type $\int k \Delta(k)$, or variations thereof [47]; in dimensional regularization they give rise to terms of the type $m_0^2 (1/\epsilon)$, while, in the case of a hard cutoff $\Lambda$, they correspond to terms proportional to $\Lambda^2$ (quadratic divergences). Evidently, their disposal would require the introduction in the original Lagrangian of a counter-term of the form $m_0^2 A^2_\mu$, which would be violating the basic assumptions stated above. Nonetheless, it turns out that, due to a set of subtle relations, particular to the PT-BFM framework, all such divergences are completely canceled [47].

(ii) Even though there is no “bare gluon mass”, in the sense explained above, the momentum-dependent $m^2(q^2)$ undergoes renormalization, which, however, is not associated with a new renormalization constant, but is implemented by the (already existing) wave-function renormalization constant of the gluon, namely $Z_A$. Specifically, from Eq. (2.14), and given that $\Delta^{-1}(0) = m^2(0)$, we have that the gluon masses before and after renormalization are related by

$$m^2_A(q^2) = Z_A m^2_0(q^2). \quad (2.15)$$

(iii) The above renormalization condition is fully consistent with (and may be independently derived from) the general procedure that implements the gauge-invariant (i.e., STI-preserving) generation of a gluon mass. Specifically, within the PT-BFM framework, the fully dressed vertex $BQ^2$, before mass generation, satisfies the WI [54]

$$q^\alpha \tilde{\Gamma}_{\alpha\mu\nu}(q, r, p) = p^2 J(p^2)P_{\mu\nu}(p) - r^2 J(r^2)P_{\mu\nu}(r), \quad (2.16)$$

and, given the first relation in Eq. (2.8), the corresponding vertex renormalization constant, $\tilde{Z}_3$, must obey

$$\tilde{Z}_3 = Z_A. \quad (2.17)$$

Then, for gauge-invariance to be preserved, one must modify this vertex according to [20]

$$\tilde{\Gamma}'_{\alpha\mu\nu}(q, r, p) = \left[ \tilde{\Gamma}(q, r, p) + \tilde{V}(q, r, p) \right]_{\alpha\mu\nu}, \quad (2.18)$$

where the special vertex $\tilde{V}(q, r, p)$ is completely longitudinal, i.e.,

$$P^{\alpha'\alpha}(q)P^{\mu'\mu}(r)P^{\nu'\nu}(p)\tilde{V}_{\alpha\mu\nu}(q, r, p) = 0, \quad (2.19)$$
\[ \mathcal{U}_{\alpha \mu \nu}(q, r, p) = I_{\alpha}(q) + \ldots + B_{\mu \nu}(q, r, p) \]

FIG. 1: The vertex \( \mathcal{U}_{\alpha \mu \nu} \) is composed of three main ingredients: the transition amplitude, \( I_{\alpha}(q) \), which mixes the gluon with a massless excitation, the propagator of the massless excitation \( i/q^2 \), and the massless excitation gluon vertex \( B_{\mu \nu} \). The omitted terms are not relevant for this analysis; they can be found in \[65, 66\].

and contains massless poles of purely non-perturbative origin \[40-44\], which will be ultimately responsible for triggering the well-known Schwinger mechanism \[45, 46\]. Now, \( \tilde{\Gamma} \) and \( \tilde{\Gamma}_{\alpha \mu \nu}' \) must be renormalized by \( \tilde{Z}_3 \), and so,

\[ \tilde{V}_{\alpha \mu \nu}(q, r, p) = Z_{\Lambda} \tilde{V}_{\alpha \mu \nu}^0(q, r, p). \] (2.20)

Since, in order for the WIs to remain intact, \( \tilde{V}_{\alpha \mu \nu} \) must satisfy

\[ q^\alpha \tilde{V}_{\alpha \mu \nu}(q, r, p) = m^2(r^2)P_{\mu \nu}(r) - m^2(p^2)P_{\mu \nu}(p), \] (2.21)

one finally concludes that Eq. (2.15) must be fulfilled.

(iv) We emphasize that the “mass renormalization” introduced above is not associated with a counter-term of the type \( \delta m^2 = m_R^2 - m_0^2 \), as is typical in the case of hard boson masses, such as in scalar theories, or the electroweak sector of the Standard Model. Instead, it is akin to the renormalization that higher order Green’s functions must undergo, in order to be made finite, even though no individual counter-term is assigned to them.

Consider, for instance, a scalar \( \phi^4 \) theory (in \( d = 4 \)), and the (one-particle irreducible) \( n \)-point functions, \( G^{(n)}(p_i) \) with \( n \geq 5 \). It is well-known that any such function ought to be made finite by means of the renormalization constants already defined for \( n \leq 5 \), since no counter-terms of the form \( \phi^n \) (with \( n \geq 5 \)) are allowed \[64\]. Indeed, \( G^{(n)}(p_i) \) can be made finite by expressing the bare mass and coupling constant \( (\mu_0, \lambda_0) \) in terms of their renormalized counterparts \( (\mu_R, \lambda_R) \), and then multiplying by \( Z_{\phi}^{1/2} \) for each external leg, i.e.,

\[ G_R^{(n)}(p_i, \mu_R, \lambda_R) = Z_{\phi}^{1/2} G_0^{(n)}(p_i, \mu_0, \lambda_0). \]

A similar situation arises when considering the gluon mass within the so-called “massless bound-state formalism” \[65, 66\], where one focuses on the details of the nonperturbative
formation of the pole vertex mentioned in (iii). Specifically, the relevant vertex part, denoted by $U_{\alpha\mu\nu}$ (see Fig. 1), has the form

$$U_{\alpha\mu\nu}(q, r, p) = I_\alpha(q) \left( \frac{i}{q^2} \right) B_{\mu\nu}(q, r, p), \quad (2.22)$$

where $I_\alpha(q)$ represents the transition amplitude that mixes a quantum gluon with the massless excitation, $i/q^2$ corresponds to the propagator of the massless excitation, and $B$ is an effective vertex describing the interaction between the massless excitation and gluons. Obviously, Lorentz invariance dictates that $I_\alpha(q) = q_\alpha I(q^2)$. In addition [66],

$$I_\alpha(q) = \int \Gamma_{\alpha\mu\nu} \Delta^{\mu\sigma}(k + q) \Delta^{\nu\rho}(k) B_{\rho\sigma} + \cdots, \quad (2.23)$$

where the ellipses indicate the graphs omitted in Fig. 1 (see [65] for the complete version); their inclusion does not modify the basic argument, it simply makes it lengthier. In the equations above we have introduced the dimensional regularization measure $\int k = \mu^\epsilon \int d^d k/(2\pi)^d$ where $d = 4 - \epsilon$ is the space-time dimension and $\mu$ the 't Hooft mass.

We now renormalize the effective vertex $B$ by introducing the renormalization constant $Z_B$,

$$B^\rho_\sigma_R = Z_B^{-1} B^\rho_\sigma_0, \quad (2.24)$$

and combine Eq. (2.22) and Eq. (2.23). Since $U$ forms part of the three-gluon vertex (of the type $Q^3$), it renormalizes as $U_{\mu\alpha\beta}^R = Z_3 U_{0\mu\alpha\beta}^\lambda$, and with the help of Eqs. (2.7) and (2.9), one concludes that (note that the dependence of $U$ on $B$ is effectively quadratic)

$$Z_B = Z_A^{-1}. \quad (2.25)$$

With these ingredients at hand, we now turn to the basic formula relating the gluon mass with the transition amplitude [65, 66], namely

$$m(q^2) = g I(q^2). \quad (2.26)$$

Let us consider Eq. (2.26) written in terms of unrenormalized quantities, and substitute in its rhs the corresponding renormalized ones, by introducing the appropriate renormalization constants. Suppressing Lorentz indices and using $Z_g = Z_3 Z_A^{-3/2}$ [see Eq. (2.10)], one finds

$$m_0(q^2) = Z_A^{-1/2} g R \int \Gamma_R \Delta_R(k + q) \Delta_R(k) B_R, \quad (2.27)$$

which clearly requires the renormalization dictated by Eq. (2.15) in order to be converted into the manifestly renormalized form

$$m_R(q^2) = g R I_R(q^2). \quad (2.28)$$
C. The basic RGI quantities

Let us finally consider certain RGI combinations of Green’s functions, that will be useful in the ensuing analysis. We recall that, by definition, a RGI combination maintains exactly the same form when written in terms of unrenormalized or renormalized quantities.

To begin with, as is well-known, and easy to verify directly using Eq. (2.12), the combination \( d(q^2) = g^2 \Delta(q^2) = \frac{g^2 \Delta(q^2)}{[1 + G(q^2)]^2}, \) (2.29)
is an RGI quantity (note that in the second equality the BQI of Eq. (2.4) was employed). It is then natural to define a RGI gluon mass, to be denoted by \( \overline{m}(q^2) \) \([21]\), as

\[
\overline{m}^2(q^2) = g^{-2} \hat{m}^2(q^2) = g^{-2}[1 + G(q^2)]^2 m^2(q^2).
\] (2.30)

We emphasize that the \( \overline{m}^2(q^2) \) defined above is a convenient quantity to introduce, because, as will become apparent in the rest of this work, it helps us quantify the faithfulness of certain approximations with respect to the RG. Note, however, that no special physical meaning is ascribed to \( \overline{m}(q^2) \) at this stage; in particular, despite its RGI nature we explicitly refrain from promoting it to a physical observable, for the simple reason that, at least within our present understanding, it is a quantity that depends on the gauge-fixing parameter. Specifically, all recent work related to the gluon mass equation has been performed in the Landau gauge, mainly because the corresponding lattice simulations have been carried out in this privileged gauge. In fact, the question whether the gluon propagator continues to saturate in the infrared when computed away from the Landau gauge is practically unexplored, both on the lattice as well as within the SDE framework.

We finally point out that the definition of the RGI gluon mass introduced here differs from the alternative proposed in \([67]\), namely \( \overline{m}^2(q^2) = m^2(q^2) J^{-1}(q^2) \). The problem with this latter definition is that, while formally RGI, gives rise to an ill-defined expression, due to the singular behavior of the quantity \( J(q^2) \). Specifically, the contribution of the massless ghost loop forces \( J(q^2) \) to reverse its sign and finally diverge logarithmically in the deep infrared \([68]\); of course, the combination \( q^2 J(q^2) \), appearing in the definition of \( \Delta^{-1}(q^2) \) [see Eq. (2.14)] is perfectly finite.

Let us next introduce three additional RGI quantities, to be generically denoted by \( R_i \), formed out of special combinations of propagators, vertices, and the gauge coupling constant.
\[ m^2(q^2) = \frac{1}{q^2} q^\mu \times \left( \begin{array}{c}
(a_0) \\
(a_5) \\
\end{array} \right) \]

FIG. 2: Diagrammatic representation of the gluon mass equation.

In particular, we define

\[ \mathcal{R}_1^{\mu\alpha\beta}(q, r, p) = g \Delta^{1/2}(q) \Delta^{1/2}(r) \Delta^{1/2}(p) \Gamma^{\mu\alpha\beta}(q, r, p), \]
\[ \mathcal{R}_2^\mu(q, r, p) = g \Delta^{1/2}(q) \frac{1}{\Delta^{1/2}(r)} D^{1/2}(p) \Gamma^\mu(q, r, p), \]
\[ \mathcal{R}_3^{\mu\alpha\beta\nu}(q, r, s) = g^2 \Delta^{1/2}(q) \Delta^{1/2}(r) \Delta^{1/2}(p) \Delta^{1/2}(s) \Gamma^{\mu\alpha\beta\nu}(q, r, s, s). \] (2.31)

The RGI nature of the above quantities may be verified directly, by employing the relations listed in Eq. (2.10).

III. RG PROPERTIES OF THE FULL GLUON MASS EQUATION

In this section we study the RG structure of the integral equation that controls the momentum evolution of the gluon mass. The main result of this analysis is that the complete kernel of this equation acquires a form that allows both of its sides to be written in terms of the RGI quantities introduced in the previous section.

As has been demonstrated in [21], the complete gluon mass equation is given by (see Fig. 2)

\[ m^2(q^2) = \frac{1}{2} \frac{i g^2 C_A}{1 + G(q^2)} \frac{q_\mu q_\nu}{q^2} \int_k [(a_0) + 2(a_5)]^{\mu\alpha\beta} \Delta_{\alpha\rho}(k) \Delta_{\beta\sigma}(k + q) \tilde{V}^{\rho\sigma}(q, k, -k - q), \] (3.1)

where \( C_A \) is the Casimir eigenvalue in the adjoint representation \([C_A = N \text{ for } SU(N)]\), \( \tilde{V} \) is the pole vertex introduced in the previous section, \((a_0)\) is simply the tree-level three-gluon vertex,

\[ (a_0)_{\mu\alpha\beta} = \Gamma^{(0)}_{\mu\alpha\beta}(q, k, -k - q), \] (3.2)

with

\[ \Gamma^{(0)}_{\mu\alpha\beta}(q, r, p) = (q - r)_\beta g_{\alpha\mu} + (r - p)_\mu g_{\alpha\beta} + (p - q)_\alpha g_{\mu\beta}, \] (3.3)
FIG. 3: The SDE for the three gluon vertex, in the conventional (first row) and Bethe-Salpeter version (second row). Note that the Bose symmetry of $\Gamma_{abc}^{\mu\alpha\beta}(q, r, p)$ implies that $(a_4)_{\mu\alpha\beta}(q, r, p) = (a_5)_{\alpha\beta\mu}(q, p, r)$; when the color has been factored out, as in Eq. (3.5), we have instead $(a_4)_{\mu\alpha\beta}(q, r, p) = -(a_5)_{\mu\beta\alpha}(q, p, r)$.

and $(a_5)$ denotes the vertex subgraph nested in the “two-loop” self-energy graph (see also Fig. 3).

Using the fact that $V$ satisfies the WI of Eq. (2.21) i.e.,

$$ q^\nu \tilde{V}_{\nu\rho\sigma}(q, k, -k - q) = m^2(k) P_{\rho\sigma}(k) - m^2(k + q) P_{\rho\sigma}(k + q), $$

(3.4)

and after appropriate shifts of the integration variable, we arrive at

$$ m^2(q^2) = \frac{ig^2 C_A}{1 + G(q^2)} \frac{q_\mu}{q^2} \int_k [(a_0) + (a_4) + (a_5)\mu^\alpha\beta \Delta_{\alpha\rho}(k) \Delta_{\beta\rho}(k + q) m^2(k^2)], $$

(3.5)

where $(a_4)_{\mu\alpha\beta}(q, r, p) = -(a_5)_{\mu\beta\alpha}(q, p, r)$ (see also the first row of Fig. 3).

Let us now turn to the SDE satisfied by the conventional $(Q^3)$ three gluon vertex $\Gamma_{abc}^{\mu\alpha\beta}(q, r, p)$, shown diagrammatically in Fig. 3 and derive a relation necessary for the treatment of Eq. (3.5). On the first line of Fig. 3 the vertex SDE is expressed in terms of the standard multiparticle kernels, $K_i$, while on the second the Bethe-Salpeter version of the same equation is presented. Note that in this latter version the vertices with the external momentum $q$ are fully dressed; consequently, the corresponding Bethe-Salpeter kernels, $\bar{K}_i$
differ from the $\mathcal{K}_i$, since certain diagrams, allotted to dress the vertices, must be excluded from them, in order to avoid overcounting ($\mathcal{K}_i$ and $\mathcal{K}_i$ are related through a non-linear integral equation (see, e.g., \cite{1} and \cite{39}).

If we express the various diagrams ($a_i$) in terms of renormalized quantities, denoting by $(a_i^R)$ the resulting expressions, it is relatively straightforward to demonstrate that

$$
(\pi_1) = Z_3^{-1}(\pi_1^R);
(\pi_2) = Z_3^{-1}(\pi_2^R);
(\pi_3) = Z_3^{-1}(\pi_3^R);
(a_4) = Z_g^2 Z^2_\Lambda Z_3^{-1}(a_4^R);
(a_5) = Z_g^2 Z^2_\Lambda Z_3^{-1}(a_5^R).
$$

(3.6)

Thus, for the original, unrenormalized vertex SDE we have (suppressing all indices)

$$
\Gamma = (a_0) + (a_4) + (a_5) + (\pi_1) + (\pi_2) + (\pi_3)
= (a_0) + Z_g^2 Z^2_\Lambda Z_3^{-1}[(a_4^R) + (a_5^R)] + Z_3^{-1}[(\pi_1^R) + (\pi_2^R) + (\pi_3^R)],
$$

(3.7)

and so, after introducing the renormalized vertex $\Gamma_R = Z_3 \Gamma$ [see Eq. (2.9)], we arrive at

$$
Z_3(a_0) + Z_g^2 Z_\Lambda^2 [(a_4^R) + (a_5^R)] = \Gamma_R - [(\pi_1^R) + (\pi_2^R) + (\pi_3^R)].
$$

(3.8)

Returning to Eq. (3.5), and rewriting it in terms of renormalized quantities, we have

$$
m^2_R(q^2) = \frac{iC_A g_R^2}{1 + G_R(q^2) q^2} \int \{ Z_3(a_0) + Z_g^2 Z_\Lambda^2 [(a_4^R) + (a_5^R)] \}^{\mu \alpha \beta} \Delta^{R}_{\alpha \rho}(k) \Delta^{R}_{\beta \rho}(k + q) m^2_R(k^2),
$$

(3.9)

which, in view of Eq. (3.8), may be written exclusively in terms of renormalized quantities (i.e., with no reference to the cutoff-dependent $Z_i$), as

$$
m^2_R(q^2) = \frac{iC_A g_R^2}{1 + G_R(q^2) q^2} \int_G^{\mu \alpha \beta} \Delta^{R}_{\alpha \rho}(k) \Delta^{R}_{\beta \rho}(k + q) m^2_R(k^2),
$$

(3.10)

where

$$
G^{\mu \alpha \beta} \equiv \left[ \Gamma_R - \sum_{i=1}^{3} (\pi_i^R) \right]^{\mu \alpha \beta},
$$

(3.11)

namely the rhs of Eq. (3.8).

We next study the properties of Eq. (3.10) under RG transformations. To that end, it is convenient to recast both sides of this equation in terms of appropriately chosen RGI quantities. Clearly, by virtue of Eq. (2.30), a simple multiplication by $g^{-2}[1 + G(q^2)]^2$ converts the lhs of Eq. (3.10) into the RGI mass $\tilde{m}^2(q^2)$ introduced in Eq. (2.30). On the other hand, the demonstration that, after the aforementioned multiplication, the rhs is also RGI, is slightly more involved.

13
To prove this statement, we will employ the three RGI quantities, \( R_i \), introduced in Eq. (2.31). In particular, it is relatively straightforward to establish that when the terms \((a_i R_i)\) are multiplied by the factor \( g R_1 \Delta_1^{1/2}(q) \Delta_1^{1/2}(r) \Delta_1^{1/2}(p) \) they become functions of the \( R_i \); so, we have (see Fig. 4)

\[
g R_1 \Delta_1^{1/2}(q) \Delta_1^{1/2}(r) \Delta_1^{1/2}(p) (\bar{\pi}_i^R) = \mathcal{F}_i(\mathcal{R}_1, \mathcal{R}_2, \mathcal{R}_3). \tag{3.12}
\]

As a consequence,

\[
g R_1 \Delta_1^{1/2}(q) \Delta_1^{1/2}(r) \Delta_1^{1/2}(p) \mathcal{G}(q, r, p) = \mathcal{R}_1 - \sum_{i=1}^{3} \mathcal{F}_i \equiv \mathcal{R}. \tag{3.13}
\]

Note finally that the ratio \( f(p_1)/f(p_2) \) of any two-point function \( f(p) \) is also a RGI quantity.

Armed with these results, we may now re-express Eq. (3.10) in terms of manifestly RGI quantities. Specifically, after the aforementioned multiplication by \( g^{-2}[1+G(q^2)]^2 \), and some appropriate manipulations, we arrive at [with \( p = -(k+q) \)]

\[
\overline{m}^2(q^2) = \frac{iCA q_\mu}{q^2 d^{1/2}(q^2)} \int_k \mathcal{R}^{\alpha \beta \mu \nu} \mathcal{P}_\alpha(k) P_\beta(p) d^{1/2}(k^2) d^{1/2}(p^2) \left\{ \frac{1 + G(p^2)}{1 + G(k^2)} \right\} \overline{m}^2(k^2), \tag{3.14}
\]

which is a manifestly RGI integral equation.

**IV. GENERAL STRUCTURE OF THE THREE-GLUON KERNEL**

In the previous section we have demonstrated that the mass equation, as captured in Eq. (3.10), has built in it the exact RG properties that one expects on general theoretical grounds. Evidently, in order to proceed further, and deduce from Eq. (3.10) the momentum dependence of the gluon mass, further information on \( \mathcal{G}^{\mu \alpha \beta} \), or directly on its divergence, \( q_\mu \mathcal{G}^{\mu \alpha \beta} \), is needed.
It is clear that the diagrammatic decomposition of $G^{\mu\alpha\beta}$ involves the three Bethe-Salpeter kernels $K_1$, $K_2$, and $K_3$, whose complicated skeleton expansion renders their full determination impossible. It is therefore necessary, for practical purposes, to introduce approximations or Ansätze for the quantity $G^{\mu\alpha\beta}$, which ought to encode, as well as possible, some of its salient field-theoretic properties.

To that end, it is essential to consider the tensorial decomposition of $G^{\mu\alpha\beta}$, and exploit its Bose-symmetric nature, together with the fact that, when inserted into Eq. (3.10), it is contracted by two transverse projectors. Specifically, in a straightforward basis composed by the momenta $r$ and $p$, one has

$$G^{\mu\alpha\beta}(q, r, p) = \sum_{i=1}^{14} C_i(q, r, p) b_i^{\mu\alpha\beta}, \quad (4.1)$$

with

$$b_1^{\mu\alpha\beta} = r^\mu g^{\alpha\beta}, \quad b_2^{\mu\alpha\beta} = p^\mu g^{\alpha\beta}, \quad b_3^{\mu\alpha\beta} = p^\alpha g^{\mu\beta};$$
$$b_4^{\mu\alpha\beta} = r^\beta g^{\mu\alpha}, \quad b_5^{\mu\alpha\beta} = p^\mu p^\alpha r^\beta, \quad b_6^{\mu\alpha\beta} = r^\mu p^\alpha r^\beta, \quad (4.2)$$

and

$$b_7^{\mu\alpha\beta} = p^\beta g^{\mu\alpha}, \quad b_8^{\mu\alpha\beta} = r^\alpha g^{\mu\beta}, \quad b_9^{\mu\alpha\beta} = r^\mu r^\alpha r^\beta, \quad b_{10}^{\mu\alpha\beta} = p^\mu p^\alpha p^\beta;$$
$$b_{11}^{\mu\alpha\beta} = p^\mu r^\alpha p^\beta, \quad b_{12}^{\mu\alpha\beta} = p^\mu r^\alpha r^\beta, \quad b_{13}^{\mu\alpha\beta} = r^\mu p^\alpha p^\beta, \quad b_{14}^{\mu\alpha\beta} = r^\mu p^\alpha r^\beta. \quad (4.3)$$

The form factors $C_i(q, r, p)$ are in general related among each other by conditions imposed by Bose-symmetry. Particularly important to our purposes are the relations

$$C_2(q, r, p) = -C_1(q, p, r); \quad C_4(q, r, p) = -C_3(q, p, r). \quad (4.4)$$

The tree-level values of the form factors $C_i$ are determined by setting $G = \Gamma^{(0)}$; as one can check by substituting $q = -(r + p)$ into Eq. (3.2), and using the above basis to express the result, one has $C_1^{(0)} = 1$, $C_2^{(0)} = -1$, $C_3^{(0)} = 2$, $C_4^{(0)} = -2$, $C_7^{(0)} = -1$, $C_8^{(0)} = 1$, with all the remaining $C$s vanishing.

Now, when contracted with $P_{\alpha \rho}(r) P_{\beta \rho}(p)$, the second set of tensors, $(b_7 - b_{14})$, vanishes identically, while for the first set, one can effectively use the replacements

$$b_3^{\mu\alpha\beta} \to -q^\alpha g^{\mu\beta}, \quad b_4^{\mu\alpha\beta} \to -q^\beta g^{\mu\alpha}, \quad b_5^{\mu\alpha\beta} \to p^\mu q^\alpha q^\beta, \quad b_6^{\mu\alpha\beta} \to r^\mu q^\alpha q^\beta. \quad (4.5)$$

 alternatively, one may use the standard Ball and Chiu decomposition [69], arriving at exactly the same conclusions.
It is then relatively straightforward to establish that
\[
q \mu G^{\mu \alpha \beta} P_{\alpha \rho}(r) P^\rho_{\beta}(p) = \{[(p^2 - r^2)S + q^2 A]g^{\alpha \beta} + B q^\alpha q^\beta\} P_{\alpha \rho}(r) P^\rho_{\beta}(p). \tag{4.6}
\]
where
\[
S(q, r, p) = \frac{1}{2}[C_1(q, r, p) + C_1(q, p, r)],
\]
\[
A(q, r, p) = \frac{1}{2}[C_1(q, p, r) - C_1(q, r, p)],
\]
\[
B(q, r, p) = (q \cdot p) C_5(q, r, p) + (q \cdot r) C_6(q, r, p) + [C_3(q, p, r) - C_3(q, r, p)]. \tag{4.7}
\]
The terms \(A\) and \(B\) emerge when writing the total contribution from \(b_1\) and \(b_2\) as the sum of a symmetric and an antisymmetric piece under \(r \leftrightarrow p\), namely
\[
[C_1(q, r, p)r^\mu + C_2(q, r, p)p^\mu]g^{\alpha \beta} = [S(q, r, p)(r - p)^\mu + A(q, r, p)q^\mu]g^{\alpha \beta}. \tag{4.8}
\]
In addition, note that we have used Eq. (4.4) to eliminate \(C_2\) and \(C_4\) in favor of \(C_1\) and \(C_3\), respectively.

Let us now comment on the way that the terms of Eq. (4.7) contribute to the mass equation in the limit \(q \to 0\). It is easy to verify that the terms associated with \(A(q, r, p)\) and \(B(q, r, p)\) are subleading in this limit. Indeed, first of all, the \(q^2\) that multiplies the \(A(q, r, p)\) and the \(q^\alpha q^\beta\) that multiplies \(B(q, r, p)\) compensate the \((1/q^2)\) in front of the mass equation. Then, since \(A(q, r, p)\) is antisymmetric under \(r \leftrightarrow p\), we have that \(A(0, -p, p) = 0\), and therefore, when \(q \to 0\), \(A(q, r, p) \to \mathcal{O}(q)\). Similarly, the terms in \(B\) proportional to \(C_5\) and \(C_6\) are multiplied by an additional power of \(q\), and are manifestly subleading, while the remaining term is antisymmetric under \(r \leftrightarrow p\), and therefore this too is of order \(\mathcal{O}(q)\). Thus, the only term that contributes to the mass equation in the IR limit is the one associated with \(S\). Note finally that out of the three terms defined in Eq. (4.7), only \(S\) has a tree level value, namely \(S^{(0)} = 1\).

After these considerations, we can write down the final form taken by the mass equation. Setting \(r = k\), \(p = -(k + q)\), and passing to Euclidean space following standard rules \cite{21}, (and suppressing the index “E” throughout), we have
\[
m^2(q^2) = -\frac{g^2 C_A}{1 + G(q^2)} \frac{1}{q^2} \int_k m^2(k^2) \Delta_{\alpha \rho}(k) \Delta^\rho_\beta(k + q) \mathcal{K}^{\alpha \beta}(q, k, -k - q), \tag{4.9}
\]
where, according to the above discussion, the total kernel \(\mathcal{K}^{\alpha \beta}\) may be naturally decomposed into a contribution that is leading in the IR, to be denoted by \(\mathcal{K}_L^{\alpha \beta}\), and one that is subleading,
to be denoted by $\mathcal{K}_{\text{SL}}^{\alpha\beta}$, namely

$$
\mathcal{K}^{\alpha\beta} = \mathcal{K}_{\text{L}}^{\alpha\beta} + \mathcal{K}_{\text{SL}}^{\alpha\beta},
$$

(4.10)

with

$$
\mathcal{K}_{\text{L}}^{\alpha\beta} = [ (k + q)^2 - k^2 ] S g^{\alpha\beta},
$$

$$
\mathcal{K}_{\text{SL}}^{\alpha\beta} = q^2 A g^{\alpha\beta} + B q^\alpha q^\beta,
$$

(4.11)

where the common argument $(q, k, -q - k)$ in all above quantities has been suppressed.

V. RG PROPERTIES OF THE ORIGINAL MASS EQUATION

Let us now compare Eq. (4.9) with the one derived originally in [21]. There, the mass equation considered had the form of Eq. (3.9); in other words, one dealt directly with the term $\left[ Z_3(a_0) + Z_g^2 Z_A^2 (a_4^R) + (a_5^R) \right]$, without passing to the rhs of Eq. (3.8). The way to handle the renormalization constants was to set them directly equal to unity, and assume that the remaining terms had been rendered UV finite. This procedure finally amounts to the effective replacement

$$
q_{\mu} \left\{ Z_3(a_0) + Z_g^2 Z_A^2 (a_4^R) + (a_5^R) \right\}^{\mu\alpha\beta} \rightarrow \mathcal{K}^{\alpha\beta}(k, q),
$$

(5.1)

with

$$
\mathcal{K}^{\alpha\beta}(k, q) = \left[ (k + q)^2 - k^2 \right] \{ 1 - [ Y_R(k + q) + Y_R(k) ] \} g^{\alpha\beta}
$$

$$
+ \left[ Y_R(k + q) - Y_R(k) \right] (q^2 g^{\alpha\beta} - 2q^\alpha q^\beta),
$$

(5.2)

where

$$
Y(k^2) = \frac{g^2 C_A}{4k^2} k_{\alpha} \int_\ell \Delta^{\alpha\rho}(\ell) \Delta^{\beta\sigma}(\ell + k) \Gamma_{\sigma\rho\beta}(-\ell - k, \ell, k).
$$

(5.3)

The renormalized version of $Y$ is simply

$$
Y_R(k) = Y(k) - Y(\mu),
$$

(5.4)

namely the form corresponding to the momentum-subtraction (MOM) scheme.

A direct comparison of Eq. (5.2) with the generic form given in Eq. (4.11) establishes that, in this case,

$$
S = 1 - [ Y_R(k + q) + Y_R(k) ]; \quad A = Y_R(k + q) - Y_R(k); \quad B = -2A.
$$

(5.5)
Note that $S$ is symmetric under the interchange $k \leftrightarrow (k + q)$, as expected from its general property given in Eq. (4.7); similarly, the $A$ of Eq. (5.5) is antisymmetric under the same interchange, exactly as the $A$ of Eq. (4.7). Finally, $S^{(0)} = 1$, as it should.

In [21] an approximate form for $Y(k)$ was obtained by substituting tree-level expressions for all quantities appearing inside the integral in Eq. (5.3). The result is given by

$$Y_R(k^2) = -\frac{15}{16} t(k), \quad (5.6)$$

where

$$t(k) \equiv \left(\frac{\alpha_s C_A}{4\pi}\right) \log \left(\frac{k^2}{\mu^2}\right), \quad (5.7)$$

and $\alpha_s = g^2/4\pi$ is the value of the Yang-Mills charge at the subtraction point $\mu$ chosen.

In the analysis of the gluon mass equation presented in [21], the rhs of Eq. (5.6) was multiplied by a constant $C$, with $C > 1$. As has been explained in detail there, the main reason for this is the need to counteract the (destabilizing) effect of the negative sign in front of the integral on the rhs of Eq. (4.9), and obtain positive-definite solutions for the gluon mass, at least within a reasonable range of physical momenta. In particular, for $\alpha_s = 0.22$, which is the “canonical” MOM value for $\mu = 4.3$ GeV, and $C = 9.2$, the function $m^2(q^2)$ is positive in the range of momenta between 0 to 5.5 GeV; past that point it turns negative (but its magnitude is extremely small, around $10^{-5}$ GeV$^2$, as shown in the inset of Fig. [10] [70]. As we will see in the next section, this unwanted feature may be eventually rectified, by modifying appropriately the form of $S$.

A. Quantifying the kernel quality: The basic procedure

In order to quantitatively determine to what extent a given approximation for $S$ respects the RG properties of the full mass equation, it is necessary to establish a reference situation, and then compute possible deviations from it. To that end, we will employ a general procedure that consists of the following main steps.

(i) We consider the RGI quantity

$$d(q^2) = g^2 F^2(q^2) \Delta(q^2), \quad (5.8)$$

namely that of Eq. (2.29) with the approximation Eq. (2.5) implemented, and compute its shape using $F(q^2)$ and $\Delta(q^2)$ from the lattice, for different values of the renormalization
point $\mu$. To that end, we use the standard formulas

$$\Delta(q^2, \mu^2) = \frac{\Delta(q^2, \nu^2)}{\mu^2 \Delta(\mu^2, \nu^2)}, \quad F(q^2, \mu^2) = \frac{F(q^2, \nu^2)}{F(\mu^2, \nu^2)},$$

(5.9)

which allow one to connect a set of lattice data renormalized at $\mu$ with the corresponding set renormalized at $\nu$. It is clear that, since these changes amount to the multiplication of the product $F^2(q^2)\Delta(q^2)$ by an overall constant, we can adjust the value of $g^2$ (or $\alpha_s$) for each $\mu$, such that the curves of $d(q^2)$ so produced lie exactly on top of each other. Thus, this procedure fixes the values of $\alpha_s(\mu)$, such that, the (formally RGI) $d(q^2)$ is indeed RGI.

As we will see, the resulting values for $\alpha_s(\mu)$ are rather compatible with those predicted by standard MOM calculations.

(iii) We next solve the gluon mass equation for the same set of $\mu$’s used in the previous step. Specifically, for the ingredients entering in the rhs of Eq. (4.9), such as $g^2$, $F$, and $\Delta$, we use the corresponding quantities found in (i), for any given $\mu$; note that $Y_R$ is also $\mu$-dependent, and is accordingly modified. This procedure furnishes a set of $\mu$-dependent solutions, $m^2(q^2, \mu^2)$; note that the value of the constant $C$ that multiplies $Y_R$ also varies (rather mildly) with $\mu$.

(iii) The various masses, $m^2(q^2, \mu^2)$, found in (ii) are now used to construct the RGI mass defined in Eq. (2.30) [using again Eq. (2.5)], namely

$$\overline{m}^2(q^2) = \frac{m^2(q^2)}{g^2F^2(q^2)}.$$  \hspace{1cm} (5.10)

Now, ideally speaking, when the various $m^2(q^2, \mu^2)$ are inserted into Eq. (5.10), together with the corresponding ($\mu$-dependent) $g^2F^2(q^2)$, one ought to obtain the same identical curve for each value of $\mu$.

In practice, of course, deviations between the various curves are expected, precisely because our knowledge of $S$ is imperfect. Therefore, a theoretically motivated way to discriminate between possible approximation for $S$ is to choose the one that produces the best coincidence (in the sense of minimizing the relative error) for the various $\overline{m}^2(q^2)$.

B. Numerical analysis

Throughout the numerical study presented here, as well as in the next section, we will evaluate the relevant field-theoretic quantities at three different values of the renormalization
FIG. 5: (color online) The quenched lattice data and the corresponding fits for the $SU(3)$ gluon propagator (left panel) and ghost dressing function (right panel) renormalized at three different scales $\mu_i$. Lattice data are taken from [31].

point $\mu_i$; in particular, we will use $\mu_1 = 4.3$ GeV, $\mu_2 = 3.0$ GeV, and $\mu_3 = 2.5$ GeV. In the various plots, the curves of a quantity $A(q^2, \mu_i^2)$ produced for these three different values of $\mu_i$ will be depicted as follows: $A(q^2, \mu_1^2)$ with squares or solid (black) curve; $A(q^2, \mu_2^2)$ with circles or dotted (red) curve; $A(q^2, \mu_3^2)$ with triangles or dashed (blue) curve.

The first step in this analysis is to consider the lattice data for $\Delta(q^2)$ and $F(q^2)$ given in [31]; these data are fitted using the functional forms reported in various recent articles [20, 37, 71]. Then, repeated use of Eq. (5.9) allows us to generate the three curves for $\Delta(q^2)$ and $F(q^2)$ renormalized at $\mu_i$ (with $i = 1, 2, 3$), which are shown in Fig. 5. It is clear that, due to multiplicative renormalizability, expressed by Eq. (5.9), each curve may be obtained from the other by a simple rescaling. Specifically, the curves $\Delta(q^2, \mu_2^2)$ and $\Delta(q^2, \mu_3^2)$ are obtained from $\Delta(q^2, \mu_1^2)$ through multiplication by the factors of 1.20 and 1.33, respectively; in the case of $F(q^2)$, the corresponding rescaling factors are 1.09 and 1.15.

Next, we form the RGI combination $d(q^2)$ given in Eq. (5.8). Concretely, for each specific value of $\mu_i$, we combine the corresponding ingredients entering into the definition of $d(q^2)$. As mentioned before in step (i), the value of $g^2$ (or $\alpha_s$) for each $\mu_i$ is fixed by requiring that the three curves of $d(q^2)$ so produced lie exactly on top of each other; so, the corresponding $\alpha_s(\mu_i)$ must be rescaled by an amount that will exactly compensate the corresponding rescalings introduced to the product $\Delta(q^2, \mu_i^2)F^2(q^2, \mu_i^2)$. Specifically, starting with $\alpha_s(\mu_1^2) = 0.220,$
which is the value that best fits the lattice data in the recent SDE analysis presented in [72], we obtain the values \( \alpha_s(\mu_i^2) = 0.320 \) and \( \alpha_s(\mu_2^2) = 0.392 \).

On the left panel of Fig. 6 we plot the three curves for the dimensionful quantity \( d(q^2)/4\pi \). As expected, by construction, we can see that the three curves are indeed on top of each other, thus manifesting that, for the particular set of values of \( \alpha_s(\mu_i) \) quoted above, \( d(q^2) \) is \( \mu \)-independent.

It is important at this point to check whether the values for \( \alpha_s(\mu_i) \) obtained from the above procedure are compatible with the MOM expectations. This is done in the right panel of the same figure, where the grey continuous line represents the \( \alpha_{\text{MOM}}(q^2) \) obtained from the nonperturbative analysis of [73], for \( \Lambda_{\text{QCD}} = 350\text{ MeV} \) and \( N_f = 0 \); the aforementioned three values used for \( \alpha_s(\mu_i) \) are denoted by the corresponding symbols. As we can see, the values of \( \alpha_s(\mu_i) \) that implement the \( \mu \)-independence of \( d(q^2) \) are indeed in good agreement with the MOM predictions.

We now turn to the gluon mass equation; evidently, since its kernel is composed of \( \mu \)-dependent quantities, for each value of \( \mu_i \) we will obtain a different solution, \( m^2(q^2, \mu_i^2) \).

On the left panel of Fig. 7 we show the corresponding solutions for the three renormalization points chosen. The corresponding infrared saturation points, \( m^2(0, \mu_i^2) = \Delta^{-1}(0, \mu_i^2) \), are
FIG. 7: (color online) Left panel: The numerical solution for the dynamical gluon mass, $m^2(q^2, \mu^2)$, for the three values of $\mu_i$. Right panel: The corresponding RGI mass $4\pi m^2(q^2)$ obtained from Eq. (2.30) for the three values of $\mu_i$.

given by $m(0, \mu_1^2) = 375$ MeV, $m(0, \mu_2^2) = 412$ MeV, and $m(0, \mu_3^2) = 434$ MeV. In addition, as anticipated, also the values of the arbitrary constant $C$ display a mild $\mu$-dependence: $C(\mu_1) = 9.2$, $C(\mu_2) = 8.5$, and $C(\mu_3) = 8.4$.

Now we are in the position to determine the behavior of the RGI mass $m^2(q^2)$. To that end, we substitute into Eq. (5.10) the $\mu$-dependent results for $m^2(q^2, \mu_i^2)$, $F(q^2, \mu_i^2)$ and $\alpha_s(\mu_i)$ obtained above. This is shown on the right panel of Fig. 7 where we plot the quantity $4\pi m^2(q^2)$ for the three values of $\mu_i$. As we can see, we have a nice agreement between the three curves in the range from 0 to 0.05 GeV$^2$. However, for higher values of $q^2$ they separate from the other, reaching the biggest discrepancy at $q^2 = 7.5$ GeV$^2$, where the percentage error between the (black) continuous and the (blue) dashed curves is around 64%.

Evidently, the considerable deviations from the exact RG-invariance displayed in Fig. 7 indicate that the form of the function $S$ employed in the mass equation needs to be improved. As we will see in the next section with some specific examples, such an improvement is indeed possible, and can be obtained by resorting to basic RGI arguments.
VI. RG IMPROVED VERSIONS OF THE KERNEL

As has been established in Eq. (3.13), the quantity $G$ must be such that, when multiplied by $g\Delta^{1/2}(q)\Delta^{1/2}(p)$, ought to give rise to an RGI combination. This information may be used to obtain some well-motivated Ansätze for $S$, which, in turn, may lead to solutions for $m^2(q^2)$ that are better behaved under the RG. In this section we will explore the explicit realization of this possibility. The study presented here is by no means exhaustive; it is simply indicative of how RG-improved versions of the gluon mass equation may be obtained in principle.

A. Two simple models

Specifically, let us set

$$S(q, k, k + q) = F(q)W(k, k + q), \quad (6.1)$$

where, in accordance with the general properties of $S$, the $W$ is symmetric under the exchange $k \leftrightarrow k+q$. In addition, at tree level we must have $W(0) = 1$, so that, since $F(0)(q) = 1$, we get $S(0) = 1$, as required.

If we now use the $S$ of Eq. (6.1) to construct the lhs of Eq. (3.13), we have

$$g\Delta^{1/2}(q)\Delta^{1/2}(k)\Delta^{1/2}(k + q)S = [gF(q)\Delta^{1/2}(q)] \{ \Delta^{1/2}(k)\Delta^{1/2}(k + q)W(k, k + q) \}$$

$$= d^{1/2}(q^2) \{ \Delta^{1/2}(k)\Delta^{1/2}(k + q)W(k, k + q) \}. \quad (6.2)$$

It is clear now that the presence of $F(q)$ facilitates the realization of the RGI combination, by providing the missing ingredient for the formation of $d^{1/2}(q^2)$; it is, therefore, an advantageous starting point. The remaining structure must obviously come from $W$, which must convert the combination inside the curly bracket into another RGI quantity.

In order to devise an approximate expression for the (dimensionless) $W$, let us first consider the one-loop expression of $\Delta^{-1}(k) = k^2 J(k)$, in the MOM scheme. For the (dimensionless) $J(k^2)$ we have

$$J(k) = 1 + \frac{13}{6} t(k), \quad (6.3)$$

and so,

$$J^{1/2}(k)J^{1/2}(k + q) = 1 + \frac{13}{12} \left[ t(k) + t(k + q) \right] + \mathcal{O}(\alpha_s^2). \quad (6.4)$$
Thus, at order $O(\alpha_s)$ the minimal necessary structure for $W$ is

$$W^{(1)} = 1 + \frac{13}{12} \left[ t(k) + t(k + q) \right]. \quad (6.5)$$

Of course, this minimal form may be multiplied by a $\mu$-independent function, which, at the given order, will provide the (unknown) rhs of Eq. (3.13). Evidently, use of the minimal $W^{(1)}$ gives rise to a lhs equal to unity.

These observations motivate the study of two simple extensions of Eq. (6.5), where some additional structure has been added in order to model higher order effects or purely non-perturbative contributions.

The cases we will consider are

$$W_1 = 1 + \frac{13}{12} \left[ t(k) + t(k + q) \right] + c_1 \left[ t^2(k) + t^2(k + q) \right] + c_2 t(k) t(k + q), \quad (6.6)$$

and

$$W_2 = 1 + \frac{13}{12} \left[ t(k) + t(k + q) \right] + c. \quad (6.7)$$

We next study the numerical implications of the above two possibilities.

B. Numerical analysis

On the left panel of Fig. 8 we show the numerical solution for $m^2(q^2, \mu^2)$ using the model presented in Eq. (6.6). In particular, we choose, for the three different $\mu_i$, the parameters
FIG. 9: (color online) The numerical solution for $m^2(q^2, \mu^2)$ (left panel) using the model of Eq. (6.7) for the three renormalization scale $\mu_i$; the corresponding RGI mass $4\pi\overline{m}^2(q^2)$ given by Eq. (2.30) is shown on the right panel.

$c_1(\mu_1) = -3.62$ and $c_2(\mu_1) = -33.97$; $c_1(\mu_2) = -7.36$ and $c_2(\mu_2) = -17.13$; $c_1(\mu_3) = -7.42$ and $c_2(\mu_3) = -13.81$.

Although the general qualitative behavior of $m^2(q^2)$ appears rather similar to that shown in Fig. 7, the RGI masses obtained from them show a definite improvement with respect to those of Fig. 7. Indeed, as one can clearly see on the right panel of Fig. 8, the three curves coincide within a wider range of momenta than in the previous case. More specifically, the less favorable region of momenta is around $q^2 \approx 3.5 \text{ GeV}^2$, where the relative error between the curves is smaller than 12%. However, the downside of the form $W_1$ is that the appearance of a negative UV tail for $m^2(q^2)$ (past $q^2 \approx 3.5 \text{ GeV}^2$) persists.

It is important to mention that the mass equation admits solutions for a variety of additional choices for $c_1(\mu_i)$ and $c_2(\mu_i)$; however, the particular values quoted above are singled out because they yield $\overline{m}^2(q^2)$ that are as close to being perfectly RGI as possible. In that sense, our scanning through the possible values of $c_1(\mu_i)$ and $c_2(\mu_i)$ is by no means exhaustive, but only indicative of certain general trends in the type of solutions obtained.

We next analyze the second model, where Eq. (6.7) is used in the kernel of the gluon mass equation. The results for this particular case are presented in Fig. 9. On the left panel we plot $m^2(q^2, \mu^2)$, for the three values of $\mu_i$ chosen. The right panel shows the RGI quantity $4\pi\overline{m}^2(q^2)$; evidently, the results for the three $\mu_i$ practically collapse on a unique curve. In fact, the less favorable point is located at $q^2 \approx 25 \text{ GeV}^2$, where the relative
error is around 10%. In addition, the solutions obtained with $W_2$ remain positive and monotonically decreasing through the entire range of physical momenta. For the curves presented in Eq. (6.7), we have chosen $c = -1.50$ for $\mu_1$; $c = -1.62$ for $\mu_2$, and $c = -1.72$ for $\mu_3$.

In Fig. 10 we compare the numerical solutions for $m^2(q^2, \mu_1^2)$ obtained from the three different models. The solution of the original version of the gluon mass equation is represented by the (black) continuous curve, while the solutions using Eq. (6.6) and Eq. (6.7) are indicated by (blue) dashed and (red) dotted curves, respectively. When the gluon propagator is renormalized at the point $\mu_1$, its saturation value in the deep IR is given by

$$\Delta^{-1}(0) = 0.14 \text{ GeV}^2 = m^2(0) \equiv m_0^2.$$  

Therefore, the three masses coincide at the origin, i.e., $m_0 = 375$ MeV. However, in the intermediate region we clearly see differences in their momentum dependence. Notice that, in this particular region, the original equation produces a $m^2(q^2)$ that falls off slower than the improved versions. On the other hand, the $m^2(q^2)$ obtained with the $W_1$ decreases considerably faster than the other two cases. The UV tails of these solutions are shown separately in the insert; as already mentioned, only the one originating from Eq. (6.7) stays
FIG. 11: (color online) The numerical solution for $m^2(q^2)$ obtained using the RG-improved Ansatz $W_2$ of Eq. (6.7) (black circles). The (black) continuous curve represents the fit of Eq. (6.9) while the (blue) dashed curve is the asymptotic fit for the ultraviolet tail given by Eq. (6.10), strictly positive for all momenta.

C. A physically motivated fit

It turns out that the three different masses in Fig. 10 may be fitted very accurately by a single, particularly simple function, namely

$$m^2(q^2) = \frac{m_0^2}{1 + (q^2/M^2)^{1+p}}.$$  \hspace{1cm} (6.9)

The corresponding sets of optimal values, $(M, p)$, for the mass scale $M$ and the exponent $p$ are as follows: $(i)$ (557 MeV, 0.08) for the black continuous curve; $(ii)$ (381 MeV, 0.26) for the blue dashed curve; $(iii)$ (436 MeV, 0.15) for the red dotted curve. All fits have a reduced $\chi^2 \approx 0.99$. Note that $M$ is just a dimensionful fitting parameter, not to be confused with the characteristic QCD mass scale, $\Lambda$; in fact, within the MOM scheme that we use, and for $\alpha_s = 0.22$, we have that $\Lambda_{\text{MOM}} = 280$ MeV \cite{73}.

In order to appreciate the quality of the above fit, in Fig. 11 we superimpose the numerical solution for the RG-improved Ansatz $W_2$ when $\alpha(\mu_1) = 0.22$ (black circles) and the fit of Eq. (6.9) (black continuous curve). Clearly, the coincidence between the two curves is striking.
Let us now take a closer look at the asymptotic form of \( m^2(q^2) \) for large \( q^2 \), to be denoted by \( m_{\text{UV}}^2(q^2) \). From Eq. (6.9) it is clear that, for sufficiently large values of \( q^2 \), the 1 may be depreciated in the denominator of Eq. (6.9), yielding

\[
m_{\text{UV}}^2(q^2) = \frac{m_0^2 \Lambda^2}{q^2} (\frac{q^2}{\mathcal{M}^2})^{-\nu}.
\]

(6.10)

As is shown in Fig. 11, the onset of the asymptotic form (6.10) is clear already at momenta of the order of a few GeV.

The particular asymptotic behavior described in Eq. (6.10) corresponds precisely to the so-called “power-law” running of the effective gluon mass, first conjectured in [74], and subsequently studied in [75, 76]. Its main physical implication is that the condensates of dimension two do not contribute to the OPE expansion of \( m_{\text{UV}}^2(q^2) \), because otherwise the corresponding running would have been logarithmic. Then, in the absence of quarks, the lowest order condensates appearing in the OPE of the mass are those of dimension four, namely the (gauge-invariant) \( \langle 0|:G^a_{\mu\nu}G^a_{\mu\nu}:|0\rangle \), and possibly the ghost condensate \( \langle 0|:\overline{c}^a\Box c^a:|0\rangle \) [77, 78].

Since, on dimensional grounds, these condensates must be divided by \( q^2 \), one obtains (up to logarithms) the aforementioned power-law running for the mass.

It remains to be seen if Eq. (6.10) is a fortuitous coincidence related to a particular Ansatz for the kernel (namely \( W_2 \)), or if it really reflects an intrinsic feature of the gluon mass.

VII. DISCUSSION AND CONCLUSIONS

In this work we have presented a detailed study of the RG structure of the integral equation that controls the dynamical evolution of the gluon mass. Specifically, we have shown that the renormalization of this equation can be carried out entirely by means of the renormalization constants employed in the standard perturbative treatment, namely those associated with the gluon and ghost wave functions and the fundamental vertices of the theory. In addition, by making explicit use of the diagrammatic equivalence between the skeleton expansion of the three gluon vertex in the SDE and BS formalisms, the kernel of the gluon mass equation can be written exclusively in terms of the renormalized Green’s functions, with no reference to any cutoff-dependent renormalization constants [see Eq. (3.10)].

The RG properties of the full mass equation are inevitably distorted when approximate expressions are used for its kernel. The departure of the solutions from the correct RG
behavior is quantitatively described in terms of the RGI gluon mass, $\overline{m}^2(q^2)$, and can serve as a discriminant for the various Ansätze employed for the kernel. Using this criterion, we have established that the $\overline{m}^2(q^2)$ constructed using as input the solution $m^2(q^2)$ obtained from the original version of the mass equation [21], deviates considerably from the optimal RGI behavior (see Fig. 7).

Then, motivated by the RG properties that the kernel must satisfy, two new versions of the gluon mass equation were put forth [see Eqs. (6.6) and (6.7)], which are expected to display an improved RG behavior. Indeed, our numerical analysis reveals that the $\overline{m}^2(q^2)$ obtained from both RG-improved Ansätze capture more faithfully the RG properties of the exact equation. Specifically, the deviations between the $\overline{m}^2(q^2)$ obtained for different $\mu$'s displays, in the less favorable regions, a relative error around 12% and 10%, respectively. In addition, and contrary to the other two cases, the Ansatz of Eq. (6.7) presents a well-defined positive UV tail in all range of momenta. We therefore conclude that, overall, the best available functional form for the kernel is given by Eq. (6.7).

Interestingly enough, $W_2$ has a simpler structure than $W_1$, in the sense that it contains a single adjustable parameter instead of two, and yet it produces results that are in better compliance with the basic theoretical principles that we have considered. The reason for that may be related to the overall sign of the gluon mass equations, and the degree at which each Ansatz succeeds to effectively reverse it. Specifically, as already mentioned after Eq. (5.7), the negative sign on the rhs of Eq. (4.9) must be compensated by negative contributions coming from the kernel. In the case of $W_2$ this is accomplished directly, and in a rather elementary way, because the parameter $c$ is simply chosen such that $1 + c$ becomes sufficiently negative. Instead, $W_1$ performs the same task in a less efficient way, which may be reflected in the slightly enhanced departure of the resulting mass from the perfect RG-invariance, and the change of its sign in the deep UV.

It is clear that a more rigorous determination of the kernel is required, in order to further substantiate our analysis. It is worth pointing out that, in this effort, one may want to keep open the possibility of working with the lhs of Eq. (3.8), rather than its rhs. Indeed, whereas for the formal demonstration presented in Section III the rhs of Eq. (3.8) seems to be advantageous, because it is free of the renormalization constants $Z$, for the actual computation of $G^{\mu \alpha \beta}$ the lhs may turn out to be easier to handle. Of course, in order to make progress with the lhs, in addition to obtaining a better approximation for the quantity $Y(k)$, one ought to
provide appropriate expressions for the renormalization constants $Z$. These tasks are technically particularly subtle and laborious, because they require, among other things, a tight control on the structure of the various fully-dressed vertices of the theory. In fact, the multiplicative renormalizability and the correct cancellation of overlapping divergences depends crucially on the detailed knowledge of the transverse (automatically conserved) part of the corresponding vertex (in our case of the three-gluon vertex), which forces one to go beyond the usual gauge-technique inspired Ansätze for the vertex in question [3]. These difficulties have been exemplified, and only partially circumvented, in the studies of the gap equation that controls the chiral symmetry breaking and the dynamical generation of a constituent quark mass [1–3, 37]. We hope to make progress on some of these issues in future works.
