Abstract

We generalize the Stueckelberg formalism in the (1/2, 1/2)
representation of the Lorentz Group. Some relations to other
modern-physics models are found.

*Presented at the 5th Mexican School “The Early Universe and Observational
Cosmology.” Nov. 25-29, 2002, Playa del Carmen, México and the Jornadas de
Investigación UAZ-2002, Zacatecas, Oct. 8-11, 2002.
I. OUTLINE.

The plan of my talk is following:

- Antecedents. Mapping between the Weinberg-Tucker-Hammer (WTH) formulation and antisymmetric tensor (AST) fields of the 2nd rank. Modified Bargmann-Wigner (BW) formalism. Pseudovector potential. Parity.

- Matrix form of the general equation in the (1/2, 1/2) representation.

- Lagrangian in the matrix form. Masses.

- Standard Basis and Helicity Basis.

- Dynamical invariants. Field operators. Propagators.

- Indefinite metric.

II. ANTECEDENTS.

Somebody may think that I am presenting well-known things. Therefore, I am going to give some overview of my previous works in order you to understand motivations better. In ref. [1] I derived the Maxwell-like equations with the additional gradient of a scalar field $\chi$ from the first principles. Here they are:

\begin{align}
\nabla \times E &= -\frac{1}{c} \frac{\partial B}{\partial t} + \nabla Im\chi , \\
\nabla \times B &= \frac{1}{c} \frac{\partial E}{\partial t} + \nabla Re\chi , \\
\nabla \cdot E &= -\frac{1}{c} \frac{\partial Re\chi}{\partial t} , \\
\nabla \cdot B &= \frac{1}{c} \frac{\partial Im\chi}{\partial t} .
\end{align}

Of course, similar equations can be obtained in the massive case $m \neq 0$, i.e., within the Proca-like theory. We should then consider...
\[(E^2 - c^2 p^2 - m^2c^4)\Psi^{(3)} = 0.\]  

In the spin-1/2 case the equation (2) can be written for the two-component spinor \((c = \hbar = 1)\)

\[(EI^{(2)} - \sigma \cdot p)(EI^{(2)} + \sigma \cdot p)\Psi^{(2)} = m^2\Psi^{(2)},\]  

or, in the 4-component form\(^1\)

\[[i\gamma_\mu \partial_\mu + m_1 + m_2\gamma^5]\Psi^{(4)} = 0.\]  

In the spin-1 case we have

\[(EI^{(3)} - S \cdot p)(EI^{(3)} + S \cdot p)\Psi^{(3)} - p(p \cdot \Psi^{(3)}) = m^2\Psi^{(3)},\]  

that lead to (1a-1d), when \(m = 0\). We can continue writing down equations for higher spins in a similar fashion.

On this basis we are ready to generalize the BW formalism [2,3]. Why is that convenient? In ref. [4] I presented the mapping between the WTH equation [5] and the equations for AST fields. The equation for a 6-component field function is\(^2\)

\[^1\text{There exist various generalizations of the Dirac formalism. For instance, the Barut generalization is based on}

\[[i\gamma_\mu \partial_\mu + a(\partial_\mu \partial_\mu)/m - \omega]\Psi = 0,\]  

which can describe states of different masses. If one fixes the parameter \(a\) by the requirement that the equation gives the state with the classical anomalous magnetic moment, then \(m_2 = m_1(1 + \frac{3}{2a})\), i.e., it gives the muon mass. Of course, one can propose a generalized equation:

\[[i\gamma_\mu \partial_\mu + a + b\Box + \gamma_5(c + d\Box)]\Psi = 0,\]  

\(\Box = \partial_\mu \partial_\mu\); and, perhaps, even that of higher orders in derivatives.

\[^2\text{In order to have solutions satisfying the Einstein dispersion relations } E^2 - p^2 = m^2 \text{ we have to assume } B/(A + 1) = 1, \text{ or } B/(A - 1) = 1.\]
\[[\gamma_{\alpha\beta} p_\alpha p_\beta + A p_\alpha + B m^2] \Psi^{(6)} = 0. \tag{8}\]

Corresponding equations for the AST fields are:

\[
\begin{align*}
\partial_\alpha \partial_\mu F^{(I)}_{\mu\beta} &- \partial_\beta \partial_\mu F^{(I)}_{\mu\alpha} + \frac{A-1}{2} \partial_\mu F^{(I)}_{\alpha\beta} - \frac{B}{2} m^2 F^{(I)}_{\alpha\beta} = 0, \tag{9a} \\
\partial_\alpha \partial_\mu F^{(II)}_{\mu\beta} &- \partial_\beta \partial_\mu F^{(II)}_{\mu\alpha} - \frac{A+1}{2} \partial_\mu F^{(II)}_{\alpha\beta} + \frac{B}{2} m^2 F^{(II)}_{\alpha\beta} = 0, \tag{9b}
\end{align*}
\]

depending on the parity properties of \(\Psi^{(6)}\) (the first case corresponds to the eigenvalue \(P = -1\); the second one, to \(P = +1\)).

We noted:

- One can derive equations for the dual tensor \(\tilde{F}_{\alpha\beta}\), which are similar to (9a,9b), refs. [20a,7].
- In the Tucker-Hammer case \((A = 1, B = 2)\), the first equation gives the Proca theory \(\partial_\alpha \partial_\mu F_{\mu\beta} - \partial_\beta \partial_\mu F_{\mu\alpha} = m^2 F_{\alpha\beta}\). In the second case one finds something different, \(\partial_\alpha \partial_\mu F_{\mu\beta} - \partial_\beta \partial_\mu F_{\mu\alpha} = (\partial_\mu \partial_\mu - m^2) F_{\alpha\beta}\)
- If \(\Psi^{(6)}\) has no definite parity, e. g., \(\Psi^{(6)} = \text{column}(E + iB, B + iE)\), the equation for the AST field will contain both the tensor and the dual tensor, e. g.,

\[
\partial_\alpha \partial_\mu F_{\mu\beta} - \partial_\beta \partial_\mu F_{\mu\alpha} = \frac{1}{2} (\partial_\mu \partial_\mu) F_{\alpha\beta} + \left[-\frac{A}{2} (\partial_\mu \partial_\mu) + \frac{B}{2} m^2\right] \tilde{F}_{\alpha\beta}. \tag{10}
\]

- Depending on the relation between \(A\) and \(B\) and on which parity solution do we consider, the WTH equations may describe different mass states. For instance, when \(A = 7\) and \(B = 8\) we have the second mass state \((m')^2 = 4m^2/3\).

We tried to find relations between the generalized WTH theory and other spin-1 formalisms. Therefore, we were forced to modify the Bargmann-Wigner formalism [6,7]. For instance, we introduced the sign operator in the Dirac equations which are the input for the formalism for symmetric 2-rank spinor:

\[
\begin{align*}
[i \gamma_\mu \partial_\mu + \epsilon_1 m_1 + \epsilon_2 m_2 \gamma_5]_{\alpha\beta} \Psi_{\beta\gamma} = 0, \tag{11a} \\
[i \gamma_\mu \partial_\mu + \epsilon_3 m_1 + \epsilon_4 m_2 \gamma_5]_{\gamma\beta} \Psi_{\alpha\beta} = 0, \tag{11b}
\end{align*}
\]
In general we have 16 possible combinations, but 4 of them give the same sets of the Proca-like equations. We obtain \[7\]:

\[
\begin{align*}
\partial_\mu A_\lambda - \partial_\lambda A_\mu + 2m_1 A_1 F_{\mu\lambda} + im_2 A_2 \epsilon_{\alpha\beta\mu\lambda} F_{\alpha\beta} &= 0, \\
\partial_\lambda F_{\mu\lambda} - \frac{m_1}{2} A_1 A_\mu - \frac{m_2}{2} B_2 \tilde{A}_\mu &= 0,
\end{align*}
\]

with \( A_1 = (\epsilon_1+\epsilon_3)/2, A_2 = (\epsilon_2+\epsilon_4)/2, B_1 = (\epsilon_1-\epsilon_3)/2, \) and \( B_2 = (\epsilon_2-\epsilon_4)/2. \)

So, we have the dual tensor and the pseudovector potential in the Proca-like sets. The pseudovector potential is the same as that which enters in the Duffin-Kemmer set for the spin 0.

Moreover, it appears that the properties of the polarization vectors with respect to parity operation depend on the choice of the spin basis. For instance, in refs. \[8,7\] the following momentum-space polarization vectors have been listed (in the pseudo-Euclidean metric):

\[
\begin{align*}
\epsilon_\mu(p, \lambda = +1) &= \frac{1}{\sqrt{2}} e^{i\phi} \left( 0, \frac{p_x p_z - ip_y p_r}{\sqrt{p_x^2 + p_y^2}}, \frac{p_y p_z + ip_x p_r}{\sqrt{p_x^2 + p_y^2}}, -\sqrt{p_x^2 + p_y^2} \right), \\
\epsilon_\mu(p, \lambda = -1) &= \frac{1}{\sqrt{2}} e^{-i\phi} \left( 0, -\frac{p_x p_z - ip_y p_r}{\sqrt{p_x^2 + p_y^2}}, -\frac{p_y p_z + ip_x p_r}{\sqrt{p_x^2 + p_y^2}}, +\sqrt{p_x^2 + p_y^2} \right), \\
\epsilon_\mu(p, \lambda = 0) &= \frac{1}{m} (p_x - E, -p_y, -p_z), \\
\epsilon_\mu(p, \lambda = 0_t) &= \frac{1}{m} (E, -p_x, -p_y, -p_z).
\end{align*}
\]

Berestetskii, Lifshitz and Pitaevski claimed too \[9\] that the helicity states cannot be the parity states. If one applies common-used relations between fields and potentials it appears that the \( E \) and \( B \) fields have no ordinary properties with respect to space inversions:

\[
\begin{align*}
E(p, \lambda = +1) &= \frac{-iEp_z}{\sqrt{2pp_l}} p - \frac{E}{\sqrt{2p_l}} \tilde{p}, \\
B(p, \lambda = +1) &= \frac{p_z}{\sqrt{2p_l}} p - \frac{ip}{\sqrt{2p_l}} \tilde{p}, \\
E(p, \lambda = -1) &= \frac{iEp_z}{\sqrt{2pp_r}} p - \frac{E}{\sqrt{2p_r}} \tilde{p}^*, \\
B(p, \lambda = -1) &= \frac{p_z}{\sqrt{2p_r}} p + \frac{ip}{\sqrt{2p_r}} \tilde{p}^*.
\end{align*}
\]

\[3\]See the additional constraints in the cited paper.
\( E(p, \lambda = 0) = \frac{im}{p} p \). \( B(p, \lambda = 0) = 0 \)  \quad \text{(14b)}

\[
\mathbf{p} = \begin{pmatrix} p_y \\ -p_x \\ -ip \end{pmatrix}.
\]

Thus, the conclusions of our previous works are:

- There exists the mapping between the WTH formalism for \( S = 1 \) and the AST fields of four kinds (provided that the solutions of the WTH equations are of the definite parity).

- Their massless limits contain additional solutions comparing with the Maxwell equations. This was related to the possible theoretical existence of the Ogievetski˘ı-Polubarinov-Kalb-Ramond notoph [10].

- In some particular cases \( (A = 0, B = 1) \) massive solutions of different parities are naturally divided into the classes of causal and tachyonic solutions.

- If we want to take into account the solutions of the WTH equations of different parity properties, this induces us to generalize the BW, Proca and Duffin-Kemmer formalisms.

- In the \( (1/2, 0) \oplus (0, 1/2), (1, 0) \oplus (0, 1) \) etc. representations it is possible to introduce the parity-violating frameworks. The corresponding solutions are the mixture of various polarization states.

- The addition of the Klein-Gordon equation to the \( (S, 0) \oplus (0, S) \) equations may change the theoretical content even on the free level. For instance, the higher-spin equations may actually describe various spin and mass states.

- There also exist the mappings between the WTH solutions of undefined parity and the AST fields, which contain both tensor and dual tensor. They are eight.
The 4-potentials and electromagnetic fields \([8,7]\) in the helicity basis have different parity properties comparing with the standard basis of the polarization vectors.

In the previous talk \([11]\) we presented a theory in the \((1/2, 0) \oplus (0, 1/2)\) representation in the helicity basis. Under space inversion operation, different helicity states transform each other, \(P u_h(-p) = -i u_{-h}(p)\), \(P v_h(-p) = +i v_{-h}(p)\).

I hope, this is enough for the antecedents. Everybody has already understood the importance of \(\tilde{A}_\mu \sim \partial_\mu \chi\) term in the electrodynamics and in the Proca theory.

**III. THE THEORY OF 4-VECTOR FIELD.**

First of all, we show that the equation for the 4-vector field can be presented in a matrix form. Recently, S. I. Kruglov proposed \([12,13]\)^4 a general form of the Lagrangian for 4-potential field \(B_\mu\), which also contains the spin-0 state. Initially, we have (provided that derivatives commute)

\[
\alpha \partial_\mu \partial_\nu B_\nu + \beta \partial^2_\nu B_\mu + \gamma m^2 B_\mu = 0.
\]

(15)

When \(\partial_\nu B_\nu = 0\) (the Lorentz gauge) we obtain spin-1 states only. However, if it is not equal to zero we have a scalar field and a pseudovector potential. We can also check this by consideration of the dispersion relations of (15). One obtains 4+4 states (two of them may differ in mass from others).

Next, one can fix one of the constants \(\alpha, \beta, \gamma\) without losing any physical content. For instance, when \(\alpha = -2\) and taking into account that the action of the symmetrized combination of Kronecker's \(\delta\)'s is

\[
(\delta_\mu \delta_\alpha - \delta_\mu \delta_\beta - \delta_\mu \delta_\nu) \partial_\alpha \partial_\beta B_\nu = \partial^2_\alpha B_\mu - 2 \partial_\mu \partial_\nu B_\nu,
\]

(16)

\[^4\]I acknowledge the discussion of physical significance of the gauge with M. Kirchbach in 1998. See also: R. A. Berg, Nuovo Cim. A **XLII**, 148 (1966) and D. V. Ahluwalia and M. Kirchbach, Mod. Phys. Lett. **A16**, 1377 (2001).
one gets the equation

\[ \left[ \delta_{\mu\nu} \delta_{\alpha\beta} - \delta_{\mu\alpha} \delta_{\nu\beta} - \delta_{\mu\beta} \delta_{\nu\alpha} \right] \partial_\alpha \partial_\beta B_\nu + A \partial_\alpha^2 \delta_{\nu\beta} B_\nu - B m^2 \delta_{\mu\nu} B_\nu = 0, \quad (17) \]

where \( \beta = A + 1 \) and \( \gamma = -B \). In the matrix form the equation (17) reads:

\[ \left[ \gamma_{\alpha\beta} \partial_\alpha \partial_\beta + A \partial_\alpha^2 - B m^2 \right] \mu_\nu B_\nu = 0, \quad (18) \]

with

\[ [\gamma_{\alpha\beta}]_{\mu\nu} = \delta_{\mu\nu} \delta_{\alpha\beta} - \delta_{\mu\alpha} \delta_{\nu\beta} - \delta_{\mu\beta} \delta_{\nu\alpha}. \quad (19) \]

Their explicit forms are the following ones:

\[ \gamma_{44} = \begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & -1 \end{pmatrix}, \quad \gamma_{14} = \gamma_{41} = \begin{pmatrix} 0 & 0 & 0 & -1 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ -1 & 0 & 0 & 0 \end{pmatrix}, \quad (20a) \]

\[ \gamma_{24} = \gamma_{42} = \begin{pmatrix} 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & -1 \\ 0 & 0 & 0 & 0 \\ 0 & -1 & 0 & 0 \end{pmatrix}, \quad \gamma_{34} = \gamma_{43} = \begin{pmatrix} 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & -1 \\ 0 & 0 & -1 & 0 \end{pmatrix}, \quad (20b) \]

\[ \gamma_{11} = \begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{pmatrix}, \quad \gamma_{22} = \begin{pmatrix} 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 \end{pmatrix}, \quad (20c) \]

\[ \gamma_{33} = \begin{pmatrix} 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & -1 & 0 \\ 0 & 0 & 0 & 1 \end{pmatrix}, \quad \gamma_{12} = \gamma_{21} = \begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & -1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{pmatrix}, \quad (20d) \]

\[ \gamma_{31} = \gamma_{13} = \begin{pmatrix} 0 & 0 & -1 & 0 \\ 0 & 0 & 0 & 0 \\ -1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{pmatrix}, \quad \gamma_{23} = \gamma_{32} = \begin{pmatrix} 0 & 0 & 0 & 0 \\ 0 & 0 & -1 & 0 \\ 0 & -1 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{pmatrix}. \quad (20e) \]

They are the analogs of the Barut-Muzinich-Williams (BMW) \( \gamma \)-matrices for bivector fields. However, \( \sum_\alpha [\gamma_{\alpha\alpha}]_{\mu\nu} = 2 \delta_{\mu\nu} \). It is easy to prove by the textbook method [19] that \( \gamma_{44} \) can serve as the parity matrix.
One can also define the analogs of the BMW $\gamma_{5,\alpha\beta}$ matrices

$$
\gamma_{5,\alpha\beta} = \frac{i}{6} [\gamma_{\alpha\kappa}, \gamma_{\beta\kappa}]_{-\mu\nu} = i [\delta_{\alpha\mu} \delta_{\beta\nu} - \delta_{\alpha\nu} \delta_{\beta\mu}] .
$$

As opposed to $\gamma_{\alpha\beta}$ matrices they are totally anti-symmetric. The explicit forms of the anti-symmetric $\gamma_{5,\alpha\beta}$ are

$$
\gamma_{5,41} = -\gamma_{5,14} = i \begin{pmatrix} 0 & 0 & 0 & -1 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 1 & 0 & 0 & 0 \end{pmatrix}, \quad \gamma_{5,42} = -\gamma_{5,24} = i \begin{pmatrix} 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & -1 \\ 0 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \end{pmatrix},
$$

$$
\gamma_{5,43} = -\gamma_{5,34} = i \begin{pmatrix} 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & -1 \\ 0 & 0 & 1 & 0 \end{pmatrix}, \quad \gamma_{5,12} = -\gamma_{5,21} = i \begin{pmatrix} 0 & 1 & 0 & 0 \\ -1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{pmatrix},
$$

$$
\gamma_{5,31} = -\gamma_{5,13} = i \begin{pmatrix} 0 & 0 & -1 & 0 \\ 0 & 0 & 0 & 0 \\ 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{pmatrix}, \quad \gamma_{5,23} = -\gamma_{5,32} = i \begin{pmatrix} 0 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & -1 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{pmatrix}.
$$

$\gamma$-matrices are pure real; $\gamma_{5}$-matrices are pure imaginary. In the $(1/2, 1/2)$ representation, we need 16 matrices to form the complete set (as opposed to the bi-vector representation, when we have to define also $\gamma_{6,\alpha\beta,\mu\nu}$). Please note that in the pseudo-Euclidean metric the symmetry properties of the $\gamma$’s and $\gamma_{5}$’s are not the same (comparing with our consideration in the Euclidean metric) in such a representation.

**Lagrangian and the equations of motion.** Let us try

$$
\mathcal{L} = (\partial_\alpha B_{\mu}^*) [\gamma_{\alpha\beta}]_{\mu\nu} (\partial_\beta B_{\nu}) + A (\partial_\alpha B_{\mu}^*) (\partial_\alpha B_{\mu}) + B m^2 B_{\mu}^* B_{\mu} .
$$

$^5$They are related to boost and rotation generators of this representation.
On using the Lagrange-Euler equation

\[ \frac{\partial \mathcal{L}}{\partial B^*_\mu} - \partial_v \left( \frac{\partial \mathcal{L}}{\partial (\partial_v B^*_\mu)} \right) = 0, \tag{24} \]

or

\[ \frac{\partial \mathcal{L}}{\partial B_\mu} - \partial_v \left( \frac{\partial \mathcal{L}}{\partial (\partial_v B_\mu)} \right) = 0, \tag{25} \]

we have

\[ [\gamma_{\nu\beta}]_{\kappa\tau} \partial_\nu \partial_\beta B_\tau + A \partial^2_\nu B_\kappa - B m^2 B_\kappa = 0, \tag{26} \]

or

\[ [\gamma_{\beta\nu}]_{\kappa\tau} \partial_\beta \partial_\nu B^*_\tau + A \partial^2_\nu B^*_\kappa - B m^2 B^*_\kappa = 0. \tag{27} \]

Thus, they may be presented in the form of (15). The Lagrangian is correct.

**Masses.** We are convinced that in the case of spin 0, we have \( B_\mu \rightarrow \partial_\mu \chi \); in the case of spin 1 we have \( \partial_\mu B_\mu = 0 \).

So,

\[ (\delta_{\mu\nu} \delta_{\alpha\beta} - \delta_{\mu\alpha} \delta_{\nu\beta} - \delta_{\mu\beta} \delta_{\nu\alpha}) \partial_\alpha \partial_\beta \partial_\nu \chi = -\partial^2 \partial_\mu \chi. \tag{28} \]

1. Hence, from (26) we have

\[ [(A - 1) \partial^2_\nu - B m^2] \partial_\mu \chi = 0. \tag{29} \]

If \( A - 1 = B \) we have the spin-0 particles with masses \( \pm m \) with the correct relativistic dispersion.

2. In another case

\[ [\delta_{\mu\nu} \delta_{\alpha\beta} - \delta_{\mu\alpha} \delta_{\nu\beta} - \delta_{\mu\beta} \delta_{\nu\alpha}] \partial_\alpha \partial_\beta B_\nu = \partial^2 B_\mu. \tag{30} \]

Hence,

\[ [(A + 1) \partial^2_\nu - B m^2] B_\mu = 0. \tag{31} \]

If \( A + 1 = B \) we have the spin-1 particles with masses \( \pm m \) with the correct relativistic dispersion.
The equation (26) can be transformed in two equations:

\[
\gamma_{\alpha\beta} \partial_\alpha \partial_\beta + (B + 1) \partial_\nu^2 - Bm^2 \mu_\nu B_\nu = 0, \quad \text{spin 0 with masses } \pm m, \quad (32a)
\]

\[
\gamma_{\alpha\beta} \partial_\alpha \partial_\beta + (B - 1) \partial_\nu^2 - Bm^2 \mu_\nu B_\nu = 0, \quad \text{spin 1 with masses } \pm m. \quad (32b)
\]

The first one has the solution with spin 0 and masses \( \pm m \). However, it has also the spin-1 solution with the different masses, \( \partial_\nu^2 + (B+1) \partial_\nu^2 - Bm^2 \mu_\nu = 0 \):

\[
\tilde{m} = \pm \sqrt{\frac{B}{B+2}} m. \quad (33)
\]

The second one has the solution with spin 1 and masses \( \pm m \). But, it also has the spin-0 solution with the different masses, \( -\partial_\nu^2 + (B-1) \partial_\nu^2 - Bm^2 \partial_\mu \chi = 0 \):

\[
\tilde{m} = \pm \sqrt{\frac{B}{B-2}} m. \quad (34)
\]

One can come to the same conclusion by checking the dispersion relations from \( \text{Det}[\gamma_{\alpha\beta}p_\alpha p_\beta - A p_\alpha + Bm^2] = 0 \). When \( \tilde{m}^2 = \frac{4}{3}m^2 \), we have \( B = -8, A = -7 \), that is compatible with our consideration of bi-vector fields [4].

One can form the Lagrangian with the particles of spins 1, masses \( \pm m \), the particle with the mass \( \sqrt{\frac{4}{3}} m \), spin 1, for which the particle is equal to the antiparticle, by choosing the appropriate creation/annihilation operators; and the particles with spins 0 with masses \( \pm m \) and \( \pm \sqrt{\frac{2}{3}} m \) (some of them may be neutral).

**The Standard Basis** [14–16]. The polarization vectors of the standard basis are defined:

\[
\epsilon_\mu(0, +1) = -\frac{1}{\sqrt{2}} \begin{pmatrix} 1 \\ i \\ 0 \\ 0 \end{pmatrix}, \quad \epsilon_\mu(0, -1) = +\frac{1}{\sqrt{2}} \begin{pmatrix} 1 \\ -i \\ 0 \\ 0 \end{pmatrix}, \quad (35a)
\]

\[
\epsilon_\mu(0, 0) = \begin{pmatrix} 0 \\ 0 \\ 1 \\ 0 \end{pmatrix}, \quad \epsilon_\mu(0, 0_t) = \begin{pmatrix} 0 \\ 0 \\ 0 \\ i \end{pmatrix}. \quad (35b)
\]
Hence, for the particles of the mass $m$ we have:

$$u^\mu(p, +1) = \frac{N}{\sqrt{2m}} \begin{pmatrix} m + \frac{p_1 p_r}{E_p + m} \\ im + \frac{p_2 p_r}{E_p + m} \\ \frac{1}{E_p + m} - ip_r \\ \frac{1}{E_p + m} - ip_3 \end{pmatrix}, \quad u^\mu(p, -1) = \frac{N}{\sqrt{2m}} \begin{pmatrix} m + \frac{p_1 p_l}{E_p + m} \\ -im + \frac{p_2 p_l}{E_p + m} \\ \frac{1}{E_p + m} + ip_r \\ \frac{1}{E_p + m} + ip_3 \end{pmatrix},$$

(37a)

$$u^\mu(p, 0) = \frac{N}{m} \begin{pmatrix} \frac{p_1 p_3}{E_p + m} \\ \frac{p_2 p_3}{E_p + m} \\ m + \frac{E_p^2}{E_p + m} \\ -ip_3 \end{pmatrix}, \quad u^\mu(p, 0_t) = \frac{N}{m} \begin{pmatrix} -p_1 \\ -p_2 \\ -p_3 \\ iE_p \end{pmatrix}. \quad (37b)$$

The Euclidean metric was again used; $N$ is the normalization constant. They are the eigenvectors of the parity operator:

$$Pu_\mu(-p, \sigma) = +u_\mu(p, \sigma), \quad Pu_\mu(-p, 0_t) = -u_\mu(p, 0_t). \quad (38)$$

The Helicity Basis. [8,17] The helicity operator is:

$$\frac{(J \cdot p)}{p} = \frac{1}{p} \begin{pmatrix} 0 & -ip_z & ip_y & 0 \\ ip_z & 0 & -ip_x & 0 \\ -ip_y & ip_x & 0 & 0 \\ 0 & 0 & 0 & 0 \end{pmatrix}, \quad \frac{(J \cdot p)}{p} \epsilon^0_{\pm 1} = \pm \epsilon^0_{\pm 1}, \quad \frac{(J \cdot p)}{p} \epsilon^0_{0,0 т} = 0.$$  

(39)

The eigenvectors are:

$$\epsilon^\mu_{\pm 1} = \frac{1}{\sqrt{2}} e^{i\alpha} \begin{pmatrix} \sqrt{p_x^2 + p_y^2} \\ \sqrt{p_x^2 + p_y^2} \\ \sqrt{p_x^2 + p_y^2} \\ 0 \end{pmatrix}, \quad \epsilon^\mu_{\pm 1} = \frac{1}{\sqrt{2}} e^{i\beta} \begin{pmatrix} \sqrt{p_x^2 + p_y^2} \\ \sqrt{p_x^2 + p_y^2} \\ \sqrt{p_x^2 + p_y^2} \\ 0 \end{pmatrix}, \quad (40a)$$

$$\epsilon^\mu_0 = \frac{1}{m} \begin{pmatrix} E \rho_x \\ E \rho_y \\ E \rho_z \\ iE_p \end{pmatrix}, \quad \epsilon^\mu_0 = \frac{1}{m} \begin{pmatrix} p_x \\ p_y \\ p_z \\ 0 \end{pmatrix}. \quad (40b)$$

12
The eigenvectors $\epsilon_{\pm 1}^\mu$ are not the eigenvectors of the parity operator ($\gamma_{44}$) of this representation. However, $\epsilon_{1,0}^\mu, \epsilon_{0,0}^\mu$ are. Surprisingly, the latter have no well-defined massless limit.\(^6\)

**Energy-momentum tensor.** According to definitions [3] it is defined as

$$T_{\mu\nu} = -\sum_\alpha \left[ \frac{\partial \mathcal{L}}{\partial (\partial_\mu B_\alpha)} \partial_\nu B_\alpha + \partial_\nu B_\alpha^* \frac{\partial \mathcal{L}}{\partial (\partial_\mu B_\alpha^*)} \right] + \mathcal{L} \delta_{\mu\nu}, \quad (41a)$$

$$P_\mu = -i \int T_{4\mu} d^3x. \quad (41b)$$

Hence,

$$T_{\mu\nu} = -(\partial_\kappa B_\nu^*) [\gamma_{\kappa\mu}] \tau_\alpha (\partial_\nu B_\alpha) - (\partial_\kappa B_\alpha^*) [\gamma_{\kappa\mu}] \tau_\alpha (\partial_\nu B_\alpha) - A \left[ (\partial_\kappa B_\nu^*) (\partial_\nu B_\alpha) + (\partial_\kappa B_\alpha^*) (\partial_\nu B_\alpha) \right] + \mathcal{L} \delta_{\mu\nu} =$$

$$= -(A + 1) \left[ (\partial_\kappa B_\nu^*) (\partial_\nu B_\alpha) + (\partial_\kappa B_\alpha^*) (\partial_\nu B_\alpha) \right] + \left[ (\partial_\kappa B_\nu^*) (\partial_\nu B_\alpha) + (\partial_\kappa B_\alpha^*) (\partial_\nu B_\alpha) \right] + \mathcal{L} \delta_{\mu\nu}. \quad (42)$$

Remember that after substitutions of the explicit forms $\gamma$'s, the Lagrangian is

$$\mathcal{L} = (A + 1) (\partial_\kappa B_\mu^*) (\partial_\mu B_\kappa) - (\partial_\kappa B_\nu^*) (\partial_\mu B_\nu) - (\partial_\kappa B_\mu^*) (\partial_\nu B_\nu) + Bm^2 B_\mu^* B_\mu, \quad (43)$$

and the third term cannot be removed by the standard substitution $\mathcal{L} \rightarrow \mathcal{L} + \partial_\mu \Gamma_\mu, \Gamma_\mu = B_\nu^* \partial_\nu B_\mu - B_\mu^* \partial_\nu B_\nu$ to get the textbook Lagrangian $\mathcal{L}' = (\partial_\kappa B_\mu^*) (\partial_\mu B_\kappa) + m^2 B_\mu^* B_\mu$.

The **current vector** is defined

$$J_\mu = -i \sum_\alpha \left[ \frac{\partial \mathcal{L}}{\partial (\partial_\mu B_\alpha)} B_\alpha - B_\alpha^* \frac{\partial \mathcal{L}}{\partial (\partial_\mu B_\alpha^*)} \right], \quad (44a)$$

$$Q = -i \int J_4 d^3x. \quad (44b)$$

Hence,

\(^6\)In order to get the well-known massless limit one should use the basis of the light-front form representation, cf. [18].
\[ J_\lambda = -i \left\{ (\partial_\alpha B_\mu^*)[\gamma_{\alpha\lambda}]_{\mu\kappa} B_\kappa - B_\mu^*[\gamma_{\alpha\lambda}]_{\mu\kappa}(\partial_\alpha B_\kappa) + A(\partial_\lambda B_\mu^*) B_\kappa - AB_\mu^*(\partial_\lambda B_\kappa) \right\} \]
\[ = -i \left\{ (A + 1)[(\partial_\lambda B_\mu^*) B_\kappa - B_\mu^*(\partial_\lambda B_\kappa)] + [B_\mu^*(\partial_\kappa B_\lambda) - (\partial_\kappa B_\mu^*) B_\lambda] + [B_\lambda^*(\partial_\kappa B_\mu) - (\partial_\kappa B_\lambda^*) B_\mu] \right\}. \] (45)

Again, the second term and the last term cannot be removed at the same time by adding the total derivative to the Lagrangian. These terms correspond to the contribution of the scalar (spin-0) portion.

**Angular momentum.** Finally,
\[ \mathcal{M}_{\mu\alpha,\lambda} = x_\mu T_{(\alpha\lambda)} - x_\alpha T_{(\mu\lambda)} + S_{\mu\alpha,\lambda} = \]
\[ = x_\mu T_{(\alpha\lambda)} - x_\alpha T_{(\mu\lambda)} - i \left\{ \sum_{\kappa\tau} \frac{\partial L}{\partial(\partial_\lambda B_\kappa)} T_{\mu\alpha,\kappa\tau} B_\tau + B_\tau^* T_{\mu\alpha,\kappa\tau} \frac{\partial L}{\partial(\partial_\lambda B_\kappa^*)} \right\}, \] (46a)
\[ \mathcal{M}_{\mu\nu} = -i \int \mathcal{M}_{\mu\nu,4} d^3x, \] (46b)

where \( T_{\mu\alpha,\kappa\tau} \sim [\gamma_{\mu,\alpha}]_{\kappa\tau} \).

**The field operator.** Various-type field operators are possible in this representation. Let us remind the textbook procedure to get them. During the calculations below we have to present \( 1 = \theta(k_0) + \theta(-k_0) \) in order to get positive- and negative-frequency parts. However, one should be warned that in the point \( k_0 = 0 \) this presentation is ill-defined.

\[ A_\mu(x) = \frac{1}{(2\pi)^3} \int d^4k \delta(k^2 - m^2)e^{+ik\cdot x} A_\mu(k) = \]
\[ = \frac{1}{(2\pi)^3} \sum_\lambda \int d^4k \delta(k_0^2 - E_k^2)e^{+ik\cdot x} \epsilon_\mu(k, \lambda) a_\lambda(k) = \]
\[ = \frac{1}{(2\pi)^3} \int \frac{d^4k}{2E_k} \left[ \delta(k_0 - E_k) + \delta(k_0 + E_k) \right] \left[ \theta(k_0) - \theta(-k_0) \right] e^{+ik\cdot x} A_\mu(k) = \]
\[ = \frac{1}{(2\pi)^3} \int \frac{d^4k}{2E_k} \left[ \delta(k_0 - E_k) + \delta(k_0 + E_k) \right] \left[ \theta(k_0) A_\mu(k) e^{+ik\cdot x} + \theta(-k_0) A_\mu(-k) e^{-ik\cdot x} \right] \]
\[ + \theta(k_0) A_\mu(-k) e^{-ik\cdot x} = \frac{1}{(2\pi)^3} \int \frac{d^3k}{2E_k} \theta(k_0) \left[ A_\mu(k) e^{+ik\cdot x} + A_\mu(-k) e^{-ik\cdot x} \right] = \]
\[ = \frac{1}{(2\pi)^3} \sum_\lambda \int \frac{d^3k}{2E_k} \left[ \epsilon_\mu(k, \lambda) a_\lambda(k) e^{+ik\cdot x} + \epsilon_\mu(-k, \lambda) a_\lambda(-k) e^{-ik\cdot x} \right]. \] (47)
Moreover, we should transform the second part to \( \epsilon^*_\mu(k, \lambda)b^\dagger_\lambda(k) \) as usual. In such a way we obtain the charge-conjugate states. Of course, one can try to get \( P \)-conjugates or \( CP \)-conjugate states too. One should proceed in a similar way as in the Appendix. We set

\[
\sum_\lambda \epsilon_\mu(-k, \lambda)a_\lambda(-k) = \sum_\lambda \epsilon^*_\mu(k, \lambda)b^\dagger_\lambda(k),
\]

(48)
multiply both parts by \( \epsilon_\nu[\gamma_{44}]_{\nu\mu} \), and use the normalization conditions for polarization vectors.

In the \((\frac{1}{2}, \frac{1}{2})\) representation we can also expand (apart the equation (48)) in the different way:

\[
\sum_\lambda \epsilon_\mu(-k, \lambda)a_\lambda(-k) = \sum_\lambda \epsilon_\mu(k, \lambda)a_\lambda(k).
\]

(49)

From the first definition we obtain (the signs \( \mp \) depends on the value of \( \sigma \)):

\[
b^\dagger_\sigma(k) = \mp \sum_{\mu, \lambda} \epsilon_\nu(k, \sigma)[\gamma_{44}]_{\nu\mu}\epsilon_\mu(-k, \lambda)a_\lambda(-k),
\]

(50)
or

\[
b^\dagger_\sigma(k) = \frac{E_k^2}{m^2} \begin{pmatrix}
1 + \frac{k^2}{E_k^2} & \sqrt{2} \frac{k_\lambda}{E_k} & -\sqrt{2} \frac{k_\lambda}{E_k} & -\frac{2k_\lambda}{E_k} \\
-\sqrt{2} \frac{k_\lambda}{E_k} & -\frac{k_\lambda^2}{k^2} & -\frac{m^2k_\lambda^2}{E_k^2} + \frac{k_\lambda k_\mu}{E_k} & \frac{\sqrt{2}k_\lambda k_\mu}{k^2} \\
\sqrt{2} \frac{k_\lambda}{E_k} & -\frac{m^2k_\lambda^2}{E_k^2} + \frac{k_\lambda k_\mu}{E_k} & -\frac{k_\lambda^2}{k^2} & -\frac{\sqrt{2}k_\lambda k_\mu}{k^2} \\
\frac{2k_\lambda}{E_k} & \frac{\sqrt{2}k_\lambda k_\mu}{k^2} & \frac{\sqrt{2}k_\lambda k_\mu}{k^2} & \frac{m^2}{E_k^2} - \frac{2k_\lambda}{k^2}
\end{pmatrix} \begin{pmatrix}
a_{00}(-k) \\
a_{11}(-k) \\
a_{1-1}(-k) \\
a_{10}(-k)
\end{pmatrix}.
\]

(51)

From the second definition \( \Lambda^2_\sigma = \mp \sum_{\nu, \mu} \epsilon^*_\nu(k, \sigma)[\gamma_{44}]_{\nu\mu}\epsilon_\mu(-k, \lambda) \) we have

\[
a_\sigma(k) = \begin{pmatrix}
-1 & 0 & 0 & 0 \\
0 & \frac{k^2}{E_k^2} & \frac{2k_\lambda k_\mu}{k^2} & \frac{\sqrt{2}k_\lambda k_\mu}{k^2} \\
0 & \frac{k_\lambda k_\mu}{k^2} & \frac{k_\lambda^2}{k^2} & -\frac{\sqrt{2}k_\lambda k_\mu}{k^2} \\
0 & \frac{\sqrt{2}k_\lambda k_\mu}{k^2} & -\sqrt{2}k_\lambda k_\mu & 1 - \frac{2k_\lambda}{k^2}
\end{pmatrix} \begin{pmatrix}
a_{00}(-k) \\
a_{11}(-k) \\
a_{1-1}(-k) \\
a_{10}(-k)
\end{pmatrix}.
\]

(52)

It is the strange case: the field operator will only destroy particles. Possibly, we should think about modifications of the Fock space in this case, or introduce several field operators for the \((\frac{1}{2}, \frac{1}{2})\) representation.
Propagators. From ref. [19] it is known for the real vector field:

\[
< 0| T(B_\mu(x) B_\nu(y)) |0> = -i \int \frac{d^4 k}{(2\pi)^4} e^{i k(x-y)} \left( \frac{\delta_{\mu\nu} + k_\mu k_\nu/\mu^2}{k^2 + \mu^2 + i\epsilon} - \frac{k_\mu k_\nu/\mu^2}{k^2 + m^2 + i\epsilon} \right).
\]

(53)

If \( \mu = m \) (this depends on relations between \( A \) and \( B \)) we have the cancellation of divergent parts. Thus, we can overcome the well-known difficulty of the Proca theory with the massless limit.

If \( \mu \neq m \) we can still have a causal theory, but in this case we need more than one equation, and should apply the method proposed in ref. [20].

The case of the complex-valued vector field will be reported in a separate publication.

Indefinite metrics. Usually, one considers the hermitian field operator in the pseudo-Euclidean metric for the electromagnetic potential:

\[
A_\mu = \sum_\lambda \int \frac{d^3 k}{(2\pi)^3 2 E_k} \left[ \epsilon_\mu(k,\lambda) a_\lambda(k) + \epsilon_\mu^*(k,\lambda) a_\lambda^+(k) \right]
\]

(55)

with all four polarizations to be independent ones. Next, one introduces the Lorentz condition in the weak form

\[
[a_0(k) - a_0^+(k)]|\phi> = 0
\]

(56)

\footnote{In that case we applied for the bi-vector fields

\[
\left[ \gamma_{\mu\nu} \partial_\mu \partial_\nu - m^2 \right] \int \frac{d^3 p}{(2\pi)^3 8 i \hbar^2 E_p} \left[ \theta(t_2 - t_1) u_\sigma(p) \otimes \tilde{u}_\sigma(p) e^{i p x} + \right.
\]

\[
\left. + \theta(t_1 - t_2) v_\sigma(p) \otimes \tilde{v}_\sigma(p) e^{-i p x} \right] + \right.
\]

\[
+ \left[ \gamma_{\mu\nu} \partial_\mu \partial_\nu + m^2 \right] \int \frac{d^3 p}{(2\pi)^3 8 i \hbar^2 E_p} \left[ \theta(t_2 - t_1) u_\sigma^2(p) \otimes \tilde{u}_\sigma^2(p) e^{i p x} + \right.
\]

\[
\left. + \theta(t_1 - t_2) v_\sigma^2(p) \otimes \tilde{v}_\sigma^2(p) e^{-i p x} \right] + \text{parity-transformed} \sim \delta^{(4)}(x_2 - x_1)
\]

for the bi-vector fields, see [20] for notation. The reasons were that the Weinberg equation propagates both causal and tachyonic solutions [20].
and the indefinite metrics in the Fock space [21, p.90 of the Russian edition]:
\[ a_0^* = -a_0, \quad \eta a_\lambda = -a_\lambda \eta, \quad \eta^2 = 1, \]
in order to get the correct sign in the energy-momentum vector and to not have the problem with the vacuum average.

We observe: 1) that the indefinite metric problems may appear even on the massive level in the Stueckelberg formalism; 2) The Stueckelberg theory has a good massless limit for propagators, and it reproduces the handling of the indefinite metric in the massless limit (the electromagnetic 4-potential case); 3) we generalized the Stueckelberg formalism (considering, at least, two equations); instead of charge-conjugate solutions we may consider the \( P^- \) or \( CP^- \) conjugates. The potential field becomes to be the complex-valued field, that may justify the introduction of the anti-hermitian amplitudes.

IV. CONCLUSIONS

- The \((1/2, 1/2)\) representation contains both the spin-1 and spin-0 states (cf. with the Stueckelberg formalism).

- Unless we take into account the fourth state (the “time-like” state, or the spin-0 state) the set of 4-vectors is not a complete set in a mathematical sense.

- We cannot remove terms like \((\partial_\mu B^*_\mu)(\partial_\nu B_\nu)\) terms from the Lagrangian and dynamical invariants unless apply the Fermi method, i.e., manually. The Lorentz condition applies only to the spin 1 states.

- We have some additional terms in the expressions of the energy-momentum vector (and, accordingly, of the 4-current and the Pauli-Lubanski vectors), which are the consequence of the impossibility to apply the Lorentz condition for spin-0 states.

- Helicity vectors are not eigenvectors of the parity operator. Meanwhile, the parity is a “good” quantum number, \([P, \mathcal{H}]_-=0\) in the Fock space.

- We are able to describe states of different masses in this representation from the beginning.
Various-type field operators can be constructed in the \((1/2, 1/2)\) representation space. For instance, they can contain \(C, P\) and \(CP\) conjugate states. Even if \(b_\lambda^\dagger = a_\lambda\) we can have complex 4-vector fields.\(^8\) We found the relations between creation, annihilation operators for different types of the field operators \(B_\mu\).

Propagators have good behaviours in the massless limit as opposed to those of the Proca theory.

The detailed explanations of several claims presented in this talk will be given in journal publications.

**ACKNOWLEDGMENTS**

I am grateful to Profs. Y. S. Kim, S. I. Kruglov, V. Onoochin, Z. Oziewicz, W. Rodrigues, R. Santilli, R. Yamaleev and participants of the recent conferences for useful discussions.

**APPENDIX**

In the Dirac case we should assume the following relation in the field operator:

\[
\sum_\lambda v_\lambda(k) b_\lambda^\dagger(k) = \sum_\lambda u_\lambda(-k) a_\lambda(-k). \tag{57}
\]

We know that [22]

\[
\bar{u}_\mu(k) u_\lambda(k) = +m\delta_{\mu\lambda}, \tag{58a}
\]

\[
\bar{u}_\mu(k) u_\lambda(-k) = 0, \tag{58b}
\]

\[
\bar{v}_\mu(k) v_\lambda(k) = -m\delta_{\mu\lambda}, \tag{58c}
\]

\[
\bar{v}_\mu(k) u_\lambda(k) = 0, \tag{58d}
\]

\(^8\)Perhaps, there are some relations to the old Weyl idea, recently employed by Kharkov physicists. The sense of this idea is the unification through the complex potential.
but we need $\Lambda_{\mu\lambda}(k) = \bar{v}_\mu(k)u_\lambda(-k)$. By direct calculations, we find

$$-mb^\dagger_\mu(k) = \sum_\nu \Lambda_{\mu\lambda}(k)a_\lambda(-k). \quad (59)$$

Hence, $\Lambda_{\mu\lambda} = -im(\sigma \cdot n)_{\mu\lambda}$ and

$$b^\dagger_\mu(k) = i(\sigma \cdot n)_{\mu\lambda}a_\lambda(-k). \quad (60)$$

Multiplying (57) by $\bar{u}_\mu(-k)$ we obtain

$$a_\mu(-k) = -i(\sigma \cdot n)_{\mu\lambda}b^\dagger_\lambda(k). \quad (61)$$

The equations (60) and (61) are self-consistent.

In the $(1,0) \oplus (0,1)$ representation we have somewhat different situation:

$$a_\mu(k) = [1 - 2(S \cdot n)^2]_{\mu\lambda}a_\lambda(-k). \quad (62)$$

This signifies that in order to construct the Sankaranarayanan-Good field operator (which was used by Ahluwalia, Johnson and Goldman [Phys. Lett. B (1993)], it satisfies $[\gamma_{\mu\nu}\partial_\mu\partial_\nu - \frac{(\partial/\partial n)^2}{E}m^2]\Psi = 0$, we need additional postulates, which are possibly related to the recent Santilli discoveries (see, for instance, ref. [23]).
