**Abstract.** Given a prime $p$, a finite extension $L/\mathbb{Q}_p$, a connected $p$-adic reductive group $G/L$, and a smooth irreducible representation $\pi$ of $G(L)$, Fargues-Scholze [FS21] recently attached a semisimple $L$-parameter to such $\pi$, giving a general candidate for the local Langlands correspondence. It is natural to ask whether this construction is compatible with known instances of the correspondence after semisimplification. For $G = \text{GL}_n$ and its inner forms, Fargues-Scholze and Hansen-Kaletha-Weinstein [HKW21] showed that the correspondence is compatible with the correspondence of Harris-Taylor/Henniart [Hen00, HT01]. We verify a similar compatibility for $G = \text{GSp}_4$ and its unique non-split inner form $G = \text{GU}_2(D)$, where $D$ is the quaternion division algebra over $L$, assuming that $L/\mathbb{Q}_p$ is unramified and $p > 2$. In this case, the local Langlands correspondence has been constructed by Gan-Takeda and Gan-Tantono [GT11, GT14]. Analogous to the case of $\text{GL}_n$ and its inner forms, this compatibility is proven by describing the Weil group action on the cohomology of a local Shimura variety associated to $\text{GSp}_4$, using basic uniformization of abelian type Shimura varieties due to Shen [She17], combined with various global results of Kret-Shin [KS16] and Sorensen [Sor10] on Galois representations in the cohomology of global Shimura varieties associated to inner forms of $\text{GSp}_4$ over a totally real field. After showing the parameters are the same, we apply some ideas from the geometry of the Fargues-Scholze construction explored recently by Hansen [Han20]. This allows us to give a more precise description of the cohomology of this local Shimura variety, verifying a strong form of the Kottwitz conjecture in the process.

ACKNOWLEDGEMENTS

It is a pleasure to thank my advisor David Hansen for giving me this project and for numerous suggestions and ideas related to it, as well as Eric Chen, Arthur-César Le-Bras, Yoichi Mieda, Jack Sempliner, and Zhiyu Zhang for some nice conversations related to this work. Special thanks also go to Peter Scholze for sharing with me the draft of [FS21], pointing out some errors, and generously initiating me in these ideas during my masters thesis, as well as Thomas Haines and Sug-Woo Shin for pointing out some errors in section 3 and section 5 respectively. Lastly, I would like to thank the MPIM Bonn for their hospitality during part of the completion of this project and the anonymous referee for pointing out several mistakes and inaccuracies.

1. Introduction

1.1. Background and Main Theorems. Fix distinct primes $\ell \neq p$, let $\mathbb{Q}_p$ denote the $p$-adic numbers, and let $G/\mathbb{Q}_p$ be a connected reductive group. Set $\mathcal{C}_p := \widehat{\mathbb{Q}}_p$ to be the completion of the algebraic closure of $\mathbb{Q}_p$. We fix an isomorphism $i : \overline{\mathbb{Q}}_\ell \simto \mathbb{C}$. Let $\mathcal{W}_\mathbb{Q}_p$ be the Weil group of $\mathbb{Q}_p$ and set $\hat{G}$ to be the reductive group over $\mathbb{Q}_\ell$ with root datum dual to $G$. Let $Q$ be the finite quotient through which $\mathcal{W}_\mathbb{Q}_p$ acts on $\hat{G}$. We define the $L$-group $L^G := Q \times \hat{G}$. We let $\Pi(G)$ denote the set of isomorphism classes of smooth irreducible representations of the $p$-adic group $G(\mathbb{Q}_p)$, and let $\Phi(G)$ denote the set of $L$-parameters, i.e the set of conjugacy classes of homomorphisms

$$\phi : W_{\mathbb{Q}_p} \times SL_2(\mathbb{C}) \rightarrow L^G(\mathbb{C})$$

where $SL_2(\mathbb{C})$ acts via an algebraic representation and $W_{\mathbb{Q}_p}$ acts via a continuous semisimple homomorphism in a way that commutes with the natural projection $L^G(\mathbb{C}) \rightarrow Q$, where $L^G(\mathbb{C})$ is endowed with the discrete topology. The local Langlands correspondence is a conjectural map $LLC_G : \Pi(G) \rightarrow \Phi(G)$

$$\pi \mapsto \phi_\pi$$

that builds a bridge between $L$-parameters and the smooth irreducible representations of $G(\mathbb{Q}_p)$. Conjecturally (under some additional constraints on $\Phi(G)$ if $G$ is not split), these maps should be surjective with finite fibers called $L$-packets and satisfy various properties such as compatibility with products, maps of $L$-groups, character twists, as well as $L$, $\epsilon$, and $\gamma$-factors. Moreover, one expects that the correspondence is uniquely characterized by some such finite list of properties.

In general, the existence and uniqueness of such a correspondence is completely unknown. However, very recently, Fargues and Scholze [FS21], using the action of the excursion algebra on the moduli space of $G$-bundles on the Fargues-Fontaine curve, were able to construct a completely general candidate, analogous to the work of V. Lafforgue in the function field setting [Laf18]. Namely, they construct a map $LLC^{FS}_G : \Pi(G) \rightarrow \Phi^{ss}(G)$

$$\pi \mapsto \phi^{FS}_\pi$$

where $\Phi^{ss}(G)$ denotes the set of conjugacy classes of continuous semisimple maps

$$\phi : W_{\mathbb{Q}_p} \rightarrow L^G(\overline{\mathbb{Q}}_\ell)$$

that commute with the projection $L^G(\overline{\mathbb{Q}}_\ell) \rightarrow Q$ as above. Fargues and Scholze showed that their map has several good properties such as compatibility with parabolic induction; however, one would
also like to check that this correspondence agrees with known instances of the local Langlands correspondence. Precisely, given a candidate for the local Langlands correspondence

\[ \text{LLC}_G : \Pi(G) \to \Phi(G) \]

\[ \pi \mapsto \phi_\pi \]

we expect a commutative diagram of the form

\[ \Pi(G) \xrightarrow{\text{LLC}_G} \Phi(G) \xrightarrow{\text{LLC}^{FS}_G} \Phi^{ss}(G) \]

where the semisimplification map \((-)^{ss}\) precomposes an \(L\)-parameter \(\phi \in \Phi(G)\) with the map

\[ g \in W_{\mathbb{Q}_p} \mapsto (g, \begin{pmatrix} |g|^{\frac{1}{2}} & 0 \\ 0 & |g|^{-\frac{1}{2}} \end{pmatrix}) \in W_{\mathbb{Q}_p} \times SL_2(\mathbb{C}) \]

and then applies the fixed isomorphism \(i^{-1} : \mathbb{C} \xrightarrow{\sim} \overline{\mathbb{Q}}_\ell\), where \(|\cdot| : W_{\mathbb{Q}_p} \to W_{\mathbb{Q}_p}^{ab} \simeq \mathbb{Q}_p^* \to \mathbb{C}^*\) is the norm character. We make the following definition.

**Definition 1.1.** For \(\pi \in \Pi(G)\), we say that a local Langlands correspondence \(\text{LLC}_G\) is compatible with the Fargues-Scholze local Langlands correspondence if we have an equality: \(\phi^{FS}_\pi = \phi^{ss}_\pi\) as conjugacy classes of semi-simple \(L\)-parameters.

For \(GL_n\), the local Langlands correspondence was constructed by Harris-Taylor/Henniart [Hen00, HT01] and is uniquely characterized by the preservation of \(L\), \(\epsilon\), and \(\gamma\)-factors. In this case, compatibility with the Fargues-Scholze local Langlands correspondence follows from the description of the cohomology of the Lubin-Tate and Drinfeld towers proven in [HT01] and was verified by Fargues and Scholze [FS21, Theorem I.9.6]. The main goal of this note is to extend compatibility of the cohomology of the Lubin-Tate and Drinfeld towers proven in [HT01] and is uniquely characterized by the preservation of \(L\)-parameters.

This allows us to introduce a bit of terminology. Namely, we say that a parameter \(\phi\) in \(\Phi(G)\) or \(\Phi(J)\) is supercuspidal if the \(SL_2(\mathbb{C})\)-factor acts trivially and \(\phi\) does not factor through any proper Levi subgroup of \(GSp_4\). This terminology is justified by the fact that this is precisely the case when the \(L\)-packets over \(\phi\) contain only supercuspidal representations. In what follows, we will often abuse notation and drop the superscript \((-)^{ss}\) when speaking about such parameters, as in this case it merely corresponds to forgetting the trivially acting \(SL_2(\mathbb{C})\)-factor and applying the isomorphism \(i^{-1}\). We now come to our main theorem.

**Theorem 1.1.** The following is true.

1. For any \(\pi \in \Pi(G)\) (resp. \(\rho \in \Pi(J)\)) such that the Gan-Takeda (resp. Gan-Tantono) parameter is not supercuspidal, we have that the Gan-Takeda (resp. Gan-Tantono) correspondence is compatible with the Fargues-Scholze correspondence.

2. If \(L/\mathbb{Q}_p\) is unramified and \(p > 2\), we have, for all \(\pi \in \Pi(G)\) (resp. \(\rho \in \Pi(J)\)) such that the Gan-Takeda (resp. Gan-Tantono) parameter is supercuspidal, that the Gan-Takeda (resp. Gan-Tantono) correspondence is compatible with the Fargues-Scholze correspondence.
Remark 1.1. As will be explained more below, the restrictions in the case where the parameter is supercuspidal are necessary to apply basic uniformization of the generic fiber of abelian type Shimura varieties due to Shen [She17]. If one were not to impose this assumption, the relevant Shimura varieties would have had reduction at $p$, which, to the best of our knowledge, prevents the methods of Shen from working. In particular, if one could establish the expected description of basic locus in the sense of the isomorphism (2) of Definition 4.1, for Shimura varieties associated to the group $\text{Res}_{F/Q}G$, where $G$ is an inner form of $\text{GSp}_4$ over a totally real field $F$ with an inert prime $p$ such that $F_p \simeq L$ for $L$ any extension then our result would hold in complete generality.

As mentioned above, the proof of compatibility for $\text{GL}_n$ uses the results of Harris-Taylor [HT01] on the cohomology of the Lubin-Tate/Drinfeld Towers. In particular, if one looks at the rigid generic fiber of the Lubin-Tate tower

$$\lim_{m \to \infty} \text{LT}_{n,m,\bar{Q}_p}$$

a tower of $n-1$-dimensional rigid spaces over $\bar{Q}_p$, for fixed $n \geq 1$ and varying $m \geq 1$, where $\bar{Q}_p$ denotes the completion of the maximal unramified extension of $Q_p$. The cohomology of this tower

$$R\Gamma_c(\text{LT}_{n,\infty}, \bar{Q}_\ell) := \colim_{m \to \infty} R\Gamma_c(\text{LT}_{n,m,\bar{Q}_p}, \bar{Q}_\ell)$$

based changed to $\mathbb{C}_p$ carries commuting actions of $\text{GL}_n(Q_p)$ and $D^*_n$, the units in the division algebra over $Q_p$ of invariant $\frac{1}{n}$, as well as an action of the Weil group $W_{Q_p}$. In particular, given $\pi \in \Pi(\text{GL}_n)$ (resp. $\rho \in \Pi(D^*_n)$), we can consider the complexes

$$R\Gamma_c(\text{LT}_{n,\infty}, \bar{Q}_\ell)[\pi] := R\Gamma_c(\text{LT}_{n,\infty}, \bar{Q}_\ell) \otimes_{H(\text{GL}_n)} \pi$$

and

$$R\Gamma_c(\text{LT}_{n,\infty}, \bar{Q}_\ell)[\rho] := R\Gamma_c(\text{LT}_{n,\infty}, \bar{Q}_\ell) \otimes_{\mathcal{H}(D^*_n)} \rho$$

where $\mathcal{H}(\text{GL}_n) := C^\infty_c(\text{GL}_n(Q_p), \bar{Q}_\ell)$ (resp. $\mathcal{H}(D^*_n)$) is the usual smooth Hecke algebra of $G$ (resp. $D^*_n$). Then the key result of Harris-Taylor and later refined by Boyer and Dat [Boy09 Dat07] is as follows.

Theorem 1.2. [HT01 Boy09 Dat07] Fix $\pi \in \Pi(\text{GL}_n)$, a supercuspidal representation of $\text{GL}_n(Q_p)$, let

$$\text{JL} : \Pi(D^*_n) \to \Pi(\text{GL}_n(Q_p))$$

be the map defined by the Jacquet-Langlands correspondence and $\rho := \text{JL}^{-1}(\pi) \in \Pi(D^*_n)$ a Jacquet-Langlands lift of $\pi$. Then the complexes $R\Gamma_c(G, b, \mu)[\pi]$ and $R\Gamma_c(G, b, \mu)[\rho]$ are concentrated in middle degree $n-1$. The middle degree cohomology of $R\Gamma_c(G, b, \mu)[\pi]$ is isomorphic to

$$\rho \boxtimes \phi_\pi \otimes \cdot |^{1-n}/2$$

as a $D^*_n \times W_{Q_p}$ representation. Similarly, the middle degree cohomology of $R\Gamma_c(G, b, \mu)[\rho]$ is isomorphic to

$$\pi \boxtimes \phi_\pi \otimes \cdot |^{1-n}/2$$

where $\phi_\pi \in \Phi^{ss}(G)$ is the (semisimplified) $L$-parameter associated to $\pi$ by Harris-Taylor.

To see why this result is relevant for compatibility, we invoke the observation, due to Scholze-Weinstein [SW13 SW20], that, using Grothendieck-Messing theory, the Lubin-Tate tower at infinite level

$$\text{LT}_{n,\infty} := \lim_{m \to \infty} \text{LT}_{n,m,\bar{Q}_p}$$

is representable by a space admitting a moduli interpretation as a space of shtukas over the Fargues-Fontaine curve; namely, the space denoted $\text{Sht}(\text{GL}_n, b, \mu)_\infty$ in the notation of [SW20], where $b \in$
$B(\text{GL}_n)$ is an element in the Kottwitz set of $\text{GL}_n$ corresponding to a rank $n$ isocrystal of slope $\frac{1}{n}$ and $\mu = (1, 0, \ldots, 0, 0)$ is a dominant cocharacter of $\text{GL}_n$. If $X$ denotes the Fargues-Fontaine curve, then this this parametrizes modifications

$$\mathcal{O}_X(-\frac{1}{n}) \rightarrow \mathcal{O}_X^n$$

of type $(1, 0, \ldots, 0, 0)$ (i.e. this map is an embedding with cokernel a length 1 torsion sheaf on $X$), where $\mathcal{O}_X(-\frac{1}{n})$ is the unique rank $n$ vector bundle on $X$ of slope $-\frac{1}{n}$. This interpretation allows one to relate the complex $R\Gamma_c(\text{LT}_{n, \infty}(\mathbb{Q}_\ell))[\pi]$ to the action of a Hecke operator $T_{\mu^{-1}}$ on $\text{Bun}_G$, acting on a sheaf $\mathcal{F}_\pi$ constructed from the supercuspidal representation $\pi$, where $\mu^{-1} = (0, 0, \ldots, 0, -1)$ is a dominant inverse of $\mu$. The Fargues-Scholze parameter of $\pi$ is built from the action of the excursion algebra on the sheaf $\mathcal{F}_\pi$, which in turn is built from Hecke operators equipped with a factorization structure coming from geometric Satake. It thus is reasonable to expect that the cohomology group $R\Gamma_c(\text{LT}_{n, \infty}(\mathbb{Q}_\ell))[\pi]$ should have $W_{\mathbb{Q}_p}$-action given by the Fargues-Scholze parameter $\phi^{FS}_\pi : W_{\mathbb{Q}_p} \rightarrow L\text{GL}_n(\mathbb{Q}_\ell) \simeq \text{GL}_n(\mathbb{Q}_\ell)$ composed with the highest weight representation of $L\text{GL}_n(\mathbb{Q}_\ell)$ corresponding to the dominant cocharacter $\mu^{-1}$. However, this is just the dual of the standard representation of $\text{GL}_n(\mathbb{Q}_\ell)$. Thus, using Theorem 1.2, we can see that

$$\phi^\vee_\pi = (\phi^{FS}_\pi)^\vee$$

where the twist by the norm-character $| \cdot |^{(1-n)/2}$ is cancelled out by a perverse normalization (also related to the middle degree being the relevant one) in the definition of the Hecke operator $T_{\mu^{-1}}$. This implies compatibility for supercuspidal $\pi$, which, by using compatibility of the Fargues-Scholze correspondence with parabolic induction, is enough to conclude the general case. In a similar fashion, using the description of the $\rho$-isotypic part one can prove compatibility for the inner form $D^*_\pi$.

One may expect, given the above sketch of compatibility for $\text{GL}_n$, that, to prove Theorem 1.1, one must similarly provide a description of the cohomology of the $\pi \in \Pi(G)$ (resp. $\rho \in \Pi(J)$)-isotypic part of a local Shimura variety/shtuka space at infinite level associated to $G$. In the case where the associated $L$-parameters are supercuspidal, this is the content of the Kottwitz conjecture [RV14, Conjecture 7.3]. To this end, we consider the cohomology of a Shtuka space associated to the group $G = \text{Res}_{L/\mathbb{Q}_p}(\text{GSp}_4)$. Namely, the space denoted $\text{Sht}(G, b, \mu)_\infty$, where $\mu$ is the Siegel cocharacter and $b \in B(\mathbb{Q}_p)$ is a basic element in the Kottwitz set of $G$, corresponding to a rank 4 isocrystal with a polarization and automorphism group equal to $J = \text{Res}_{L/\mathbb{Q}_p}(\text{GU}_2(D))$. This space carries a commuting $G(\mathbb{Q}_p)$ and $J(\mathbb{Q}_p)$ action. The quotients

$$\text{Sht}(G, b, \mu)_K := \text{Sht}(G, b, \mu)_\infty/K$$

for varying compact open $K \subset G(\mathbb{Q}_p)$ are, as before, representable by rigid analytic varieties over $\text{Spa}(\mathbb{L})$ of dimension 3, where $\mathbb{L} := L\mathbb{Q}_p$. They define a tower of local Shimura varieties in the sense of Rapoport-Viehmann [RV14], which uniformize the basic locus of certain global Shimura varieties analogous to the Lubin-Tate case described above. Letting $\text{Sht}(G, b, \mu)_{K, \mathbb{C}_p}$ be the base-change of these spaces to $\mathbb{C}_p$, we can then consider the analog of the complexes described above

$$R\Gamma_c(G, b, \mu) := \text{colim}_{K \rightarrow 1} R\Gamma_c(\text{Sht}(G, b, \mu)_{K, \mathbb{C}_p}, \mathbb{Q}_\ell)$$

This complex is concentrated in degrees $0 \leq i \leq 6 = 2\text{dim}(\text{Sht}(G, b, \mu)_K)$ and admits an action of $G(\mathbb{Q}_p) \times J(\mathbb{Q}_p) \times W_L$. This allows one to consider the $\rho$ and $\pi$-isotypic parts, i.e. we set

$$R\Gamma_c(G, b, \mu)[\rho] := R\Gamma_c(G, b, \mu) \otimes^\mathbb{L}_{\mathcal{H}(J)} \rho$$

and

$$R\Gamma_c(G, b, \mu)[\pi] := R\Gamma_c(G, b, \mu) \otimes^\mathbb{L}_{\mathcal{H}(G)} \pi$$
where $\mathcal{H}(G)$ (resp. $\mathcal{H}(J)$) are the usual smooth Hecke algebra of $G$ (resp. $J$). To deduce compatibility, one needs to realize the (semi-simplified) $L$-parameter $\phi_\pi$ (resp. $\phi_\rho$) of Gan-Takeda (resp. Gan-Tantono) in these two cohomology groups. We will sketch how to do this in the next section using uniformization and global methods. Interestingly, after knowing compatibility, one can use ideas from the geometry of the Fargues-Scholze construction to provide a more precise of the complexes $R\Gamma_c(G, b, \mu)[\rho]$ and $R\Gamma_c(G, b, \mu)[\pi]$. Namely, recent work of Hansen [Han20] allows us to deduce that if $\phi_\rho$ (resp. $\phi_\pi$) is supercuspidal the complexes $R\Gamma_c(G, b, \mu)[\rho]$ (resp. $R\Gamma_c(G, b, \mu)[\pi]$) are concentrated in middle degree 3. It then follows from work of Hansen-Kaletha-Weinstein [HKW21] on a weakening of the Kottwitz conjecture and work of Fargues-Scholze [FS21, Section X.2] describing the Hecke action on objects with supercuspidal Fargues-Scholze parameter that one can actually deduce a weakening of the Kottwitz conjecture and work of Fargues-Scholze [FS21, Section X.2] describing the Hecke action on objects with supercuspidal Fargues-Scholze parameter that one can actually deduce a strong form of the Kottwitz conjecture for these representations. To state this result, we first note that, if we are given a supercuspidal parameter $\phi$ over $\Gamma$, then $\pi = \phi^G$ is irreducible, its composition with the standard embedding $std : \text{GSp}_4(\bar{\mathbb{Q}}_\ell) \hookrightarrow \text{GL}_4(\bar{\mathbb{Q}}_\ell)$ may not be. In particular, the size of the $L$-packets $\Pi_\phi(G) := \text{LLC}_G^{-1}(\phi)$ and $\Pi_\phi(J) := \text{LLC}_J^{-1}(\phi)$ over $\phi$ are governed by this.

1. (stable) $\text{std} \circ \phi$ is irreducible. In this case, the $L$-packets each contain one supercuspidal member.
2. (endoscopic) $\text{std} \circ \phi \simeq \phi_1 \oplus \phi_2$, where $\phi_1 : W_L \to \text{GL}_2(\bar{\mathbb{Q}}_\ell)$ are distinct irreducible 2-dimensional representations with $\det(\phi_1) = \det(\phi_2)$. In this case, the $L$-packets over $\phi$ each contain two supercuspidal members.

This allows us to state our main consequence of Theorem 1.1, which (almost) verifies the strong form of the Kottwitz conjecture for $\text{GSp}_4/L$ and $\text{GU}_2(D)/L$.

**Theorem 1.3.** Let $L/\mathbb{Q}_p$ be an unramified extension with $p > 2$. Let $\pi$ (resp. $\rho$) be members of the $L$-packet over a supercuspidal parameter $\phi : W_L \to \text{GSp}_4(\bar{\mathbb{Q}}_\ell)$ as above. Then the complexes

$$R\Gamma_c(G, b, \mu)[\pi]$$

and

$$R\Gamma_c(G, b, \mu)[\rho]$$

are concentrated in middle degree 3.

1. If $\phi$ is stable supercuspidal, with singleton $L$-packets $\{\pi\} = \Pi_\phi(G)$ and $\{\rho\} = \Pi_\phi(J)$, then the cohomology of $R\Gamma_c(G, b, \mu)[\pi]$ in middle degree is isomorphic to

$$\rho \boxtimes (\text{std} \circ \phi)^\vee \otimes \cdot \cdot\cdot^{-3/2}$$

as a $J(\mathbb{Q}_p) \times W_L$-module, and the cohomology of $R\Gamma_c(G, b, \mu)[\rho]$ in middle degree is isomorphic to

$$\pi \boxtimes \text{std} \circ \phi \otimes \cdot \cdot\cdot^{-3/2}$$

as a $G(\mathbb{Q}_p) \times W_L$-module.

2. If $\phi$ is an endoscopic parameter, with $L$-packets $\Pi_\phi(G) = \{\pi^+, \pi^-, \ldots\}$ and $\Pi_\phi(J) = \{\rho_1, \rho_2, \ldots\}$, the cohomology of $R\Gamma_c(G, b, \mu)[\pi]$ in middle degree is isomorphic to

$$\rho_1 \boxtimes \phi_1^\vee \otimes \cdot \cdot\cdot^{-3/2} \oplus \rho_2 \boxtimes \phi_2^\vee \otimes \cdot \cdot\cdot^{-3/2}$$

or

$$\rho_1 \boxtimes \phi_2^\vee \otimes \cdot \cdot\cdot^{-3/2} \oplus \rho_2 \boxtimes \phi_1^\vee \otimes \cdot \cdot\cdot^{-3/2}$$

as a $J(\mathbb{Q}_p) \times W_L$-module. Similarly, the cohomology of $R\Gamma_c(G, b, \mu)[\rho]$ in middle degree is isomorphic to

$$\pi^+ \boxtimes \phi_1 \otimes \cdot \cdot\cdot^{-3/2} \oplus \pi^- \boxtimes \phi_2 \otimes \cdot \cdot\cdot^{-3/2}$$

\[1\] For an explanation of the notation, see the discussion at the end of section 2.2.
or
\[ \pi^+ \boxtimes \phi_2 \otimes | \cdot |^{-3/2} + \pi^- \boxtimes \phi_1 \otimes | \cdot |^{-3/2} \]
as a $G(Q_p) \times W_L$-module. Here we write $\text{std} \circ \phi \simeq \phi_1 \oplus \phi_2$, with $\phi_i$ distinct irreducible 2-dimensional representations of $W_L$ and $\det(\phi_1) = \det(\phi_2)$.

Moreover, both possibilities for the cohomology of $R\Gamma_c(G, b, \mu)[\rho]$ (resp. $R\Gamma_c(G, b, \mu)[\pi]$) in the endoscopic case occur for some choice of representation $\rho \in \Pi_\phi(J)$ (resp. $\pi \in \Pi_\phi(G)$).

In particular, knowing the precise form of either $R\Gamma_c(G, b, \mu)[\rho]$ or $R\Gamma_c(G, b, \mu)[\pi]$ for some $\rho \in \Pi_\phi(J)$ or $\pi \in \Pi_\phi(G)$ determines the precise form of the cohomology in all other cases.

Remark 1.2. (1) Results of this form when $L = Q_p$ have also been shown by Ito-Meida [IM21].

(2) If one knew Arthur’s multiplicity formula for inner forms of $\text{GSp}_4$ over totally real fields, one should be able to determine the cohomology in the endoscopic case more precisely, using basic uniformization and the more precise description of the cohomology of the global Shimura variety this multiplicity formula would provide (See for example [Ngu19], Section 3.2] for this kind of analysis in the case of unitary groups.). However, to our knowledge the multiplicity formula is unknown in this case. In the case that $L = Q_p$, one can apply what is known about the multiplicity formula for $\text{GSp}_4/Q$ [Art04, GT19]. This is carried out by Ito-Meida [IM21]. The correct answer, for the $\rho$-isotypic part, should be that, if $\rho = \rho_1$, we are in the first case, and if $\rho = \rho_2$, we are in the second case. Similarly, for the $\pi$-isotypic part, if $\pi = \pi^+$ is the unique generic member of the $L$-packet for a fixed choice of Whittaker datum, we should be in the first case and, if $\pi = \pi^-$, we should be in the second case. It might also be possible to show this using a weaker argument. Our analysis reduces us to checking that $R\Gamma_c(G, b, \mu)[\rho_1]$ admits a sub-quotient isomorphic to $\pi_+ \boxtimes \phi_1 \otimes | \cdot |^{-3/2}$, which may be possible to show through basic uniformization and a small global argument.

(3) We hope that the perspective we take on the Kottwitz conjecture in this paper will help provide further advancements in our knowledge of the cohomology of local Shimura varieties. In particular, by invoking the use of these very general geometric tools from the Fargues-Scholze construction, we require global input only to show compatibility, which, as we will see in the next section, requires substantially less than the input needed to determine the precise form of the cohomology such as a multiplicity formula for the automorphic spectrum.

We will now conclude the introduction by providing a sketch of the proof of Theorem 1.1.

1.2. Proof Sketch of the Main Theorems. As before, we set $G = \text{Res}_{L/Q_p} \text{GSp}_4$ and $J = \text{Res}_{L/Q_p} \text{GU}_2(D)$. Similar to the case of $\text{GL}_n$, the idea behind proving compatibility for $G$ and $J$ is to use the compatibility of the Fargues-Scholze local Langlands correspondence with parabolic induction to reduce to the case where $\pi$ is a supercuspidal representation. However, this is a little bit more subtle than the case of $\text{GL}_n$. Unlike $\text{GL}_n$, the local Langlands correspondence for these groups is not a bijection. As seen before, the $L$-packets can be either of size 1 or 2. Given an $L$-parameter $\phi : W_L \times \text{SL}_2(Q_\ell) \to \text{GSp}_4(Q_\ell)$, there are three distinct possibilities.

(1) The $L$-packets $\Pi(G)_{\phi}$ and $\Pi(J)_{\phi}$ do not contain any supercuspidal representations.

(2) The $L$-packets $\Pi(G)_{\phi}$ and $\Pi(J)_{\phi}$ contain a mix of supercuspidal and non-supercuspidal representations.

(3) The $L$-packets $\Pi(G)_{\phi}$ and $\Pi(J)_{\phi}$ contain only supercuspidals.

Case (1) is straight forward. Since compatibility is known for $\text{GL}_n$ and its inner forms and any proper Levi subgroup of $G$ (resp. $J$) is a product of such groups, it follows from compatibility of the Fargues-Scholze correspondence with parabolic induction and products that the correspondences are compatible for any representation lying in such an $L$-packet.
Case (2) is a bit more subtle, here $\phi^{ss}$ factors through a Levi subgroup of $\text{GSp}_4(\mathbb{Q}_l)$, but $\phi$ itself does not. In particular, the restriction to the $\text{SL}_2$ factor of $\phi$ is non-trivial. In this case, we can write $\Pi_0(G) = \{\pi_{\text{disc}}, \pi_{sc}\}$ (resp. $\Pi_0(J) := \{\rho_{\text{disc}}, \rho_{sc}\}$ or $\Pi_0(J) = \{\rho_{\text{disc}}, \rho_{\text{disc}}^2\}$, depending on whether the parameter is of Saito-Kurokawa or Howe-Piatetski–Shapiro type), where $\pi_{\text{disc}}$ (resp. $\rho_{\text{disc}}$, $\rho_{\text{disc}}^2$, and $\rho_{\text{disc}}$) are non-supercuspidal (essentially) discrete representation of $G$ (resp. $J$), and $\pi_{sc}$ (resp. $\rho_{sc}$) is a supercuspidal representation of $G(\mathbb{Q}_p)$ (resp. $J(\mathbb{Q}_p)$). The key observation is that $\pi_{\text{disc}}$ (resp. $\rho_{\text{disc}}$) is an irreducible sub-quotient of a parabolic induction, so, in this case, we can apply the same argument as in case (1) to deduce compatibility of the two correspondences. It remains to see that the same is true for $\pi_{sc}$. To do this, we use a description of the $\rho$-isotypic part of the Shtuka space $\text{Sht}(G, b, \mu)_\infty$ introduced in section 1.1. Namely, we consider the complex

$$R\Gamma_c(G, b, \mu)[\rho_{\text{disc}}] \simeq R\Gamma_c(G, b, \mu) \otimes_{\text{H}(G)} \rho_{\text{disc}}$$

of $G(\mathbb{Q}_p) \times W_L$-modules. Recent work of Hansen-Kaletha-Weinstein \cite{HKW21} then tells us the form of this cohomology group (or rather a small variant thereof) as a $(\rho_{\text{disc}}, \rho_{sc})$-representation. In particular, if we let $R\Gamma_c(G, b, \mu)[\rho_{\text{disc}}]_{\text{sc}}$ denote the summand of $R\Gamma_c(G, b, \mu)[\rho_{\text{disc}}]$ where $J(\mathbb{Q}_p)$ acts via a supercuspidal representation, then in the Grothendieck group of admissible $J(\mathbb{Q}_p)$-representations of finite length $R\Gamma_c(G, b, \mu)[\rho_{\text{disc}}]_{\text{sc}}$ is equal to $-2\pi_{sc}$.

Similar to the case of $G = \text{GL}_n$, this complex describes the action of the Hecke operator $T_\mu$ acting on a sheaf $\mathcal{F}_{\rho_{\text{disc}}}$ constructed from $\rho_{\text{disc}}$ on $\text{Bun}_G$. Moreover, the complex $R\Gamma_c(G, b, \mu)[\rho_{\text{disc}}]_{\text{sc}}$ can be interpreted as a complex of sheaves on the open Harder-Narasimhan (−HN)-strata $\text{Bun}_G^1 \subset \text{Bun}_G$ corresponding to the trivial $G$-bundle on the Fargues-Fontaine curve $X$. It follows from the above description in the Grothendieck group that the excursion algebra will act on this complex via eigenvalues valued in the parameter $\phi^{\text{FS}}_{\pi_{sc}}$. However, since the excursion algebra is built from Hecke operators, it will also commute with the action of Hecke operators on $\mathcal{F}_{\rho_{\text{disc}}}$.

This allows us to conclude that it also must act via eigenvalues valued in $\phi^{\text{FS}}_{\rho_{\text{disc}}}$ giving a chain of equalities

$$\phi^{\text{FS}}_{\pi_{sc}} = \phi^{\text{FS}}_{\rho_{\text{disc}}} = \phi^{ss}_{\rho_{\text{disc}}} = \phi^{ss}_{\pi_{sc}}$$

where the first equality follows from the previous argument and the second equality follows from the above analysis of induced representations. Similarly, one deduces compatibility for $\rho_{sc}$ by applying a similar argument to the $\pi$-isotypic part.

Case (3) is by far the most involved and takes up the majority of the paper. This is the case in which the $L$-parameter $\phi$ is supercuspidal. First, one can make a reduction to showing compatibility for just $\rho \in \Pi(J)$ with supercuspidal Gan-Tantono parameter $\phi$, by using the commutation of Hecke operators and the excursion algebra similar to what was done in case (2). Now, the key point again is that the complex $R\Gamma_c(G, b, \mu)[\rho]$ describes the action of the Hecke operator $T_\mu$ on a sheaf $\mathcal{F}_\rho$ on $\text{Bun}_G$. To make further progress towards compatibility, we use that the Hecke operators can be in turn described using the spectral action of the derived category of perfect complexes on the stack of $L$-parameters, as constructed in \cite{FS21} Chapter X. In particular, a Hecke operator defines a vector bundle on the stack of $L$-parameters, whose action on the sheaf $\mathcal{F}_\rho$ via the spectral action is precisely $T_\mu$. Using this, we argue using the support of the spectral action of certain averaging operators, considered by \cite{AL21} in the case of $\text{GL}_n$, to show that, if $\text{std} \circ \phi \otimes | \cdot |^{-3/2}$ occurs as a $W_L$-stable sub-quotient of the complex

$$\bigoplus_{\rho' \in \Pi(J)} R\Gamma_c(G, b, \mu)[\rho']$$

we have an equality:

$$\text{std} \circ \phi^{\text{FS}}_{\rho} = \text{std} \circ \phi$$
for all $\rho \in \Pi_\phi(J)$. Now a $\text{GSp}_4$-valued parameter is in turn determined by its composition with $\text{std}$ and its similitude character, which is precisely the central character of $\rho$. Therefore, since the Fargues-Scholze correspondence is compatible with central characters, this is enough to conclude that $\phi = \phi_{FS}^\rho$. This reduces the question of showing compatibility for $\rho \in \Pi(\text{GU}_2(D))$ with supercuspidal Gan-Tantono parameter $\phi$ to the following.

**Proposition 1.4.** Let $\phi$ be a supercuspidal parameter with associated $L$-packet $\Pi_\phi(J)$. Then the direct summand of

$$\bigoplus_{\rho' \in \Pi_\phi(J)} R\Gamma_c(G, b, \mu)[\rho']$$

where $G(\mathbb{Q}_p)$ acts via a supercuspidal representation

$$\bigoplus_{\rho' \in \Pi_\phi(J)} R\Gamma_c(G, b, \mu)[\rho'_{sc}]$$

is concentrated in middle degree 3 and admits a non-zero $W_L$-stable sub-quotient with $W_L$-action given by $\text{std} \circ \phi \otimes | \cdot |^{-3/2}$.

Just as one does in proving Theorem 1.2, the key idea is to directly relate the complex

$$\bigoplus_{\rho' \in \Pi_\phi(J)} R\Gamma_c(G, b, \mu)[\rho'_{sc}]$$

to the cohomology of a global Shimura variety using basic uniformization of the generic fiber as proven by Shen [She17] and an analogue of Boyer’s trick [Boy09]. This allows us to in turn prove Proposition 1.4 using global results on Galois representations in the cohomology of these Shimura varieties due to Kret-Shin [KS16] and Sorensen [Sor10]. More specifically, in this case the relevant uniformization result is then applicable if $L/\mathbb{Q}_p$ is an unramified extension and $p > 2$. To state the key consequence of this uniformization result, we introduce some notation. We let $\mathbb{A}$ and $\mathbb{A}_f$ denote the adeles and finite adeles of $\mathbb{Q}$, respectively. If $K^p \subset G(\mathbb{A}_f^p)$ denotes the level away from $p$ and $K_p \subset G(\mathbb{Q}_p)$ denotes the level at $p$, we let $S(G, X)_{K_pK^p}$ be the rigid analytic Shimura variety over $\mathbb{C}_p$ of level $K_pK^p$. We set $\xi$ be a regular weight of an algebraic representation $\nu_\xi$ of $G$ over $\mathbb{Q}$ and let $L_\xi$ denote the associated $\mathbb{Q}_\ell$ local system on $S(G, X)_{K_pK^p}$. We then define

$$R\Gamma_c(S(G, X)_{K_pK^p}, L_\xi) := \text{colim}_{K_p \rightarrow \{1\}} R\Gamma_c(S(G, X)_{K_pK^p}, L_\xi)$$

The basic uniformization result of Shen then furnishes a $\mathbb{Q}$-inner form $G'$ of $G$ satisfying that $G'_{Q_p} \simeq J$ together with a $G(\mathbb{Q}_p) \times W_L$-invariant map

$$\Theta : R\Gamma_c(G, b, \mu) \otimes_{H(J)} L_\xi A(G'(\mathbb{Q}) \backslash G'(\mathbb{A}_f) / K^p, L_\xi) \rightarrow R\Gamma_c(S(G, X)_{K_pK^p}, L_\xi)$$

functorial in the level $K^p$. Here $A(G'(\mathbb{Q}) \backslash G'(\mathbb{A}_f) / K^p, L_\xi)$ denotes the space of algebraic automorphic forms of level $K^p$ valued in the algebraic representation $\nu_\xi$ in the sense of [Gro99]. We want to use this uniformization map to apply global results on the cohomology of $R\Gamma_c(S(G, X)_{K_pK^p}, L_\xi)$ to study the action of $W_L$ on $R\Gamma_c(G, b, \mu)$. To do this, we show an analogue of Boyer’s trick, which says that the non-basic Newton strata of the adic flag variety $F_{\ell, G, \mu^{-1}} := (G / F_{\mu^{-1}})^{nd}$ are parabolically induced as spaces with $G(\mathbb{Q}_p)$-action. Using the Hodge-Tate period map from the Shimura variety $S(G, X)_{K_pK^p}$ to $F_{\ell, G, \mu^{-1}}$, this implies that, if we pass to the part of the cohomology on both sides where $G(\mathbb{Q}_p)$ acts via a supercuspidal representation, we get a $W_L \times G(\mathbb{Q}_p)$-equivariant isomorphism:

$$\Theta_{sc} : R\Gamma_c(G, b, \mu)_{sc} \otimes_{H(J)} L_\xi A(G'(\mathbb{Q}) \backslash G'(\mathbb{A}_f) / K^p, L_\xi) \rightarrow R\Gamma_c(S(G, X)_{K_pK^p}, L_\xi)_{sc}$$

After showing this, we fix a $\rho$ having supercuspidal Gan-Tantono parameter $\phi$, and, via an argument using the simple trace formula, choose a globalization of $\rho$ to a cuspidal automorphic representation.
Π' of G', which occurs as a J(Qp)-stable direct summand of \( \mathcal{A}(G'(\mathbb{Q}) \backslash G'(\mathbb{A}_f)/K^p, \mathcal{L}_\xi) \) and is an unramified twist of Steinberg at some non-empty set of places \( S_{st} \), for some sufficiently large regular weight \( \xi \) and sufficiently small level \( K^p \). We set \( S \) to be a finite set of places outside of which \( \Pi' \) is unramified. The Hecke eigenvalues of \( \Pi' \) then define a maximal ideal \( m \subset T^S \) in the abstract commutative Hecke algebra of \( G' \) away from the finite places \( S \). Regarding both sides of \( \Theta \) as \( T^S \)-modules, we can localize at \( m \) to get a map

\[
\Theta_m : (R\Gamma_c(G, b, \mu) \otimes_{H_\mathcal{L}(J_b)} \mathcal{A}(G'(\mathbb{Q}) \backslash G'(\mathbb{A}_f)/K^p, \mathcal{L}_\xi))_m \to R\Gamma_c(S(G, X)_{K^p}, \mathcal{L}_\xi)_m
\]

We write \( K^p = K^{S_{st} \cup \{p\}}_{S_{st}} \) for \( K^{S_{st} \cup \{p\}} \subset \mathcal{G}(\mathbb{A}_{f}^{S_{st} \cup \{p\}}) \). Taking colimits on both sides as \( K^p_{S_{st}} \to \{1\} \), we see that \( \Theta_m \) induces a map:

\[
(R\Gamma_c(G, b, \mu) \otimes_{H_\mathcal{L}(J_b)} \mathcal{A}(G'(\mathbb{Q}) \backslash G'(\mathbb{A}_f)/K^{S_{st} \cup \{p\}}, \mathcal{L}_\xi))_m \to R\Gamma_c(S(G, X)_{K^{S_{st} \cup \{p\}}}, \mathcal{L}_\xi)_m
\]

For \( v \in S_{st} \), we consider the projection of both side to the Bernstein component of \( G(F_v) \simeq G'(F_v) \) corresponding to the Steinberg representation. This gives us a map:

\[
\Theta^{st}_m : (R\Gamma_c(G, b, \mu) \otimes_{H_\mathcal{L}(J_b)} \mathcal{A}(G'(\mathbb{Q}) \backslash G'(\mathbb{A}_f)/K^{S_{st} \cup \{p\}}, \mathcal{L}_\xi))^{st}_m \to R\Gamma_c(S(G, X)_{K^{S_{st} \cup \{p\}}}, \mathcal{L}_\xi)^{st}_m
\]

A priori, this only implies that \( G(F_v) \simeq G'(F_v) \) acts via an unramified twist of the Steinberg or trivial representation, but the latter case is ruled out since \( \xi \) is regular, by a standard strong approximation argument (See the proof of Theorem 5.2). The key point is now, by analyzing the simple twisted trace formula of Kottwitz-Shelstad [KS99] and stable trace formulas of Arthur [Art02], we can prove a strong multiplicity one type result (Proposition 5.4), for cuspidal automorphic representations that are unramified twists of Steinberg at some sufficiently large non-empty set of places and regular of weight \( \xi \) at infinity. This implies that the representations of \( G' \) occurring on LHS of \( \Theta^{st}_m \) must have local constituent at \( p \) with Langlands parameter \( \phi \), since we localized at the Hecke eigensystem defined by \( \Pi' \) at the unramified places. Moreover, since we know \( \Theta^{st}_{sc} \) is an isomorphism, this implies that we have an isomorphism

\[
\Theta^{st}_{m,sc} : (R\Gamma_c(G, b, \mu)_{sc} \otimes_{H_\mathcal{L}(J_b)} \mathcal{A}(G'(\mathbb{Q}) \backslash G'(\mathbb{A}_f)/K^{S_{st} \cup \{p\}}, \mathcal{L}_\xi))^{st}_{m,sc} \simeq R\Gamma_c(S(G, X)_{K^{S_{st} \cup \{p\}}}, \mathcal{L}_\xi)^{st}_{m,sc}
\]

and, since the local constituents of the automorphic representations of \( G' \) at \( p \) occurring in the LHS are all in the L-packet \( \Pi_\phi(J) \) by the strong multiplicity one result, we can reduce Proposition 1.4 to showing that \( R\Gamma_c(S(G, X)_{K^p}, \mathcal{L}_\xi)^{st}_{m,sc} \) is concentrated in degree 3 and has \( W_L \)-action given (up to multiplicity) by \( \text{std} \circ \phi \otimes | \cdot |^{-3/2} \). This follows from the analysis carried out in Kret-Shin [KS16]. In particular, it follows from their results that this complex will be concentrated in degree 3 and that the traces of Frobenius in \( \Gamma_F := \text{Gal}(\overline{F}/F) \) on the étale cohomology of the associated global Shimura variety over \( F \) are given by \( \text{std} \circ \phi_{\tau_v} \), where \( \tau_v \) are the local constituents of some weak transfer \( \tau \) of \( \Pi' \) to an automorphic representation of \( \text{Res}_{F/\mathbb{Q}} \text{GSp}_4 =: G^* \) and \( \phi_{\tau_v} \) is the associated Gan-Takeda parameter. This allows one, up to multiplicities, to describe the Galois action on the global Shimura variety in terms of the composition \( \text{std} \circ \rho_{\tau} \), where \( \rho_{\tau} \) is a global \( \text{GSp}_4(\overline{\mathbb{Q}}_l) \)-valued representation of the absolute Galois group of \( F \) constructed by Sorensen [Sor10] from \( \tau \) characterized by the property that \( i\text{WD}(\text{std} \circ \rho_{\tau})|_{W_{F_v}} \simeq \phi_{\tau_v} \otimes | \cdot |^{-3/2} \) for all but finitely many places \( v \) of \( F \). This would give one precisely the desired description of the \( W_L \)-action on \( R\Gamma_c(G, b, \mu)_{[\rho]_{sc}} \) if one knew that \( \phi_{\tau_p} = \phi_p \). Since \( \Pi' \) is globalization of \( \rho \), one needs to choose \( \tau \) to be a strong transfer of \( \Pi' \) at the prime \( p \). This latter goal is accomplished using analysis of the simple trace formula as done in Kret-Shin [KS16] Section 6] combined with the character identities proven by Chan-Gan [CG15]. These results on strong transfers also aid us in deducing the strong multiplicity one type result mentioned above.

In section 2, we give an overview of the Gan-Takeda and Gan-Tantono local Langlands correspondence, putting it in the framework of the refined local Langlands correspondence of Kaletha.
in preparation for applications to the Kottwitz conjecture. In section 3, we describe the Fargues-Scholze local Langlands correspondence and related ideas, giving the proof of compatibility in cases (1) and (2) and reducing case (3) to Proposition 1.4, via some properties of the spectral action discussed in section 3.2. In section 4, we discuss basic uniformization of the relevant Shimura varieties and prove the aforementioned analogue of Boyer’s trick, showing that the uniformization map $\Theta_{sc}$ is an isomorphism. In section 5, we analyze the simple trace formula with fixed central character in a fashion similar to Kret-Shin [KS16] to deduce the existence of the required strong transfers, as well as combine this with analysis of the simple twisted trace formula to deduce the required strong multiplicity one result. In section 6, we apply the results of section 5 combined with results of Kret-Shin [KS16] and Sorensen [Sor10] to compute the relevant Galois action on the global Shimura variety. Finally, in section 7, we put the results of the previous sections together to prove Proposition 1.4. We then conclude with the application to the proofs of Theorem 1.1 and 1.3, as well as formally deduce compatibility for the local Langlands correspondence for $Sp_4$ and its non quasi-split inner form $SU_2(D)$, as constructed by Gan-Takeda [GT10] and Cho [Cho17], respectively. We finish the section with a brief discussion of an application to the cohomology of the related (non-minuscule) local Shtuka spaces.

Conventions and Notations

For a diamond or $v$-stack, we freely use the formalism in [Sch18; FS21] of $\ell$-adic cohomology of diamonds and $v$-stacks. We will fix isomorphisms $i : \overline{\mathbb{Q}}_\ell \rightarrow \mathbb{C}$ and $j : \mathbb{Q}_p \rightarrow \mathbb{C}$ and use the (geometric) normalization of local class field theory that sends the Frobenius to the inverse of the uniformizer. For a supercuspidal $L$-parameter, we will often abuse notation and use $\phi$ to denote both the $L$-parameter and the semisimplified parameter $\phi^{sm}$, as in this case this merely corresponds to forgetting the trivially acting $SL_2(\mathbb{C})$-factor and applying the isomorphism $i$. For a reductive group $H/\mathbb{Q}_p$, we will write $R\mathcal{H}om_{\mathbb{Q}_p}(\mathbb{Q}_p, \overline{\mathbb{Q}}_\ell) : D(H(\mathbb{Q}_p), \overline{\mathbb{Q}}_\ell) \rightarrow D(H(\mathbb{Q}_p), \overline{\mathbb{Q}}_\ell)$ for the derived smooth duality functor, where $D(H(\mathbb{Q}_p), \overline{\mathbb{Q}}_\ell)$ is the unbounded derived category of smooth representations. Namely, it is derived functor induced by the left exact smooth duality functor $V \mapsto (V^*)^{sm}$, where $(V^*)^{sm}$ is the set of all functions $f : V \rightarrow \overline{\mathbb{Q}}_\ell$ such that there exists $K \subset H(\mathbb{Q}_p)$ a compact open such that for all $v \in V$ and $k \in K$ we have that $f(kv) = f(v)$. Normally, in the literature the space $\text{Sht}(G, b, \mu)_{sc}$ parametrizes modifications $E_0 \rightarrow E_b$ with meromorphy $\mu$. For us, it will denote the space parametrizing modifications of type $\mu^{-1}$. This convention limits the appearances of duals (cf. Remark 3.8).

2. Local Langlands for $GSp_4$ and $GU_2(D)$

2.1. Local Langlands for $GSp_4$. In this section, we will describe the local Langlands correspondence of Gan-Takeda for the group $G := GSp_4/L$, where $L/\mathbb{Q}_p$ is a finite extension. We fix a choice of Whittaker datum $m := (B, \psi)$ throughout section 2, where $B$ is the Borel and $\psi$ is a generic character of $L$.

As before, we consider the set $\Phi(G)$ of admissible homomorphisms

$$\phi : W_L \times SL_2(\mathbb{C}) \rightarrow \hat{G}(\mathbb{C}) = GSpin_5(\mathbb{C}) \simeq GSp_4(\mathbb{C})$$

taken up to $\hat{G}$-conjugacy, where $W_L$ acts via a continuous semisimple homomorphism with respect to the discrete topology and $SL_2(\mathbb{C})$ acts via an algebraic representation. Similarly, let $\Pi(G)$ denote the isomorphism classes of smooth irreducible representations of the group $G(L)$. We can now state the main theorem of Gan-Takeda.

Theorem 2.1. [GT11] There is a surjective finite to one map

$$\text{LLC}_G : \Pi(GSp_4) \rightarrow \Phi(GSp_4)$$
Definition 2.1.\[\pi \mapsto \phi_{\pi}\]

with the following properties:

1. \(\pi\) is an (essentially) discrete series representation of \(\text{GSp}_4(L)\) if and only if its \(L\)-parameter does not factor through any proper Levi subgroup of \(\text{GSp}_4(\mathbb{C})\).
2. Given an \(L\)-parameter \(\phi\), we set \(S_{\phi} := Z_G(\text{Im}(\phi))\) to be the centralizer of \(\phi\). The fiber \(\Pi_{\phi}(G)\) can be naturally parametrized by the set of irreducible characters of the component group \(A_{\phi} := \pi_0(S_{\phi}) \simeq \pi_0(S_{\phi}/Z(\text{GSp}_4))\) which is either trivial or equal to \(\mathbb{Z}/2\mathbb{Z}\). When \(A_{\phi} = \mathbb{Z}/2\mathbb{Z}\), exactly one of the two representations in \(\Pi_{\phi}(G)\) is generic for the fixed choice of Whittaker datum, and is indexed by the trivial character of \(A_{\phi}\).
3. The similitude character \(\text{sim}(\phi_{\pi})\) of \(\text{GSp}_4(L)\) is equal to the central character \(\omega_{\pi}\) via the isomorphism given by local class field theory.
4. Given a character \(\chi\) of \(L^*\) and letting \(\lambda : \text{GSp}_4 \to L^*\) be the similitude character of \(\text{GSp}_4(L)\), we have, via local class field theory, that the \(L\)-parameter of \(\pi \otimes (\chi \circ \lambda)\) is equal to \(\phi_{\pi} \otimes \chi\).
5. If \(\pi \in \Pi(\text{GSp}_4)\) is a representation, for any smooth irreducible representation \(\sigma\) of \(\text{GL}_r(L)\), we have that
   \[\gamma(s, \pi \times \sigma, \psi) = \gamma(s, \phi_{\pi} \otimes \phi_{\sigma}, \psi)\]
   \[L(s, \pi \times \sigma, \psi) = L(s, \phi_{\pi} \otimes \phi_{\sigma}, \psi)\]
   \[\epsilon(s, \pi \times \sigma, \psi) = \epsilon(s, \phi_{\pi} \otimes \phi_{\sigma}, \psi)\]
   where the RHS are the Artin local factors associated to the representations of \(W_L \times \text{SL}_2(\mathbb{C})\) and the LHS are the local factors of Shahidi \[\text{Shah90}\] with respect to the morphisms of \(L\)-groups defined in \[\text{GT11}\] Section 4 in the case that \(\pi\) is a generic supercuspidal or nonsupercuspidal and are the local factors defined by Townsend \[\text{Tow13}\] if \(\pi\) is a non-generic supercuspidal representation.

The map \(\text{LLC}_G\) is uniquely determined by the properties (1),(3), and (5), where one can take \(r \leq 2\) in (5).

Remark 2.1. When the paper of Gan-Takeda was released there was no good theory of \(L,\epsilon\), and \(\gamma\) factors for nongeneric supercuspidal representations satisfying the usual properties. (See the 10-Commandments in \[\text{LR05}\].) Instead, to uniquely characterize the correspondence for these representations, they use an equality between the Plancharel measure on the family of inductions from \(\text{GSpin}_5(L) \times \text{GL}_r(L) \simeq \text{GSp}_4(L) \times \text{GL}_r(L)\) to \(\text{GSpin}_{2r+5}(L)\) for \(r \leq 2\). However, this theory of \(L,\epsilon\), and \(\gamma\) factors was later constructed by Nelson Townsend in his PhD thesis \[\text{Tow13}\].

We now make the following definition.

Definition 2.1. Write \(\text{std} : \text{GSp}_4 \hookrightarrow \text{GL}_4\) for the standard embedding. We say a discrete \(L\)-parameter is stable if the \(L\)-packet \(\Pi_{\phi}(G)\) has size 1 and is endoscopic if it has size 2. Equivalently, by Theorem 2.1 (2), this is equivalent to saying that the character group \(A_{\phi}\) of the component group \(A_{\phi}\) has cardinality 1 or 2, respectively. By \[\text{GT11}\] Lemma 6.2], this can be characterized as follows.

- (stable) \(\text{std} \circ \phi\) is an irreducible representation of \(W_L \times \text{SL}_2(\mathbb{C})\). In this case, \(S_{\phi} = Z(\hat{G}) = \mathbb{G}_m\), so \(A_{\phi}\) is trivial.
- (endoscopic) \(\text{std} \circ \phi \simeq \phi_1 \oplus \phi_2\), where the \(\phi_i : W_L \times \text{SL}_2(\mathbb{C}) \to \text{GL}_2(\mathbb{C})\) for \(i = 1, 2\) are distinct irreducible 2-dimensional representations of \(W_L \times \text{SL}_2(\mathbb{C})\) with \(\det(\phi_1) = \det(\phi_2)\). In this case, \(A_{\phi} \simeq \mathbb{Z}/2\mathbb{Z}\). We recall that \(\text{GSp}_4(\mathbb{C})\) has a unique endoscopic group \(\text{GSO}_{2,2}\), and the endoscopic parameters lie in the image of the map \(\Phi(\text{GSO}_{2,2}) \to \Phi(\text{GSp}_4)\). More specifically, the dual group of \(\text{GSO}_{2,2}\) is \(\text{GSpin}_4\) and one has an identification \(\text{GSpin}_4 \simeq (\text{GL}_2(\mathbb{C}) \times \text{GL}_2(\mathbb{C}))^0 := \{(g_1, g_2) \in \text{GL}_2(\mathbb{C}) \times \text{GL}_2(\mathbb{C}) | \det(g_1) = \det(g_2)\}\) and the map
For an $L$-parameter $\phi$ we see, by Theorem 2.1 (2), that the size of the $L$-packet $\Pi_{\phi}(G)$ is at most 2, this allows us to subdivide into three cases:

1. The $L$-packet $\Pi_{\phi}(G)$ does not contain any supercuspidal representations.
2. The $L$-packet $\Pi_{\phi}(G)$ contains one supercuspidal and one non-supercuspidal.
3. The $L$-packet contains only supercuspidals.

In Case (1) the parameter will not be discrete. Case (2) is where the parameter $\phi$ does not factor through a Levi-subgroup so it is discrete, but its semisimplification $\phi^{ss}$ as defined in section 1 does. Case (2) does not occur when the parameter is a stable discrete parameter, by definition. The relevant case is when the parameter is discrete endoscopic. To understand this, we let $\nu(n)$ denote the unique $n$-dimensional irreducible representation of $\text{SL}_2(\mathbb{C})$ then there are two cases:

1. (Saito-Kurokawa Type) We have $\text{std} \circ \phi = \phi_0 \oplus \chi \boxtimes \nu(2)$, where $\phi_0$ is a 2-dimensional irreducible representation of $W_L$ and $\chi$ is a character, with $\chi^2 = \det(\phi_0)$. Therefore, the semisimplification $\phi^{ss}$ satisfies: $\text{std} \circ \phi^{ss} = \phi_0 \oplus \chi \otimes \nu(1) \oplus \chi \otimes | \cdot |^{-\nu(2)}$.
2. (Howe-Piatetski–Shapiro Type) We have $\text{std} \circ \phi = \chi_1 \boxtimes \nu(2) \oplus \chi_2 \boxtimes \nu(2)$, where $\chi_1$ and $\chi_2$ are distinct characters of $W_L$ satisfying $\chi_1^2 = \chi_2^2$. Therefore, the semisimplification $\phi^{ss}$ satisfies: $\text{std} \circ \phi^{ss} = \chi_1 \otimes | \cdot |^{\frac{1}{2}} \oplus \chi_2 \otimes | \cdot |^{-\nu(1)} \oplus \chi_2 \otimes | \cdot |^{\frac{1}{2}} \oplus \chi_1 \otimes | \cdot |^{-\nu(2)}$.

Remark 2.2. (1) The terminology here is explained by Arthur’s classification [Art04] of the global automorphic representations of $\text{GSp}_4$ appearing in the papers [Kur78] and [HP79], respectively.

(2) We will mention in the next section how to distinguish these two cases via the number of supercuspidals in the $L$-packet $\Pi_{\phi}(\text{GU}_2(D))$ defined by the Gan-Tantono local Langlands correspondence.

Case (3) is the situation where the parameter $\phi$ is supercuspidal as defined in the introduction. In particular, in the supercuspidal case the restriction of the parameter $\phi$ to the $\text{SL}_2(\mathbb{C})$ factor is trivial, so the irreducible representations occurring in the decomposition of $\text{std} \circ \phi$ are just representations of $W_L$.

For the purposes of applying the weak form of the Kottwitz Conjecture proven in Hansen-Kaletha-Weinstein [HKW21], we formulate this correspondence in terms of the refined local Langlands of Kaletha [Kal16] with respect to the fixed choice of Whittaker datum $\mathfrak{m}$. Now, given a parameter $\phi$ that is either mixed supercuspidal or supercuspidal, we have by Theorem 2.1 (2) a correspondence between the $L$-packet $\Pi_{\phi}(G)$ and the set of irreducible characters $A_{\phi}^\vee$. This in turn gives rise to an irreducible character of the group $S_{\phi}$ via the composition:

$$S_{\phi} \to \pi_0(S_{\phi}) = A_{\phi}$$

This allows us to make the following definition.

Definition 2.2. For $\phi$ a supercuspidal or mixed-supercuspidal parameter $\phi$ as above and $\pi \in \Pi_{\phi}(G)$, we denote the character of $S_{\phi}$ described above by $\tau_\pi$.

2.2. Local Langlands for $\text{GU}_2(D)$. In this section, we describe the local Langlands correspondence for the unique non-split inner form $J = \text{GU}_2(D)$, the group of similitudes of the unique 2-dimensional Hermitian vector space over the quaternion division algebra $D/L$. As in the previous section, we let $\Pi(J)$ denote the set of irreducible admissible representations of $J$, and $\Phi(J)$ be the
set of $L$-parameters of $J$. This is a subset of the previous set $\Phi(GSp_4)$ as we will now explain. $J$ has a unique up to conjugacy minimal parabolic whose Levi factor is

$$D^* \times GL_1.$$ 

This defines a form of the Siegel parabolic of $GSp_4$ and it determines a dual parabolic subgroup $P^\vee(\mathbb{C})$ in the dual group $GSp_4(\mathbb{C})$ of $GU_2(D)$. This is the Heisenberg parabolic subgroup of $GSp_4(\mathbb{C})$, its conjugacy class is said to be relevant for $J$ while all other conjugacy classes of proper parabolics are said to be irrelevant. We say $\phi \in \Phi(GSp_4)$ is relevant if it does not factor through any irrelevant parabolic subgroups of $GSp_4(\mathbb{C})$. We define $\Phi(J)$ to be the subset of relevant $\phi$ in $\Phi(GSp_4)$. We set $B_\phi := \pi_0(ZSp_4(\text{Im}(\phi)))$. One has an exact sequence:

$$\langle \pm 1 \rangle \to B_\phi \to A_\phi \to 0$$

Implying that one has an injection on the group of irreducible characters $\hat{A}_\phi \hookrightarrow \hat{B}_\phi$, which identifies $\hat{A}_\phi$ as the subgroup of (index at most 2) of characters trivial on the image of the center $Z(Sp_4)(\mathbb{C})$. One can check that $\hat{B}_\phi \neq \hat{A}_\phi$ if and only if $\phi$ is relevant for $GU_2(D)$. Now we can state the main theorem of Gan and Tantono.

**Theorem 2.2.** [GT14] There is a natural surjective finite-to-one map

$$\text{LLC}_J : \Pi(GU_2(D)) \to \Phi(GU_2(D))$$

$$\rho \mapsto \phi_\rho$$

with the following properties:

1. $\rho$ is an (essentially) discrete series representation of $GU_2(D)$ if and only if its parameter $\phi_\rho$ does not factor through any proper Levi subgroup of $GSp_4(\mathbb{C})$.
2. For an $L$-parameter $\phi$, the fiber $\Pi_\phi(J)$ can be naturally parametrized by the set $\hat{B}_\phi \setminus \hat{A}_\phi$. This set has size either 1 or 2.
3. The similitude character $\text{sim}(\phi_\rho)$ of $\phi_\rho$ is equal to the central character $\omega_\rho$ of $\rho$, via the isomorphism given by local class field theory.
4. Given a character $\chi$ of $L^*$ and letting $\lambda : GU_2(D) \to L^*$ be the similitude character of $GU_2(D)$, we have, via local class field theory, that the $L$-parameter of $\rho \otimes (\chi \circ \lambda)$ is equal to $\phi_\rho \otimes \chi$.
5. If $\rho \in \Pi(GU_2(D))$ is a non-supercuspidal representation then, for any smooth irreducible representation $\sigma$ of $GL_r(L)$, we have that

$$\gamma(s, \rho \times \sigma, \psi) = \gamma(s, \phi_\rho \otimes \phi_\sigma, \psi)$$

$$L(s, \rho \times \sigma, \psi) = L(s, \phi_\rho \otimes \phi_\sigma, \psi)$$

$$\epsilon(s, \pi \times \sigma, \psi) = \epsilon(s, \phi_\rho \otimes \phi_\sigma, \psi)$$

where the RHS are the Artin local factors associated to the representations of $W_L \times SL_2(\mathbb{C})$ and the LHS are the local factors of Shahidi, as defined in [GT14, Section 8].

6. Suppose that $\rho$ is a supercuspidal representation. For any irreducible supercuspidal representation $\sigma$ of $GL_r(L)$ with $L$-parameter $\phi_\sigma$, if $\mu(s, \rho \boxtimes \sigma, \psi)$ denotes the Plancharel measure associated to the family of induced representations $I_P(\pi \boxtimes \sigma, s)$ on $GSpin_{r+4, r+4}$, where we have regarded $\rho \boxtimes \sigma$ as a representation of the Levi subgroup $GSpin_{4,1} \times GL_r \simeq GU_2(D) \times GL_r$, then $\mu(s, \rho \boxtimes \sigma)$ is equal to

$$\gamma(s, \phi_\rho^\vee \otimes \phi_\sigma, \psi) \cdot \gamma(-s, \phi_\rho \otimes \phi_\sigma^\vee, \overline{\psi}) \cdot \gamma(2s, \text{Sym}^2 \phi_\sigma \otimes \text{sim}(\phi_\rho)^{-1}, \psi) \cdot \gamma(-2s, \text{Sym}^2 \phi_\rho^\vee \otimes \text{sim}(\phi_\rho), \overline{\psi})$$

The map LLC$_J$ is uniquely determined by the properties (1), (3), (5), and (6), with $r \leq 4$ in (5) and (6).
We now further elaborate on the structure of the $L$-packets $\Pi_\phi(J) := \text{LLC}_J^{-1}(\phi)$ in the case where the parameter $\phi$ is mixed supercuspidal. If the parameter $\phi$ is of this form, then, it follows from \cite[Proposition 5.4]{GT14} and the description of LLC$_J$ provided in \cite[Section 7]{GT14}, that the $L$-packet $\Pi_\phi(J)$ has following structure, as alluded to in Remark 2.2 (2).

1. (Saito-Kurokawa Type) The $L$-packet $\Pi_\phi(J) = \{\rho_{\text{disc}}, \rho_{\text{sc}}\}$ contains one supercuspidal representation $\rho_{\text{sc}}$ and one non-supercuspidal representation $\rho_{\text{disc}}$.

2. (Howe-Piatetski-Shapiro Type) The $L$-packet $\Pi_\phi(J) = \{\rho_{\text{disc}}^1, \rho_{\text{disc}}^2\}$ contains no supercuspidal representations.

We now would also like to briefly comment on the structure of the set $\hat{B}_\phi \setminus \hat{A}_\phi$, confirming the expectation that the size of the $L$-packets $\Pi_\phi(G)$ and $\Pi_\phi(J)$ is always the same.

- (stable) In the case that the $L$-parameter $\phi$ is stable, we have that $B_\phi = \mathbb{Z}/2\mathbb{Z}$ and, as noted in section 2.1, $A_\phi = 1$. This means the set $\hat{B}_\phi \setminus \hat{A}_\phi$ consists of one element corresponding to the non-trivial character.

- (endoscopic) In the case that the parameter $\phi$ is endoscopic, we have that the decomposition $\text{std} \circ \phi \simeq \phi_1 \oplus \phi_2$ induces an exact sequence

$$A_\phi = \mathbb{Z}/2\mathbb{Z} \xrightarrow{\Delta} B_\phi = \mathbb{Z}(\text{SL}_2) \times \mathbb{Z}(\text{SL}_2) = \mathbb{Z}/2\mathbb{Z} \times \mathbb{Z}/2\mathbb{Z}$$

and so the set $\hat{B}_\phi \setminus \hat{A}_\phi$ has size 2 and is indexed by two characters $\eta_+$ and $\eta_-$ each non-trivial on one of the two $\mathbb{C}^*$-factors under the isomorphism

$$S_\phi \simeq \{(a, b) \in \mathbb{C}^* \times \mathbb{C}^* | a^2 = b^2\} \subset (\text{GL}_2(\mathbb{C}) \times \text{GL}_2(\mathbb{C}))^0$$

from section 2.1.

We now wish to put this local Langlands correspondence for the inner form in the context of the refined local Langlands correspondence of Kaletha \cite{Kal16}. We consider the Kottwitz set $B(G)$ \cite{Kot85, RR96} and let $b \in B(G)$ be the basic element whose associated $\sigma$-centralizer $J_b = J$. We take this to be the basic element whose slope homorphism is the dominant rational cocharacter of $G$ given by $(1/2, 1/2, 1/2, 1/2)$. Let $Z(\text{GSp}_4) \simeq \mathbb{G}_m$ be the center. We recall that we have an isomorphism $\pi_1(G) \simeq X_*(Z(G)) \simeq \mathbb{Z}$ and that the $\kappa$-invariant of $b$ is sent to the element $1 \in \mathbb{Z}$ under this isomorphism. This indexes the identity representation of $\mathbb{G}_m$, denoted $id_{\mathbb{G}_m}$. Thus, given a discrete parameter (= supercuspidal or mixed supercuspidal) $\phi : W_L \times \text{SL}_2(\mathbb{C}) \to \text{GSp}_4(\mathbb{C})$, the refined local Langlands correspondence asserts bijections

$$\Pi_\phi(G) \longleftrightarrow \{\text{irreducible algebraic representations } \tau \text{ of } S_\phi \text{ s.t } \tau|_{Z(G)} = 1\}$$

$$\pi \mapsto \tau_\pi$$

$$\Pi_\phi(J) \longleftrightarrow \{\text{irreducible algebraic representations } \tau \text{ of } S_\phi \text{ s.t } \tau|_{Z(G)} = id_{\mathbb{G}_m}\}$$

$$\rho \mapsto \tau_\rho$$

where $1$ is the trivial representation. In section 2.1, we saw how for $\pi \in \Pi_\phi(G)$ to construct the desired $\tau_\pi$. Here it is uniquely pinned down by the property that the trivial representation corresponds to the unique $\mathfrak{m}$-generic representation. In the case of the inner form, the situation is a bit more tricky. Consider $\rho \in \Pi(J)$ with associated $L$-parameter $\phi_\rho$. If $\phi_\rho$ is stable then $S_\phi = \mathbb{G}_m$ and $\tau_\rho$ is simply $id_{\mathbb{G}_m}$. If $\phi$ is endoscopic, then, as noted in section 2.1, we have an inclusion:

$$Z(\text{GSp}_4)(\mathbb{C}) = \mathbb{C}^* \xrightarrow{\Delta} S_\phi \simeq \{(a, b) \in \mathbb{C}^* \times \mathbb{C}^* | a^2 = b^2\}$$

We consider the characters $\tau_i : S_\phi \to \mathbb{C}^*$ for $i = 1, 2$ given by projecting to the first and second coordinate. These satisfy the property that $\tau_{i}|_{\mathbb{C}^*} = id_{\mathbb{C}^*}$ on the diagonally embedded center as desired. Similarly, under the parametrization of Gan-Tantono $\Pi_\phi(J) = \{\rho_+, \rho_-\}$, where $\rho_+$ and
\( \rho_{-+} \) correspond to the characters \( \eta_{-+} \) and \( \eta_{+-} \) described above. Specifically, if \( \pi_1 \) and \( \pi_2 \) are the unique discrete series representations of \( \text{GL}_2(L) \) in the \( L \)-packet over \( \phi_1 \) and \( \phi_2 \) then

\[
\rho_{-+} := \theta(JL^{-1}(\tau_2) \boxtimes \tau_1) \quad \text{and} \quad \rho_{+-} := \theta(JL^{-1}(\tau_1) \boxtimes \tau_2)
\]

where \( \theta \) denotes the non-zero local theta lift from \( D^* \times \text{GL}_2(F) \) to \( \text{GU}_2(D) \), as \( \text{GT14} \) Proposition 5.4, and \( JL : \Pi(D^*) \to \Pi(\text{GL}_2) \) is the Jacquet-Langlands correspondence. Now we would like to match these two representations with \( \tau_1 \) and \( \tau_2 \) under the refined local Langlands of Kaletha. Suppose we fix such a matching. Now, we consider a refined endoscopic datum \( \epsilon \) for the quasi-split reductive group \( G \), which we recall is a tuple \((H, s, \mathcal{H}, \eta)\) which consists of

- a quasi-split group \( H \) over \( F \),
- an extension \( \mathcal{H} \) of \( W_F \) by \( \hat{H} \) such that the map \( W_F \to \text{Out}(\hat{H}) \) coincides with the map \( \rho_H : W_F \to \text{Out}(\hat{H}) \) induced by the action of \( W_F \) on \( H \subset L H \),
- an element \( s \in Z(\hat{H})^\Gamma \),
- an \( L \)-homomorphism \( \eta : \mathcal{H} \to L G \),

satisfying the condition:

- we have \( \eta(\hat{H}) = Z_{\hat{G}}(s)^\circ \).

Considering \( J \) as the \( \sigma \)-centralizer of the unique basic element \( b_1 \in B(G) \) of the Kottwitz invariant 1, this defines for us an extended pure inner twisting of \( (\xi, b) : G \to J_b \) in the sense of \( \text{Kot97} \) Section 5.2, and we can attach a canonical transfer factor \( \Delta[m, \epsilon, b_1] \) to this datum, as defined in \( \text{K16} \) Section 4.1. Given a test function \( f \in C_c^\infty(J(\mathbb{Q}_p), \mathfrak{g}_\ell) \), we can use these transfer factors to say what it means for \( f^\epsilon \in C_c^\infty(\mathcal{H}(\mathbb{Q}_p), \mathfrak{g}_\ell) \) to be matching in the sense that their stable orbital integrals normalized with respect to these transfer factors match up.

Now, suppose we have a discrete parameter \( \phi \in \Phi(J) \) and a refined endoscopic datum \( \epsilon \), such that \( \phi = \eta \circ \phi^\epsilon \) as conjugacy classes of parameters for an \( L \)-parameter \( \phi^\epsilon : W_L \times \text{SL}(2, \mathbb{Q}_p) \to \mathcal{H} \). Then the matching is uniquely described using the endoscopic character identities. This assert an equality

\[
\Theta_{\phi^\epsilon}^1(f^\epsilon) = \sum_{\pi \in \Pi^\epsilon(J)} \text{tr}(1|\tau_\pi)\theta_\pi(f^\epsilon) = e(J) \sum_{\rho \in \Pi_\rho(J)} \text{tr}(s|\tau_\rho)\theta_\pi(f) = \Theta_{\phi^\epsilon}\ast(f)
\]

where \( e(J) = -1 \) is the Kottwitz sign of \( J \), as defined in \( \text{Kot83} \) and \( \theta_\pi \) denotes the Harish-Chandra character of \( \pi \). Using the linear independence of the distributions \( \Theta_\pi \) and the fact that the packets \( \Pi_\rho(J) \) are disjoint, we can see that the matching between \( \rho \mapsto \tau_\rho \) is uniquely characterized by these relations. To show that there exists a matching between the representations \( \tau_1 \) and \( \tau_2 \) and \( \rho_{-+} \) and \( \rho_{+-} \), we need to show that these identities are satisfied under the parametrization of Gan-Takeda-Tantono. This will follow from the endoscopic character identities verified by Chan-Gan \( \text{CG15} \). Namely, in the case that the parameter \( \phi \) is stable, one only needs to consider the trivial endoscopic datum \( \epsilon_{\text{triv}} = (G, 1, LG, \text{id}) \), and these identities follow from \( \text{CG15} \) Proposition 11.1 (1)]. In the case that the parameter \( \phi \) is endoscopic, the case \( \epsilon_{\text{triv}} = (G, 1, LG, \text{id}) \) follows from \( \text{CG15} \) Proposition 11.1 (1)], but one also needs to consider the refined endoscopic datum given by \( \epsilon = (\text{SO}_{2,2}, (1, -1), \text{GSpin}_4, i : \text{GSpin}_4 \to \text{GSpin}_5 \simeq \text{GSp}_4) \), where \( i \) is the map from before and \((1, -1) \in S_\phi \subset (\text{GL}_2(\mathbb{C}) \times \text{GL}_2(\mathbb{C}) \). In this case, the identities (up to a sign) follow from combining \( \text{CG15} \) Proposition 11.1 (1)] as before and \( \text{CG15} \) Proposition 11.1 (2)], where we note that since \( \tau_1 \) and \( \tau_2 \) are by definition two projections their traces against \((-1, 1)\) have the opposite sign, which is consistent with \( \text{CG15} \) Proposition 11.1 (2)]. This shows the refined local Langlands correspondence of Kaletha holds for the group \( G \); however, in order to describe the exact matching between \( \rho_{-+} \) and \( \rho_{+-} \) with \( \tau_1 \) and \( \tau_2 \) one needs to exactly compare the signs of the ad-hoc transfer factors fixed in the statement of \( \text{CG15} \) Proposition 11.1 (2)] with the canonical ones \( \Delta(m, c, b_1) \) constructed by Kaletha. The above argument only shows that there is some matching; nonetheless,
for our purposes the choice ends up being irrelevant, so we denote the representations in the $L$-packet $\Pi_\phi(J)$ corresponding to the projections $\tau_1$ and $\tau_2$ by $\rho_1$ and $\rho_2$, respectively. Similarly, for the representations obtained by pre-composing a character with the composition

$$S_\phi \to A_\phi$$

we denote the elements of the $L$-packet $\Pi_\phi(G)$ corresponding to the trivial (non-trivial) character of $A_\phi$ by $\pi^+$ (resp. $\pi^-$). We note that, by Theorem 2.1 (2), $\pi^+$ can be characterized by the unique $m$-generic representation of this $L$-packet.

**Definition 2.3.** Given a supercuspidal or mixed supercuspidal $L$-parameter $\phi$ as above and $\rho \in \Pi_\phi(J)$, we let $\tau_\rho$ be the irreducible representation of $S_\phi$ associated to it via the matching described above. Given $\pi \in \Pi_\phi(G)$ and $\rho \in \Pi_\phi(J)$, we set

$$\delta_{\pi, \rho} := \tau_\pi \otimes \tau_\rho$$

where $\tau_\pi^\vee$ denotes the contragredient.

**Remark 2.3.** Changing the choice of Whittaker datum scales the representations by a 1-dimensional character of $S_\phi$ that is trivial when restricted to the center, so in particular this pairing is independent of the choice of Whittaker datum (See [HKW21, Lemma 2.3.3]).

3. THE FARGUES-SCHOLZE LOCAL LANGLANDS CORRESPONDENCE

We will now discuss the Fargues-Scholze local Langlands correspondence and deduce compatibility in the cases where the Gan-Takeda/Gan-Tantono parameter is not supercuspidal. We will then conclude by reducing the question of compatibility in the supercuspidal case to Proposition 1.4.

3.1. Overview of the Fargues-Scholze Local Langlands Correspondence. For now, let $G$ be any connected reductive group over $\mathbb{Q}_p$. Since we are going to be using geometric Satake, we fix a choice of the square root of $p$ in $\overline{\mathbb{Q}}_\ell$, so that half Tate-twists are well-defined. For us, we will always take $i^{-1}(\sqrt{p})$, where $i : \overline{\mathbb{Q}}_\ell \cong \mathbb{C}$ is the fixed isomorphism. Fargues-Scholze [FS21] consider the moduli space of $G$-bundles on the Fargues-Fontaine curve $X$, denoted $\text{Bun}_G$. This moduli space is an Artin $v$-stack (in the sense of [FS21, Section IV.1]) and has the structure that the underlying points of its topological space $\text{Bun}_G$ are in natural bijection with elements of the Kottwitz set $B(G)$, where the slopes of the $G$-isocrystal associated to $b \in B(G)$ are the negatives of the slopes of the associated vector bundle $E_b$ and the specializations between points of $|\text{Bun}_G|$ is dictated by the partial ordering on $B(G)$ induced by the kappa invariant and the slope homomorphism $[\text{Vie21}]$. In particular, the connected components of $\text{Bun}_G$ are in bijection with $B(G)_{\text{basic}} \cong \pi_1(G)_\Gamma$. Specifically, for any $b \in B(G)_{\text{basic}}$, there is a unique open Harder-Narasimhan strata $\text{Bun}_G^b \subset \text{Bun}_G$ dense inside the associated connected component. We recall that the elements of $B(G)_{\text{basic}}$ parametrize extended pure inner forms of $G$, via sending an element $b \in B(G)_{\text{basic}}$ to its $\sigma$-centralizer $J_b/\mathbb{Q}_p$. For such a basic $b$, we have an identification $\text{Bun}_G^b \cong [*/J_b(\mathbb{Q}_p)] =: J_b(\mathbb{Q}_p)$ of the HN-strata defined by $b$ and the classifying stack of $J_b(\mathbb{Q}_p)$. For any Artin $v$-stack $Z$, Fargues-Scholze define a triangulated category $D_{\bullet}(Z, \overline{\mathbb{Q}}_\ell)$ of solid $\overline{\mathbb{Q}}_\ell$-sheaves [FS21, Section VII.1] and isolate a nice full subcategory $D_{\text{lis}}(Z, \overline{\mathbb{Q}}_\ell) \subset D_{\bullet}(Z, \overline{\mathbb{Q}}_\ell)$ of étale-lisse $\overline{\mathbb{Q}}_\ell$-sheaves [FS21, Section VII.6], which may be roughly thought of as the unbounded derived category of étale $\overline{\mathbb{Q}}_\ell$-sheaves on $Z$, where one has made an enlargement to capture information about the topology of $p$-adic groups. In any case, the key point for us is that we have the following basic result.

**Lemma 3.1.** [FS21, Proposition VII.7.1] There is an equivalence of categories

$$D_{\text{lis}}(J_b(\mathbb{Q}_p), \overline{\mathbb{Q}}_\ell) \simeq D(J_b(\mathbb{Q}_p), \overline{\mathbb{Q}}_\ell)$$

where the RHS denotes unbounded derived category of smooth $J_b(\mathbb{Q}_p)$-representations with coefficients in $\overline{\mathbb{Q}}_\ell$. Under this equivalence, Verdier duality corresponds to smooth duality.
Remark 3.1. The main reason for constructing this category $D_{lis}$ is that, if one were to take the usual definition for the category of étale $\mathbb{Q}_\ell$-sheaves on $BJ_b(\mathbb{Q}_p)$, this equivalence would no longer be true. In particular, one would obtain the bounded derived category of representations of $J_b(\mathbb{Q}_p)$ admitting a $J_b(\mathbb{Q}_p)$-stable $\mathbb{Z}_\ell$-lattice, where the representation is continuous with respect to the $\ell$-adic topology on the target. This would limit the scope of the Fargues-Scholze LLC as, in general, one wants to consider smooth $\mathbb{Q}_\ell$-representations of $J_b(\mathbb{Q}_p)$, and hence the need for the enlargement of the derived category to $D_{lis}$.

Lemma 3.1 tells us that, given an irreducible smooth representation $\pi$ of $G(\mathbb{Q}_p)$, we can consider the associated sheaf, denoted $F_{\pi}$, on $Bun_G^1$ the open HN-strata corresponding to the trivial element $1 \in B(G)$, and take the extension by zero along the open inclusion $j(F_{\pi})\subset$. This realizes the representation $\pi$ in terms of a sheaf on the moduli space $Bun_G$ in an analogous way to how the function-sheaf dictionary realizes cuspidal automorphic forms as functions associated to sheaves in the context of curves over finite fields. Following V. Lafforgue [Laf18], Fargues and Scholze construct a semisimple $L$-parameter associated to this sheaf by looking at the action of the excursion algebra on this category $D_{lis}(Bun_G, \overline{\mathbb{Q}}_\ell)$. This relies on a form of the geometric Satake correspondence for the $B_{dR}$-affine Grassmannians. For any finite set $I$, let $X^I$ be the product of $I$-copies of the diamond $X = \text{Spd}(\mathbb{Q}_p)/\text{Frob}\mathbb{Z}$. We then have the Hecke stack

$$
\xymatrix{ \text{Hck} \ar[rd]_{h^\rightarrow \times \text{supp}} & \ar[l]_{h^\leftarrow} \text{Bun}_G \times X^I \\
\text{Bun}_G }$

defined as the functor that parametrizes, for $S$ a perfectoid space in characteristic $p$ together with a map $S \to X^I$ defining a tuple of Cartier divisors in the relative Fargues-Fontaine $X_S$ over $S$, corresponding to characteristic 0 untilts $S^i_I$ for $i \in I$ of $S$, a pair of $G$-torsors $E_1$, $E_2$ together with an isomorphism

$$
\beta : E_1|_{X_S \setminus \cup_{i \in I} S^i_I} \cong E_2|_{X_S \setminus \cup_{i \in I} S^i_I}
$$

where $h^\leftarrow((E_1, E_2, i, (S^i_I)_{i \in I})) = E_1$ and $h^\rightarrow \times \text{supp}((E_1, E_2, \beta, (S^i_I)_{i \in I})) = (E_2, (S^i_I)_{i \in I})$. We set $L^G$ to be $I$-copies of the Langlands dual group of $G$, i.e $L^G = Q \ltimes \hat{G}(\overline{\mathbb{Q}_p})$, where $\hat{G}$ is the reductive group having dual root datum to $G$ and is viewed as a reductive group over $\overline{\mathbb{Q}_p}$. The Weil group acts on $\hat{G}$ via the induced action on root datum through some finite quotient $Q$, which we now fix. Let $\text{Rep}_{\overline{\mathbb{Q}}_p}(L^G)$ denote the category of algebraic $\overline{\mathbb{Q}}_p$-representations of $I$-copies of $L^G$. For each element $W \in \text{Rep}_{\overline{\mathbb{Q}}_p}(L^G)$, the geometric Satake correspondence of Fargues-Scholze [FS21] Chapter VI furnishes a solid $\overline{\mathbb{Q}}_p$-sheaf $S_W$ on Hck. This allows us to define Hecke operators.

Definition 3.1. For each $W \in \text{Rep}_{\overline{\mathbb{Q}}_p}(L^G)$, we define the Hecke operator

$$
T_W : D_{lis}(\text{Bun}_G, \overline{\mathbb{Q}}_\ell) \to D_{lis}(\text{Bun}_G \times X^I)
$$

$$
A \mapsto R(h^\rightarrow \times \text{supp})_!(h^\leftarrow )^!(A) \otimes^L S_W
$$

where $S_W$ is a solid $\overline{\mathbb{Q}}_\ell$-sheaf and the functor $R(h^\rightarrow \times \text{supp})_!$ is the natural push-forward. I.e the left adjoint to the restriction functor in the category of solid $\overline{\mathbb{Q}}_\ell$-sheaves [FS21] Proposition VII.3.1.

Remark 3.2. These satisfy various compatibilities with respect to composition and restriction to the diagonal. In particular, given two representations $V, W \in \text{Rep}_{\overline{\mathbb{Q}}_p}(L^G)$, we have that

$$
(T_V \times id)(T_W)(\cdot)|_\Delta \simeq T_{V \otimes W} (\cdot)
$$

\(^2\)The shriek push-forward is not in general well-defined in the context of solid $\overline{\mathbb{Q}}_\ell$-sheaves. However, for the inclusion of HN-strata into Bun$_G$, its existence follows from [FS21] Proposition VII.7.3, using [FS21] Proposition VII.6.7.
where $\Delta : X \to X^2$ is the diagonal map.

We then consider $D_{\text{lis}}(\text{Bun}_G, \overline{\mathbb{Q}}_\ell)^{BW^I_{\mathcal{Q}_p}}$, the category of objects in $D_{\text{lis}}(\text{Bun}_G, \overline{\mathbb{Q}}_\ell)$ with continuous action by $W^I_{\mathcal{Q}_p}$. Examples of objects in this category are objects of $D_{\text{lis}}(\text{Bun}_G, \overline{\mathbb{Q}}_\ell)$ tensored by a continuous representation of $W^I_{\mathcal{Q}_p}$, for a more precise description see [FS21, Section IX.1]. With this in hand, we then have the following theorem of Fargues-Scholze.

**Theorem 3.2.** [FS21, Theorem I.7.2, Proposition IX.2.1, Corollary IX.2.3] The Hecke operator $T_W$ for $W \in \text{Rep}_{\mathbb{Q}_p}(^L G^I)$ induces a functor

$$D_{\text{lis}}(\text{Bun}_G, \overline{\mathbb{Q}}_\ell) \to D_{\text{lis}}(\text{Bun}_G, \overline{\mathbb{Q}}_\ell)^{BW^I_{\mathcal{Q}_p}}$$

and the induced endofunctors of $D_{\text{lis}}(\text{Bun}_G, \overline{\mathbb{Q}}_\ell)$ given by forgetting the Weil group action preserve compact and ULA objects.

**Remark 3.3.** This should be thought of as a manifestation of Drinfeld’s Lemma, where (roughly) the étale fundamental group of $\text{Spd}(\mathbb{Q}_p)/\text{Frob}^2 = X$ should be the same as $W_{\mathcal{Q}_p}$.

From now on, when talking about Hecke operators we shall always refer to this induced functor, which we will also abusively denote by $T_W$. Theorem 3.2 has direct implications for the cohomology of local Shimura varieties. To study this, consider a minuscule cocharacter $\mu$ with field of definition $E$, and let $b \in B(G, \mu)$ be the unique basic element in the $\mu$-admissible locus (See [RV14, Definition 2.3]). We say that the triple $(G, b, \mu)$ defines a local Shimura datum in the sense of Rapoport-Viehmann [RV14]. Attached to such a data, Scholze-Weinstein [SW20] construct a tower of diamonds

$$p_K : (\text{Sh}(G, b, \mu)_K)_{K \subset G(\mathbb{Q}_p)} \to \text{Spd}(\widetilde{E})$$

for varying open compact $K \subset G(\mathbb{Q}_p)$. This is obtained by considering the space $\text{Sh}(G, b, \mu)_{\infty}$ which parametrizes modifications $\mathcal{E}_b \to \mathcal{E}_0$ with meromorphy bounded by $\mu$, where $\mathcal{E}_b$ (resp. $\mathcal{E}_0$) is the bundle corresponding to $b \in B(G)$ (resp. the trivial bundle) on the Fargues-Fontaine curve. It has commuting actions by $G(\mathbb{Q}_p)$ and $J_b(\mathbb{Q}_p)$ given by acting via automorphisms on $\mathcal{E}_0$ and $\mathcal{E}_b$, respectively. The tower is then given by considering the quotients of this space for varying open compact $K \subset G(\mathbb{Q}_p)$ under the action of $G(\mathbb{Q}_p)$.

**Definition 3.2.** Let $\text{Sh}(G, b, \mu)_{K, \mathbb{Q}_p}$ be the base-change of the above tower to $\mathbb{Q}_p$. We define the complex

$$R\Gamma_c(G, b, \mu) := \text{colim}_{K \to 1} R\Gamma_c(\text{Sh}(G, b, \mu)_{K, \mathbb{Q}_p}, \overline{\mathbb{Q}}_\ell)$$

a colimit of smooth $W_E \times J_b(\mathbb{Q}_p)$-modules with a $G(\mathbb{Q}_p)$-action, where $W_E$ is the Weil group of $E$. A priori it only has an action by the inertia group, but this space admits a non-effective Frobenius descent datum. We then define, for $\rho$ a smooth admissible $J_b(\mathbb{Q}_p)$-representation, the complex

$$R\Gamma_c(G, b, \mu)[\rho] := R\Gamma_c(G, b, \mu) \otimes \mathbb{H}(J_b)^\vee \rho$$

where $\mathbb{H}(J_b)$ is the usual smooth Hecke algebra. We also define

$$R\Gamma_c^b(G, b, \mu)[\rho] := \text{colim}_{K \to 1} \text{RHom}_{J_b(\mathbb{Q}_p)}(R\Gamma_c(G, b, \mu)_K, \rho)[-2d][-d]$$

Similarly, for $\pi$ a smooth admissible $G(\mathbb{Q}_p)$-representation, we define $R\Gamma_c(G, b, \mu)[\pi]$ and $R\Gamma_c^b(G, b, \mu)[\pi]$.

**Remark 3.4.** We note that, by Hom-Tensor duality, $\text{RHom}(R\Gamma_c(G, b, \mu)[\rho], \overline{\mathbb{Q}}_\ell)[-2d][-d]$ is isomorphic to $R\Gamma_c^b(G, b, \mu)[\rho^\vee]$, where $\rho^\vee$ is the contragredient. We will end up using both of these cohomology groups throughout this manuscript. The former is more natural from the point of view of basic uniformization, while the latter is disposable to the results of Hansen-Kaletha-Weinstein [HKW21] on the Kottwitz conjecture.
To study these complexes, we specialize the above discussion of Hecke operators to the case where \( W = V_{\mu^{-1}} \) is specified by the highest weight representation of highest weight \( \mu^{-1} \) a dominant inverse of \( \mu \) and \( I = \{ * \} \) is a singleton. The sheaf \( S_W \) will then be supported on the closed subspace \( Hck_{\leq \mu^{-1}} = Hck_{\mu^{-1}} \) of \( Hck \), parametrizing modifications with meromorphy bounded by or equal to \( \mu^{-1} \), where the equality follows by the minuscule assumption. The space \( Hck_{\mu^{-1}} \) is cohomologically smooth of dimension \( d := (2\rho_G, \mu) \), and the sheaf \( S_W \), as in the geometric Satake correspondence of [MV07], behaves like the intersection cohomology of this space, so we have \( S_W \simeq \mathbb{Q}[d](\frac{d}{2}) \). This implies that, to study the action of the Hecke operator \( T_W \) on \( Bun_G \), we can look at the restriction of the diagram defining the Hecke correspondence to this subspace

\[
\begin{array}{ccc}
Hck_{\mu^{-1}} & \xrightarrow{h_{\mu^{-1}} - \supp} & Bun_G \\
\downarrow & & \downarrow \\
h_{h_{\mu^{-1}} - \supp} & & Bun_G \times \Spd(\hat{E})/\text{Frob}^Z
\end{array}
\]

In particular, we have an isomorphism:

\[
T_{\mu^{-1}}(A) := T_W(A) \simeq R(h_{\mu^{-1}} - \supp)_{\mu} (h_{h_{\mu^{-1}} - \supp}(A))[d](\frac{d}{2})
\]

Now consider a smooth admissible representation \( \pi \) of \( G(\mathbb{Q}_p) \) and apply the Hecke operator to the sheaf:

\[
j_!(\mathcal{F}_\pi)
\]

Then the fiber of \( Hck_{\mu^{-1}} \) of \( h_{\mu^{-1}} - \supp \) over \( Bun_G^1 \) is identified with

\[
[Gr_{G,\mu^{-1}}/G(\mathbb{Q}_p)]
\]

the Schubert cell/variety associated to \( \mu^{-1} \) in the \( B_{dR}^+ \)-affine Grassmannian, quotiented out by \( G(\mathbb{Q}_p) \) acting on the trivial bundle via automorphisms. The sheaf

\[
\mathcal{T}_{\mu^{-1}} j_!(\mathcal{F}_\pi)
\]

is then supported on the HN-strata given by the Kottwitz elements in \( B(G, \mu) \) since, by [Rap18, Proposition A.9], any \( G \)-bundle occurring as a modification of type \( \mu^{-1} \) of the trivial bundle has associated Kottwitz element lying in this set. We then consider the restriction

\[
j_b^* \mathcal{T}_{\mu^{-1}} j_!(\mathcal{F}_\pi) \in \mathcal{D}(J_b(\mathbb{Q}_p), \mathcal{O}_X)\text{BMW}
\]

where \( j_b : Bun_G^b \rightarrow Bun_G \) is the inclusion of the open HN-strata defined by \( b \). The complex \( j_b^* \mathcal{T}_{\mu^{-1}} j_!(\mathcal{F}_\pi) \) will be computed in terms of the cohomology of sheaves supported on the Newton strata

\[
[Gr_{G,\mu^{-1}}^b/G(\mathbb{Q}_p)]
\]

parametrizing modifications of type \( \mu^{-1} \) of the trivial bundle such that the resulting bundle has associated Kottwitz element of type \( b \) after pulling back to each geometric point, modulo automorphisms of the trivial bundle. The space \( \text{Sht}(G, b, \mu)_\infty \) defined above is a pro-étale \( J_b(\mathbb{Q}_p) \)-torsor with respect to the \( J_b(\mathbb{Q}_p) \)-action by automorphisms of \( E_b \)

\[
\text{Sht}(G, b, \mu)_\infty \rightarrow Gr_{G,\mu^{-1}}^b
\]

over this Newton strata. Using this description of the infinite level Shimura variety, it then follows from base change and the fact that the sheaves \( S_W \) are ULA over \( X \) (See [FS21, Chapter IX.3] for details) that we have an isomorphism

\[
R\Gamma_c(G, b, \mu)[\pi][d](\frac{d}{2}) \simeq j_b^* \mathcal{T}_{\mu^{-1}} j_!(\mathcal{F}_\pi) \in \mathcal{D}(J_b(\mathbb{Q}_p), \mathcal{O}_X)\text{BMW}
\]
of $J_b(\mathbb{Q}_p) \times W_E$-modules. For our purposes, it will also be useful to have a description of the $\rho$-isotypic part of this cohomology in terms of Hecke operators, for $\rho$ a smooth irreducible representation of $J_b(\mathbb{Q}_p)$. In particular, analysis similar to the above gives us an isomorphism

$$RT_c(G, b, \mu)[\rho][d](\frac{d}{2}) \cong j_\mu^*j_b!_!(\mathcal{F}_\rho)$$

as $G(\mathbb{Q}_p) \times W_E$-modules. We record these two isomorphisms as a corollary of the above discussion.

**Corollary 3.3.** Given a local Shimura datum $(G, b, \mu)$ as above and $\pi$ (resp. $\rho$) a smooth irreducible representation of $G(\mathbb{Q}_p)$ (resp. $J_b(\mathbb{Q}_p)$). There exists an isomorphism

$$RT_c(G, b, \mu)[\pi][d](\frac{d}{2}) \cong j_\mu^*j_b^!(\mathcal{F}_\pi)$$

of complexes of $G(\mathbb{Q}_p) \times W_E$-modules and an isomorphism

$$RT_c(G, b, \mu)[\pi][d](\frac{d}{2}) \cong j_\mu^*j_b^!(\mathcal{F}_\pi)$$

of complexes of $J_b(\mathbb{Q}_p) \times W_E$-modules.

We have the following basic structural result which, in more generality, follows from the analysis in Fargues-Scholze, but, in the case of a local Shimura datum, also partially follows from standard finiteness results for rigid spaces (See RV14, Section 6). In particular, one can show the following.

**Theorem 3.4.** [FS21] Corollary I.7.3, Page 317] For a local Shimura datum $(G, b, \mu)$ as above, the cohomology groups of $RT_c(G, b, \mu)[\rho]$ and $RT_c(G, b, \mu)[\rho]$ are valued in smooth admissible $G(\mathbb{Q}_p)$-representations of finite length with an action of $W_E$. Moreover, they are concentrated in degrees $0 \leq i \leq 2d$.

**Remark 3.5.** A sheaf $\mathcal{F} \in D_{lis}(\text{Bun}_G, \overline{Q}_\ell)$ being ULA is equivalent to its stalks at different HN-strata being valued in complexes of smooth admissible representations [FS21] Theorem V.7.1, Proposition VII.7.9], so indeed the admissibility of the above complex is a consequence of Theorem 3.2 and Corollary 3.3.

Fargues-Scholze use the endofunctors defined by the Hecke algebra on $D_{lis}(\text{Bun}_G, \overline{Q}_\ell)$ to define the excursion algebra.

**Definition 3.3.** For a finite set $I$, a representation $W \in \text{Rep}_{\overline{Q}_\ell}(^L G^I)$, maps $\alpha : \overline{Q}_\ell \to \Delta^*W$ and $\beta : \Delta^*W \to \overline{Q}_\ell$, and elements $\gamma_i \in W_{\mathbb{Q}_p}$ for $i \in I$, one defines the excursion operator on $D_{lis}(\text{Bun}_G, \overline{Q}_\ell)$ to be the composition:

$$id = T_{\overline{Q}_\ell} \xrightarrow{\alpha} T_{\Delta^*W} = T_W \xrightarrow{(\gamma_i)_{i \in I}} T_W = T_{\Delta^*W} \xrightarrow{\beta} T_{\overline{Q}_\ell} = id$$

where $\Delta^*(W)$ is the precomposition of $W$ with the diagonal embedding $^L G \to ^L G^I$.

This defines a natural endomorphism of the identity functor on $D_{lis}(\text{Bun}_G, \overline{Q}_\ell)$. If one looks at the induced endofunctor given by the inclusion $D(G(\mathbb{Q}_p), \overline{Q}_\ell) \subset D_{lis}(\text{Bun}_G, \overline{Q}_\ell)$ induced by the open immersion $j : \text{Bun}_G^1 \hookrightarrow \text{Bun}_G$ then one obtains a natural endomorphism of the identity functor on $D(G(\mathbb{Q}_p), \overline{Q}_\ell)$. In other words, we get a family of compatible endomorphisms for all complexes of smooth representations of $G(\mathbb{Q}_p)$; namely, an element of the Bernstein center. One can verify that this excursion algebra satisfies similar properties to that considered by V. Lafforgue, so, using Lafforgue’s reconstruction theorem [Laf18] Proposition 11.7, one can show the following.

**Theorem 3.5.** To an irreducible smooth $\overline{Q}_\ell$-representation $\pi$ of $G(\mathbb{Q}_p)$ (or more generally $A \in D_{lis}(\text{Bun}_G, \overline{Q}_\ell)$ any Schur-irreducible object (i.e End$(A) = \overline{Q}_\ell$)), there is a unique continuous semisimple map

$$\phi^{FS}_\pi : W_{\mathbb{Q}_p} \to ^L G(\overline{Q}_\ell)$$
characterized by the property that for all $I, W, \alpha, \beta$, and $\gamma_i \in W_{Q_p}$ for $i \in I$, the corresponding endomorphism of $\pi$ defined above is given by multiplication by the scalar that results from the composite

$$
\mathcal{U}_\ell \xrightarrow{\alpha \Delta} \Delta^* W = W \xrightarrow{(\phi_\pi(\gamma_i))_{i \in I}} W = \Delta^* W \xrightarrow{\beta} \mathcal{U}_\ell
$$

By further studying the geometry of $\text{Bun}_G$ and the Hecke stacks, one can deduce various good properties of this correspondence.

**Theorem 3.6.** [FS21, Theorem I.9.6] The mapping defined above

$$
\pi \mapsto \phi^\text{FS}_\pi
$$

enjoys the following properties:

1. **(Compatibility with Local Class Field Theory)** If $G = T$ is a torus, then $\pi \mapsto \phi_\pi$ is the usual local Langlands correspondence.
2. **The correspondence is compatible with character twists, passage to contragredients, and central characters.**
3. **(Compatibility with products)** Given two irreducible representations $\pi_1$ and $\pi_2$ of two connected reductive groups $G_1$ and $G_2$ over $Q_p$, respectively. We have

$$
\pi_1 \boxtimes \pi_2 \mapsto \phi^\text{FS}_{\pi_1} \times \phi^\text{FS}_{\pi_2}
$$

under the Fargues-Scholze local Langlands correspondence for $G_1 \times G_2$.
4. **(Compatibility with parabolic induction)** Given a parabolic subgroup $P \subset G$ with Levi factor $M$ and a representation $\pi_M$ of $M$, then the semisimple $L$-parameter corresponding to any sub-quotient of $\text{ind}_P^G(\pi_M)$ the (normalized) parabolic induction is the composition

$$
W_{Q_p} \xrightarrow{\phi^\text{FS}_M} L^M(\mathcal{U}_\ell) \xrightarrow{L} G(\mathcal{U}_\ell)
$$

where the map $L^M(\mathcal{U}_\ell) \to L^G(\mathcal{U}_\ell)$ is the natural embedding.
5. **(Compatibility with Harris-Taylor/Henniart LLC)** For $G = \text{GL}_n$ or an inner form of $G$ the semisimple $L$-parameter associated to $\pi$ is the (semi-simplified) parameter $\phi^\text{ss}_\pi$. associated to $\pi$ by Harris-Taylor/Henniart.
6. **(Compatibility with Restriction of Scalars)** The above story works the same for $G'$ a connected reductive group over any finite extension $E'/Q_p$, where one then gets a semisimple $L$-parameter valued on $W_{E'}$. If $G = \text{Res}_{E'/Q_p} G'$ is the Weil restriction of some $G'/E'$ then $L$-parameters for $G/Q_p$ agree with $L$-parameters for $G'/E'$ in the usual sense.
7. **(Compatibility with Isogenies)** If $G' \to G$ is a map of reductive groups inducing an isomorphism of adjoint groups, $\pi$ is an irreducible smooth representation of $G(E)$ and $\pi'$ is an irreducible constituent of $\pi|_{G'(E)}$ then $\phi_{\pi'}$ is the image of $\phi_\pi$ under the induced map $\hat{G} \to \hat{G}'$.

**Remark 3.6.** In (5), the compatibility of the Fargues-Scholze local Langlands correspondence with the Harris-Taylor/Henniart local Langlands correspondence for an arbitrary inner form of $\text{GL}_n$ is not included in the paper of Fargues-Scholze [FS21]. However, it follows from the work of Hansen-Kaletha-Weinstein on the Kottwitz conjecture [HKW21, Theorem 1.0.3].

### 3.2. The Spectral Action

With these basic structural properties out of the way, we turn our attention to the "spectral action" on $\text{Bun}_G(\mathcal{U}_\ell)$, which will be very important to proving compatibility of the two correspondences in the case where the parameter is supercuspidal, as well as deducing applications to the Kottwitz conjecture. We recall that an $L$-parameter over $\mathcal{U}_\ell$ can be thought of as a continuous (not necessarily semisimple) homomorphism

$$
\phi : W_{Q_p} \to L^G(\mathcal{U}_\ell)
$$

commuting with the natural projection to $Q$. One can use the classical construction of Grothendieck-Deligne to see that this coincides with the definition given in section 2 for $\text{GSp}_4$ after applying...
the isomorphism $i$, where the monodromy operation is recovered through the exponential of the action of $W_{Q_p}$ on the $\ell$-power roots of unity, and assuming Frobenius semi-simplicity of $\phi$. Such a continuous map can be thought of as a continuous 1-cocycle $W_{Q_p} \to \hat{G}(\overline{\mathbb{Q}_\ell})$, with respect to the action of $W_{Q_p}$ on $\hat{G}(\overline{\mathbb{Q}_\ell})$. If we let $A/\mathbb{Z}_\ell$ be any $\mathbb{Z}_\ell$-algebra endowed with a topology given by writing $A = \operatorname{colim}_A A'$, where $A'$ is a finitely generated $\mathbb{Z}_\ell$-module with its $\ell$-adic topology, then we can defined a moduli space, denoted $Z^1(W_{Q_p}, \hat{G})$, over $\mathbb{Z}_\ell$, whose $A$-points are the continuous 1-cocycles $W_{Q_p} \to \hat{G}(A)$ with respect to the natural action of $W_{Q_p}$ on $\hat{G}(A)$. This defines a scheme considered in [Dat+20] and [Zhu20] which, by [FS21, Theorem I.9.1], can be written as a union of open and closed affine subschemes $Z^1(W_{Q_p}/P, \hat{G})$ as $P$ runs through subgroups of wild inertia of $W_E$, where each $Z^1(W_{Q_p}/P, \hat{G})$ is a flat local complete intersection over $\mathbb{Z}_\ell$ of dimension $\dim(G)$. This allows us to consider the Artin stack quotient $[Z^1(W_{Q_p}, \hat{G})/\hat{G}]$, where $\hat{G}$ acts via conjugation. We then consider the base change to $\overline{\mathbb{Q}_\ell}$, denoted $[Z^1(W_{Q_p}, \hat{G})_{\overline{\mathbb{Q}_\ell}}/\hat{G}]$ and referred to as the stack of Langlands parameters, as well as the category $\operatorname{Perf}(Z^1(W_{Q_p}, \hat{G})_{\overline{\mathbb{Q}_\ell}}/\hat{G})$ of perfect complexes of coherent sheaves on this space. We let $D_{lis}(\operatorname{Bun}_G, \overline{\mathbb{Q}_\ell})^\omega$ denote the triangulated subcategory of compact objects in $D_{lis}(\operatorname{Bun}_G, \overline{\mathbb{Q}_\ell})$ (which are precisely the objects with quasi-compact support on $\operatorname{Bun}_G$ and which restrict to compact objects in $D(J_b(Q_p), \overline{\mathbb{Q}_\ell})$ for all $b \in B(G)$ by [FS21, Theorem V.4.1, Proposition VII.7.4]). We then have the key theorem of Fargues-Scholze.

**Theorem 3.7.** [FS21, Corollary X.1.3] There exists a natural compactly supported $\overline{\mathbb{Q}_\ell}$-linear action of $\operatorname{Perf}(Z^1(W_{Q_p}, \hat{G})_{\overline{\mathbb{Q}_\ell}}/\hat{G})$ on $D_{lis}(\operatorname{Bun}_G, \overline{\mathbb{Q}_\ell})^\omega$ satisfying the property that the restriction along the map

$$\operatorname{Rep}_{\overline{\mathbb{Q}_\ell}}(L(G) \to \operatorname{Perf}(Z^1(W_{Q_p}, \hat{G})_{\overline{\mathbb{Q}_\ell}}/\hat{G}))^{BW_{Q_p}}$$

induces the action of Hecke operators

$$\operatorname{Rep}_{\overline{\mathbb{Q}_\ell}}(L(G)^I \to \operatorname{End}(D_{lis}(\operatorname{Bun}_G, \overline{\mathbb{Q}_\ell})^\omega)^{BW_{Q_p}}$$

for a varying finite index set $I$.

**Remark 3.7.**

1. Here the map

$$\operatorname{Rep}_{\overline{\mathbb{Q}_\ell}}(L(G) \to \operatorname{Perf}(Z^1(W_{Q_p}, \hat{G})_{\overline{\mathbb{Q}_\ell}}/\hat{G}))^{BW_{Q_p}}$$

associates to a representation $V$, with associated map $r_V : L(G)_{\overline{\mathbb{Q}_\ell}} \to GL(V)_{\overline{\mathbb{Q}_\ell}}$ a vector bundle on $Z^1(W_{Q_p}, \hat{G})_{\overline{\mathbb{Q}_\ell}}/\hat{G}$ of rank equal to $\dim(V)$ with $W_{Q_p}$-action. This bundle, denoted $C_V$, has the property that its evaluation at a $\overline{\mathbb{Q}_\ell}$-point corresponding to a parameter $\phi : W_{Q_p} \to \hat{G}(\overline{\mathbb{Q}_\ell})$ is precisely $r_V \circ \phi$.

2. The compactly supported condition means that, for all $\mathcal{F} \in D_{lis}(\operatorname{Bun}_G, \overline{\mathbb{Q}_\ell})^\omega$, the functor $\operatorname{Perf}(Z^1(W_{Q_p}, \hat{G})_{\overline{\mathbb{Q}_\ell}}/\hat{G}) \to D_{lis}(\operatorname{Bun}_G, \overline{\mathbb{Q}_\ell})^\omega$ induced by acting on $\mathcal{F}$ factors through an action of $\operatorname{Perf}(Z^1(W_{Q_p}/P, \hat{G})_{\overline{\mathbb{Q}_\ell}}/\hat{G}))$, where $P$ is a subgroup of wild inertia. Fargues and Scholze state this action in terms of a $(\infty, 1)$-category acting on an $(\infty, 1)$-category, we suppress this technicality for simplicity. However, we note that this enhanced action has the concrete implication that if one has a morphism, cone, or homotopy limit/colimit in the derived category $\operatorname{Perf}(Z^1(W_{Q_p}, \hat{G})_{\overline{\mathbb{Q}_\ell}}/\hat{G})$ that acting on an object $\mathcal{A} \in D_{lis}(\operatorname{Bun}_G, \overline{\mathbb{Q}_\ell})^\omega$ will produce a corresponding morphism, cone, or homotopy limit/colimit.

3. In fact, Fargues-Scholze show that giving such a compactly supported $\overline{\mathbb{Q}_\ell}$-linear action is equivalent (when properly formulated) to giving a $\operatorname{Rep}_{\overline{\mathbb{Q}_\ell}}(Q)$-linear monoidal functor

$$\operatorname{Rep}_{\overline{\mathbb{Q}_\ell}}(L(G)^I) \to \operatorname{End}_{\overline{\mathbb{Q}_\ell}}(D_{lis}(\operatorname{Bun}_G, \overline{\mathbb{Q}_\ell})^\omega)^{BW_{Q_p}}$$
In the case that \( I = \{ \ast \} \), the fact that the Hecke action satisfies this monoidal property is precisely Remark 3.2.

To study this spectral action, we consider, as in \([FS21\) Section VIII.3.], the coarse quotient in the category of schemes

\[ Z^1(W_{Q_p}, \hat{G})_{\overline{W}_\ell}/\hat{G} \]

of \( Z^1(W_{Q_p}, \hat{G})_{\overline{W}_\ell} \) by the action of \( \hat{G} \) via conjugation. Given an \( L \)-parameter \( \phi : W_{Q_p} \to L G(\overline{\Q}_\ell) \), it follows by \([Dat+20\] Proposition 4.13] or \([FS21\) Proposition VIII.3.2], that the \( \hat{G} \)-orbit of \( \phi \) defines a closed \( \overline{W}_\ell \)-point of \( Z^1(W_{Q_p}, \hat{G})_{\overline{W}_\ell}/\hat{G} \) if and only if \( \phi \) is a semisimple parameter. Moreover, the natural map

\[ \pi : [Z^1(W_{Q_p}, \hat{G})_{\overline{W}_\ell}/\hat{G}] \to Z^1(W_{Q_p}, \hat{G})_{\overline{W}_\ell}/\hat{G} \]

evaluated on a \( \overline{W}_\ell \)-point in the stack quotient defined by an \( L \)-parameter \( \phi \) defines a closed \( \overline{W}_\ell \)-point in the coarse moduli space given by its semisimplification \( \phi^{ss} \). We can fit excursion operators into this picture as follows. We let \( Z^{spec}(G, \overline{W}_\ell) := O(Z^1(W_{Q_p}, \hat{G})_{\overline{W}_\ell})^{\hat{G}} \) be the ring of functions on the stack of \( L \)-parameters/the coarse moduli space, which we refer to as the spectral Bernstein center. As noted above, the excursion operators define a family of commuting endomorphisms of the identity functor on \( D_{lis}(Bun_G, \overline{W}_\ell) \). We let \( Z^{geom}(G, \overline{W}_\ell) \) be the ring of such endomorphisms as in \([FS21\) Definition IX.0.2], which we refer to as the geometric Bernstein center. In \([FS21\) Corollary IX.0.3], Fargues and Scholze construct a canonical map of rings

\[ Z^{spec}(G, \overline{W}_\ell) \to Z^{geom}(G, \overline{W}_\ell) \]

which is given by excursion operators in the following sense. By \([FS21\) Theorem VIII.3.6], there is an identification between \( Z^{spec}(G, \overline{W}_\ell) \) and the algebra of excursion operators. In particular, an excursion operator, as in Definition 3.3, associated to the datum \( (I, W, \alpha, \beta, \gamma_i) \in I \) for \( i \in I \) defines a function \( f_{I, W, \alpha, \beta, (\gamma_i) i \in I} \in O[Z^1(W_{Q_p}, \hat{G})_{\overline{W}_\ell}/\hat{G}] = Z^{spec}(G, \overline{W}_\ell) \) on \( Z^1(W_{Q_p}, \hat{G})_{\overline{W}_\ell}/\hat{G} \), whose evaluation on the closed point of the coarse moduli space associated to a semisimple parameter \( \phi : W_{Q_p} \to L G(\overline{\Q}_\ell) \) is precisely the scalar that results from the endomorphism:

\[ \overline{W}_\ell \ni \phi \mapsto \Delta^* W = W(\phi(\gamma_i)) i \in I \to W = \Delta^* W \beta \to \overline{W}_\ell \]

We note that multiplication by \( f_{I, W, \alpha, \beta, (\gamma_i) i \in I} \) defines an endomorphism

\[ O[Z^1(W_{Q_p}, \hat{G})_{\overline{W}_\ell}/\hat{G}] \to O[Z^1(W_{Q_p}, \hat{G})_{\overline{W}_\ell}/\hat{G}] \]

of the structure sheaf on the Artin stack \([Z^1(W_{Q_p}, \hat{G})_{\overline{W}_\ell}/\hat{G}] \). If we act on a Schur-irreducible object \( A \in D_{lis}(Bun_G, \overline{W}_\ell) \), then we obtain an endomorphism

\[ \{O[Z^1(W_{Q_p}, \hat{G})_{\overline{W}_\ell}/\hat{G}] \ast A = A \to O[Z^1(W_{Q_p}, \hat{G})_{\overline{W}_\ell}/\hat{G}] \ast A = A \} \in \text{End}(A) = \overline{W}_\ell \]

which will be precisely the scalar given by evaluating \( \phi_{A}^{FS} \) on the excursion datum (See also \([Zou22\) Theorem 5.2]). In this way, we see that the action of excursion operators can be obtained through the spectral action. We will leverage this interpretation of excursion operators to prove the following key lemma.

**Lemma 3.8.** Let \( A \in D_{lis}(Bun_G, \overline{W}_\ell)^{\omega} \) be any Schur-irreducible object with Farquges-Scholze parameter \( \phi_{A}^{FS} \). Set \( x \) to be the closed point defined by the parameter \( \phi_{A}^{FS} \) in the coarse moduli space \( Z^1(W_{Q_p}, \hat{G})_{\overline{W}_\ell}/\hat{G} \) and let \( \pi^{-1}(x) \) denote the closed subset defined by the preimage in \([Z^1(W_{Q_p}, \hat{G})_{\overline{W}_\ell}/\hat{G}] \). Suppose we have \( C \in \text{Perf}([Z^1(W_E, \hat{G})_{\overline{W}_\ell}/\hat{G}]) \) with support disjoint from \( \pi^{-1}(x) \) then \( C \) acts by zero on \( A \) via the spectral action.
Proof. If we look at the action on $A \in D_{lis}(\text{Bun}_G, \overline{Q}_\ell)$ via the map
\[ Z^{spec}(G, \overline{Q}_\ell) \to Z^{geom}(G, \overline{Q}_\ell) \]
given by excursion operators this factors through the maximal ideal $m_A \subset Z^{spec}(G, \overline{Q}_\ell) = \mathcal{O}(Z^1(W_{Q_p}, \hat{G})_{\overline{Q}_\ell})^G$
defined by the closed point $\phi^FS$ in the coarse moduli space. By the conditions on the support of $C$, this implies that we can write the identity element as $1 = 1_C + 1_A \in Z^{spec}(G, \overline{Q}_\ell)$, where $1_C$
is a function that annihilates $C$ and $1_A$ is in the annihilator of $Z^{spec}(G, \overline{Q}_\ell)/m_A$. We consider the spectral action of $C$ on $A$
\[ C \ast A \in D_{lis}(\text{Bun}_G, \overline{Q}_\ell) \]
and look at the endomorphism induced by multiplication by 1 on $C$
\[ C \ast A \to C \ast A \]
which is just the identity. However, since $1_C$ annihilates $C$, this is the same as the action of $1_A$ on $C \ast A$, but, it follows by the above discussion that acting via multiplication by $1_A$ is the same as acting via the map
\[ Z^{spec}(G, \overline{Q}_\ell) \to Z^{geom}(G, \overline{Q}_\ell) \]
given by excursion operators, and the action of $1_A$ after applying this map is zero. This would lead to a contradiction unless $C \ast A$ is also zero. \qed

To take advantage of this lemma, we now introduce the following endofunctors of $D_{lis}(\text{Bun}_G, \overline{Q}_\ell)^{\omega}$, which are analogues of the averaging operators considered by [AL21] in the Fargues-Scholze geometric Langlands correspondence for $GL_n$ and by [FGV02; Gai04] in the classical geometric Langlands correspondence over function fields.

**Definition 3.4.** Let $\phi$ be a representation of $W_{Q_p}$ and $V$ a representation of $L^G$ with $T_V$ the associated Hecke operator. We consider the endofunctor of $D_{lis}(\text{Bun}_G, \overline{Q}_\ell)$
\[ A \mapsto R\Gamma(W_{Q_p}, T_V(A) \otimes \phi^V) \]
where $R\Gamma(W_{Q_p}, -) : D_{lis}(\text{Bun}_G, \overline{Q}_\ell)^{BW_{Q_p}} \to D_{lis}(\text{Bun}_G, \overline{Q}_\ell)$ is the derived functor given by continuous group cohomology with respect to $W_{Q_p}$. We denote this endofunctor by $A_{UV,\phi} : D_{lis}(\text{Bun}_G, \overline{Q}_\ell) \to D_{lis}(\text{Bun}_G, \overline{Q}_\ell)$.

We now would like to realize the functor $A_{UV,\phi}$ as the spectral action of an object in $\text{Perf}([Z^1(W_{Q_p}, \hat{G})_{\overline{Q}_\ell}/\hat{G}])$ similar to [AL21] Section 5.5. An obvious guess would be that one should take the vector bundle $C_V$
corresponding to the Hecke operator $T_V$, as in Remark 3.7 (1), and then twist this by the constant sheaf defined by $\phi^V$, which we denote by
\[ C_V \otimes \phi^V \in \text{Perf}([Z^1(W_{Q_p}, \hat{G})_{\overline{Q}_\ell}/\hat{G}])^{BW_{Q_p}} \]
More precisely, this is the vector bundle with $W_{Q_p}$-action whose evaluation at a $\overline{Q}_C$-point corresponding to a $L$-parameter $\tilde{\phi} : W_{Q_p} \to L^G(\overline{Q}_\ell)$ is the vector space with $W_{Q_p}$-action given by tensoring the representation
\[ \tilde{\phi} : W_{Q_p} \to L^G(\overline{Q}_\ell) \xrightarrow{T_V} GL(V) \]
with $\phi^V$. To obtain the desired perfect complex, it is natural to apply $R\Gamma(W_{Q_p}, -)$ to the vector bundle to $C_V \otimes \phi^V$, which we denote by $A_{UV,\phi}$. We note that $A_{UV,\phi}$ is a perfect complex. Indeed, as $p$ is invertible in $\overline{Q}_\ell$, the wild inertia $P \subset W_{Q_p}$ will always act through a finite quotient on $C_V \otimes \phi^V$ and has no higher cohomology which implies that the invariants
\[(C_V \otimes \phi^V)^P \]
are a direct summand of the vector bundle $C_V \otimes \phi^\vee$. If we choose a generator $\tau \in I/P$ in the tame quotient of the inertia subgroup $I \subset W_{Q_p}$ together with a Frobenius lift $\sigma \in W_{Q_p}/P$ then the complex $\mathcal{A}_V,\phi$ is computed as the homotopy limit of the diagram:

$$
\begin{align*}
(C_V \otimes \phi^\vee)^P \xrightarrow{\tau-1} (C_V \otimes \phi^\vee)^P \\
\downarrow \sigma^{-1} \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad
Proposition VII.7.3], we can assume, without loss of generality, that $T_V(A)$ is supported on a single stalk, where it is given by a complex of smooth irreducible representations of $J_b(Q_p)$ for $b \in B(G)$. Moreover, since $A$ is ULA, by Theorem 3.2 the sheaf $T_V(A)$ is also ULA and therefore it follows that, for all open compact $K \subset J_b(Q_p)$, $T_V(A)^K$ is a perfect complex of $\mathbb{Q}_p$-vector spaces. Writing $T_V(A) := \operatorname{colim}_{K \rightarrow \{1\}} T_V(A)^K$ and using that cohomology commutes with colimits, this allows us to apply results from the Galois cohomology of $W_{Q_p}$ on finite-dimensional $\mathbb{Q}_\ell$ vector spaces to $T_V(A)$. To do this, we consider the spectral sequence

$$E_2^{0,q} = H^p(W_{Q_p}, H^q(T_V(A) \otimes \phi^\vee)) \Longrightarrow H^{p+q}(R\Gamma(W_{Q_p}, T_V(A) \otimes \phi^\vee))$$

where cohomology is being taken with respect to the standard $t$-structure on $\text{D}_{\text{lis}}(\text{Bun}_G, \mathbb{Q}_\ell)$. Now recall that the cohomological dimension of $W_{Q_p}$ acting on finite dimensional $\mathbb{Q}_\ell$-vector spaces is 2. Therefore, this sequence degenerates at the $E_3$ page. Moreover, the only non-zero degeneracy maps are given by

$$E_2^{0,q+1} = H^0(W_{Q_p}, H^{q+1}(T_V(A) \otimes \phi^\vee)) \to E_2^{2,q} = H^2(W_{Q_p}, H^q(T_V(A) \otimes \phi^\vee))$$

However, using local Tate-duality on the RHS, we can rewrite this differential as a map:

$$(H^{q+1}(T_V(A)) \otimes \phi^\vee)^{W_{Q_p}} \to H^0(W_{Q_p}, H^q(T_V(A) \otimes \phi^\vee)^\vee(1))^\vee \simeq ((H^q(T_V(A))^\vee \otimes \phi(1))^{W_{Q_p}})^\vee$$

Now the term on the RHS (resp. LHS) will only be non-zero if $\phi(1)$ (resp. $\phi$) occurs as a subquotient of $H^q(T_V(A))$ (resp. $H^{q+1}(T_V(A))$). By assumption, this will be true for some value of $q$, but now, since the Euler-Poincaré characteristic of $W_{Q_p}$ acting on $\mathbb{Q}_\ell$-vector spaces is 0, one of these values being non-zero implies the $H^1(W_{Q_p}, -)$ of some cohomology sheaf of $T_V$ must also be non-zero. This will then give rise to a non-zero contribution to the cohomology of $R\Gamma(W_{Q_p}, T_V(A) \otimes \phi^\vee)$ so the averaging operator $W_{Q_p}$ applied to $A$ is non-zero. Lemma 3.9 therefore tells us that the spectral action of the perfect complex $A\mathcal{V}_{\phi}(A)$ applied to $A$ is non-trivial. If $x$ denotes the closed $\mathbb{Q}_\ell$-point in the coarse moduli space of Langlands parameters defined by $\phi_A^{\text{FS}}$ with preimage $\pi^{-1}(x)$ in the stack of Langlands parameters, Lemma 3.8 tells us that $A\mathcal{V}_{\phi}$ must have non-zero support on $\pi^{-1}(x)$. The $\mathbb{Q}_\ell$-points of $\pi^{-1}(x)$ correspond to the set of Langlands parameters whose semisimplification is precisely $\phi_A^{\text{FS}}$. The previous analysis tells us that the evaluation of the perfect complex $R\Gamma(W_{Q_p}, C_V \otimes \phi^\vee)$ at some such point, corresponding to an $L$-parameter $\tilde{\phi} : W_{Q_p} \to L\Gamma(\mathbb{Q}_\ell)$, must be non-zero. This evaluation is precisely the complex

$$R\Gamma(W_{Q_p}, r_V \circ \tilde{\phi} \otimes \phi^\vee)$$

However, by again applying local Tate-duality, this can only be the case if $r_V \circ \tilde{\phi}$ has a subquotient isomorphic to $\phi$ or $\phi(1)$. Since $\phi$ is irreducible, this can only happen if $r_V \circ \phi^{\text{FS}} = r_V \circ \phi_A^{\text{FS}}$ has this property.

We conclude this section by reviewing how the spectral action behaves on objects with supercuspidal Fargues-Scholze parameter along the lines of [FS21, Section X.2]. These results will be used to deduce a strong form of the Kottwitz conjecture from compatibility. We recall that a supercuspidal parameter, viewed as a continuous 1-cocycle with respect to the $W_{Q_p}$-action on $\hat{G}(\mathbb{Q}_\ell)$, denoted $\phi : W_{Q_p} \to \hat{G}(\mathbb{Q}_\ell)$, satisfies the property that it doesn’t factor through any $\tilde{P}(\mathbb{Q}_\ell)$ for $P$ a parabolic subgroup of $G$. Equivalently, this is the same as insisting that, if $S_\phi := Z_G(\text{Im}(\phi))$ as before, then the quotient $S_\phi/Z(\hat{G})^\Gamma$ is finite, where $\Gamma := \text{Gal}(\mathbb{Q}_p/Q_p)$. From this, it follows by deformation theory (See the proof of [Dat + 20, Theorem 1.6] for more details) that the unramified twists of the parameter $\phi$ define a connected component

$$C_\phi \hookrightarrow [\mathbb{Z}^1(W_{Q_p}, \hat{G})_{\mathbb{Q}_\ell}/\hat{G}]$$

giving rise to a direct summand

$$\text{Perf}(C_\phi) \hookrightarrow \text{Perf}([\mathbb{Z}^1(W_{Q_p}, \hat{G})_{\mathbb{Q}_\ell}/\hat{G}])$$
Therefore, the spectral action gives rise to a corresponding direct summand
\[ D^{C_\phi}_{\text{lis}}(\Bun_G, \overline{\mathbb{Q}_\ell})^\omega \subset D_{\text{lis}}(\Bun_G, \overline{\mathbb{Q}_\ell})^\omega \]
such that the Schur-irreducible objects in this subcategory all have Fargues-Scholze parameter given by an unramified twist of \( \phi \). Now, it follows by Proposition 3.14 in the next section and Theorem 3.6 (4), that, since \( \phi \) is supercuspidal, the restriction of any object in \( D^{C_\phi}_{\text{lis}}(\Bun_G, \overline{\mathbb{Q}_\ell})^\omega \) to any non-basic HN-strata of \( \Bun_G \) must be zero. Therefore, one obtains a decomposition
\[ D^{C_\phi}_{\text{lis}}(\Bun_G, \overline{\mathbb{Q}_\ell})^\omega \cong \bigoplus_{b \in B(G)_{\text{basic}}} D^{C_\phi}(J_b(E), \overline{\mathbb{Q}_\ell})^\omega \]
where \( J_b \) is the \( \sigma \)-centralizer of \( b \) and \( D^{C_\phi}(J_b(E), \overline{\mathbb{Q}_\ell})^\omega \subset D(J_b(E), \overline{\mathbb{Q}_\ell})^\omega \) is a full subcategory of the derived category of compact objects in smooth representations of \( J_b(E) \). It also follows again by Theorem 3.6 (4) that the Schur-irreducible objects of any \( D^{C_\phi}(J_b(E), \overline{\mathbb{Q}_\ell})^\omega \) must lie only in the supercuspidal components of the Bernstein center. Now to further analyze this we fix a character \( \chi \) of \( Z(G)(\mathbb{Q}_p) \) and consider the subcategory
\[ D^{C_\phi}_{\text{lis}, \chi}(\Bun_G, \overline{\mathbb{Q}_\ell})^\omega \cong \bigoplus_{b \in B(G)_{\text{basic}}} D^{C_\phi}(J_b(E), \overline{\mathbb{Q}_\ell})^\omega \]
where \( D^{C_\phi}(J_b(E), \overline{\mathbb{Q}_\ell})^\omega \) is the derived subcategory of \( D^{C_\phi}(J_b(E), \overline{\mathbb{Q}_\ell})^\omega \) generated by compact objects with fixed central character \( \chi \), via the natural isomorphism \( Z(J_b)(\mathbb{Q}_p) \cong Z(G)(\mathbb{Q}_p) \) (where we recall that \( J_b \) is an extended pure inner form of \( G \)). One can see that the spectral action of \( \text{Perf}(C_\phi) \) preserves this subcategory. Indeed, it follows by [FS21, Theorem I.8.2] that \( \text{Perf}\left(\mathcal{Z}\left(W_{\mathbb{Q}_p}, G\right)_{Z(G)/G}\right) \) and in turn \( \text{Perf}(C_\phi) \) is generated under cones and retracts by the image of \( \text{Rep}_{\overline{\mathbb{Q}_\ell}}(bG) \) in \( \text{Perf}\left(\mathcal{Z}\left(W_{\mathbb{Q}_p}, G\right)_{Z(G)/G}\right) \). This reduces us to checking that Hecke operators preserve this subcategory, which, in turn reduces to the observation that, if one looks at the simultaneous action of \( J_b(\mathbb{Q}_p) \times J_{b'}(\mathbb{Q}_p) \) on the space parametrizing modifications \( \mathcal{E}_b \rightarrow \mathcal{E}_{b'} \), for \( b \) and \( b' \) in \( B(G)_{\text{basic}} \) that, under the canonical identification \( Z(J_{b'})(\mathbb{Q}_p) \cong Z(J_b)(\mathbb{Q}_p) \), the diagonally embedded center acts trivially. This follows since an element in the center of \( J_b(\mathbb{Q}_p) \) acts on the modification by the inverse of an element in the corresponding center of \( J_{b'}(\mathbb{Q}_p) \), where the inverse appears from the fact that \( J_b(\mathbb{Q}_p) \) is acting on the left and \( J_{b'}(\mathbb{Q}_p) \) is acting on the right.

Now, via local class field theory, we take \( \chi \) to be the central character determined by \( \phi \) and local class field theory (as in [Bor79, Section 10.1]). Since all Schur-irreducible objects in \( D^{C_\phi}(J_b(E), \overline{\mathbb{Q}_\ell})^\omega \) lie in the supercuspidal component of the Bernstein-center and have fixed central character \( \chi \) and, by [Cas95, Theorem 5.4.1], supercuspidal representations are injective/projective in the category of smooth representations with fixed central character, we can write \( D^{C_\phi}(J_b(E), \overline{\mathbb{Q}_\ell})^\omega = \bigoplus_{\pi} \text{Perf}(\overline{\mathbb{Q}_\ell}) \otimes \pi \), where \( \pi \) runs over all supercuspidal representations of \( J_b(E) \) with central character \( \chi \) which, a priori, have Fargues-Scholze parameter given by an unramified twist of \( \phi \), but, by Theorem 3.6 (2), must indeed be equal to \( \phi \).

Now, the closed point of \( C_\phi \) determined by the parameter \( \phi \) gives rise to a closed embedding
\[ [\overline{\mathbb{Q}_\ell}/S_\phi] \hookrightarrow C_\phi \]
and in turn a fully faithful embedding
\[ \text{Perf}(\overline{\mathbb{Q}_\ell}/S_\phi) \hookrightarrow \text{Perf}(C_\phi) \]
The above discussion and Lemma 3.8 imply that the action of \( \text{Perf}(C_\phi) \) factors over this subcategory in the sense that everything not in the image of this must act by zero. All in all, we conclude that
we have a decomposition
\[ D^C_{\text{lis}, \chi}(\text{Bun}_G, \overline{\mathcal{Q}_\ell})^{\omega} = \bigoplus_{b \in B(G)_{\text{basic}}} \bigoplus_{\pi_b} \text{Perf}(\overline{\mathcal{Q}_\ell}) \otimes \pi_b \]
where the \( \pi_b \) runs over all supercuspidal representations of \( J_b(E) \) with Fargues-Scholze parameter \( \phi^{FS}_{\eta_b} = \phi \). Moreover, the RHS carries an action of \( \text{Rep}_{\mathbb{Q}_\ell}(S_{\phi}) \), the category of finite-dimensional \( \mathbb{Q}_\ell \)-representations of \( S_{\phi} \). Therefore, given \( W \in \text{Rep}_{\mathbb{Q}_\ell}(S_{\phi}) \), we get an object:
\[ \text{Act}_W(\pi_b) \in \bigoplus_{b \in B(G)_{\text{basic}}} \bigoplus_{\pi_b} \text{Perf}(\overline{\mathcal{Q}_\ell}) \otimes \pi_b \]
Assume that \( W|_{\mathbb{Z}(\mathbb{G}^{\Gamma})} \) is isotypic, given by some character \( \eta : \mathbb{Z}(\mathbb{G}^{\Gamma}) \to \overline{\mathbb{Q}_\ell}^* \). As \( \mathbb{Z}(\mathbb{G}^{\Gamma}) \) is diagonalizable with characters given by \( B(G)_{\text{basic}} \cong \pi_1(\mathbb{G}^{\Gamma}) \) via the \( \kappa \) map, we obtain an element \( b_\eta \in B(G)_{\text{basic}} \). Then \( \text{Act}_W(\pi_b) \) is concentrated on the basic HN-strata given by \( b' = b + b_\eta \). Therefore, we get an isomorphism
\[ \text{Act}_W(\pi_b) \cong \bigoplus_{\pi_{b'}} V_{\pi_{b'}} \otimes \pi_{b'} \]
where \( V_{\pi_{b'}} \in \text{Perf}(\overline{\mathcal{Q}_\ell}) \) and \( \pi_{b'} \) runs over all supercuspidals of \( J_{b'} \) with Fargues-Scholze parameter \( \phi^{FS}_{\eta_{b'}} = \phi \). With this in hand, we can elucidate the \( \text{W}_{\mathbb{Q}_p} \)-action on the Hecke operator applied to a smooth irreducible object with supercuspidal Fargues-Scholze parameter, similar to what was done in Lemma 3.10 in the general case. Namely, given \( V \in \text{Rep}_{\mathbb{Q}_\ell}(\mathbb{L}G) \), we obtain a vector bundle on \([\overline{\mathcal{Q}_\ell}/S_{\phi}]\) with \( \text{W}_{\mathbb{Q}_p} \)-action given by \( \phi \). In other words, we have a functor:
\[ \text{Rep}_{\mathbb{Q}_\ell}(\mathbb{L}G) \to \text{Rep}_{\mathbb{Q}_\ell}(S_{\phi})^{\text{BW}_{\mathbb{Q}_p}} \]
Theorem 3.7 and the above discussion imply that the action of the image of \( V \) in \( \text{Rep}_{\mathbb{Q}_\ell}(S_{\phi})^{\text{BW}_{\mathbb{Q}_p}} \) acting via the spectral action on \( D^C_{\text{lis}, \chi}(\text{Bun}_G, \overline{\mathcal{Q}_\ell}) \) is precisely the Hecke operator \( T_V \). This tells us that, if we decompose \( r_V \circ \phi \) viewed as a representation of \( S_{\phi} \) as a direct sum \( \bigoplus_{i \in I} W_i \otimes \sigma_i \) where \( W_i \in \text{Rep}(S_{\phi}) \) is irreducible and \( \sigma_i \) is a continuous finite-dimensional representation of \( \text{W}_{\mathbb{Q}_p} \), then we have an isomorphism
\[ T_V(\pi) \cong \bigoplus_{i \in I} \text{Act}_{W_i}(\pi) \otimes \sigma_i \]
as \( J_{b'}(\mathbb{Q}_p) \times \text{W}_{\mathbb{Q}_p} \)-modules. We now summarize the above discussion as a corollary for future use.

**Corollary 3.11.** Let \( \phi \) be a supercuspidal parameter of \( G \), \( b \in B(G)_{\text{basic}} \) a basic element, \( V \in \text{Rep}_{\mathbb{Q}_\ell}(\mathbb{L}G) \) an irreducible representation of some highest weight \( \mu \) with dominant inverse \( \mu^{-1} \), and \( \pi_b \) a representation of \( J_b(E) \) with Fargues-Scholze parameter equal to \( \phi \). If we set \( b_\mu \in B(G, \mu^{-1}) \) to be the unique basic element and \( b' = b + b_\mu \). If we decompose \( r_V \circ \phi \) viewed as representation of \( S_{\phi} \) as a direct sum \( \bigoplus_{i \in I} W_i \otimes \sigma_i \), where \( W_i \in \text{Rep}(S_{\phi}) \) is irreducible and \( \sigma_i \) is a continuous finite-dimensional representation of \( \text{W}_{\mathbb{Q}_p} \), then there exists an isomorphism of \( \text{W}_{\mathbb{Q}_p} \times J_{b'}(\mathbb{Q}_p) \)-modules
\[ T_\mu(\pi_b) \cong \bigoplus_{i \in I} \text{Act}_{W_i}(\pi) \otimes \sigma_i \]
where \( \text{Act}_{W_i}(\pi) \cong \bigoplus_{\pi_{b'}} V_{\pi_{b'}} \otimes \pi_{b'} \) with \( V_{\pi_{b'}} \in \text{Perf}(\overline{\mathcal{Q}_\ell}) \) and \( \pi_{b'} \) ranging over supercuspidal representation of \( J_{b'}(\mathbb{Q}_p) \) with Fargues-Scholze parameter equal to \( \phi \).

**Remark 3.9.** As we will start to see in the next section, the work of Hansen [Han20], Hansen-Kaletha-Weinstein [HKW21], and compatibility of the Fargues-Scholze and Gan-Takeda/Gan-Tantono local
Langlands correspondence will allow us to use this Corollary to prove Theorem 1.3. This is suggested already by Corollary 3.3, which shows us that $T_{\mu}(\pi_b)$ can be computed explicitly using the cohomology of local Shimura varieties.

### 3.3 Compatibility with the Local Langlands for $G_{Sp_4}$ and $GU_2(D)$

With the results of the previous section in place, we can now start making progress towards our goal of proving compatibility. So we again let $G = \text{Res}_{L/Q_p} G_{Sp_4}$ and $J = \text{Res}_{L/Q_p} GU_2(D)$, for $L/Q_p$ a finite extension. As mentioned in section 1, the case where a representation $\pi \in \Pi(G)$ (resp. $\rho \in \Pi(J)$), is a sub-quotient of a parabolic induction easily follows from Theorem 3.6 (3), (4), (5), and compatibility of the (semi-simplified) Gan-Takeda (resp. Gan-Tantono) parameter with parabolic induction. We record this as a corollary now.

**Corollary 3.12.** Let $\pi \in \Pi(G)$ (resp. $\rho \in \Pi(J)$) be representations occurring as a sub-quotient of a parabolic induction. For such $\pi$ (resp. $\rho$), the Fargues-Scholze and Gan-Takeda (resp. Gan-Tantono) local Langlands correspondences are compatible.

To tackle the remaining cases where the $L$-parameter $\phi$ is mixed supercuspidal or supercuspidal, we note that these are the cases where the $L$-parameter is discrete (i.e the $L$-parameter does not factor through a Levi subgroup). This case is disposable to the results of Hansen-Kaletha-Weinstein [HKW21]. We will now let $\mu$ be the Siegel cocharacter of $G$ so that the $\sigma$-centralizer of the unique basic element $b \in B(G, \mu)$ is $J$. We now state the main result of [HKW21] specialized to the case of the Shimura datum $(G, b, \mu)$.

**Theorem 3.13.** [HKW21, Theorem 1.0.2] Let $\phi$ be a mixed supercuspidal or supercuspidal parameter and $S_\phi := Z_G(\text{im}(\phi))$ as before. Let $\Pi_\phi(G)$ and $\Pi_\phi(J)$ denote the $L$-packets over $\phi$. Set $\pi \in \Pi_\phi(G)$ (resp. $\rho \in \Pi_\phi(J)$) to be smooth irreducible representations of $G$ (resp. $J$). If $\phi$ is supercuspidal or mixed supercuspidal, we have the following equality in the Grothendieck group $K_0(G(\mathbb{Q}_p))^{ell}$ of elliptic admissible representations of $G(\mathbb{Q}_p)$ of finite length

$$[\text{RG}_c^\phi(G, b, \mu)[\rho]] = - \sum_{\pi \in \Pi_\phi(G)} \text{Hom}_{S_\phi}(\delta_{\pi, \rho}, \text{std} \circ \phi)\pi$$

and the following equality

$$[\text{RG}_c^\phi(G, b, \mu)[\pi]] = - \sum_{\rho \in \Pi_\phi(J)} \text{Hom}_{S_\phi}(\delta_{\pi, \rho}^\vee, (\text{std} \circ \phi)^\vee)\rho$$

in the Grothendieck group of elliptic admissible $J(\mathbb{Q}_p)$-representations of finite length, where $\delta_{\pi, \rho}$ is the algebraic representation of $S_\phi$ in Definition 2.3. Moreover, if the Fargues-Scholze parameter of $\pi$ (resp. $\rho$) is supercuspidal this is true in the Grothendieck group $K_0(G(\mathbb{Q}_p))$ (resp. $K_0(J(\mathbb{Q}_p))$) of all admissible representations of finite length.

**Remark 3.10.** (1) To deduce the result for the $\pi$-isotypic part, we have implicitly used the two towers isomorphism $\text{Sht}(G, b, \mu)_\infty \simeq \text{Sht}(J, \hat{b}, \mu^{-1})_\infty$, where $\mu^{-1}$ is a dominant inverse to $\mu$ and $\hat{b} = b^{-1} \in B(G, \mu^{-1})$ is the unique basic element [SW20, Corollary 23.3.2], and $B(G, \mu^{-1}) \simeq B(J, \mu^{-1})$ under the inner twisting. This inverse explains the appearance of duals in the formula for the $\pi$-isotypic part.

(2) We see that, via Corollary 3.3, this, in the case that $\phi$ is supercuspidal, should provide us insight into the multiplicity spaces $V_{\pi, \rho}$ appearing in Corollary 3.11, assuming compatibility of the Fargues-Scholze and Gan-Tantono/Gan-Takeda local Langlands correspondences. Namely, we will see later (Theorem 3.17 and 3.18) that $\text{RG}_c^\phi(G, b, \mu)[\rho] \simeq \text{RG}_c^\phi(G, b, \mu)[\rho]$ and is concentrated in middle degree $3$ if $\phi_{FS}^\rho$ is supercuspidal. Assuming compatibility, Corollary 3.11 will therefore tell us that $\text{RG}_c^\phi(G, b, \mu)[\rho]$ will be a direct sum over representations $\pi \in \Pi_\phi(G)$ with $W_L$-action given by $\text{std} \circ \phi_{FS}^\rho = \text{std} \circ \phi_\rho$ decomposed as a representation of
$S_\phi$. The summands in the decomposed $S_\phi$-representation correspond to the weight spaces appearing in the above description in the Grothendieck group.

We now wish to write out the precise formula for the $\rho$ and $\pi$-isotypic parts, using the refined local Langlands discussed in section 2.

(1) ($\phi$ stable) In this case, the $L$-packet $\Pi_\phi(G) = \{\pi\}$ is a singleton so the RHS of the above formula for the $\rho$-isotypic part has one term

$$-\rho \text{Hom}_{S_\phi}(\delta_{\pi,\rho}, \text{std} \circ \phi_\rho)$$

In this case, $S_\phi = \mathbb{G}_m$ and $\delta_{\pi,\rho}$ is simply the identity representation. Thus, this Hom space gets identified with the characters of $GL_4$, so the formula reduces to

$$-4\rho$$

(2) ($\phi$ endoscopic) In this case, the $L$-packet has size 2 and, as seen in section 2.1, $\Pi_\phi(G) = \{\pi^+, \pi^\ast\}$, where $\pi^+$ (resp. $\pi^\ast$) corresponds to the trivial (resp. non-trivial) character of the component group. $\rho$ can be either of the two representations corresponding to the irreducible representation of $S_\phi$ given by $\tau_i$ for $i = 1, 2$ the projection to the two coordinates of $S_\phi$. However, the RHS remains the same regardless of which one it corresponds to. So, without loss of generality, we assume that $\rho = \rho_1$. Then the RHS of the above formula for the $\rho$-isotypic part has two terms

$$\pi^+ \text{Hom}_{S_\phi}(\tau_1, \text{std} \circ \phi_\rho)$$

and

$$\pi^\ast \text{Hom}_{S_\phi}(\tau_1 \otimes \tau_{\pi^\ast} \simeq \tau_2, \text{std} \circ \phi_\rho)$$

However, writing $\text{std} \circ \phi_\rho \simeq \phi_1 \oplus \phi_2$, these get identified with

$$-\pi^+ \text{Hom}_{\mathbb{Q}_\ell}(\mathbb{Q}_\ell^*, \phi_1)$$

and

$$-\pi^\ast \text{Hom}_{\mathbb{Q}_\ell}(\mathbb{Q}_\ell^*, \phi_2)$$

which will both be identified with characters of $GL_2$. Thus, the RHS is equal to

$$-2\pi^+ - 2\pi^\ast$$

Similarly, for the $\pi$-isotypic part, we get that the RHS of the above formula is given by

$$-4\pi$$

in the stable case and

$$-2\rho_1 - 2\rho_2$$

in the endoscopic case.

As mentioned in section 1.2, we will now use the previous result to perform a bootstrap to the supercuspidal representations occurring in the $L$-packets $\Pi_\phi(G)$ (resp. $\Pi_\phi(J)$), for $\phi$ a mixed supercuspidal parameter. For this, we will mention one last result from the Fargues-Scholze local Langlands correspondence.

**Proposition 3.14.** [FS21, Section IX.7.1] For $G$ any connected reductive group over $\mathbb{Q}_p$, the action of the excursion algebra on $D_{\text{lis}}(\text{Bun}_G, \mathbb{Q}_\ell)$ commutes with Hecke operators. Moreover, it is compatible with restriction to the HN-strata $\text{Bun}^b_{\text{J}}$ for $b \in B(G)$ in the following sense. Given a Schur irreducible object $A \in D_{\text{lis}}(\text{Bun}_G, \overline{\mathbb{Q}}_\ell)$ and $b \in B(G)$, if we let $B$ be a smooth irreducible constituent of $j_b^!(A)$ then we can view it as a sheaf on the neutral strata of $\text{Bun}^1_J$ and let $\phi_B^{\text{FS}}$ denote its
Fargues-Scholze parameter with respect to the excursion algebra on $\text{Bun}_J$. Then the Fargues-Scholze parameter of $A$ is the composition

$$W_{Q_p} \xrightarrow{\phi^{\text{FS}}_c} L J_b(\overline{Q}_\ell) \rightarrow L G(\overline{Q}_\ell)$$

where $L J_b(\overline{Q}_\ell) \rightarrow L G(\overline{Q}_\ell)$ is the twisted embedding, as defined in [FS21, Page 327].

Remark 3.11. The commutation of Hecke operators and the excursion algebra follows from the interpretation of the excursion algebra in terms of endomorphisms coming from multiplication by the ring of global functions of the stack of $L$-parameters, as discussed in Section 3.2.

From this, we can deduce the following useful corollary.

**Corollary 3.15.** For $G$ any connected reductive group with $(G, b, \mu)$ a local Shimura datum and $\pi \in \Pi(G)$ and $\rho \in \Pi(J_b)$ smooth irreducible representations. All smooth irreducible representations occurring in the cohomology of $\text{RT}^\gamma_c(G, b, \mu)[\pi]$ have Fargues-Scholze parameter equal to $\phi^{\text{FS}}_c\pi$. Similarly, all smooth irreducible representations occurring in the cohomology of $\text{RT}^\gamma_c(G, b, \mu)[\rho]$ have Fargues-Scholze parameter equal to $\phi^{\text{FS}}_c\rho$. The same is also true for $\text{RT}^\gamma_c(G, b, \mu)[\rho]$ and $\text{RT}^\gamma_c(G, b, \mu)[\pi]$.

**Proof.** The first part follows immediately from Proposition 3.14 and Corollary 3.3. It remains to see the same is true for the complexes $\text{RT}^\gamma_c(G, b, \mu)[\rho]$ and $\text{RT}^\gamma_c(G, b, \mu)[\pi]$. This can be done by writing them as $J_1 T_\mu R_{J_{hs}}(\rho)$ and $J_2 T_{\mu-1} R_{J_{fs}}(\pi)$, as in [FS21, Section IX.7.1], where it again follows from Proposition 3.14 and Corollary 3.3.

We now exploit this corollary to deduce compatibility in the mixed supercuspidal case.

**Corollary 3.16.** Let $\phi$ be an $L$-parameter of Howe-Piatetski-Schapiro or Saito-Kurokawa type. Then, for any $\pi \in \Pi_\phi(G)$ (resp. $\rho \in \Pi_\phi(J)$), the Fargues-Scholze and Gan-Takeda (resp. Gan-Tantono) local Langlands correspondences are compatible.

**Proof.** We give the proof for the Gan-Takeda local Langlands correspondence with the proof for the Gan-Tantono correspondence being completely analogous. If $\phi$ is of Saito-Kurokawa type then, as seen in section 2.2, we can write $\Pi_\phi(G) = \{\pi_{\text{sc}}, \pi_{\text{disc}}\}$ and $\Pi_\phi(J) = \{\rho_{\text{sc}}, \rho_{\text{disc}}\}$, where $\pi_{\text{sc}}$ (resp. $\rho_{\text{sc}}$) is a supercuspidal representation of $G$ (resp. $J$) and $\pi_{\text{disc}}$ (resp. $\rho_{\text{disc}}$) is a non-supercuspidal representation. We note that the Gan-Takeda (resp. Gan-Tantono) correspondences are compatible with the Fargues-Scholze correspondence for $\pi_{\text{disc}}$ (resp. $\rho_{\text{disc}}$), by Corollary 3.12.

We know we can describe this complex in the Grothendieck group of admissible $G(Q_p)$-representations of finite length as

$$[\text{RT}^\gamma_c(G, b, \mu)[\rho_{\text{disc}}]_{\text{sc}}] = -2\pi_{\text{sc}}$$

which tells us that $\pi_{\text{sc}}$ occurs as a non-zero sub-quotient of the complex $\text{RT}^\gamma_c(G, b, \mu)[\rho_{\text{disc}}]$. By Corollary 3.15, we know that we have an equality:

$$\phi^{\text{FS}}_{\rho_{\text{disc}}} = \phi^{\text{FS}}_{\pi_{\text{sc}}}$$

However, Corollary 3.12 tells us that $\phi^{\text{FS}}_{\rho_{\text{disc}}} = \phi^{\text{FS}}_{\pi_{\text{sc}}}$, which is equal to $\phi^{\text{FS}}_{\pi_{\text{sc}}}$, so we get the desired equality. The analysis in the Howe-Piatetski-Schapiro case is the same, where one can look at the $\rho$-isotypic part for any of the two non-supercuspidals in $\Pi_\phi(J)$.
In the remaining part of this section, we address proving compatibility in the case where the parameter $\phi$ is supercuspidal. Before tackling the question of compatibility, we address some geometric properties of the sheaves $\mathcal{F}_\rho$, for $\rho$ with supercuspidal Fargues-Scholze parameter. This will be leveraged in proving the strong form of the Kottwitz Conjecture for the $\rho$ and $\pi$-isotypic parts in section 8, as mentioned in Remark 3.10 (2).

Now, considering again $G$ a general connected reductive group, $b \in B(G)_{\text{basic}}$ a basic element, and a smooth irreducible representation $\rho$ of the $\sigma$-centralizer $J_b(\mathbb{Q}_p)$. We will now address some further consequences of the Fargues-Scholze parameter $\phi^{FS}_\rho$ being supercuspidal. It turns out that the sheaves defined by representations with these parameters have interesting geometric properties, which were leveraged in [Han20] to prove various general results on the cohomology groups. In particular, Hansen shows the following:

**Theorem 3.17.** [Han20] Theorem 1.1. Let $(G, b, \mu)$ be a basic local Shimura datum with $E$ the reflex field of $\mu$ as before, and let $\rho$ be a smooth irreducible representation of $J_b(\mathbb{Q}_p)$. Suppose the following conditions hold:

1. The spaces $(\text{Sh}(G, b, \mu)_K)_{K \subseteq G(\mathbb{Q}_p)}$ occur in the basic uniformization at $p$ of a global Shimura variety in the sense of Definition 4.1.
2. The Fargues-Scholze parameter $\phi^{FS}_\rho : W_{\mathbb{Q}_p} \rightarrow L G(\overline{\mathbb{Q}}_\ell)$ is supercuspidal.

Then the complex $R\Gamma_c(G, b, \mu)[p]$ defined above is concentrated in middle degree $d = \dim(\text{Sh}(G, b, \mu)_\infty) = (2\rho_G, \mu)$.

One of the key ideas in the argument is to exploit the behavior of the sheaf $j_{ib}(\mathcal{F}_\rho)$ under Verdier duality, where $j_b : \text{Bun}^b_G \hookrightarrow \text{Bun}_G$ is the inclusion of the open HN-strata corresponding to $b \in B(G)_{\text{basic}}$. In particular, by Proposition 3.14 and Theorem 3.6 (4), one can see that the natural map $j_{ib}(\mathcal{F}_\rho) \rightarrow Rj_{ib}(\mathcal{F}_\rho)$ is an isomorphism. Namely, Proposition 3.14 implies that a non-zero restriction of $Rj_{ib}(\mathcal{F}_\rho)$ to any non-basic HN-strata must be valued in representations having Fargues-Scholze parameter $\phi^{FS}_\rho$ under the relevant twisted embedding, which is impossible since the $\sigma$-centralizers of non-basic elements are extended pure inner forms of proper Levi subgroups of $G$ and, by assumption, the parameter $\phi^{FS}_\rho$ is supercuspidal. This implies that, if we apply Verdier duality to both sides of the isomorphism

$$j^*_1 T_\mu j_{ib}(\mathcal{F}_\rho) \simeq R\Gamma_c(G, b, \mu)[p][d](d)$$

supplied by Corollary 3.3, we see that the LHS is isomorphic to

$$j^*_1 T_\mu j_{ib}(\mathcal{F}_\rho^\star) \simeq R\Gamma_c(G, b, \mu)[p^\star][d](d)$$

On the other hand, on the RHS we act through Verdier duality on the tower $(\text{Sh}(G, b, \mu)_K)_{K \subseteq G(\mathbb{Q}_p)}$, which are smooth rigid spaces of dimension $d$. So, in particular, the dualizing object is isomorphic to $\mathbb{Q}_\ell[2d](d)$. This allows one to deduce the following consequence for the cohomology groups $R\Gamma_c(G, b, \mu)[p]$.

**Theorem 3.18.** [Han20] Theorem 1.3, Theorem 2.23] Fix a basic local Shimura datum $(G, b, \mu)$ and let $\rho$ be representation of $J_b(\mathbb{Q}_p)$ with supercuspidal Fargues-Scholze parameter. Then there is a natural isomorphism

$$R\text{Hom}(R\Gamma_c(G, b, \mu)[p], \overline{\mathbb{Q}}_\ell) \simeq R\Gamma_c(G, b, \mu)[p^\star][2d](d)$$

as $W_E$-equivariant objects of $D(J_b(\mathbb{Q}_p), \overline{\mathbb{Q}}_\ell)$, where $p^\star$ is the contragredient of $p$. In particular, we have a natural $W_E$-equivariant isomorphism of admissible $G(\mathbb{Q}_p)$-representations for all $0 \leq i \leq 2d$

$$H^i(R\Gamma_c(G, b, \mu)[p])^* \simeq H^{2d-i}(R\Gamma_c(G, b, \mu)[p^\star])(d)$$
Remark 3.12. As noted in Remark 3.4, the LHS of the above formula is isomorphic to \( R\Gamma^n_c(G, b, \mu)[\rho]\, | 2d| \, |d| \), so it follows by cancelling the shifts and Tate twists and relaxing contragradients that one has an isomorphism

\[
R\Gamma^b_c(G, b, \mu)[\rho] \simeq R\Gamma^c_e(G, b, \mu)[\rho]
\]
as \( J_b(\mathbb{Q}_p) \times W_E \)-representations for all such \( \rho \).

Now we turn our attention to the question of showing compatibility for supercuspidal parameters assuming Proposition 1.4. So again let \( L/\mathbb{Q}_p \) be a finite extension and let \( G := \text{Res}_{L/\mathbb{Q}_p}(GSp_4) \) be the restriction of scalars of \( GSp_4 \) and \( J := \text{Res}_{L/\mathbb{Q}_p}(GU_2(\mathbb{D})) \) the unique non-split inner form as before. As we will see in section 8, it essentially follow from Theorem 3.13 and Corollary 3.15 that showing compatibility for \( \rho \in \Pi(J) \) with supercuspidal Gan-Tantono parameter implies the corresponding statement for \( \pi \in \Pi(G) \) with supercuspidal Gan-Takeda parameter. So we fix such a \( \rho \) and assume that the Gan-Tantono parameter \( \phi_\rho \) is endoscopic supercuspidal with the stable case being strictly easier. We will write \( \text{std} \circ \phi_\rho \simeq \phi_1 \oplus \phi_2 \) for \( \phi_1 \) distinct irreducible 2-dimensional representations of \( W_L \) and let \( \mu \) be the Siegel cocharacter. The Shtuka space \( \text{Sht}(G, b, \mu)_\infty \) in this case will have dimension \( d := \langle 2\rho_G, \mu \rangle = 3 \). We will assume for the rest of this section that Proposition 1.4 is true.

**Proposition 3.19.** Let \( \phi \) be a supercuspidal parameter with associated \( L \)-packet \( \Pi_\phi(J) \). Then the direct summand of

\[
\bigoplus_{\rho' \in \Pi_\phi(J)} R\Gamma_c(G, b, \mu)[\rho']
\]
where \( G(\mathbb{Q}_p) \) acts via a supercuspidal representation

\[
\bigoplus_{\rho' \in \Pi_\phi(J)} R\Gamma_c(G, b, \mu)[\rho' \, | sc]
\]
is concentrated in middle degree 3 and admits a non-zero \( W_L \)-stable sub-quotient with \( W_L \)-action given by \( \text{std} \circ \phi \otimes | \cdot |^{-3/2} \).

First, we combine this with the following lemma.

**Lemma 3.20.** Let \( \phi \) be a supercuspidal parameter then all representations in the \( L \)-packet \( \Pi_\phi(J) \) have the same Fargues-Scholze parameter.

**Proof.** We choose a \( \pi \in \Pi_\phi(G) \) and then apply Corollary 3.15 to deduce that all representations occurring in the cohomology of \( R\Gamma^b_c(G, b, \mu)[\pi] \) have Fargues-Scholze parameter equal to \( \phi_\pi^{FS} \). However, by Theorem 3.13, we have that all representations in \( \rho \in \Pi_\phi(J) \) occur in the cohomology of \( R\Gamma^b_c(G, b, \mu)[\pi] \), so their Fargues-Scholze parameters are the same as desired. \( \square \)

With this in hand, we are ready to prove the key consequence of Proposition 1.4 using the results on the spectral action obtained in section 3.2.

**Corollary 3.21.** Assume that \( L/\mathbb{Q}_p \) is an unramified extension and that \( p > 2 \) and that Proposition 1.4 is true. Then, for \( \rho \) a smooth irreducible representation of \( J(\mathbb{Q}_p) \) with supercuspidal Gan-Tantono parameter \( \phi \), the Gan-Tantono and Fargues-Scholze correspondences coincide.

**Proof.** As mentioned in the introduction, the key will be the isomorphism

\[
\bigoplus_{\rho' \in \Pi_\phi(J)} j_1^T(\mu)j_{\mu}(F_{\rho'}) \simeq \bigoplus_{\rho' \in \Pi_\phi(J)} R\Gamma_c(G, b, \mu)[\rho']|3|^{3/2}
\]
supplied by Corollary 3.3. Now Proposition 1.4 tells us that one of the summands on the RHS admits a sub-quotient with \( W_L \)-action given by \( \phi_1 \) and one of them admits a sub-quotient with \( W_L \)-action given by \( \phi_2 \). Applying Lemma 3.20 and 3.10 therefore tells us that \( \text{std} \circ \phi_{\rho}^{FS} \) admits a
sub-quotient isomorphic to $\phi_1$ or $\phi_1(1)$ and a sub-quotient isomorphic to $\phi_2$ or $\phi_2(1)$. This gives four possibilities for what the parameter $\text{std} \circ \phi_p^{FS}$ is. Since $\phi_p^{FS}$ is a $\text{GSp}_4$-valued parameter only two of these are possible; namely, $\phi_1 \oplus \phi_2$ or $(\phi_1 \oplus \phi_2)(1)$. However, the second possibility can be ruled out since the similitude character of $\text{std} \circ \phi_p = \phi_1 \oplus \phi_2$. Therefore, we conclude that $\text{std} \circ \phi = \text{std} \circ \phi_p^{FS}$ and, by the aforementioned equality of similitude characters of these two parameters and [GT11, Lemma 6.1], this is enough to conclude that $\phi_p = \phi_p^{FS}$, as conjugacy classes of $\text{GSp}_4$-valued parameters.

4. Basic Uniformization

In this section, we will briefly review what basic uniformization of the generic fiber of a global Shimura variety means, following [Han20] Section 3.1. Then we will apply it to our particular case and derive an analogue of Boyer’s trick, providing useful consequences for the proof of Proposition 1.4.

4.1. A Review of Basic Uniformization. We now recall briefly what basic uniformization means. Let $G/\mathbb{Q}$ be a connected reductive group over $\mathbb{Q}$ and let $(G, X)$ be a Shimura datum, with associate conjugacy class of Hodge cocharacters $\mu : \mathbb{G}_m, \mathbb{C} \to G_{\mathbb{C}}$. Fix a prime $p$, and set $G := G_{\mathbb{Q}_p}$. Using our fixed isomorphism $\mathbb{C} \simeq \overline{\mathbb{Q}}_p$, we can and do regard $\mu$ as a conjugacy class of cocharacters $\mu : \mathbb{G}_m, \overline{\mathbb{Q}}_p \to G_{\overline{\mathbb{Q}}_p}$. This allows us to consider the $\mu$-admissible locus $B(G, \mu)$ in the Kottwitz set of $G$. Let $\mathbb{A}$ (resp. $\mathbb{A}_f$) denote the adeles (resp. finite adeles) of $\mathbb{Q}$ and $\mathbb{A}_f^p$ denote the finite adeles away from $p$. For any compact open subgroup $K \subset G(\mathbb{A}_f)$, let $S(G, X)_K$ be the associated rigid analytic Shimura variety over $\mathbb{C}_p$ of level $K$. We let $K = K^pK_p$, where $K^p \subset G(\mathbb{A}_f^p)$ and $K_p \subset G(\mathbb{Q}_p)$ are open compact subgroups. We set

$$S(G, X)_{K^p} = \lim_{K_p \to \{1\}} S(G, X)_{K^K_p}$$

If $(G, X)$ is of pre-abelian type, this is (up to completing the structure sheaf) representable by a perfectoid space and in general it is a diamond. By the results of [Han16], there exists a canonical $G(\mathbb{Q}_p)$-equivariant Hodge-Tate period map

$$\pi_{HT} : S(G, X)_{K^p} \to F_{\ell \mu^{-1}}$$

where $F_{\ell \mu^{-1}} := (G_{\mathbb{Q}_p}/P_{\mu^{-1}})^{ad}$ is the adic space associated to the flag variety defined by the parabolic $P_{\mu^{-1}} \subset G_{\mathbb{Q}_p}$ given by $\mu^{-1}$ via the dynamical method. By the $G(\mathbb{Q}_p)$-equivariance, $\pi_{HT}$ descends to a map:

$$\pi_{HT,K^p} : S(G, X)_{K_pK^p} \to [F_{\ell \mu^{-1}}/K_p]$$

We let $b \in B(G, \mu)$ be the unique basic element, and let $F_{G, \mu^{-1}}$ be the basic Newton stratum. This parametrizes, for $S$ a perfectoid space in characteristic $p$, modifications $E_0 \to E$ of type $\mu^{-1}$ between the trivial $G$-bundle $E_0$ on the relative Fargues-Fontaine curve $X_S$ and $E$ a bundle isomorphic to the $G$-bundle $E_b$ corresponding to $b \in B(G)$ after pulling back to a geometric point of $S$. $(G, b, \mu)$ defines a local Shimura datum, as in section 3.1, so we may consider the infinite level Shimura variety/Shtuka space $\text{Sht}(G, b, \mu)_\infty$ and its base change $\text{Sht}(G, b, \mu)_{\infty, \mathbb{C}_p}$. By pulling back along $\pi_{HT}$, we get an open subspace $S(G, X)^b_{K^p} \subset S(G, X)_{K^p}$, which descends to an open subspace $S(G, X)^b_K$, for $K \subset G(\mathbb{A}_f)$ an open compact. We now have the key definition.

**Definition 4.1.** We say a global Shimura datum $(G, X)$ satisfies basic uniformization at $p$ if there exists (in fact this is always true see [Han20 Proposition 3.1]) a unique up to isomorphism $\mathbb{Q}$-inner form $G'$ of $G$ satisfying

- $G'_{\mathbb{A}_f} \simeq G_{\mathbb{A}_f}$ as algebraic groups over $\mathbb{A}_f^p$,
\( G'_{\mathbb{Q}_p} \simeq J_b \), where \( J_b \) is the inner form of \( G \) given by the \( \sigma \)-centralizer of the basic element \( b \in B(G, \mu) \),

- \( G'(\mathbb{R}) \) is compact modulo center,

and a \( G(\mathbb{A}_f) \)-equivariant isomorphism of diamonds over \( \mathbb{C}_p \)

\[
\lim_{K_p \to \{1\}} S(G, X)_{K_p}^b \simeq (G'(\mathbb{Q}) \setminus G'(\mathbb{A}_f)) \times_{\text{Spd}(\mathbb{C}_p)} \text{Sht}(G, b, \mu, \infty, \mathbb{C}_p)/J_b(\mathbb{Q}_p)
\]

where \( J_b(\mathbb{Q}_p) \) acts diagonally, such that, under the identification \( \mathcal{F} \ell_{G, \mu^{-1}}^b \simeq \text{Sht}(G, b, \mu, \infty, \mathbb{C}_p)/J_b(\mathbb{Q}_p) \), the morphism

\[
\pi_{HT} : \lim_{K_p \to \{1\}} S(G, X)_{K_p}^b \to \mathcal{F} \ell_{G, \mu^{-1}}^b
\]

identifies with the projection

\[
(G'(\mathbb{Q}) \setminus G'(\mathbb{A}_f)) \times_{\text{Spd}(\mathbb{C}_p)} \text{Sht}(G, b, \mu, \infty, \mathbb{C}_p)/J_b(\mathbb{Q}_p) \to \text{Sht}(G, b, \mu, \infty, \mathbb{C}_p)/J_b(\mathbb{Q}_p)
\]

where \( G(\mathbb{A}_f) \simeq G'(\mathbb{A}_f) \times G(\mathbb{Q}_p) \) acts on the RHS via the natural action of \( G'(\mathbb{A}_f) \) on \( G'(\mathbb{Q}) \setminus G'(\mathbb{A}_f) \) and \( G(\mathbb{Q}_p) \) acts on \( \text{Sht}(G, b, \mu, \infty, \mathbb{C}_p) \). Moreover, if the reflex field of the cocharacter \( \mu : \mathbb{G}_{m, \mathbb{Q}_p} \to \mathbb{G}_{\mathbb{Q}_p} \) is \( E/\mathbb{Q}_p \), then this isomorphism descends to an isomorphism of diamonds over \( \overline{E} := E\overline{\mathbb{Q}_p} \).

We now mention some consequences of uniformization which will be key to us in what follows. Let \( \mathcal{H}(J_b) := C^c_{\mathbb{A}_f}(J_b(\mathbb{Q}_p), \mathbb{Q}_p) \) be the usual smooth Hecke algebra. We fix an algebraic representation of \( G/\mathbb{Q} \), denoted \( \mathcal{V}_\xi \), of some regular highest weight \( \xi \). The isomorphism \( i : \overline{\mathbb{Q}_\xi} \isom \mathbb{C} \) then determines a \( \mathbb{Q}_\xi \)-local system \( \mathcal{L}_\xi \) on the Shimura variety \( S(G, X)_{K_p} \). We now consider the space of algebraic automorphic forms valued in \( \mathcal{V}_\xi \):

\[
\mathcal{A}(G'(\mathbb{Q}) \setminus G'(\mathbb{A}_f)/K_p, \mathcal{L}_\xi) := \text{colim}_{K_p \to \{1\}} A(G'(\mathbb{Q}) \setminus G'(\mathbb{A}_f)/K_p)_{\text{K}_p}, \mathcal{L}_\xi
\]

in the sense of Gross \cite{Gro99}. Namely, it is the space of all continuous functions \( \phi : G'(\mathbb{A}_f) \to \mathcal{V}_\xi(\overline{\mathbb{Q}_\xi}) \) with respect to the pro-finite topology on the target and the discrete topology on the source such that, for all \( k \in K_p, \gamma \in G(\mathbb{Q}) \), and \( g \in G'(\mathbb{A}_f) \), we have that \( \phi(\gamma k) = \phi(g) \) and \( \phi(\gamma g) = \gamma \phi(g) \), where \( \gamma \) acts via \( \mathcal{V}_\xi \). The isomorphism \((2)\) then allows us to deduce an isomorphism

\[
R\Gamma_c(G, b, \mu, \mathbb{Q}_p) \otimes_{\mathcal{H}(J_b)} \mathcal{A}(G'(\mathbb{Q}) \setminus G'(\mathbb{A}_f)/K_p, \mathcal{L}_\xi) \cong R\Gamma_c(S(G, X)_{K_p}^b, \mathcal{L}_\xi)
\]

of \( G(\mathbb{Q}_p) \times W_{E'} \)-modules, which when composed with the morphism

\[
R\Gamma_c(S(G, X)_{K_p}^b, \mathcal{L}_\xi) \to R\Gamma_c(S(G, X)_{K_p}^b, \mathcal{L}_\xi)
\]

coming from excision with respect to the open strata \( S(G, X)_{K_p}^b \hookrightarrow S(G, X)_{K_p} \), gives rise to the uniformization map mentioned in the introduction. We show this now.

**Corollary 4.1.** Assume that \( (G, X) \) satisfies basic uniformization at \( p \), then there exists a \( G(\mathbb{Q}_p) \times W_{E'} \)-equivariant map

\[
\Theta : R\Gamma_c(G, b, \mu, \mathbb{Q}_p) \otimes_{\mathcal{H}(J_b)} \mathcal{A}(G'(\mathbb{Q}) \setminus G'(\mathbb{A}_f)/K_p, \mathcal{L}_\xi) \to R\Gamma_c(S(G, X)_{K_p}^b, \mathcal{L}_\xi)
\]

functorial in the level \( K_p \).

**Proof.** We fix a level at \( K_p \subset G(\mathbb{A}_f) \) and write \( \pi_{HT,K_p} : S(G, X)_{K_p} \to [\mathcal{F} \ell_{G, \mu^{-1}}/K_p] \) for the induced Hodge-Tate period map. Then we have an isomorphism:

\[
R\Gamma_c(S(G, X)_{K_p}, \mathcal{L}_\xi) \simeq \text{colim}_{K_p \to \{1\}} R\Gamma([\mathcal{F} \ell_{G, \mu^{-1}}/K_p], R\pi_{HT,K_p}(\mathcal{L}_\xi))
\]

Write \( j_{K_p} : [\mathcal{F} \ell_{G, \mu^{-1}}/K_p] \hookrightarrow [\mathcal{F} \ell_{G, \mu^{-1}}/K_p] \) for the open inclusion of the basic locus quotiented out by \( K_p \). Now, we claim that, under this identification, the desired map is given by

\[
R\Gamma_c([\mathcal{F} \ell_{G, \mu^{-1}}/K_p], j_{K_p}R\pi_{HT,K_p}(\mathcal{L}_\xi)) \to R\Gamma([\mathcal{F} \ell_{G, \mu^{-1}}/K_p], R\pi_{HT,K_p}(\mathcal{L}_\xi))
\]
coming from applying excision with respect to \( j_{K_p} \) for varying \( K_p \). Here we stress that, since we are finite level, this is happening in the usual (not solid) category of étale \( \mathbb{Q}_\ell \)-sheaves, where excision is well-defined. The claim would now follow from showing a natural identification

\[
R\Gamma_c([\mathcal{F}^b_{G,\mu^{-1}}/K_p], j_{K_p}^* R\pi_{HT,K_p!}(\mathcal{L}_\xi)) \simeq R\Gamma_c(G, b, \mu)_{K_p} \otimes_{\mathbb{H}(J_b)} \mathcal{A}(G'(\mathbb{Q}) \setminus G'(\mathbb{A}_f)/K_p, \mathcal{L}_\xi)
\]

for all \( K_p \). There is a natural map

\[
q_{K_p}^b : [\mathcal{F}^b_{G,\mu^{-1}}/K_p] \to [\text{Spd}(\mathbb{C}_p)/J_b(Q_p)]
\]

which is cohomologically smooth as in [Han20] Proposition 2.16. Since we are working with the usual category of étale \( \mathbb{Q}_\ell \)-sheaves, the derived category of \( \mathbb{Q}_\ell \)-sheaves on the target is not identified with the unbounded derived category of smooth representations of \( J_b(Q_p) \), but rather the unbounded derived category of smooth \( \ell \)-complete representations (see Remark 3.1). However, by fixing a \( K_p \) stable lattice in the \( \mathbb{Z}_\ell \)-lattice in the \( \mathbb{Q}_\ell \) realization of the algebraic representation \( \mathcal{V}_\xi \), we can endow \( \Pi := \mathcal{A}(G'(\mathbb{Q}) \setminus G'(\mathbb{A}_f)/K_p, \mathcal{L}_\xi) \) with the structure of such a \( J_b(Q_p) \)-representation, and we write \( \mathcal{F}_\Pi \) for this sheaf. By [Han20] Corollary 3.7, the fact that we know basic uniformization at \( p \) implies we have a natural in \( K_p \) isomorphism:

\[
(q_{K_p}^b)(\mathcal{F}_\Pi) \simeq j_{K_p}^* R\pi_{HT,K_p!}(\mathcal{L}_\xi)
\]

Applying \( R\Gamma_c([\mathcal{F}^b_{G,\mu^{-1}}/K_p], -) \), we obtain

\[
R\Gamma_c([\mathcal{F}^b_{G,\mu^{-1}}/K_p], (q_{K_p}^b)(\mathcal{F}_\Pi)) \simeq R\Gamma_c([\mathcal{F}^b_{G,\mu^{-1}}/K_p], j_{K_p}^* R\pi_{HT,K_p!}(\mathcal{L}_\xi))
\]

but now, by [Han20] Proposition 2.17, we have an isomorphism

\[
R\Gamma_c(G, b, \mu)_{K_p} \otimes_{\mathbb{H}(J_b)} \mathcal{A}(G'(\mathbb{Q}) \setminus G'(\mathbb{A}_f)/K_p, \mathcal{L}_\xi) \simeq R\Gamma_c([\mathcal{F}^b_{G,\mu^{-1}}/K_p], (q_{K_p}^b)(\mathcal{F}_\Pi))
\]

and this gives the desired result.

4.2. Boyer’s Trick. We will now be interested in applying uniformization to the situation we are interested in, proving an analogue of Boyer’s trick [Boy99] and deducing some relevant consequences. The relevant results are due to Shen.

**Theorem 4.2.** [She17] If \((G, X)\) is a Shimura datum of abelian type and \( p > 2 \) is a prime where \( G \) is unramified then \((G, X)\) satisfies basic uniformization at \( p \).

**Remark 4.1.** To see a full proof of this exact statement for the full integral model at hyperspecial level, one can look at the proof of [Li-22] Theorem D.

Now, consider a Shimura datum \((G, X)\), where \( G \) is a \( \mathbb{Q} \)-inner form of \( G^* := \text{Res}_{F/\mathbb{Q}} \text{GSp}_4 \), with \( F/\mathbb{Q} \) a totally real field such that \( p \) is totally inert and \( F_p \simeq L \), a fixed unramified extension of \( \mathbb{Q}_p \), and assume that \( G_{\mathbb{Q}_p} \simeq \text{Res}_{L/\mathbb{Q}_p} \text{GSp}_4 = G \). We fix a level \( K = K_pK_p^p \subset G(\mathbb{A}_f) \) as before, and assume from now on that \((G, X)\) is such that the corresponding cocharacter \( \mu \) is the Siegel cocharacter. Therefore, the unique basic \( b \in B(G, \mu) \) will have \( \sigma \)-centralizer given by \( \text{Res}_{L/\mathbb{Q}_p} \text{GU}_2(D) \), with \( D/L \) the quaternionic division algebra. Since \( L/\mathbb{Q}_p \) is unramified and \( p > 2 \), we can apply Theorem 4.2 to deduce basic uniformization at \( p \). Let \( G' \) be the \( \mathbb{Q} \)-inner form defined above. Now we prove the following result, which plays a similar role to Boyer’s trick [Boy99] in the study of the cohomology of the Lubin-Tate/Drinfeld towers.

**Lemma 4.3.** For \( b \in B(G, \mu) \) non-basic, the adic Newton strata \( \mathcal{F}^b_{G,\mu^{-1}} \) is parabolically induced as a space with \( G(\mathbb{Q}_p) \)-action from a proper parabolic subgroup \( P = LU \) of \( G \) and a diamond \( S_P \) with \( P(\mathbb{Q}_p) \)-action. Moreover, the action of \( U(\mathbb{Q}_p) \) on the \( \ell \)-adic cohomology of \( R\Gamma_c(S_P, \mathbb{Q}_\ell) \) is trivial.
Proof. We recall [RV14] Definition 4.28 that we say \( b \in B(G, \mu) \) is Hodge-Newton reducible if there exists a proper Levi subgroup \( L \) together with a basic element \( b_L \in B(L, \mu_L) \) mapping to \( b \in B(G, \mu) \) under the natural map \( B(L) \to B(G) \), where \( \mu_L \) is a choice of representative for \( \mu \) as a geometric dominant cocharacter of \( L \). Given such a \( b \), we let \( P \) be the standard parabolic of \( G \) with respect to \( b \) and its Levi factor is \( L \), and fix \( \mu_L \) to be the conjugacy class of dominant cocharacters of \( L \) that is dominant respect to \( b \). It now follows by [GI16, Proposition 4.13] that \( P(\mathbb{Q}_p) \subset G(\mathbb{Q}_p) \) stabilizes a subdiamond \( \mathcal{C}_{b_L}^\mu \) and that we have a \( L(\mathbb{Q}_p) \)-equivariant isomorphism:

\[
\mathcal{O}_{b_L}^{\mu_L} \times P(\mathbb{Q}_p) G(\mathbb{Q}_p) \simeq \mathcal{F}_{G,\mu^{-1}}^{b_L}
\]

We recall that, if \( \mathcal{J}_b \) denotes the group diamond parametrizing automorphisms of the bundle corresponding to \( b \in B(G) \), this has a semi-direct product decomposition

\[
\mathcal{J}_b := J_b(\mathbb{Q}_p) \ltimes \mathcal{J}_b^U
\]

given by the splitting of the IH-filtration of \( \mathcal{E}_b \) [PS21 Proposition III.5.1]. By [GI16 Proposition 4.24], the space \( \mathcal{O}_{b_L}^{\mu_L} \) is isomorphic to

\[
\mathcal{F}_{b_L}^{\mu_L} \times \mathcal{J}_b^U
\]

and, by [GI16 Lemma 4.28], it follows that the action of \( U_b(\mathbb{Q}_p) \) on \( \mathcal{R}_c(\mathcal{C}_{b_L}^{\mu_L}, \overline{\xi}_T) \) is trivial. Therefore, the claim will follow from checking that the non-basic elements in \( B(G, \mu) \) are Hodge-Newton reducible. This follows immediately from the classification of this condition in [GHN19 Theorem 2.5]. For clarity, we recall how this works in our case. There are two non-basic elements \( b \in B(G, \mu) \). The \( \mu \)-ordinary element, defined by the maximal element \( b_{\text{max}} \in B(G, \mu) \) with respect to the partial ordering on \( B(G, \mu) \), and the intermediate strata corresponding to the element lying between the basic element and \( b_{\text{max}} \) with respect to the partial ordering on \( B(G) \). The element \( b_{\text{max}} \) admits a reduction to the unique basic element \( b_L \in B(T, \mu_T) \), where \( T \) is the maximal torus inside \( \text{GSp}_4 / L \). Similarly, the element \( b \in B(G, \mu) \) corresponding to the intermediate strata admits a reduction to the unique basic element \( b_L \in B(L, \mu_L) \), where \( L \) is the Levi factor of the Klingen parabolic of \( \text{GSp}_4 \).

We now consider some irreducible representation \( \xi \) as above and look at the uniformization map

\[
\Theta : \mathcal{R}_c(G, b, \mu) \otimes_{\mathcal{H}(\mathcal{J}_b)} \mathcal{A}(G' / \mathcal{K}^p, L_\xi) \to \mathcal{R}_c(\mathcal{S}(G, X) \otimes_{\mathcal{K}^p} L_\xi)
\]

furnished by Corollary 4.1 and Theorem 4.2. We let \( \mathcal{R}_c(G, b, \mu)_{sc} \) and \( \mathcal{R}_c(\mathcal{S}(G, X) \otimes_{\mathcal{K}^p} L_\xi)_{sc} \) be the direct summands where \( G(\mathbb{Q}_p) \) acts via a supercuspidal representation. Then we have the following key consequence of the previous lemma, which justifies why we are referring to this as Boyer’s trick.

**Proposition 4.4.** The uniformization map \( \Theta \) induces an isomorphism

\[
\Theta_{sc} : \mathcal{R}_c(G, b, \mu)_{sc} \otimes_{\mathcal{H}(\mathcal{J}_b)} \mathcal{A}(G' / \mathcal{K}^p, L_\xi) \cong \mathcal{R}_c(\mathcal{S}(G, X) \otimes_{\mathcal{K}^p} L_\xi)_{sc}
\]

on the summand where \( G(\mathbb{Q}_p) \) acts via a supercuspidal representation.

**Proof.** We let \( \mathcal{F}_{G,\mu^{-1}}^{b_{\text{bas}}} \) denote the closed complement of \( \mathcal{F}_{G,\mu^{-1}}^{b_L} \) for \( b \in B(G, \mu) \) the unique basic element. The space \( \mathcal{F}_{G,\mu^{-1}}^{b_{\text{bas}}} \) is stratified by \( \mathcal{F}_{G,\mu^{-1}}^{b_L} \) for \( b \in B(G, \mu) \) non-basic. For varying \( K_p \subset G(\mathbb{Q}_p) \), we set \( \mathcal{F}_{G,\mu^{-1}}^{b_{\text{bas}}} / K_p \) to be the \( v \)-stack quotient. We let \( \mathcal{S}(G, X) \otimes_{\mathcal{K}^p} L_\xi \) denote the preimage of \( \mathcal{F}_{G,\mu^{-1}}^{b_{\text{bas}}} / K_p \) under the map \( \pi_{HT,K_p} : \mathcal{S}(G, X) \otimes_{\mathcal{K}^p} L_\xi \to \mathcal{F}_{G,\mu^{-1}}^{b_{\text{bas}}} / K_p \). It follows from the proof of Corollary 4.1 that the cone of \( \Theta \) is identified with

\[
\mathcal{R}_c(\mathcal{S}(G, X) \otimes_{\mathcal{K}^p} L_\xi) := \operatorname{colim}_{K_p \to \{1\}} \mathcal{R}_c(\mathcal{S}(G, X) \otimes_{\mathcal{K}^p} L_\xi).
\]

We want to show that the cohomology is parabolically induced as a \( G(\mathbb{Q}_p) \) representation from proper Levi subgroups of \( G \). For this, we consider the Hodge-Tate period morphism:

\[
\pi_{HT,K_p} : \mathcal{S}(G, X) \otimes_{\mathcal{K}^p} L_\xi \to \mathcal{F}_{G,\mu^{-1}}^{b_{\text{bas}}} / K_p
\]
The Cartan-Leray spectral sequence then gives us

\[ E_2^{p,q} = H_c^p(\mathcal{F}_{G,μ}^{μbas}/K_p, R^q\pi_{HT,K_p}(\mathcal{L}_ξ)) \implies H_c^{p+q}(S(G,X)^{μbas}, \mathcal{L}_ξ). \]

Using the \( G(\mathbb{Q}_p) \)-equivariance of the Hodge-Tate period map, the colimit over \( K_p \to \{1\} \) gives rise to a spectral sequence

\[ \text{colim}_{K_p \to \{1\}} H_c^p(\mathcal{F}_{G,μ}^{μbas}/K_p, R^q\pi_{HT,K_p}(\mathcal{L}_ξ)) \implies H_c^{p+q}(S(G,X)^{μbas}, \mathcal{L}_ξ) \]

with \( G(\mathbb{Q}_p) \)-equivariant maps. Therefore, we are reduced to showing the following.

**Lemma 4.5.** For all integers \( p, q \geq 0 \) the cohomology of \( \text{colim}_{K_p \to \{1\}} H_c^p(\mathcal{F}_{G,μ}^{μbas}/K_p, R^q\pi_{HT,K_p}(\mathcal{L}_ξ)) \) is parabolically induced as a \( G(\mathbb{Q}_p) \)-representation from a proper Levi subgroup of \( G \).

**Proof.** We apply excision with respect to the locally closed stratification given by \( \mathcal{F}_{G,μ}^b \) for \( b \in B(G,μ) \) which is not basic. We write \( j_{b,K_p} : [\mathcal{F}_{G,μ}^b/K_p] \to [\mathcal{F}_{G,μ}^b/K_p] \) for the associated locally closed immersion at level \( K_p \). Since the Newton strata \( \mathcal{F}_{G,μ}^b \) are stable under the \( G(\mathbb{Q}_p) \) action, this reduces us to showing that the cohomology of

\[ \text{colim}_{K_p \to \{1\}} H_c^p(\mathcal{F}_{G,μ}^{μbas}/K_p, j_{b,K_p} R^q\pi_{HT,K_p}(\mathcal{L}_ξ)) \]

is parabolically induced as a \( G(\mathbb{Q}_p) \)-representation. However, this now follows from Lemma 4.3, where one uses the second part of the claim to see the unipotent radical acts trivially. \( \square \)

This result will be the key tool in allowing us to describe the \( W_L \)-action on the local Shimura variety by global methods. We start this global analysis by constructing strong transfers between \( \text{GSp}_4 \) and its inner forms over a number field \( F \) and proving a strong multiplicity one result.

## 5. Existence of Strong Transfers and a Strong Multiplicity One Result

In this section, we will show the existence of strong transfers of certain automorphic representations of an inner form of \( \text{GSp}_4 \) over a number field \( F \), using the analysis of the trace formula similar to that of [KS16, Section 6]. We will then combine this with analysis of the simple twisted trace formula of Kottwitz-Shelstad [KS99] to deduce a kind of strong multiplicity one result for inner forms of \( \text{GSp}_4 \).

### 5.1. The Simple Trace Formula and Existence of Strong Transfers

In order to describe the Galois action on the global Shimura variety, we will need to construct strong transfers for inner forms of \( \text{GSp}_4 \) over a totally real field \( F \). This will allow us to compute the traces of Frobenius on the global Shimura variety in terms of the Langlands parameters of the strong transfer. The construction of strong transfers will be accomplished by applying the elliptic part of the stable trace formula with respect to the Lefschetz functions constructed by Kret-Shin [KS16] at the Steinberg-Infinite places and pseudo-coefficients at some finite number places where the representation has supercuspidal \( L \)-parameter, applying the character identities of Chan-Gan [CG15] to conclude equality of the orbital integrals at these latter places. First, we recall the key results of Kret-Shin on the trace formula with fixed central character. For now, we will work generally. Let \( G \) denote a connected reductive group over a number field \( F \) with center \( Z \), write \( A_Z \) for the maximal \( \mathbb{Q} \)-split torus of \( \text{Res}_{F/Q} Z \), and set \( A_{Z,∞} = A_Z(\mathbb{R})^0 \) to be the connected component of the identity. Let \( \mathbb{A}_F \) be the adeles of \( F \) and write \( G(\mathbb{A}_F)^1 \) for a choice of subgroup so that \( G(\mathbb{A}_F) = G(\mathbb{A}_F)^1 \times A_{Z,∞} \), as in [Art81, Page 11]. We consider a closed subgroup \( \mathcal{X} \subset Z(\mathbb{A}_F) \) which contains \( A_{Z,∞} \) such that \( Z(F)\mathcal{X} \) is closed inside \( Z(\mathbb{A}_F) \) and a continuous character \( \chi : (\mathcal{X} \cap Z(F)) \setminus \mathcal{X} \to \mathbb{C}^* \).

We write \( \mathbb{P}_1(F) \) for the set of places of \( F \), and, for \( v \in \mathbb{P}_1(F) \), let \( \mathcal{X}_v \subset Z(F_v) \) denote a closed subgroup. We let \( \chi_v : \mathcal{X}_v \to \mathbb{C}^* \) be a smooth character. Write \( \mathcal{H}(G(F_v), χ_v^{-1}) \) for the space of
smooth compactly supported functions modulo center on $G(F_v)$ which transform under $\mathfrak{X}_v$ via $\chi_v^{-1}$. We also require the functions to be $K_v$-finite for some maximal compact subgroup $K_v$ of $G(F_v)$ if $v$ is archimedean. We now take $\mathfrak{X}_v := \mathfrak{X}(F_v)$, where $\mathfrak{X}$ is as above. Given a semisimple element $\gamma_v \in G(F_v)$ and an admissible representation $\pi_v$ of $G(F_v)$ with central character $\chi_v$ on $\mathfrak{X}_v$, we define the orbital integral and trace character for $f_v \in \mathcal{H}(G(F_v),\chi_v^{-1})$ as follows. Let $I_{\gamma_v}$ denote the connected centralizer of $\gamma_v$ in $G$. We have

$$O_{\gamma_v}(f_v) := \int_{I_{\gamma_v}(F_v) \backslash G(F_v)} f_v(x^{-1}\gamma_v x) dx$$

and

$$\text{tr}(f_v|\pi_v) := \text{tr}(\int_{G(F_v)/Z(F_v)} f_v(g)\pi_v(g) dg)$$

where we have fixed compatible choices of Haar measure on $G$ and $Z$ throughout. We note that this operator is well defined since the above operator is of finite rank if $v$ is finite and is of trace class if $v$ is infinite, by the $K_v$-finiteness assumption.

We define the adelic Hecke algebra $\mathcal{H}(G(\mathcal{A}_F),\chi^{-1})$, as well as the global orbital integrals by taking a restricted tensor product over the local Hecke algebras defined above and products of the local integrals. Write $\Gamma_{\text{ell}}(G)$ to be the set of $F$-elliptic conjugacy classes in $G(F)$. Let $\mathcal{A}_{f,F}$ denote the finite adeles of $F$. For our purposes, it will suffice to consider a central character datum $(\mathfrak{X},\chi)$, where $\mathfrak{X} = Z(\mathcal{A}_F)$, and we write $\chi = \bigotimes_{v \in \text{Pl}_F} \chi_v$ for smooth characters $\chi_v : Z(F_v) \to \mathbb{C}^*$ and all $v \in \text{Pl}_F$. We let $L^2_{\text{disc},X}(G(F) \backslash G(\mathcal{A}_F))$ denote the space of functions on $G(F) \backslash G(\mathcal{A}_F)$ transforming under $\mathfrak{X}$ by $\chi$ and square-integrable on $G(F) \backslash G(\mathcal{A}_F)^1 / \mathfrak{X}(\mathcal{A}_F) \cap G(\mathcal{A}_F)^1$. Write $A_{\text{cusp},X}(G)$ for the set of isomorphism classes of cuspidal automorphic representations of $G(\mathcal{A}_F)$ whose central characters restricted to $\mathfrak{X}$ are $\chi$. For $f \in \mathcal{H}(G(\mathcal{A}_F),\chi^{-1})$, define the invariant distributions $T^G_{\text{ell},\chi}$ and $T^G_{\text{disc},\chi}$ by

$$T^G_{\text{ell},\chi}(f) := \sum_{\gamma \in \Gamma_{\text{ell}}(G)} i(\gamma)^{-1} \text{vol}(I_\gamma(F) \backslash I_\gamma(\mathcal{A}_F) / \mathfrak{X}(\mathcal{A}_F)) O_{\gamma}(f)$$

and

$$T^G_{\text{disc},\chi}(f) := \text{tr}(f|L^2_{\text{disc},X}(G(F) \backslash G(\mathcal{A}_F)))$$

where $i(\gamma)$ is the number of connected components in the centralizer of $\gamma$. Analogously, we define $T^G_{\text{cusp},X}(f)$ by taking the trace on the space of square-integrable cusp forms whose central character restricted to $\mathfrak{X}$ is $\chi$. Let $G^*$ denote the quasi-split inner form of $G$ over $F$, with a fixed inner twist $G^* \simeq G$ over $\overline{F}$. Since $Z$ is canonically identified with the center of $G^*$, we may view the character $\chi$ as a central character datum for $G^*$. We then let $f^*$ denote a Langlands-Shelstad transfer of $f$ to $G^*$. One can construct such a transfer by lifting $f$ along the surjection $\mathcal{H}(G(\mathcal{A}_F)) \to \mathcal{H}(G(\mathcal{A}_F),\chi^{-1})$ applying the transfer with trivial central character due to Waldspurger and then taking the image along the analogous surjection for $G^*(\mathcal{A}_F)$. We let $\Sigma_{\text{ell},X}(G^*)$ denote the set of $Z(\mathcal{A}_F)$ orbits of stable $F$-elliptic conjugacy classes in $G^*(F)$. We define the stable elliptic distribution

$$ST_{\text{ell},\chi}(f^*) := \tau(G^*) \sum_{\gamma \in \Sigma_{\text{ell},X}(G^*)} \tilde{i}(\gamma)^{-1} SO_{\gamma \chi}(f)$$

where $SO_{\gamma \chi}(f^*)$ denotes the stable orbital integral of $f^*$ at $\gamma$, $\tau(G^*)$ is the Tamagawa number of $G^*$, and $\tilde{i}(\gamma)$ is the number of Galois fixed connected components of the centralizer of $\gamma$ in $G^*$. Let $\xi$ be an irreducible representation of $G_{F_\infty}$. Denote by $\chi_\xi : Z(F_{\infty}) \to \mathbb{C}^*$ the restriction of $\xi$ to $Z(F_{\infty})$. Write $f^G_\xi \in \mathcal{H}(G(F_{\infty}),\chi_\xi^{-1})$ for a Lefschetz function associated with $\xi$. In other words, a function such that $\text{tr}(f^G_\xi|_{\pi_{\infty}})$ computes the Euler-Poincaré characteristic for the relative Lie algebra cohomology of $\pi_{\infty} \otimes \xi$ for every irreducible admissible representation $\pi_{\infty}$ of $G(F_{\infty})$ with central character $\chi_\xi$. It follows by the Vogan-Zuckerman classification [VZ84] that, if $\xi$ is regular, this
will be non-zero if and only if \( \pi_\infty \) is an (essentially) discrete series representation cohomological of regular weight \( \xi \). For a finite place \( v_{st} \) of \( F \), we let \( f_{v_{st}} := f_{Le_f,v_{st}}^G \in H(G(F_{v_{st}})) \) denote a Lefschetz function at \( v_{st} \). Morally, this should be characterized by the property that \( \text{tr}(f_{v_{st}}|_{\pi_{v_{st}}}) \) computes the Euler-Poincaré characteristic of the continuous group cohomology of \( G(F_{v_{st}}) \) valued in \( \pi_{v_{st}} \). In the case that the center is anisotropic, it follows from the computations in [BW00] Theorem XI.3.9 that this means that the trace of \( f_{Le_f,v_{st}}^G \) will only be non-zero if \( \pi_v \) is 1-dimensional or an unramified twist of the Steinberg representation, for all irreducible admissible unitary \( \pi_v \). For finite places \( v = v_{st} \), they were originally constructed by Kottwitz; however, these results do not apply for the desired application, since the center of \( \text{GSp}_4 \) is not compact. For the construction of these functions in this case and the proof of the property that their traces detect when a representation is 1-dimensional or an unramified twist of Steinberg, see [KS16] Appendix A.

We now assume for simplicity that the center \( Z \) of \( G \) is split, which will be the case in all our applications. We consider a character \( \eta : G(F) \to \mathbb{C}^* \) such that \( \eta|Z(F_{v_{st}}) = \chi_{v_{st}} \). We can define a function \( f_{Le_f,\eta}^G \in H(G(F), \chi_{v_{st}}^{-1}) \) as \( f_{Le_f,\eta}(g) := \eta^{-1}(g) f_{Le_f}(\overline{g}) \), where \( \overline{g} \in G(F_{v_{st}})/Z(F_{v_{st}}) \) denotes the image of \( g \) under the quotient map. This (up to scaling by a non-zero constant) forms a pseudo-coefficient for the Steinberg representation twisted by \( \eta \), as constructed in [Kaz86, SS97].

In particular, by [KS16, Corollary A.8 (2)], we have, for \( \pi_{v_{st}} \) an irreducible (essentially) unitary representation of \( G(F_{v_{st}}) \) with central character \( \chi_{v_{st}} \), that \( \text{tr}(f_{Le_f,\eta}|_{\pi_{v_{st}}}) \neq 0 \) if and only if \( \pi_{v_{st}} \) is isomorphic to \( \eta \) or Steinberg twisted by \( \eta \).

Now we have the key lemma, which tells us that with respect to these choices of test functions we get the following "simple trace formula".

**Lemma 5.1.** [KS16, Lemma 6.1, 6.2] Fix a central character datum \((Z(\mathbb{A}_F), \chi)\) with \( \chi_\xi = \chi|Z(F_v) \) as above for \( \chi_\xi \) attached to some regular weight \( \xi \). For an element \( f \in H(G(\mathbb{A}_F), \chi^{-1}) \) in the global Hecke algebra as above, assume that \( f_\infty = f_\xi^G \in H(G(F_v), \chi^{-1}) \) is a Lefschetz function at \( \infty \) and assume that \( f_{v_{st}} = f_{Le_f,\eta}^G \) is the Lefschetz function described above at \( v_{st} \) for a character \( \eta \) of \( G(F_{v_{st}}) \) such that \( \eta|Z(F_{v_{st}}) = \chi_{v_{st}} \). Then we have an equality:

\[
ST_{G_\infty}^g(f^\star) = T_{G_\infty}^g(f) = T_{disc,\chi}^g(f) = T_{cusp,\chi}^g(f)
\]

**Proof.** Strictly speaking, the cited Lemmas only prove this in the case where the central character datum is \((Z(F_\infty), \chi_\xi)\); however, the result in this case easily follows using [KS16, Corollary A.8 (3)] (cf. the proof of [KS16, Corollary 8.5]).

Let \( S_{st} \) and \( S_{ac} \) be disjoint finite sets of finite places of \( F \), and let \( S_0 \) be a finite set of places contained in \( S_{st} \cup S_{ac} \). Let \( S_\infty \) denote the infinite places of \( F \). Set \( S \) to be a finite set of places containing \( S_{st} \cup S_{ac} \cup S_\infty \). We assume that the inner twist \( G_\infty \) of \( G \) is trivialized away from \( S_0 \) and \( S_\infty \) (i.e for all \( v \notin S_0 \cup S_\infty \), the inner twisting gives rise to an isomorphism \( G_{F_v} \simeq G_{F_v}^* \)). In particular, \( G \) is unramified outside \( S \) and we can fix a reductive model for \( G \) and \( G^* \) over \( \mathcal{O}_F[1/S] \). By abuse of notation, we write \( G \) and \( G^* \) for the integral models of these groups. The inner twist gives an isomorphism \( G_{F_v}^* \simeq G_{F_v} \) and isomorphisms \( G_{F_v}^\star \simeq G_{\mathcal{O}_F}^\star \) of the hyperspecial subgroups determined by this model for the finite places \( v \notin S \). The notion of unramified local representation on either side will be defined with respect to this fixed choice of hyperspecial level.

For the rest of the section, we will assume that \( G^* = \text{GSp}_4 \). We assume throughout that \( \pi \) is a global cuspidal automorphic representation of the group \( G(\mathbb{A}_F) \) satisfying the following properties:

1. \( \pi \) is cohomological of some regular weight \( \xi \) at infinity.
2. \( \pi_v \) is unramified at all finite places \( v \notin S \).
3. \( \pi_v \) has supercuspidal \( L \)-parameter for \( v \in S_{ac} \).
4. \( \pi_v \) is an unramified twist of Steinberg at all finite places \( v \in S_{st} \).
Note, as in Definition 2.1, we can further partition $S_{sc}$ into $S_{ssc}$, where std $\circ \phi_{\pi_v}$ is irreducible (ssc = stable supercuspidal) and $S_{esc}$, where std $\circ \phi_{\pi_v}$ is reducible (esc = endoscopic supercuspidal).

The main result of this section shows the existence of strong transfers from $G$ to $G^*$ at the places in $S_{sc} \cup S_{st} \cup S_{\infty}$ for a certain class of automorphic representations of $G$. It is essentially a more refined version of [KS16 Proposition 6.3] in the particular case that $G^* = GSp_4$.

**Theorem 5.2.** Suppose that $S_{st}$ is non-empty. Given a $\pi$ as above, there exists a cuspidal automorphic representation $\tau$ of $G^*(\mathbb{A}_F)$ satisfying the following:

- $\tau^{S} \simeq \pi^{S}$.
- At all $v \in S_{sc} \cup S_{st} \cup S_{\infty}$, $\tau_v$ has the same Langlands parameter as $\pi_v$.

Moreover, we can choose $\tau$ to be globally generic. For the first part, the same is true with the roles of $\tau$ and $\pi$ reversed.

**Proof.** First off note that, since $\pi$ is an unramified twist of Steinberg at some finite place, $\tau$, if it exists, is automatically (essentially) tempered at all places (cf. Remark 5.1). It follows, by [GT19 Remark 7.4.7], that the global $L$-packet of $\tau$ therefore contains a globally generic representation. So, if we can show existence of some $\tau$ with the desired properties, that means we can find $\tau$ globally generic with the same properties. For the former, we now apply the trace formula.

Let $X = Z(\mathcal{A}_F)$ and $\chi$ be the central character of $\pi$. We set $f = \bigotimes_{v \in F} f_v$ to be a test function on $G(\mathcal{A}_F)$ satisfying the following:

1. $f_\infty = f_\xi^G$ is a Lefschetz/Euler-Poincaré function of weight $\xi$ of $G(F_\infty)$.
2. At $v \in S_{st}$, $f_v = f_{Lef, \eta_v}^G$ is a Lefschetz function for $G(F_v)$, where $\eta_v$ is the unique character such that $\pi_v$ is the Steinberg twisted by $\eta_v$.
3. At $v \in S_{ssc}$, $f_v = f_{\pi_v}$ is the pseudo-coefficient of $\pi_v$, as constructed in [Kaz86 SS97].
4. At $v \in S_{esc}$, $f_v = f^{\pm}_{\pi_v}$, where $\{\tau_v^+, \tau_v^\pm\}$ is the $L$-packet over $\phi_{\pi_v}$ and $f^{\pm}_{\pi_v}$ is the pseudo-coefficient of $\pi_v$.
5. At the finite places $v \notin S$, $f_v$ is an arbitrary function of the unramified Hecke algebra.
6. For $v \in S \setminus S_{st} \cup S_{\infty} \cup S_{sc}$, choose $f_v$ to be an arbitrary function such that $\text{tr}(f_v|_{\pi_v}) > 0$.

Given such a $f$, we choose a test function $f^* = \bigotimes_{v \in F} f_v^*$ on $G^*(\mathbb{A}_F)$ satisfying the following:

1. $f^*_\infty = f_\xi^{G^*}$ is a Lefschetz/Euler-Poincaré for the representation $\xi$ of $G^*(F_\infty)$.
2. At $v \in S_{st}$, $f^*_v = f_{Lef, \eta_v}^{G^*}$ is the Lefschetz function for $G^*(F_v)$.
3. At $v \in S_{ssc}$, $f^*_v = f_{\tau_v}$ is a pseudo-coefficient of $\tau_v$, where $\tau_v$ is the unique supercuspidal representation of $G^*(F_v)$ with Langlands parameter $\phi_{\tau_v}$.
4. At $v \in S_{esc}$, $f^*_v = f^{\pm}_{\tau_v}$, where $\{\tau_v^+, \tau_v^\pm\}$ is the $L$-packet over $\phi_{\tau_v}$ of $G^*(F_v)$ and $f^{\pm}_{\tau_v}$ is the pseudo-coefficient of $\tau_v^\pm$.
5. At the finite places $v \notin S$, $f^*_v$ is the same element of the unramified Hecke algebra.
6. For $v \in S \setminus S_{st} \cup S_{\infty} \cup S_{sc}$, choose $f^*_v = f_v$.

Now we wish to check that $f$ and $f^*$ are matching up to a non-zero constant $c$, in the sense of [KS16 Section 5.5]. We can check this place by place. For the finite places $v \notin S_{st} \cup S_{sc} \cup S_{\infty}$, this is tautological. For all $v \in S_{\infty} \cup S_{st}$, this follows from [KS16 Lemma A.4, A.11]. For $v \in S_{sc}$, this follows from the character identities of Chan-Gan [CG15 Proposition 11.1]. Namely, recall for a regular semisimple elliptic element $\gamma$ the orbital integrals of the pseudo-coefficients of a discrete series representation $\pi$ is given by the Harish-Chandra character of $\pi$ evaluated at $\gamma$, and it vanishes if $\gamma$ is non-elliptic [Kaz86 Theorem K] [KST20 Proposition 3.2.2]. It follows that the orbital integrals for a sum of pseudo-coefficients over an $L$-packet of $GSp_4$ or its inner form is already a stable distribution, by [CG15 Main Theorem] combined with [CG15 Proposition 11.1 (1)] for the inner form. Therefore, the desired equality of stable orbital integrals reduces to showing an equality of
the sum of Harish-Chandra characters over the \( L \)-packets of supercuspidal parameters, and this is precisely [CG15, Proposition 11.1 (1)].

Since the test functions are matching and \( S_{st} \neq \emptyset \), we can apply Lemma 5.1 to conclude:

\[
T_{cusp, \chi}^{G^*}(f^*) = S T_{cusp, \chi}^{G^*}(f^*) = c T_{cusp, \chi}^{G}(f)
\]

Then, by linear independence of characters, we have a relationship

\[
\sum_{\Pi' \in A_{cusp, \chi}(G^*)} m(\Pi') \text{tr}(f_\pi' | \Pi') = c \cdot \sum_{\Pi \in A_{cusp, \chi}(G)} m(\Pi) \text{tr}(f_\pi | \Pi_S)
\]

where \( m(\Pi) \) (resp. \( m(\Pi') \)) denotes the multiplicity of \( \Pi \) (resp. \( \Pi' \)) in the cuspidal spectrum of \( G \) (resp. \( G^* \)). Now at the infinite places, as soon as \( \text{tr}(f_v | \Pi_v) \neq 0 \) at \( v \mid \infty \) the regularity condition on \( \xi \) implies that \( \Pi_v \) is an (essentially) discrete series representation cohomological of regular weight \( \xi \) and that \( \text{tr}(f_v | \Pi_v) = (-1)^q(\Pi_v) \) by the Vogan-Zuckerman classification of unitary cohomological representations, where \( q(G) \) is the \( F \)-rank of the derived group of \( G \). At \( v_{st} \in S_{st} \) it follows by [KS16, Corollary A.8] that \( \Pi_{v_{st}} \) is either the \( \eta_{v_{st}} \) twist of the Steinberg or trivial representation. If \( \Pi_{v_{st}} \) were one-dimensional then the global representation would also be one-dimensional by a strong-approximation argument [KST20, Lemma 6.2], implying that \( \Pi_\infty \) cannot be tempered, which would contradict the fact \( \Pi_\infty \) is an (essentially) discrete series representation. Therefore, \( \Pi_{v_{st}} \) is always the \( \eta_{v_{st}} \) twist of the Steinberg representation. At the remaining \( v \in S_{sc} \) (resp. \( v \in S_{esc} \)), it follows from the definition of pseudo-coefficients that, if \( \text{tr}(f_v | \Pi_v) > 0 \), we have \( \Pi_v \simeq \pi_v \) (resp. \( \Pi_v \in \{ \pi_v^+, \pi_v^- \} \)). Similar considerations apply for \( \Pi' \in A_{cusp, \chi}(G^*) \) occurring non-trivially in the LHS. In summary, by the above analysis, we can deduce that the RHS of the previous equation is non-zero for the term corresponding to \( \tau \) and that all the non-trivial terms on the RHS have the same sign. Therefore, the LHS is also non-zero, and we see, by choosing any non-zero term, that we obtain the desired \( \tau \).

The converse direction works similarly, where the role of \( G \) and \( G^* \), are swapped. \( \square \)

**Remark 5.1.** We note that we crucially used at the places \( v \in S_{sc} \) that \( \phi_{\pi_v} \) was supercuspidal. Otherwise, \( \text{tr}(f_v | \Pi_v) \neq 0 \) wouldn’t necessarily imply that \( \Pi_v \) lies in the \( L \)-packet over \( \phi_{\pi_v} \) without assuming that \( \Pi_v \) is tempered. However, by [KS16, Lemma 2.7] any representation of \( GSp_4 \) that is Steinberg at some non-empty finite set of places is tempered at all places. Therefore, we can relax this assumption at least for the forward direction of Theorem 5.2 to just assuming that \( \tau_v \) is a discrete series representation at all \( v \in S_{sc} \).

### 5.2. The Stable and \( \sigma \)-twisted Simple Trace Formula

For the proof of strong multiplicity one, we will need some more refined analysis of trace formulae. Namely, we will be interested in the discrete part of the stable trace formula in the particular case of \( G^* = GSp_4 \), as discussed in [CG15, Section 7.1]. To this end, fix a central character datum \( (X, \chi) = (Z(\mathbb{A}_F), \chi) \) as before. We recall that the unique elliptic proper endoscopic group of \( GSp_4 / F \) is \( C = GSO_{2,2} \simeq (GL_2 \times GL_2) / \{(t, t^{-1}) | t \in GL_1 \} \). Then, for a test function \( f^* \) on \( G^*(\mathbb{A}_F) \) as above, the discrete part of the stable trace formula is an equality:

\[
I_{disc, \chi}^{G^*}(f^*) = S T_{disc, \chi}^{G^*}(f^*) + \frac{1}{4} S T_{disc, \chi}^C(f^*)
\]

for \( f^C \) a matching test function on \( C \). Here

\[
I_{disc, \chi}^{G^*}(f^*) = \sum_M |W(G, M)|^{-1} \cdot \sum_{s \in W(M, G)_{reg}} |\det(s - 1) a_M / a_G|^{-1} \cdot \text{tr}(M_F(s, 0) \cdot I_{disc, \chi}^{G^*}(0, f^*)}
\]

is a sum indexed over classes of standard Levi subgroups of \( G^* \). The precise definition of the terms will not be important for our purposes, but the interested reader can look at [Art02, Section 3]. We simply note that the term corresponding to \( M = G^* \) is precisely equal to \( T_{disc, \chi}^{G^*}(f^*) \), as defined in

\[
\text{COMPATIBILITY OF THE FARGUES-SCHOLZE AND GAN-TAKEDA LOCAL LANGLANDS 43}
\]
section 5.1. $ST_{\text{disc,} \chi}^{G^*}$ is a stable distribution on $G^*$, similar to $ST_{\text{ell,} \lambda}^{G^*}$, and $ST_{\text{disc,} \chi}^{C}$ is the analogous stable distribution on $C(\mathbb{A}_F)$. However, since $C$ has no proper elliptic endoscopic group, we have

$$ST_{\text{disc,} \chi}^{C}(f^C) = I_{\text{disc,} \chi}^{C}(f^C) = T_{\text{disc,} \chi}^{C}(f^C) + (\text{other terms})$$

with the other terms indexed by proper standard Levi subgroups of $C$ as above.

We will be interested in combining this with the elliptic part of the twisted trace formula as described by Kottwitz-Shelstad [KS99] for the particular group $\tilde{G} := \text{GL}_4 \times \text{GL}_1/F$ with respect to involution

$$\sigma : (g,e) \mapsto (J^t g^{-1} J^{-1}, edet(g))$$

where

$$J := \begin{bmatrix} 1 & 0 \\ 0 & -1 \end{bmatrix}$$

We can enumerate the elliptic $\sigma$-twisted endoscopic groups as follows.

1. $G^* = \text{GSp}_4$
2. $C_E = \text{Res}_{E/F} \text{GL}_2' := \{(g_1, g_2) \in \text{Res}_{E/F} \text{GL}_2 | \det(g_1) = \det(g_2)\}$
3. $C_E^\sigma = (\text{GL}_2 \times \text{Res}_{E/F} \text{GL}_1)/\text{GL}_1$

where $E$ is an étale quadratic $F$-algebra and $E$ is not split in case (3). The simple stable twisted trace formula says that if $\tilde{f}$ is a test function on $\tilde{G}$ whose twisted orbital integral is supported on the regular elliptic set at at least 3 finite places, then we have an identity

$$I_{\text{disc,} \chi}^{G, \sigma}(\tilde{f}) = \frac{1}{2} ST_{\text{disc,} \chi}^{G^*}(f^*) + \frac{1}{4} \sum_{E} ST_{\text{disc,} \chi}^{C_E}(f^{\sigma}) + \frac{1}{8} \sum_{E \neq F^2} ST_{\text{disc,} \chi}^{C_E^\sigma}(f^{E^\sigma})$$

where

- $\sum_E$ is a sum over étale quadratic $F$-algebras $E$,
- $\tilde{f}$, $f^*$, $f^{C_E}$, and $f^{C_E^\sigma}$ are matching test functions,
- $ST_{\text{disc,} \chi}^{G^*}$, $ST_{\text{disc,} \chi}^{C_E}$, and $ST_{\text{disc,} \chi}^{C_E^\sigma}$ are the stable distributions appearing in the discrete part of the stable trace formula, as described above,
- $I_{\text{disc,} \chi}^{G, \sigma}$ is the invariant distribution which is the twisted analogue of $I_{\text{disc,} \chi}^{G^*}$.

It is given by [LW13] Theorem 14.3.1 and Proposition 14.3.2] and has the form

$$I_{\text{disc,} \chi}^{G, \sigma}(\tilde{f}) = \sum_{M} \left[ W(G, M) \right]^{-1} \sum_{\mathfrak{s} \in W(M, G)_{\text{reg}}} |\det(s-1)^{\mathfrak{s}}_{\mathfrak{a}^G/\mathfrak{a}_G}|^{-1} \cdot \text{tr}(M_{P}(s,0) \cdot I_{\text{disc,} \chi}^{P}(0, \tilde{f}) I_{P, \text{disc}}(\sigma))$$

where the sum runs over standard Levi subgroups $M$ of $G$.

Now we want to apply these trace formulae with respect to appropriately chosen test functions. We will assume that $S_{st}$ is a finite set of places such that $|S_{st}| \geq 3$. Then, for all $v \in S_{st}$, we let $f_v^*$ be a pseudo-coefficient for the unramified twist of Steinberg by $\eta_v$, where $\eta_v$ is a character of $G(\mathbb{F}_v)$ such that the restriction to $Z(F_v)$ is $\chi_v$. In particular, we will take $f_v^*$ to be the Lefschetz function $f_v^{C^*} \in \mathcal{H}(G^*(\mathbb{F}_v), \chi_v^{-1})$ considered in the previous section which is a pseudo-coefficient for Steinberg up to scaling. It follows, by [CG15, Corollary 10.8], that we can choose the local constituent of the matching function $\tilde{f}$ at $v$ to be the $\sigma$-twisted pseudo-coefficient of the Steinberg twisted by $\eta_v$, as defined in [MW18]. These functions orbital integrals are supported on the regular elliptic set (See the construction in [MW18, Section 7.2]) and therefore we can apply the simple twisted trace formula. Moreover, the twisted orbital integral of $f_v$ is a stable function, and hence the $\kappa$-orbital integral of $f_v$ is zero for all $\kappa \neq 1$. Therefore, it follows that the transfers of $f_v$ to
all elliptic twisted endoscopic groups $\tilde{G}_{F_v}, \sigma$ vanish, except possibly for $G^*_{F_v}$. Thus, the simple twisted trace formula simplifies giving an equality:

$$I_{\text{disc}, \chi}^{\tilde{G}, \sigma}(\tilde{f}) = \frac{1}{2} ST_{\text{disc}, \chi}^{G^*}(f^*)$$

Now we apply the discrete part of the stable trace formula for $G^*$ to the RHS this gives us an equality:

$$I_{\text{disc}, \chi}^{G^*}(f^*) - \frac{1}{4} ST_{\text{disc}, \chi}^{G^*}(f^C) = ST_{\text{disc}, \chi}^{G^*}(f^*)$$

However, for any $v \in S_{st}$, the orbital integral of $f^*_v$ is again stable, so we see that its transfer to the endoscopic group $C$ is zero. Hence, the second term vanishes. All in all, we obtain the following lemma.

**Lemma 5.3.** For $S_{st}$ a finite set of finite places with $|S_{st}| \geq 3$, $f^*$ and $\tilde{f}$ matching test functions on $G^*$ and $\tilde{G}$, respectively, such that $f^*_v$ is a pseudo-coefficient for the (essentially) discrete series Steinberg representation twisted by an unramified character $\eta_v$ such that $\eta_v|Z(F_v) = \chi_v$ and $\tilde{f}_v$ is the $\sigma$-twisted pseudo-coefficient for the Steinberg representation of $G_{F_v}$ twisted by $\eta_v$, we have an equality:

$$\frac{1}{2} I_{\text{disc}, \chi}^{G^*}(f^*) = I_{\text{disc}, \chi}^{\tilde{G}, \sigma}(\tilde{f})$$

relating spectral information on $G^*$ to $\tilde{G}$.

### 5.3. Strong Multiplicity One

We now would like to combine the analysis of sections 5.1 and 5.2 to deduce a strong multiplicity one result for $G^* = GSp_4/F$ and certain inner forms. Our analysis is very similar to [CG15, Sections 10.5 and 10.6] and benefited from reading the proofs of [RW21, Proposition 10.1 and Theorem 11.4] in a paper of Rosner and Weissauer, where they prove a similar multiplicity one result using Weselmann’s topological twisted trace formula [Wes12] instead of the simple twisted trace formula of Kottwitz-Shelstad. Let $S_{st}$ and $S_{sc}$ be disjoint finite sets of finite places. Let $S_{\infty}$ denote the set of infinite places. Set $S_0 \subset S_{st} \cup S_{sc}$ and $S_{sc} \cup S_{st} \cup S_{\infty} \subset S$ to be finite sets of places as before. We let $G$ be an inner form over $F$, as in Theorem 5.2, trivialized outside of $S_0 \cup S_{\infty}$. We have the following.

**Proposition 5.4.** Assume that $|S_{st}| \geq 3$. Let $\pi$ be a cuspidal automorphic representation of $G^* = GSp_4/F$ or the above inner form $G$ satisfying the following:

1. $\pi$ is cohomological of regular weight $\xi$ at infinity,
2. $\pi$ is unramified outside of $S$,
3. $\pi$ is an unramified twist of Steinberg at all places in $S_{st}$,
4. $\pi$ has supercuspidal $L$-parameter at all places in $S_{sc}$.

If $\pi'$ is a cuspidal automorphic representation of $G^*$ satisfying (1), (3), and $\pi'^S \simeq \pi^S$ then its Langlands parameter at all places in $S$ agrees with $\pi$. If $\pi'$ is a cuspidal automorphic representation of $G$ satisfying conditions (1), (3), and $\pi'^S \simeq \pi^S$ then its Langlands parameter at all places in $S_{st} \cup S_{sc} \cup S_{\infty}$ agrees with $\pi$.

**Proof.** Set $\chi$ to be the central character of $\pi$. We apply the above trace formulae with central character datum $(Z(\mathbb{A}_F), \chi)$. If $\pi$ is a representation of $G^* = GSp_4/F$, we take $\tau$ to be a globally generic member of the global $L$-packet of $\pi$, as in the proof of Theorem 5.2. If $\pi$ is a representation of the inner form $G$ then, using Theorem 5.2, we take $\tau$ to be a globally generic strong transfer $\tau$ of $\pi$ to a cuspidal automorphic representation of $G^*$, with Langlands parameter equal to $\phi_{\pi_v}$ at all places in $v \in S_{sc} \cup S_{st} \cup S_{\infty}$. Now we apply [GT11, Section 13] to $\tau$ to deduce the existence of a strong transfer to a globally generic automorphic representation of $GL_4(\mathbb{A}_F)$, denoted $\tilde{\tau}$. It satisfies the following:

1. $\tilde{\tau}$ is a global theta lift of $\tau$. 

Lemma 5.3 then gives us an equality:

$$f$$

in Section 5.1. We let

$$\tilde{f}$$

Steinberg of, where we can, up to scaling, take this to be the Lefschetz function

$$\eta$$

functions

$$\tilde{\eta}$$

To distinguish these two cases, we say that

$$\tilde{\tau}$$

is a stable or endoscopic lift. We choose matching test functions $$\tilde{f}$$ and $$f^*$$ on $$\tilde{G}$$ and $$G^*$$, respectively, such that, for $$v \in S_{st}$$, they are pseudo-coefficients for Steinberg twisted by $$\eta_v$$, as in Lemma 5.3, where $$\eta_v$$ the unramified character that $$\pi_v$$ is a twist of Steinberg of, where we can, up to scaling, take this to be the Lefschetz function $$f^*_{\text{Lef},\eta_{vst}}$$ considered in section 5.1. We let $$f^*_v$$ be a Lefschetz function for the discrete series $$L$$-packet given by $$\xi$$ as before. Lemma 5.3 then gives us an equality:

$$\frac{1}{2}I^*_{\text{disc},\chi}(f^*) = I^*_{\text{disc},\chi}(|\tilde{f}|)$$

We first treat the case where $$\tilde{\tau}$$ is a stable lift, and consider the part of the RHS corresponding to the cuspidal representation $$\tilde{\tau}$$ constructed above. By using linear independence of the unramified characters and the strong multiplicity one property for $$\tilde{G}$$, the above identity implies an equality

$$c_1 \cdot \sum_{\Pi' \cong \pi S} m(\Pi')\text{tr}(f^*_S|\Pi'_S) = \text{tr}_{\sigma}(\tilde{\tau}_S|\tilde{f}_S)$$

where $$c_1$$ is a non-zero constant. Here $$\text{tr}_{\sigma}(\tilde{\tau}_S|\tilde{f}_S)$$ is the $$\sigma$$-twisted trace, as defined in Section 5.16]. The LHS runs over automorphic representations satisfying the following:

1. $$\Pi'$$ has non-zero contribution to the discrete part of the trace formula $$I^*_{\text{disc},\chi}$$.

2. The coefficient $$m(\Pi')$$ is the coefficient associated with the trace of $$\Pi'$$ in $$I^*_{\text{disc},\chi}$$.

We can further simplify the LHS of (3) by noting that non-discrete spectrum representations which intervene in $$I^*_{\text{disc},\chi}$$ are parabolically induced from the discrete spectrum of proper Levi subgroups of $$G^*$$. By [CG15, Section 5.8], we know that parabolically induced representations of $$G^*$$ lift to parabolically induced representations of $$\bar{G}$$. Therefore, since $$\tilde{\tau}$$ is a stable lift and therefore cuspidal, all terms occurring in in the LHS must all come from the discrete spectrum $$T^*_{\text{disc},\chi}(f^*)$$, by strong multiplicity one for $$\bar{G}$$. Moreover, the coefficients $$m(\Pi')$$ must then be the multiplicities of $$\Pi'$$ in the discrete spectrum. However, as in Lemma 5.1, we have an equality:

$$T^*_{\text{disc},\chi}(f^*) = T^*_{\text{cusp},\chi}(f^*)$$

In other words, we may assume that the sum on the LHS of (3) ranges over $$\Pi' \in A_{\text{cusp},\chi}(G^*)$$, and that $$m(\Pi')$$ denotes the multiplicity in the cuspidal automorphic spectrum. In other words, we can rewrite the LHS as

$$\sum_{\Pi' \in A_{\text{cusp},\chi}(G^*)} m(\Pi')\text{tr}(f^*_S|\Pi'_S)$$

$$\Pi' \cong \pi S$$

Now, for the RHS, we apply the local character identities of Chan-Gan [CG15, Proposition 9.1], this tells us that we have an equality:

$$\text{tr}_{\sigma}(\tilde{\tau}_S|\tilde{f}_S) = c_2 \prod_{v \in \mathcal{S}} \sum_{\pi_v' \in \Pi_{\phi_v}(G^*)} \text{tr}(f^*_v|\pi'_v)$$
for some non-zero constant $c_2$, where we have used property (3) of the representation $\tilde{\tau}$. In summary, we have concluded
\[ \sum_{\Pi' \in \mathcal{A}_{\text{usp}, \chi}(G^*)} m(\Pi') \text{tr}(f^*_S|\Pi'_S) = c \cdot \prod_{v \in S} \sum_{\Pi'_v \in \Pi_{\sigma_v}(G^*_v)} \text{tr}(f^*_v|\pi'_v) \]
for some non-zero constant $c$. If $\pi$ was a representation of $G^*$, we know by our choice of $\tau$ that $\phi_{\tau_v} = \phi_{\pi_v}$ for all $v \in S$, so, by linear independence of characters at the places $v \in S \setminus S_{\infty} \cup S_{\text{st}}$, this tells us that the local constituents of some $\Pi'$ occurring in the LHS with non-zero trace at $S_{\infty} \cup S_{\text{st}}$ are described by members of the $L$-packet over $\phi_{\pi_v}$ occurring with some multiplicity. Since the representation $\pi'$ is by assumption cohomological of regular weight $\xi$ and an unramified twist of Steinberg at all places in $S_{\text{st}}$, by arguing as in proof of Theorem 5.2, we have that $\text{tr}(f_{S_{\text{st}}} \cup S_{\infty}|\pi'_{S_{\text{st}}} \cup S_{\infty}) \neq 0$, and this gives us the desired claim for $G^* = GSp_4$. Now, if $\pi'$ is a representation of the inner form, we apply the character identities of Chan-Gan [CG15, Proposition 11.1]. This tells us that the RHS of the previous equation is equal to
\[ c_3 \prod_{v \in S} \sum_{\Pi' \in \Pi_{\phi_{\pi_v}}(G^*_v)} \text{tr}(f_v|\rho_v) \]
for some non-zero constant $c_3$. Now, to rewrite the LHS, we apply the trace formula as in the proof of Theorem 5.2. By linear independence of characters, we obtain a relationship
\[ \sum_{\Pi' \in \mathcal{A}_{\text{usp}, \chi}(G^*)} m(\Pi') \text{tr}(f^*_S|\Pi'_S) = c_4 \cdot \sum_{\Pi \in \mathcal{A}_{\text{usp}, \chi}(G)} m(\Pi) \text{tr}(f_S|\Pi_S) \]
for some non-zero constant $c_4$. All in all, we obtain that
\[ \cdot \sum_{\Pi \in \mathcal{A}_{\text{usp}, \chi}(G)} m(\Pi) \text{tr}(f_S|\Pi_S) = c'_4 \prod_{v \in S} \sum_{\Pi' \in \Pi_{\phi_{\pi_v}}(G^*_v)} \text{tr}(f_v|\rho_v) \]
for some non-zero constant $c'$. We know by our choice of $\tau$ that $\phi_{\tau_v} = \phi_{\pi_v}$ for all $v \in S_{\text{ac}} \cup S_{\text{st}} \cup S_{\infty}$. From here, the claim follows.

In the case that $\tilde{\tau}$ is an endoscopic lift. We apply the stable trace form for $G^*$ and a test function $f^*$ of $G^*(\mathbb{A}_F)$. We recall that this is an identity:
\[ S_{\text{disc}, \chi}^{G^*}(f^*) = I_{\text{disc}, \chi}^{G^*}(f^*) - \frac{1}{4} S_{\text{disc}, \chi}^{G^C}(f^C) \]
for a $f^C$ a matching test function on $C(\mathbb{A}_F)$. Moreover, since $C$ has no proper elliptic endoscopic groups, we have
\[ S_{\text{disc}, \chi}^{G^C}(f^C) = I_{\text{disc}, \chi}^{G^C}(f^C). \]
We look at the $\sigma_1 \otimes \sigma_2$-isotypic part, where $\sigma_1 \otimes \sigma_2$ is the representation of $C$ whose theta lift is $\tau$, and use linear independence of characters at the unramified places to obtain a semi-local identity
\[ S_{\sigma_1 \otimes \sigma_2}^{G^*}(f^*_S) = \sum_{\Pi \in S} m(\Pi') \text{tr}(f^*_S|\Pi'_S) - \frac{1}{4} \sum_{(\sigma'_2 \otimes \sigma'_2) \in \Pi_{\sigma_2}} m(\sigma_{\otimes} \sigma') \text{tr}(f^*_S|((\sigma'_2 \otimes \sigma'_2)_S) \]
where the LHS is a stable distribution on $G^*(\mathbb{A}_S)$, as in [CG15, Equation 8.5]. The first term in the RHS is a sum over discrete automorphic representations $\Pi'$ of $G^*(\mathbb{A}_F)$ with the coefficient $m(\Pi')$ being the multiplicity in the discrete spectrum, and the second term is a sum over all automorphic representations $\sigma'_1 \otimes \sigma'_2$ of $C(\mathbb{A}_F)$. It follows by [CG15, Corollary 8.6] that the LHS is equal to
\[ \sum_{v \in S} \sum_{\Pi'_v \in \Pi_{\phi_{\pi_v}}(G^*_v)} \text{tr}(f^*_v|\pi'_v) \]

On the other hand, if, for \( v \in S_{st} \), we take \( f_v^* = f_{\mathcal{L}f_v}^* \) to be the Lefschetz function as above, we see that
\[
\frac{1}{4} \sum_{(\sigma_1, \sigma_2) \in (\sigma_1 \otimes \sigma_2)^3} m(\sigma \otimes \sigma') \text{tr}(f_S^*| (\sigma_1 \otimes \sigma_2)^S)
\]
vanishes, since the orbital integral of \( f_v^* \) is stable and \( S_{st} \neq \emptyset \). In summary, we have concluded an identity
\[
c'' \prod_{v \in S} \sum_{\sigma_v' \in \Phi_v} \text{tr}(f_v^*| \sigma_v') = \sum_{\Pi^S \simeq \pi^S} m(\Pi') \text{tr}(f_S^*| \Pi_S')
\]
for some non-zero constant \( c'' \). Now taking \( f_{\infty}^* \) to be our Lefschetz function at \( \infty \), we can argue just as in the stable case. \( \square \)

**Remark 5.2.** Strong multiplicity one for globally generic automorphic representations of \( \text{GSp}_4 \) has been proven by Jiang-Soudry \([JS07]\). So, in the particular case that \( \pi \) and \( \pi' \) are representations of \( \text{GSp}_4 \), we could have just assumed that \( S_{st} \) is non-empty and then applied their results to a globally generic member in the global \( L \)-packets of \( \pi \) and \( \pi' \) to deduce the desired claim.

### 6. Galois Representations in the Cohomology of Shimura Varieties

We now would like to combine the results of the previous section with results of Sorensen \([Sor10]\) on the Galois representations associated to automorphic representations of \( \text{G}^* = \text{GSp}_4/F \) to say something about the Galois action of the global Shimura varieties occurring in basic uniformization. Let \( F/\mathbb{Q} \) be a totally real field and \( \mathbb{A}_f, \mathfrak{p} \) the finite adeles of \( F \). Throughout, we will assume that \( \tau \) is a cuspidal automorphic representation of \( \text{G}^* \) satisfying the same properties as in the previous section.

1. \( \tau_{\infty} \) is cohomological of some regular weight \( \xi \) of \( \text{G}^*(F_{\infty}) \).
2. \( \tau_v \) is unramified at all finite places outside of \( S \).
3. \( \tau_v \) is an unramified twist of Steinberg at some finite set of finite places \( S_{st} \).

We have the following key result of Sorensen.

**Theorem 6.1.** \([Sor10]\) Theorem A] Fix a globally generic \( \tau \) as above such that \( S_{st} \) is non-empty. Then there exists, a unique (after fixing the isomorphism \( i : \overline{\mathbb{Q}}_{\ell} \simeq \mathbb{C} \)) irreducible continuous representation \( \rho_{\tau} : \text{Gal}(\overline{F}/F) \to \text{GSp}_4(\overline{\mathbb{Q}}_{\ell}) \) characterized by the property that, for each finite place \( v \nmid \ell \) of \( F \), we have
\[
i \text{WD}(\rho_{\tau}|_{W_{F_v}})^{F-s,s} \simeq \phi_{\tau_v} \otimes (-)^{-3/2}
\]
where \( (-)^{F-s,s} \) denotes the Frobenius semisimplification and \( \phi_{\tau_v} \) is the Gan-Takeda parameter of \( \tau_v \).

Now let us fix \( \tau \) with associated \( \rho_{\tau} \) as above and assume that \( \tau \) is a strong transfer of some cuspidal automorphic representation \( \pi \) of \( \text{G} \), as in Theorem 5.2. We assume that \( S_{st} \) contains \( q \) an odd inert prime in the number field \( F \) and choose the inner form \( \text{G} \) to be of the following form, as in Kret-Shin \([KS16]\) Section 8],

- \( \text{G}(\mathbb{R}) \simeq \text{GSp}_4(\mathbb{R}) \times \text{GU}_2(\mathbb{H})|^{[F:Q]}-1 \),
- \( \text{G}_{F_v} \simeq \text{GSp}_4/F_v \) at all finite places \( v \) if \( [F:Q] \) is odd,
- \( \text{G}_{F_v} \simeq \text{GSp}_4/F_v \) at all but the finite place \( q \) if \( [F:Q] \) is even,

where \( \mathbb{H} \) is the Hamilton quaternions. Let \( \mathcal{A}(\pi) \) be the set of isomorphism classes of cuspidal automorphic representations \( \Pi \) of \( \text{G} \) such that, for all \( v \in S_{st} \), \( \Pi_v \) is an unramified twist of Steinberg, \( \Pi_{\infty} \) is \( \xi \) cohomological, and, for all \( v \notin S_{\infty} \cup S_{st} \), \( \Pi_v \simeq \pi_v \). Our main task now is to show that \( \rho_{\tau} \) is realized in the \( \pi_{\infty} \) isotypic component of the Shimura variety associated to a Shimura datum \( (\text{G}, X) \), where \( X \) is as in \([KS16]\) Pages 41-42]. Let \( \text{Sh}(\text{G}, X)^{\overline{F}_{K,\text{st}}} \) be the associated Shimura variety over \( \overline{F} \) which we recall is 3-dimensional. We set \( \mathcal{L}_\xi \) to be the \( \overline{\mathbb{Q}}_{\ell} \) local system associated to an irreducible
representation of $G$ over $F$ of highest weight $\xi$ on it as before, and let $H^n_{\xi}^i(\text{Sh}(G, X)_{K}, \mathcal{L}_\xi)_{ss}$ denote the semisimplification as a Hecke module of the compactly supported etale cohomology valued in $\mathcal{L}_\xi$. Choose $K \subset G(H_{f,F})$ a sufficiently small compact open subgroup such that $\pi_\infty$ has a non-zero $K$-invariant vector. Let $S_{\text{bad}}$ denote the set of prime numbers $p$ for which either $p = 2$, the group $G$ is ramified, or $K_p = \prod_{v|p} K_v$ is not hyperspecial. Then we define the virtual Galois representation

$\rho_{\text{shim}}^\pi := (-1)^3 \sum_{\Pi \in A(\pi)} \sum_{i=0}^{6} (-1)^i [\text{Hom}_{G(A_{f,F})}(\Pi^\infty, H^i_{\xi}(\text{Sh}(G, X)_{K}, \mathcal{L}_\xi)_{ss})] \in K_0(\overline{\mathbb{Q}}_\ell(\Gamma_F))$

where $K_0(\overline{\mathbb{Q}}_\ell(\Gamma_F))$ denotes the Grothendieck group of continuous $\Gamma_F := \text{Gal}(\overline{F}/F)$-representations with coefficients in $\overline{\mathbb{Q}}_\ell$. We now define the rational number

$a(\pi) := (-1)^3 N\cdot \sum_{\Pi \in A(\pi)} m(\Pi) \cdot \text{ep}(\Pi^\infty \otimes \xi)$

where

1. $m(\Pi)$ is the multiplicity of $\Pi$ in the automorphic spectrum of $G$,
2. $N_\infty = |\Pi_{\infty}^G(F_\infty) : \pi_0(G(F_\infty))|$, where $\Pi_{\infty}^G(F_\infty)$ denotes the discrete series $L$-packet of representations of $G(F_\infty)$ cohomological of weight $\xi$,
3. $\text{ep}(\Pi^\infty \otimes \xi) := \sum_{i=0}^6 (-1)^i \text{dim}(H^i(\text{Lie}(G(F_\infty)), K_\infty; \Pi^\infty \otimes \xi))$.

Then we have the following proposition of Kret-Shin.

**Proposition 6.2.** [KSI16, Proposition 8.2] With notation as above, for almost all finite $F$-places $v$ not dividing a prime number in $S_{\text{bad}}$ and all sufficiently large integers $j$, we have

$\text{tr}(\rho_{\text{shim}}^\pi(\text{Frob}_v)) = a(\pi) q^{\frac{j^2}{2}} \text{tr}(\text{std} \circ \phi_{\pi_v})(\text{Frob}_v)$

Moreover, the virtual representation $\rho_{\text{shim}}^\pi$ is a true representation. In particular, the only non-zero term appearing in the above alternating sum occurs in middle degree ($= 3$).

**Remark 6.1.** The claim about it occurring in middle degree is part of the proof of the Proposition not the statement. (See the discussion after equation (8.13) in KSI16)

We use this to deduce the following corollary.

**Corollary 6.3.** The $\pi_\infty$-isotypic component of $R \Gamma_c(\text{Sh}(G, X)_{K}, \mathcal{L}_\xi)_{ss}$ is concentrated in degree 3 and has $\Gamma_F$-action given (up to multiplicity) by the semi-simplification of $\text{std} \circ \rho_\tau$.

**Proof.** The first part follows immediately from the previous Proposition, and the second part follows from the identification of the traces. In particular, by the Brauer-Nesbitt Theorem, Cheboratev density theorem, and the condition characterizing $\rho_\tau$, we can identify (up to multiplicity) the Galois representation $\rho_{\text{shim}}^\pi$ with the semi-simplification of the Galois representation $\text{std} \circ \rho_\tau$. \qed

7. PROOF OF THE KEY PROPOSITION

We will now combine the results of the previous three sections to deduce some key consequences that will be used to derive Proposition 1.4. For this, using Krasner’s lemma, we now fix a totally real number field $F$ with two odd totally inert primes $p$ and $q$ such that $F_p \simeq L$ the fixed unramified extension of $\mathbb{Q}_p$. We fix the $\mathbb{Q}$-inner form $G$ of $G^* = \text{Res}_{F/\mathbb{Q}} \text{Sp}_{4}$ defined in section 6, and let $G^\prime$ be the inner form of $G$ seen in Definition 4.1. We take $(G, X)$ to be the Shimura datum considered in KSI16 Pages 41-42 as in section 6. We note that this forces the associated geometric dominant cocharacter $\mu$ of $G := G_{\mathbb{Q}_{p}}$ to be the Siegel cocharacter; in particular, we can apply the results of section 4.2. Set $\xi$ to be a regular weight of an algebraic representation of $G$ over $\mathbb{Q}$. Let
$K^p \subseteq G(\mathbb{A}^{p_{\infty}})$ be an open compact subgroup. We set $S_{sc} = \{p\}$ and $S_{st}$ to be a disjoint finite set of finite places of $\mathbb{Q}$ containing $q$. We consider the uniformization map

$$\Theta: \Gamma_c(G, b, \mu) \otimes_{\mathcal{H}(J_0)}^L \mathcal{A}(\mathbb{G}'(\mathbb{Q}) \backslash \mathbb{G}'(\mathbb{A}_f)/K^p, \mathcal{L}_\xi) \rightarrow \Gamma_c(S(G, X)_{K^p}, \mathcal{L}_\xi)$$

supplied by Theorem 4.2 and Corollary 4.1. Now fix a smooth irreducible supercuspidal representation $\rho$ of $J = \text{Res}_{L/Q_p}(GU_2(D))(Q_p) = GU_2(D)(L)$. We have the following lemma.

**Lemma 7.1.** Suppose $\rho$ is a supercuspidal representation of $J(Q_p)$, then, for sufficiently regular $\xi$ and sufficiently small $K^p$, we can find a lift $\Pi'$ to a cuspidal automorphic representation of $G'$, such that $\Pi'^{\infty}$ occurs as a $J(Q_p)$-stable direct summand of $\mathcal{A}(\mathbb{G}'(\mathbb{Q}) \backslash \mathbb{G}'(\mathbb{A}_f)/K^p, \mathcal{L}_\xi)$. Moreover, for all places in $S_{st}$, we can assume that the local constituents at $v \in S_{st}$ are unramified twists of the Steinberg representation.

**Proof.** This follows from an argument using the simple trace formula. See for example [Han20, Proposition 2.9] or [Shi12]. We note in particular that cuspidality is vacuous, since $G'(\mathbb{R})$ is compact modulo center by construction. \hfill \Box

So let $\Pi'$ be a globalization of a fixed supercuspidal $\rho$ to a cuspidal automorphic representation of $G'$ for some sufficiently regular $\xi$ and sufficiently small $K^p$. We can and do regard $\Pi'^{\infty}$ as a representation of $G(\mathbb{A}^{p_{\infty}}) \simeq G'(\mathbb{A}_f^{p_{\infty}})$. We set $K^p = K^p_{S_{st}}K^{p_{\cup S_{st}}}$, where $K^{S} \subseteq G(\mathbb{A}_f^{S})$ is an open compact in the finite adeles away from $S$, for $S \subseteq \Pi_1$ some finite set of places of $\mathbb{Q}$ containing $S_{st} \cup \{p\} \cup \{\infty\}$, as in section 5. We assume that $S$ is sufficiently large such that outside of $S$ the automorphic representation $\Pi'$ is unramified, so, in particular, the subgroup $K^{S} \subseteq G(\mathbb{A}_f^{S})$ is a product of hyperspecial subgroups away from $S$. We consider the abstract commutative Hecke algebra

$$T^S := Z[G(\mathbb{A}^{S}_{f})//G^S]$$

of bi-invariant compactly supported smooth functions on $G(\mathbb{A}^{S}_{f})$. We regard both sides of (5) as $T^S$-modules and consider the maximal ideal $m$ defined by the Hecke eigenvalues of $\Pi'^{S}$. We then localize both sides of (5) at $m$ to obtain a map:

$$\Theta_m: (\Gamma_c(G, b, \mu) \otimes_{\mathcal{H}(J_0)}^L \mathcal{A}(\mathbb{G}'(\mathbb{Q}) \backslash \mathbb{G}'(\mathbb{A}_f)/K^p, \mathcal{L}_\xi))_m \rightarrow \Gamma_c(S(G, X)_{K^p}, \mathcal{L}_\xi)_m$$

We would like to apply Propositions 4.4 and 5.4 to the representations occurring on both sides of this map. However, to apply these results we need to make some more modifications. In particular, the automorphic representations of $G'$ occurring in the LHS (resp. RHS) of $\Theta_m$ are not necessarily unramified twists of Steinberg at all places in $S_{st}$.

To remedy this, we set $K^p = K^p_{S_{st}}K^{(p)\cup S_{st}}$, where $K^{(p)\cup S_{st}} \subseteq G(\mathbb{A}_f^{(p)\cup S_{st}}) \simeq G'(\mathbb{A}_f^{(p)\cup S_{st}})$ is an open compact subgroup. Then we consider the colimits

$$\Gamma_c(S(G, X)_{K^{p_{\cup S_{st}}}}, \mathcal{L}_\xi) := \colim K^p_{S_{st}} \rightarrow \{1\} \Gamma_c(S(G, X)_{K^p_{S_{st}}K^{(p)\cup S_{st}}}, \mathcal{L}_\xi)$$

and

$$\mathcal{A}(\mathbb{G}'(\mathbb{Q}) \backslash \mathbb{G}'(\mathbb{A}_f)/K^{S_{st} \cup \{p\}}, \mathcal{L}_\xi) := \colim K^p_{S_{st}} \rightarrow \{1\} \mathcal{A}(\mathbb{G}'(\mathbb{Q}) \backslash \mathbb{G}'(\mathbb{A}_f)/K^p_{S_{st}}K^{(p)\cup S_{st}}), \mathcal{L}_\xi)$$

Since $S_{st} \subseteq S$, the map $\theta_m$ gives rise to a map

$$(\Gamma_c(G, b, \mu) \otimes_{\mathcal{H}(J_0)}^L \mathcal{A}(\mathbb{G}'(\mathbb{Q}) \backslash \mathbb{G}'(\mathbb{A}_f)/K^{S_{st} \cup \{p\}}, \mathcal{L}_\xi))_m \rightarrow \Gamma_c(S(G, X)_{K^{S_{st} \cup \{p\}}}, \mathcal{L}_\xi)_m$$

Now, for all $v \in S_{st}$, we can project to the Bernstein component of $G(F_v) \simeq G'(F_v)$ corresponding to the unramified twists of the Steinberg representation. This gives a map:

$$\Theta^S_{m_v}: (\Gamma_c(G, b, \mu) \otimes_{\mathcal{H}(J_0)}^L \mathcal{A}(\mathbb{G}'(\mathbb{Q}) \backslash \mathbb{G}'(\mathbb{A}_f)/K^{S_{st} \cup \{p\}}, \mathcal{L}_\xi))_{m_v} \rightarrow \Gamma_c(S(G, X)_{K^{S_{st} \cup \{p\}}}, \mathcal{L}_\xi)_{m_v}$$
Moreover, passing to the Bernstein component where $G(\mathbb{Q}_p)$ acts via a supercuspidal representation, by Proposition 4.4, we obtain an isomorphism:

$$\Theta_{m, sc}^{st} : (\Gamma_c(G, b, \mu)_{sc} \otimes_{H(J_b)}^L A(G'(\mathbb{Q}) \backslash G'(/\mathbb{A}_f)/K^{st}(p), \mathcal{L}_\xi))^{st}_m \xrightarrow{\sim} R\Gamma_c(S(G, X)_{K^{st}(p)}, \mathcal{L}_\xi)^{st}_{m, sc}$$

We now apply Proposition 5.4 to obtain the following.

**Proposition 7.2.** Let $\rho \in \Pi(J)$ be a representation with supercuspidal Gan-Tantono parameter $\phi$. Assume that $|S_{st}| \geq 3$. Then, for $\Pi'$ a choice of globalization of $\rho$ as in Lemma 7.1, unramified outside $S$ with associated maximal ideal $m \subset T^S$ in the Hecke algebra defined by the Hecke eigenvalues of $\Pi^S$, the representations of $G'(\mathbb{A}_f)$ occurring in the LHS of the map

$$\Theta_{m}^{st} : (\Gamma_c(G, b, \mu) \otimes_{H(J_b)}^L A(G'(\mathbb{Q}) \backslash G'(/\mathbb{A}_f)/K^{st}(p), \mathcal{L}_\xi))^{st}_m \rightarrow R\Gamma_c(S(G, X)_{K^{st}(p)}, \mathcal{L}_\xi)^{st}_m$$

are isomorphic to $\Pi'^{\infty}$ for $\Pi'$ a cuspidal automorphic representation of $G'(/\mathbb{A})$ satisfying the following:

- $\Pi'^S \simeq \Pi^S$,
- $\Pi'$ is cohomological of regular weight $\xi$ at $\infty$,
- $\Pi'$ is unramified twist of Steinberg at all $v \in S_{st}$,
- $\Pi'$ has local constituent at $p$ with associated $L$-parameter $\phi$.

**Proof.** We localized at $m$ corresponding to $\Pi^S$ and are considering algebraic automorphic representations of $G'$ valued in the algebraic representation defined by $\xi$. Therefore, it is clear that any representation occurring in the LHS is of the form $\Pi'^{\infty}$, where $\Pi'$ is a cuspidal automorphic form of $G'$ satisfying (1) and (2). Here cuspidality is automatic since $G'(/\mathbb{R})$ is compact modulo center. Moreover, by construction, it follows that $\Pi'(\mathbb{Q}_v)$ acts on the LHS via representations in the Bernstein component of the unramified twists of Steinberg for $v \in S_{st}$. Therefore, $\Pi'$ has local constituent at $v \in S_{st}$ given by either an unramified twist of the trivial or Steinberg representation at these places. However, since $\xi$ is regular by assumption, we can argue as in the proof of Theorem 5.2 using strong approximation as in [KST20] Lemma 6.2 to show that the former case cannot occur, since it would imply that the representation $\Pi'$ is 1-dimensional contradicting the regularity of $\xi$. This allows us to apply proposition 5.4, since $|S_{st}| \geq 3$ by assumption. Proposition 5.4 applied to the inner form $G'$ of $G^*$ and the cuspidal automorphic representation $\Pi'$ of $G'$ tells us that $\Pi'$ must have Langlands parameter at $\{p\} = S_{sc}$ given by $\phi$, which was the desired claim. \qed

We now combine this with Corollary 6.3 to deduce the following.

**Corollary 7.3.** With notation as above, the map

$$\Theta_{m, sc}^{st} : (\Gamma_c(G, b, \mu)_{sc} \otimes_{H(J_b)}^L A(G'(\mathbb{Q}) \backslash G'(/\mathbb{A}_f)/K^{st}(p), \mathcal{L}_\xi))^{st}_m \rightarrow R\Gamma_c(S(G, X)_{K^{st}(p)}, \mathcal{L}_\xi)^{st}_{m, sc}$$

is an isomorphism of complexes of $G(\mathbb{Q}_p) \times W_L$-modules concentrated in degree 3 with $W_L$-action given, up to multiplicity and semi-simplification as a $W_L$-module, by $\text{std} \circ \phi \otimes |\cdot|^{-3/2}$.

**Proof.** Proposition 7.2 tells us that the LHS of $\Theta_{m, sc}^{st}$ breaks up as a direct sum of $G(\mathbb{Q}_p) \times W_L$-modules of the form

$$R\Gamma_c(G, b, \mu)_{sc} \otimes_{H(J_b)}^L \Pi^{(p, \infty); S_{st}}$$

for $\Pi'$ a cuspidal automorphic representation of $G'$ that has $L$-parameter $\phi$ at $p$, and is also cohomological of regular weight $\xi$ at infinity and an unramified twist of Steinberg at all places in $S_{st}$. It suffices to prove the claim for each one of these summands. This summand will map to the $\Pi^{(p, \infty); S_{st}}$-isotypic part of the RHS by construction. Let $\tau$ denote a strong transfer of $\Pi'$ to a cuspidal automorphic representation of $G^*$ given by Theorem 5.2, with associated Galois representation $\rho_\tau$ given by Theorem 6.1. Applying Theorem 5.2 again, we consider a strong transfer of $\tau$ to
Given by $\Pi$. We note, by Corollary 6.3, that the $\Pi^{\{p,\infty\} \cup S_{st}} \simeq \Pi^{\{p,\infty\} \cup S_{st}}$-isotypic part will be concentrated in degree 3 and have $W_L$-action given (up to multiplicity and semi-simplification) by $\phi \otimes | \cdot |^{-3/2}$, by the property characterizing $\rho_\tau$ and the fact that $\tau$ was a strong transfer.

With this in hand, we are finally ready conclude our key Proposition.

**Proposition 7.4.** Let $\phi$ be a supercuspidal parameter with associated $L$-packet $\Pi_\phi(J)$. Then the direct summand of

$$\bigoplus_{\rho' \in \Pi_\phi(J)} R\Gamma_c(G, b, \mu)[\rho']$$

where $G(\mathbb{Q}_p)$ acts via a supercuspidal representation

$$\bigoplus_{\rho' \in \Pi_\phi(J)} R\Gamma_c(G, b, \mu)[\rho']_{sc}$$

is concentrated in middle degree 3 and admits a non-zero $W_L$-stable sub-quotient with $W_L$-action given by $\text{std} \circ \phi \otimes | \cdot |^{-3/2}$.

**Proof.** This is an immediate consequence of Proposition 7.2 and Corollary 7.3.

In particular, using Corollary 3.21, we can deduce the following.

**Corollary 7.5.** If $p > 2$ and $L/\mathbb{Q}_p$ is an unramified extension, then, for all $\rho \in \Pi(J)$ with supercuspidal Gan-Tantono parameter $\phi_\rho$, the Fargues-Scholze and Gan-Tantono correspondences are compatible.

8. Applications

We will now apply Corollary 7.5 to deduce some applications to the strong form of the Kottwitz conjecture and conclude the proof of Theorem 1.1. We begin with the latter.

**Theorem 8.1.** The following is true.

1. For any $\pi \in \Pi(G)$ (resp. $\rho \in \Pi(J)$) such that the Gan-Takeda (resp. Gan-Tantono) parameter is not supercuspidal, we have that the Gan-Takeda (resp. Gan-Tantono) correspondence is compatible with the Fargues-Scholze correspondence.

2. If $L/\mathbb{Q}_p$ is unramified and $p > 2$, we have, for all $\pi \in \Pi(G)$ (resp. $\rho \in \Pi(J)$) such that the Gan-Takeda (resp. Gan-Tantono) parameter is supercuspidal, that the Gan-Takeda (resp. Gan-Tantono) correspondence is compatible with the Fargues-Scholze correspondence.

**Proof.** Part (1) follows by Corollary 3.12 and Corollary 3.16. Part (2) for the Gan-Tantono local Langlands is precisely Corollary 7.5. It remains to show that for $L/\mathbb{Q}_p$ unramified and $p > 2$, $\pi$ a smooth irreducible representation of $\text{GSp}_4/L$ with supercuspidal Gan-Takeda $\phi_\pi$ parameter that the two correspondences are compatible. To show this, we consider the complex

$$R\Gamma_c(G, b, \mu)[\pi]$$

of $J(\mathbb{Q}_p) \times W_L$-representations. We know, by Theorem 3.13, that this admits sub-quotients as a $J(\mathbb{Q}_p)$-module given by $\rho$, for all $\rho$ whose Gan-Tantono parameter $\phi_\rho$ is equal to the Gan-Takeda parameter $\phi_\pi$ of $\pi$. However, by Corollary 3.15, we know that these representations must have Fargues-Scholze parameter equal to $\phi_\pi^{FS}$. Therefore, we get a chain of equalities

$$\phi_\pi^{FS} = \phi_\rho^{FS} = \phi_\rho = \phi_\pi$$

where we have used compatibility of the Gan-Tantono and the Fargues-Scholze correspondence for the middle equality.

Now, with this out of the way, we turn our attention to proving some strong forms of the Kottwitz conjecture for these representations, verifying Theorem 1.3.
Theorem 8.2. Let $L/\mathbb{Q}_p$ be an unramified extension with $p > 2$. Let $\pi$ (resp. $\rho$) be members of the $L$-packet over a supercuspidal parameter $\phi : W_L \to \text{GSp}_4(\mathbb{Q}_\ell)$. Then the complexes

$$R\Gamma_c(G, b, \mu)[\pi]$$

and

$$R\Gamma_c(G, b, \mu)[\rho]$$

are concentrated in middle degree 3.

1. If $\phi$ is stable supercuspidal, with singleton $L$-packets $\{\pi\} = \Pi_\phi(G)$ and $\{\rho\} = \Pi_\phi(J)$, then the cohomology of $R\Gamma_c(G, b, \mu)[\pi]$ in middle degree is isomorphic to

$$\rho \boxtimes (\text{std} \circ \phi)^\vee \otimes | \cdot |^{-3/2}$$

as a $J(\mathbb{Q}_p) \times W_L$-module, and the cohomology of $R\Gamma_c(G, b, \mu)[\rho]$ in middle degree is isomorphic to

$$\pi \boxtimes \text{std} \circ \phi \otimes | \cdot |^{-3/2}$$

as a $G(\mathbb{Q}_p) \times W_L$-module.

2. If $\phi$ is an endoscopic parameter, with $L$-packets $\Pi_\phi(G) = \{\pi^+, \pi^-\}$ and $\Pi_\phi(J) = \{\rho_1, \rho_2\}$, the cohomology of $R\Gamma_c(G, b, \mu)[\pi]$ in middle degree is isomorphic to

$$\rho_1 \boxtimes \phi_1^\vee \otimes | \cdot |^{-3/2} \oplus \rho_2 \boxtimes \phi_2^\vee \otimes | \cdot |^{-3/2}$$

or

$$\rho_1 \boxtimes \phi_2^\vee \otimes | \cdot |^{-3/2} \oplus \rho_2 \boxtimes \phi_1^\vee \otimes | \cdot |^{-3/2}$$

as a $J(\mathbb{Q}_p) \times W_L$-module. Similarly, the cohomology of $R\Gamma_c(G, b, \mu)[\rho]$ in middle degree is isomorphic to

$$\pi^+ \boxtimes \phi_1 \otimes | \cdot |^{-3/2} \oplus \pi^- \boxtimes \phi_2 \otimes | \cdot |^{-3/2}$$

or

$$\pi^+ \boxtimes \phi_2 \otimes | \cdot |^{-3/2} \oplus \pi^- \boxtimes \phi_1 \otimes | \cdot |^{-3/2}$$

as a $G(\mathbb{Q}_p) \times W_L$-module. Here we write $\text{std} \circ \phi_\rho \simeq \phi_1 \oplus \phi_2$, with $\phi_\rho$ distinct irreducible 2-dimensional representations of $W_L$ and $\det(\phi_1) = \det(\phi_2)$.

Moreover, both possibilities for the cohomology of $R\Gamma_c(G, b, \mu)[\rho]$ (resp. $R\Gamma_c(G, b, \mu)[\pi]$) in the endoscopic case occur for some choice of representation $\rho \in \Pi_\phi(J)$ (resp. $\pi \in \Pi_\phi(G)$). In particular, knowing the precise form of either $R\Gamma_c(G, b, \mu)[\rho]$ or $R\Gamma_c(G, b, \mu)[\pi]$ for some $\rho \in \Pi_\phi(J)$ or $\pi \in \Pi_\phi(G)$ determines the precise form of the cohomology in all other cases.

Proof. We show the proof in the endoscopic case, with the stable case being strictly easier. We first note that, since $\phi = \phi_\rho^{FS}$ by Theorem 8.1, it follows by assumption that the Fargues-Scholze parameter $\phi_\rho^{FS}$ of $\rho$ is supercuspidal. Therefore, by Remark 3.12, we have an isomorphism

$$R\Gamma_c(G, b, \mu)[\rho] \simeq R\Gamma_c^0(G, b, \mu)[\rho]$$

of $G(\mathbb{Q}_p) \times W_L$-modules. Moreover, by Theorem 3.17, we see that both are concentrated in middle degree 3. Applying Theorem 3.13, we get the following chain of equalities in the Grothendieck group of admissible $G(\mathbb{Q}_p)$-representations of finite length

$$-[H^3(R\Gamma_c(G, b, \mu)[\rho])] = [R\Gamma_c(G, b, \mu)[\rho]] = [R\Gamma_c^0(G, b, \mu)[\rho]] = -\sum_{\pi \in \Pi_\phi(G)} \text{Hom}_{S_\phi}(\delta_{\pi, \rho}, \text{std} \circ \phi_\rho) \pi$$

Now we saw in the discussion proceeding Theorem 3.13 that the RHS takes the form:

$$-2\pi^+ - 2\pi^-$$
We set $p_1$ and $p_2$ to be the two representations of $S_\phi \simeq \{(a, b) \in \overline{\mathbb{Q}}_p^* \times \overline{\mathbb{Q}}_p^* | a^2 = b^2\} \subset (\text{GL}_2(\overline{\mathbb{Q}}_p) \times \text{GL}_2(\overline{\mathbb{Q}}_p))^0$ given by projecting to the first and second $\overline{\mathbb{Q}}_p$-factor, respectively. By Corollary 3.3, Corollary 3.11, and Theorem 8.1, we have an isomorphism of $G(\mathbb{Q}_p) \times W_L$-modules

$$ R\Gamma_c(G, b, \mu)[\rho] \simeq \text{Act}_{p_1}(\rho)[[-3]] \boxtimes \phi_1 \otimes | \cdot |^{-3/2} \oplus \text{Act}_{p_2}(\rho)[-3] \boxtimes \phi_2 \otimes | \cdot |^{-3/2} $$

where $\text{Act}_{p_1}(\rho)$ and $\text{Act}_{p_2}(\rho)$ are a priori direct sum of shifts of supercuspidal representations of $G(\mathbb{Q}_p)$ with Fargues-Scholze ($= \text{Gan-Takeda}$) parameter equal to $\phi$. However, since we know that the LHS is a complex concentrated in middle degree 3, this implies, by the above description in the Grothendieck group, that one of the $\text{Act}_{p_1}(\rho)$ and $\text{Act}_{p_2}(\rho)$ is isomorphic to $\pi^+$ and the other is isomorphic to $\pi^-$. Without loss of generality, assume that

$$ \text{Act}_{p_1}(\rho_1) \simeq \pi^+ $$

and

$$ \text{Act}_{p_2}(\rho_1) \simeq \pi^- $$

We let $p_+$ and $p_-$ be the representation of $S_\phi$ determined by the trivial and non-trivial characters of the component group, respectively. Now, given two representations of $S_\phi$, denoted $W$ and $W'$, it follows from Remark 3.7 (3) that we have an isomorphism:

$$ \text{Act}_W \circ \text{Act}_{W'}(\cdot) \simeq \text{Act}_{W \otimes W'}(\cdot) $$

In turn, we get

$$ \text{Act}_{p_1}(\rho_1) \simeq \text{Act}_{p_1}(\rho) \simeq \text{Act}_{p_2}(\rho) \simeq \rho_1 $$

where the last isomorphism follows since $p_+$ is the trivial representation. Similarly, depending on the values of $\text{Act}_{p_1}(\rho_2)$ and $\text{Act}_{p_2}(\rho_2)$ we can deduce that $\text{Act}_{p_1}(\rho_2)$ is isomorphic to $\rho_1$ or $\rho_2$. Now by Corollary 3.3, Corollary 3.11, and Theorem 8.1, we have an isomorphism

$$ R\Gamma_c(G, b, \mu)[\pi^+] \simeq \text{Act}_{p_1}(\pi^+)[-3] \boxtimes \phi_1 \otimes | \cdot |^{-3/2} \oplus \text{Act}_{p_2}(\pi^+)[-3] \boxtimes \phi_2 \otimes | \cdot |^{-3/2} $$

Since $\text{Act}_{p_1}(\pi^+) \simeq \rho_1$ it therefore follows, by Theorem 3.13 and Remark 3.11, that $\text{Act}_{p_1}(\pi^+)$ must be isomorphic to $\rho_2$. Moreover, we know that $\text{Act}_{p_1 \circ p_1}(\rho_1) \simeq \text{Act}_{p_2}(\rho_1)$ and $\text{Act}_{p_1 \circ p_1}(\rho_1) \simeq \text{Act}_{p_1}(\rho_1)$. Therefore, we obtain that $\text{Act}_{p_2}(\pi^+) \simeq \pi^-$ and $\text{Act}_{p_1}(\pi^+) \simeq \pi^+$. This allows us to determine that

$$ \text{Act}_{p_1}(\pi^-) \simeq \text{Act}_{p_1}(\rho_1) \simeq \text{Act}_{p_2}(\pi^+) \simeq \rho_1 $$

and

$$ \text{Act}_{p_2}(\pi^-) \simeq \text{Act}_{p_1}(\rho_1) \simeq \text{Act}_{p_2}(\pi^+) \simeq \rho_2 $$

which will determine the cohomology of $R\Gamma_c(G, b, \mu)[\pi^-]$. It only remains to show that the value of $R\Gamma_c(G, b, \mu)[\rho_2]$ is determined. However, this follows since

$$ \text{Act}_{p_2}(\rho_2) \simeq \text{Act}_{p_2}(\rho_2 \oplus \rho_1) \simeq \pi^+ $$

and

$$ \text{Act}_{p_1}(\rho_2) \simeq \text{Act}_{p_1}(\rho_2 \oplus \rho_1) \simeq \pi^- $$

To conclude this section, we use Theorem 8.1 to deduce compatibility with the local Langlands correspondence for $\text{Sp}_4$ and its unique non quasi-split inner form $SU_2(D)$. These correspondences are described in the papers [GT10] and [Cho17] by Gan-Takeda and Choiy, respectively. For $\text{Sp}_4$, this is described as the unique correspondence which sits in the commutative diagram:

$$ \begin{array}{ccc}
\Pi(\text{GSp}_4) & \xrightarrow{\text{LLC}_{\text{GSp}_4}} & \Phi(\text{GSp}_4) \\
\downarrow & & \downarrow \alpha \\
\Pi(\text{Sp}_4) & \xrightarrow{\text{LLC}_{\text{Sp}_4}} & \Phi(\text{Sp}_4)
\end{array} $$

\[ \blacksquare \]
Here, the left vertical arrow is not a map at all, it is a correspondence defined by the subset of $\Pi(GSp_4) \times \Pi(Sp_4)$ consisting of pairs $(\pi, \omega)$ such that $\omega$ is a constituent of the restriction of $\pi$ to $Sp_4$, and the right vertical arrow is the map on $L$-parameters induced by the natural map $GSpin_5(C) \to SO_5(C)$. One has a similar characterization of the local Langlands correspondence for $SU_2(D)$. With this description of the correspondence, compatibility for $Sp_4$ and $SU_2(D)$ follows from Theorem 8.1 and Theorem 3.6 (7).

**Corollary 8.3.** For $\pi$ (resp. $\rho$) a smooth irreducible representation of $Sp_4/L$ (resp. $SU_2(D)$), with associated Gan-Takeda (resp. Choiy) parameter $\phi_\pi: W_L \times SL_2(C) \to SO_5(C)$ (resp. $\phi_\rho$) we have that:

1. The Fargues-Scholze and Gan-Takeda (resp. Choiy) local Langlands correspondences are compatible for any representation $\pi$ (resp. $\rho$) such that $\phi_\pi$ (resp. $\phi_\rho$) is not supercuspidal.
2. If $L/Q_p$ is unramified and $p > 2$ then the Fargues-Scholze and Gan-Takeda (resp. Choiy) local Langlands correspondences are compatible for any representation $\pi$ (resp. $\rho$) such that $\phi_\pi$ (resp. $\phi_\rho$) is supercuspidal.

**Remark 8.1.** We note that Corollary 3.11, Theorem 3.18, Remark 3.11, and [HKW21, Theorem 1.0.2] apply to a triple $(G, b, \mu)$, where $\mu$ is any cocharacter and $b \in B(G, \mu)$ is the unique basic element. Therefore, by applying the same kind of analysis as in the proof of Theorem 8.2, we can prove the analogue of Theorem 8.2 in the Grothendieck group of finite length admissible representations with a smooth action of $W_E$ (cf. [HKW21, Conjecture 1.0.1]) for the cohomology of the local Shtuka spaces defined by the triple $(G, b, \mu)$. By Corollary 8.3, this works even in the case when $G = Sp_4$ and there are no Shimura varieties that these spaces uniformize. Moreover, in the case that $G = GSp_4$, one can also deduce from Theorem 8.2 that it is concentrated in middle degree $\langle 2\rho, \mu \rangle$, using the monoidal property of the $Act$-functors and Corollary 3.11, for $\mu$ any cocharacter. This in particular will imply some form of Fargues’ Conjecture for these groups (See e.g. [BHN22, Pages 37-40], for this worked out in the more complicated case of $G = U_n$).
