Abstract

We show that every 2nd order ODE defines a 4-parameter family of projective connections on its 2-dimensional solution space. In a special case of ODEs, for which a certain point transformation invariant vanishes, we find that this family of connections always has a preferred representative. This preferred representative turns out to be identical to the projective connection described in Cartan’s classic paper *Sur les Varietes a Connection Projective*. 
1 Introduction

In recent years there has been a return of interest in the two related classical issues associated with differential equations: (1) the equivalence problem (under a variety of transformation types) for the equations and (2) the natural geometric structures induced by the equations on their solution spaces. The original studies began, among others, with the work of Lie [10] and his student, Tresse [11, 12]. This was soon followed by Wünschmann’s contribution [13] and reached its peak with the work of Cartan [2] and Chern [3]. Cartan devised an extremely powerful but difficult scheme for the analysis of the equivalence problem under the three classes of transformation: fiber preserving, point and contact. Though equivalence relations were established for a variety of equations and transformation classes, the calculations were extraordinarily complicated and long, and as a consequence, many problems were only partially completed. (The modern advent of algebraic computers has allowed the completion of many of these problems and opened the door to a variety of new problems [5, 4, 7].) Early in these studies - then confined to general 2nd and 3rd order odes - it was realized that the equations themselves defined on the (finite dimensional) solution spaces certain geometric structures. For example, Wünschmann discovered that a (large) class of 3rd order ode’s define a conformal (Lorentzian) metric on the 3-dimensional solution space. This class was defined by the vanishing of a certain function of the 3rd order equation. Later, in the context of Cartan’s and Chern’s work, this function was understood as a (relative) invariant of the equation under contact transformations and became known as the Wünschmann invariant. (As an aside we mention that in the modern context of general relativity, this work was generalized to pairs of 2nd order odes whose solution space is 4-dimensional. The vanishing of a generalized Wünschmann invariant for these equations leads to a conformal Lorentzian metric on the solution space. All four dimensional Lorentzian metrics are obtainable in this manner [4, 5].)

Cartan, following Lie and Tresse, using his scheme for the analysis of 2nd order odes under point transformations, realized [1] that a large class of 2nd order odes induced a natural projective structure on their 2-dimensional solution space. This class was defined (analogously to the 3rd order ode case) by the vanishing of a certain Wünschmann-like function of the 2nd order equation.

In the present work we return to the problem of the geometry associated with any 2nd order ode. Without recourse to Cartan’s equivalence technique, we find that any 2nd order ode defines, via the torsion-free 1st Cartan structure equation, a 4-parameter family of projective connections on the solution space.

In the second section we review the general theory of normal projective connections on n-manifolds from the point of view of Cartan connections. We also define projective structures as equivalence classes of certain sets of one-forms on these manifolds.

As an example of projective connections, in the third section, we consider the geometry associated with a second order ode. We find a natural 4-parameter family of projective connections living on its two dimensional space of solutions. In general these connections are quite complicated. They are parametrized by the solutions of a certain linear ode of fourth order, which is naturally associated with our ode. We find that among all the odes \( y'' = Q(x, y, y') \) there is a large class for which the associated 4th order ode is homogeneous. This class of equations is characterized in terms of the vanishing of a certain function constructed solely from Q and its derivatives, which is directly analogous to the Wünschman function. It turns out that the trivial solution of the homogeneous 4th order ode singles out a preferred connection from the 4-parameter family. Then this class of second order odes together with this preferred connection turns out to be identical to the class that Cartan obtained from a study of the equivalence problem. In the last section we discuss the relationship...
between our and Cartan’s method of obtaining this class.

The work described here is part of a larger project, namely the study of natural geometric structures induced on the finite dimensional solution spaces of both odes and certain overdetermined pdes. In earlier work [6] we saw how all 4-dimensional conformal metrics and Cartan normal conformal connections were contained in the space of pairs of pdes satisfying generalized Wünschmann equations. (Similar results hold for all 3rd order odes satisfying the Wünschmann equation.) In the present work we have extended these results to unique Cartan normal projective connections associated with 2nd order odes satisfying a Wünschmann-like equation.

2 Projective connection

2.1 Cartan connection

In this subsection we will first define a Cartan connection and then specialize it to a Cartan projective connection (see [9] for more details).

Consider a structure \((P, H, M, G)\) such that

- \((P, H, M)\) is the principal fibre bundle, over an \(n\)-dimensional manifold, with a structure Lie group \(H\)
- \(G\) is a Lie group, of dimension \(\dim G = \dim P\), for which \(H\) is a closed subgroup.

Denote by \(B^*\) the fundamental vector field associated with an element \(B\) of the Lie algebra \(H'\) of \(H\). Let \(\omega\) be a \(G'\)-valued 1-form on \(P\) such that

\[
\begin{align*}
- \omega(B^*) &= B \text{ for each } B \in H' \\
- R_b^*\omega &= b^{-1}\omega b \text{ for each } b \in H \\
- \omega(X) &= 0 \text{ if and only if the vector field } X \text{ vanishes identically on } P.
\end{align*}
\]

Then \(\omega\) is called Cartan’s connection on \((P, H, M, G)\).

The Cartan projective connection is a Cartan connection for which

\[
G = \text{SL}(n+1, \mathbb{R})/(\text{center}),
\]
\[
H = \left\{ \begin{pmatrix} A & 0 \\ A^T & (\text{det } A)^{-1} \end{pmatrix} \middle| A \in \text{GL}(n, \mathbb{R}), A \in \mathbb{R}^n \right\}/(\text{center}).
\]

In next two subsections we present a convenient way of defining a projective connection on a local trivialization \(U \times H\) of the bundle \(P\).

2.2 Normal projective connection on \(U \subseteq M\)

Here working on the base space \(M\) we define a normal projective connection on \(U \subset M\).

Consider a coframe \((\omega^i), i = 1, 2, ..., n\) on an open neighbourhood \(U\) of \(M\). Suppose that in addition you have \(n^2\) 1-forms \(\omega^i_j, i, j = 1, 2, ..., n\) on \(M\) such that

\[
d\omega^i + \omega^i_j \wedge \omega^j = 0, \quad \forall i = 1, 2, ... n. \tag{1}
\]
Then, the system of forms \((\omega^i, \omega^i_j)\) defines a torsion-free connection on \(U\).

Take \(n\) arbitrary 1-forms \((\omega^i)\), \(i = 1, 2, \ldots n\) on \(U\). The forms \((\omega^i, \omega^i_j, \omega^j)\) define the \(n^2\) 2-forms \(\Omega^i_j\) and \(n\) 2-forms \(\Psi^j\) on \(U\) by

\[
\Omega^i_j = d\omega^i_j + \omega^i_k \wedge \omega^k_j + \omega^i \wedge \omega^j + \delta^i_j \omega^k \wedge \omega^k, \tag{2}
\]

\[
\Psi^j = d\omega_i + \omega_k \wedge \omega^k_j. \tag{3}
\]

Decompose \(\Omega^i_j\) onto the basis \((\omega^i)\),

\[
\Omega^i_j = \frac{1}{2} \Omega^i_{jkl} \omega^k \wedge \omega^l. \tag{4}
\]

Find all \((\omega^i)\) for which the so called normal condition

\[
\Omega^i_{jil} = 0, \quad \forall j, l = 1, 2, \ldots n \tag{5}
\]

is satisfied. It turns out that if \(n \geq 2\) the forms \(\omega^i\) are determined uniquely by the equations (4). Indeed, by using the Riemann 2-forms

\[
R^i_{jl} = \frac{1}{2} R^i_{jkl} \omega^k \wedge \omega^l = d\omega^i_j + \omega^i_k \wedge \omega^k_j \tag{6}
\]

and the Ricci tensor

\[
R_{jl} = R^i_{jil} \tag{7}
\]

of the connection \(\omega^i_j\) one finds that

\[
\omega_i = \left[ \frac{1}{1-n} R_{(ij)} - \frac{1}{1+n} R_{[ij]} \right] \omega^j. \tag{8}
\]

Having determined the forms \(\omega_i\), collect the system of 1-forms \((\omega^i, \omega^i_j, \omega^j)\) into a matrix

\[
\omega_u = \begin{pmatrix}
\omega^i_k - \frac{1}{n+1} \omega^j \delta^i_k & \omega^j \\
\omega_k & -\frac{1}{n+1} \omega^j_l
\end{pmatrix}. \tag{9}
\]

Note that \(\omega_u\) is a 1-form on \(U\) which has values in the Lie algebra \(G' = SL'(n+1, \mathbb{R})\). It is called a normal projective connection on \(U\).

### 2.3 Normal projective connection on \(U \times H\)

Earlier we defined a Cartan projective connection on the principal \(H\)-bundle \((P, M, H, G)\). Here we show how the normal projective connection on \(U \subset M\) can be lifted to \((P, M, H, G)\).

Choose a generic element of \(H\) in the form

\[
b = \begin{pmatrix}
A^i_k & 0 \\
A^i_k & a^{-1}
\end{pmatrix}, \tag{10}
\]

where \((A^i_j)\) is a real-valued \(n \times n\) matrix with nonvanishing determinant \(a = \det(A^i_j)\), and \((A_i)\) is a real row \(n\)-vector.
Define a $G'$-valued 1-form $\omega$ on $U \times H$ by

$$\omega = b^{-1} \omega_u b + b^{-1} db.$$ (10)

The 1-form $\omega$ defines a projective connection on $U \times H$. This projective connection on $U \times H$ is called the normal projective connection. The term normal refers to the condition (4), which this connection satisfies.

The explicit formulae for the normal projective connection (10) are written below.

$$\omega = \begin{pmatrix} \omega^i_k - \frac{1}{n+1} \delta^i_k \omega^j_l \omega^l_i - \frac{1}{n+1} \omega^j_l \\ \omega^j_i \end{pmatrix},$$ (11)

where

$$\omega^i_j = a^{-1} A^{-1i}_j \omega^j, \quad (12)$$

$$\omega^j_i = a ( \omega^j_k A^k_i - A^l_i A^{-1l}_j \omega^j_k A^k_l + A^{-1l}_i dA^k_l + \delta^j_i a^{-1} da, \quad (13)$$

and we have used the fact that

$$da = a A^{-1i}_k dA^k_i.$$ (15)

The curvature

$$\Omega = d\omega + \omega \wedge \omega$$ (16)

of $\omega$ has the form

$$\Omega = b^{-1} \Omega_u b, \quad \text{where} \quad \Omega_u = d\omega_u + \omega_u \wedge \omega_u = \begin{pmatrix} \Omega^j_i - \frac{1}{n+1} \delta^j_i \Omega^l l & 0 \\ \Psi^i_j & -\frac{1}{n+1} \Omega^j l \end{pmatrix}.$$ (17)

It is worthwhile to note that if $n \geq 3$ then the vanishing of $\Omega^j_i$ implies the vanishing of $\Psi^i$. This follows from the Bianchi identity $d\Omega - \Omega \wedge \omega + \omega \wedge \Omega = 0$. It is known that in dimension $n = 2$ the forms $\Omega^j_i$ are identically equal to zero. In this dimension all the information about the curvature of the normal projective connection is encoded in the forms $\Psi^i$.

**Remark**

To globalize the local trivialization construction of the normal projective connection described above one needs assumptions about topology of $M$. In the local treatment we use in this paper these assumptions are not necessary.

### 2.4 Projective structure on $M$

An alternative view of the formulae (12)-(14) is to consider them as an equivalence class of connections on $U$. This motivates the following definition.

A projective structure on an $n$-dimensional manifold $M$ is an equivalence class $[(\omega^i, \omega^j_i)]$ of sets of 1-forms $(\omega^i, \omega^j_i)$ on $M$ such that
• (ω^i, i = 1, 2, ..., n is a coframe on M such that
  \[ \text{dω}^i + \omega^i_j \wedge \omega^j = 0, \quad \forall i = 1, 2, ..., n \]

• two sets (ω^i, ω'^i_j) and (ω'^i, ω'^'j_i) are in the same equivalence class iff there exists functions A^i_j and A_i on M such that
  \[ \omega'^i = a^{-1} A^{-1} j \omega'^j \] (18)
  and
  \[ \omega'^i_j = A^{-1} k \omega'^k_j A^i_j + A^{-1} k \omega'^k A_i + \delta^i_j A_i A^{-1} k \omega'^k + A^{-1} k dA_k^j + \delta^i_j a^{-1} d\alpha, \] (19)
  with a = det(A^i_j) ≠ 0 at every point of M.

It turns out that all the torsion-free connections from the equivalence class of a given projective structure have the same set of geodesics on M. To see this consider a representative (ω^i, ω'^j_i) of a projective structure on M. Let (ε_i) be the set of n-vector fields dual to the coframe (ω^i), i.e. ε^i(ε_j) = δ^i_j. Let γ(t) be a geodesic curve for the connection 1-forms ω^i_j = ω'^i_j + ω^i. This means that if V = \frac{d}{dt} = V^i ε_i is a vector tangent to this curve then

  \[ \frac{dV^i}{dt} + \omega^i_j V^j V^k = f V^i, \] (20)

with a certain function f on M. If (ω'^i, ω'^'j_i) belongs to the same projective structure as (ω^i, ω'^j_i) then the equation (20) for V^i and the relations between (ω^i, ω'^j_i) and (ω'^i, ω'^'j_i) imply that in the coframe (ω'^i) the V'^i component of the vector V = V'^i ε_i' satisfies geodesic equation

  \[ \frac{dV'^i}{dt} + \omega'^i_j V'^j V'^k = f' V'^i, \] (21)

with merely new function f' = f + 2a A_j V^j. Thus the curve γ(t) is also a geodesic in connection ω'^j_i.

Note that if A^i_j = δ^i_j then

  \[ \omega'^i = \omega^i \] (22)

and

  \[ \omega'^i_j = \omega'^i_j + \omega^i A_j + \delta^i_j A_i, \] (23)

with A = A_i ω^i. Thus, for a given projective structure (ω^i, ω'^j_i), fixing the coframe does not fix the gauge in the choice of ω'^j_i. There exists an entire class (23) of connections that, together with the fixed coframe (ω^i), represents the same projective structure.

2.5 Equivalence of projective structures

We say that two projective structures (ω^i, ω'^j_i) and (ω^i, ω'^j_i) on two respective n-dimensional manifolds M and \( \tilde{M} \) are (locally) equivalent iff there exists a (local) diffeomorphism φ : M → \( \tilde{M} \) and functions A^i_j and A_j on M such that

  \[ \phi^* (\tilde{ω}^i) = a^{-1} A^{-1} j \omega^j \]

and

  \[ \phi^* (\tilde{ω}^i_j) = A^{-1} k \omega^k A^i_j + A^{-1} k \omega^k A_j + \delta^i_j A_i A^{-1} k \omega^k + A^{-1} k dA_k^j + \delta^i_j a^{-1} d\alpha, \]
with $a = \det(A^i_j) \neq 0$.

If, given a projective structure $(\omega^i, \omega^i_j)$ on $M$, we have a diffeomorphism $\phi : M \to M$ with $A^i_j$ and $A_j$ as above, such that
\[
\phi^* (\omega^i) = a^{-1} A^{-1i}_j \omega^j
\] (24)
and
\[
\phi^* (\omega^i)_j = A^{-1_i}_k \omega^j A^i_j + A^{-1_i}_k \omega^j A_j + \delta^j_j A^i_j A^{-1_i}_k \omega^k + A^{-1_i}_k dA^k_j + \delta^j_i a^{-1} da,
\] (25)
then we call $\phi$ a symmetry of $(\omega^i, \omega^i_j)$. Locally, a 1-parameter group of symmetries $\phi_t : M \to M$ of $(\omega^i, \omega^i_j)$ is expressible in terms of the corresponding vector field $X$, called an infinitesimal symmetry. Taking the Lie derivative with respect to $X$ of equations (24)-(25) one obtains the following characterization of infinitesimal symmetries.

A vector field $X$ is an infinitesimal symmetry of a projective structure $(\omega^i, \omega^i_j)$ iff there exist functions $B^i_j$ and $B_j$ on $M$ such that
\[
\mathcal{L}_X \omega^i = -(B^i_j + B^k_j \delta^i_j) \omega^j
\] (26)
\[
\mathcal{L}_X \omega^i_j = \omega^i_j B^i_j - B^i_j \omega^i_j + \omega^i \delta^j_j B_j + dB^i_j + \delta^j_j dB^i_j.
\] (27)

It is easy to check that a Lie bracket $[X_1, X_2]$ of two infinitesimal symmetries is an infinitesimal symmetry, hence the infinitesimal symmetries generate a Lie algebra. This is the Lie algebra of infinitesimal symmetries of the structure $(\omega^i, \omega^i_j)$.

3 Projective structures of second order ODEs

3.1 Contact forms associated with a second order ODE

We now show that a second order ODE defines a projective structure on the space of its solutions.

A second order ODE
\[
\frac{d^2 y}{dx^2} = Q(x, y, \frac{dy}{dx})
\] (28)
for a function $R \ni x \to y = y(x) \in R$, can be alternatively written as a system of the two first order ODEs
\[
\frac{dy}{dx} = p, \quad \frac{dp}{dx} = Q(x, y, p)
\] (29)
for two functions $R \ni x \to y = y(x) \in R$ and $R \ni x \to p = p(x) \in R$. This system defines two (contact) 1-forms
\[
\omega^1 = dy - p dx, \quad \omega^2 = dp - Q dx,
\] (30)
which live on a 3-dimensional manifold $J^1$, the first jet space, parametrized by coordinates $(x, y, p)$. All the information about the ODE (28) is encoded in these two forms. For example any solution to (28) is a curve $\gamma(x) = (x, y(x), p(x)) \subset J^1$ on which the forms (30) vanish.

Given an ODE (28), we look for a set $(\omega^1_1, \omega^1_2, \omega^2_1, \omega^2_2)$ of 1-forms on $J^1$ such that
\[
d\omega^1 + \omega^1_1 \wedge \omega^1 + \omega^1_2 \wedge \omega^2 = 0, \quad d\omega^2 + \omega^2_1 \wedge \omega^1 + \omega^2_2 \wedge \omega^2 = 0.
\] (31)
Introducing the third 1-form
\[
\omega^3 = dx
\] (32)
which together with \( \omega^1 \) and \( \omega^2 \) constitutes a basis of 1-forms on \( J^1 \), we find that
\[
d\omega^1 = -\omega^2 \wedge \omega^3, \quad d\omega^2 = -(Q_y \omega^1 + Q_p \omega^2) \wedge \omega^3,
\]
and that the general solution to the ‘vanishing torsion’ equations (31) is
\[
\begin{align*}
\omega^1_1 &= \omega^1_{11} \omega^1 + \omega^1_{12} \omega^2, \\
\omega^1_2 &= \omega^1_{12} \omega^1 + \omega^1_{22} \omega^2 - \omega^1,
\end{align*}
\]
with some unspecified functions \( (\omega^1_{11}, \omega^1_{12}, \omega^1_{22}, \omega^1_{21}, \omega^1_{22}) \) on \( J^1 \). Here, and in the following, we denoted the partial derivatives with respect to a variable, as a subscript on the function whose partial derivative is evaluated, e.g. \( Q_y := \frac{\partial Q}{\partial y} \).

The annihilator of the contact forms \( \omega^1 \) and \( \omega^2 \) is spanned by the vector field
\[
D = \partial_x + p\partial_y + Q\partial_p,
\]
which is defined up to a multiplicative factor. Its integral curves, which coincide with the solutions \( \gamma(x) \) of the original equation, are intrinsically defined. Also the notion of surfaces \( S \), transversal to \( D \) is unambiguous.

Any choice of 1-forms \( (\omega^1_1, \omega^1_2, \omega^2_1, \omega^2_2) \) of the form given by equations (34)-(35) on the jet space \( J^1 \) determines projective structures \( [(\omega^k; \omega^k_j)_S] \) on each 2-dimensional surface \( S \) transversal to \( D \). These projective structures are defined on each \( S \) by transformations (18)-(19) applied to the 1-forms \( (\omega^k; \omega^k_j)_S \). They, in turn, were defined as the restrictions of the 1-forms \( (\omega^1, \omega^2; \omega^1_1, \omega^1_2, \omega^2_1, \omega^2_2) \) from \( J^1 \) to \( S \). Given a particular choice of functions \( \omega^i_{jk} \) in (34)-(35) and a pair of transversal to \( D \) surfaces \( S \) and \( S' \), the projective structures \( [(\omega^k; \omega^k_j)_S] \) and \( [(\omega^k; \omega^k_j)_{S'}] \) will be in general inequivalent. It is therefore interesting to ask as to whether there exist a choice of forms (34) which, on all transversal surfaces \( S \), defines the same (modulo equivalence) projective structure. Locally, this requirement is equivalent to the existence of a choice of forms (34) on \( J^1 \) such that the Lie derivative of the forms \( (\omega^i; \omega^k_j) \) along \( D \) is simply the infinitesimal version of the transformations (24)-(25). Explicitly, we ask for the existence of \( \omega^i_{jk} \) of (34)-(35) and the existence of functions \( B^i_j \) and \( B_k \) on \( J^1 \) such that
\[
\mathcal{L}_D \omega^i = -(B^i_j + B^k_j \delta^i_j) \omega^i.
\]
If we were able to find a solution \( \omega^i_{jk} \), to the above equations, then it would generate the same projective structure on all surfaces transversal to \( D \). This structure would therefore descend to the 2-dimensional space of integral lines of \( D \) endowing it, or what is the same, endowing the parameter space of solutions to the original ODE, with a projective structure.

To solve equations (37)-(38) we take the most general forms \( (\omega^1, \omega^2, \omega^1_1, \omega^2_2) \) (from (34)-(35)) that are associated with the ODE. We then use the gauge freedom (22)-(23) preserving
\[
\begin{align*}
\omega^1 &= dy - pdx, \\
\omega^2 &= dp - Qdx
\end{align*}
\]
to achieve
\[
\omega^1_1 = 0
\]
everywhere on $J^1$. The forms $(\omega^1, \omega^2; \omega^1_1, \omega^1_2, \omega^2_1, \omega^2_2)$ with $\omega^1_1 = 0$, when restricted to each $S$, will therefore represent the same projective structure on $S$ as the original general forms we started with. Thus, without loss of generality, we solve equations (37)-(38) for forms
\[
\omega^1 = dy - pdx, \quad \omega^2 = dp - Qdx
\] (39)
and
\[
\omega^1_1 = 0, \quad \omega^1_2 = \omega^2_2 \omega^2 - \omega^3, \quad \omega^2_1 = \omega^2_1 \omega^1 + \omega^2_2 \omega^2 - Q_y \omega^3.
\] (40)

It is a matter of straightforward calculation to achieve the following proposition.

**Proposition 1** The forms (39)-(40) satisfy equations (37)-(38) if and only if
\[
\begin{align*}
\omega^2_{22} &= D\omega^1_{22} + 2Q_p \omega^1_{22}, \\
\omega^2_{12} &= 1/4 \left[ -D^2 \omega^1_{22} - 3Q_p D \omega^1_{22} + (3Q_y - 2Q_p - 2DQ_p) \omega^1_{22} - Q_{pp} \right], \\
\omega^2_{11} &= 1/6 \left[ D^3 \omega^1_{22} + 3D^2 \omega^1_{22} + (5DQ_p + 2Q_p^2 - 7Q_y) D \omega^1_{22} + (2D^2 Q_p - 3DQ_y + 4Q_p DQ_p - 8Q_p Q_y) \omega^1_{22} + DQ_{pp} - 4Q_{pp} \right]
\end{align*}
\] (41)

and $\omega^1_{22}$ fulfills the differential equation
\[
D^4 \omega^1_{22} + a_4 D^3 \omega^1_{22} + a_3 D^2 \omega^1_{22} + a_2 D \omega^1_{22} + a_1 \omega^1_{22} + a_0 = 0
\] (42)

with coefficients $a_0, a_1, a_2, a_3, a_4$ given by
\[
\begin{align*}
a_4 &= 2Q_p, \\
a_3 &= (8DQ_p - Q_p^2 - 10Q_y), \\
2a_2 &= (7D^2 Q_p - 10DQ_y + 3Q_p DQ_p - 2Q_p^3 - 10Q_y Q_y), \\
a_1 &= (2D^3 Q_p - 3D^2 Q_y + 4DQ_p Q_p^2 + 2Q_p D^2 Q_p - 5Q_p DQ_y - 4Q_p^2 DQ_p - 14Q_y DQ_p + 2Q_p^2 Q_y + 9Q_y^2), \\
a_0 &= D^2 Q_{pp} - 4DQ_{pp} - Q_p DQ_{pp} + 4Q_p DQ_{pp} - 3Q_{pp} Q_y + 6Q_{yy}.
\end{align*}
\] (43)

Thus, modulo equivalence, the only forms (39)-(40) that generate the same projective structure on all surfaces transversal to $D$ are given by (41) with the coefficient $\omega^1_{22}$ satisfying differential equation (42). Now, recalling that the space of solutions of the second order ODE can be identified with the 2-dimensional space of integral lines of $D$ in $J^1$, we obtain the following theorem.

**Theorem 1** Every solution $\omega^1_{22}$ to the fourth order differential equation (42)-(43) defines a natural projective structure on the space of solutions $J^1/D$ of the second order ODE $y'' = Q(x,y,y')$. The structure is given by the projection from $J^1$ to $J^1/D$ of forms
\[
\omega^1 = dy - pdx, \quad \omega^2 = dp - Qdx
\] with
\[
\begin{align*}
\omega^1_1 &= 0, \\
\omega^1_2 &= \omega^1_{22} \omega^2 - \omega^3, \\
\omega^3 &= dx,
\end{align*}
\]
we find that this connection on \( P \) on \( J \).

Thus, for this class of second order ODEs there exists a distinguished, natural projective structure

\begin{align*}
\omega^1 &= \frac{1}{6} [D^3 \omega_{122} + 3D^2 \omega_{122} + (5DQ_p + 2Q_p^2 - 7Q_y)D \omega_{122} + (2D^2Q_p - 3DQ_y + 4Q_pDQ_y - 8Q_pQ_y)\omega_{122} + DQ_{pp} - 4Q_{pp}] \omega^1 \\
&+ \frac{1}{4} [-D^2 \omega_{122} - 3Q_pD \omega_{122} + (3Q_y - 2Q_p^2 - 2DQ_p)\omega_{122} - Q_{pp}] \omega^2 \\
&- Q_y \omega^3,

\omega^2 &= \frac{1}{4} [-D^2 \omega_{122} - 3Q_pD \omega_{122} + (3Q_y - 2Q_p^2 - 2DQ_p)\omega_{122} - Q_{pp}] \omega^1 \\
&+ [D \omega_{122} + 2Q_p \omega_{122}] \omega^2 - Q_p \omega^3.
\end{align*}

Since the equation \((42)-(43)\) is of 4th order it has four independent solutions. Thus, all the corresponding projective structures on \( J^1/D \) should be treated on equal footing. However, in the case of second order ODEs satisfying some additional conditions, some of these structures may be more distinguished. In particular, Sophus Lie \([10]\) and Elie Cartan \([1]\) considered 2nd order ODEs satisfying

\[ a_0 = D^2Q_{pp} - 4DQ_{pq} - Q_pDQ_{pp} + 4Q_pQ_{pq} - 3Q_{pp}Q_y + 6Q_{yy} \equiv 0. \]  \hfill (44)

For such ODEs equation \((42)-(43)\) is homogeneous and as such has a preferred solution \( \omega_{122} = 0 \). Thus, for this class of second order ODEs there exists a distinguished, natural projective structure on \( J^1/D \) associated with the solution \( \omega_{122} = 0 \) of \((42)-(43)\). Explicitly, for any second order ODE satisfying \( a_0 \equiv 0 \), this structure is given by

\[
\begin{align*}
\omega^1 &= dy - pdx, \\
\omega^2 &= dp - Qdx 
\end{align*}
\hfill (45)

with

\[
\begin{align*}
\omega^1_1 &= 0, \\
\omega^1_2 &= -\omega^3, \\
\omega^3 &= dx, \\
\omega^2_1 &= \frac{1}{6} (DQ_{pp} - 4Q_{pq})\omega^1 - \frac{1}{4} Q_{pp} \omega^2 - Q_y \omega^3, \\
\omega^2_2 &= -\frac{1}{4} Q_{pp} \omega^1 - Q_p \omega^3. 
\end{align*}
\hfill (46-49)

In general, any projective structure described by Theorem 1 leads to a projective \( SL(3, \mathbb{R}) \) connection on an 8-dimensional bundle \( P \rightarrow J^1/D \). One of the features of the projective structures which via \( \omega_{122} = 0 \) are associated with \( a_0 \equiv 0 \), is that each of them leads to a normal projective \( SL(3, \mathbb{R}) \) connection on \( P \). Using the local parameters \((x, y, p, \alpha, \beta, \gamma, \nu, \mu)\) for \( P \) and equations \((11)-(14), \(22)-(23)\) we find that this \( SL(3, \mathbb{R}) \) connection reads

\[
\omega = \begin{pmatrix} \\
\frac{1}{3}(\Omega_2 - 2\Omega_1) & -\theta^3 & \theta^1 \\
-\Omega_3 & \frac{1}{3}(\Omega_1 - 2\Omega_2) & \theta^2 \\
\Omega_5 & -\Omega_4 & \frac{1}{3}(\Omega_1 + \Omega_2) \\
\end{pmatrix} \hfill (49)
\]

where \( (\theta^1, \theta^2, \theta^3, \Omega_1, \Omega_2, \Omega_3, \Omega_4, \Omega_5) \) are given by

\[
\theta^1 = \alpha \omega^1, \quad \theta^2 = \beta (\omega^2 + \gamma \omega^1), \quad \theta^3 = \frac{\alpha}{\beta} (\omega^3 + \nu \omega^1),
\]
\[ \Omega_1 = d \log \alpha - \mu \theta^1 + \frac{\nu}{\beta} \theta^2 - \frac{\beta \gamma}{\alpha} \theta^3 \]

\[ \Omega_2 = d \log \beta - \frac{1}{4\alpha} \left[ 6\gamma \nu + 4\nu Q_p - Q_{pp} + 2\alpha \mu \right] \theta^1 + 2 \frac{\nu}{\beta} \theta^2 + \frac{\beta}{\alpha} \left[ \gamma + Q_p \right] \theta^3 \]

\[ \Omega_3 = \frac{\beta}{\alpha} d\gamma - \frac{\beta}{6\alpha^2} \left[ DQ_{pp} - 6\gamma^2 \nu - 6\gamma \nu Q_p + 3\gamma Q_{pp} - 4Q_{py} + 6\nu Q_y \right] \theta^1 - \frac{1}{4\alpha} \left[ 2\gamma \nu - Q_{pp} + 2\alpha \mu \right] \theta^2 - \frac{\beta^2}{\alpha^2} \left[ \gamma^2 + \gamma Q_p - Q_y \right] \theta^3 \]

\[ \Omega_4 = \frac{1}{\beta} d\nu - \frac{1}{6\alpha \beta} \left[ 6\gamma \nu^2 + 6\nu^2 Q_p - 3\nu Q_{pp} + Q_{ppp} \right] \theta^1 + \frac{\nu^2}{\beta^2} \theta^2 - \frac{1}{4\alpha} \left[ -2\gamma \nu - 4\nu Q_p + Q_{pp} + 2\alpha \mu \right] \theta^3 \]

\[ 2\Omega_5 = d\mu + \mu d \log \alpha - \frac{\nu}{\alpha} d\gamma + \frac{\gamma}{\alpha} d\nu \]

\[-\frac{1}{24\alpha^2} \left[ 12\alpha^2 \mu^2 + 48\nu Q_{pp} - 48\nu^2 Q_y - 12\nu DQ_{pp} - 36\gamma^2 \nu^2 + 48\gamma \nu^2 Q_p - 36\gamma \nu Q_{pp} + 12\gamma Q_{ppp} + 8DQ_{ppp} + 8Q_p Q_{ppp} - 12Q_{pp} - 3Q_{pp}^2 \right] \theta^1 + \frac{1}{6\alpha \beta} \left[ 6\gamma \nu^2 - 3\mu Q_{pp} + Q_{ppp} + 6\alpha \nu \mu \right] \theta^2 - \frac{\beta^2}{6\alpha^2} \left[ DQ_{pp} - 6\gamma^2 \nu - 12\gamma \nu Q_p + 3\gamma Q_{pp} - 4Q_{py} + 12\nu Q_y + 6\alpha \gamma \mu \right] \theta^3. \]

The curvature of this connection reads

\[ \Omega = \begin{pmatrix} 0 & 0 & 0 \\ 0 & \frac{1}{6\alpha \beta} b_{01} \theta^1 \wedge \theta^2 & -\frac{1}{6\alpha \beta^2} b_0 \theta^1 \wedge \theta^2 \\ \frac{1}{6\alpha \beta} b_{01} \theta^1 \wedge \theta^2 & b_{01} \theta^1 \wedge \theta^2 & 0 \end{pmatrix}, \]

where we have introduced

\[ b_0 = Q_{pppp}, \quad \text{and} \quad b_{01} = D b_0 + (\gamma + 2Q_p) b_0. \]

The relatively simple form of this curvature agrees with the general theory of normal projective connections for \( n = 2 \) (compare with the note at the end of section 2.3).

The next section is devoted to explaining the Lie/Cartan motivation for considering the class of ODEs leading to the structure defined above.

### 3.2 Equivalence classes of 2nd order ODEs modulo point transformations

A point transformation of variables

\[ (x, y) = (x(\bar{x}, \bar{y}), y(\bar{x}, \bar{y})) \]

applied to the second order ODE

\[ y'' = Q(x, y, y') \]

(51)
changes it to the new form
\[ \ddot{y} = \bar{Q}(\bar{x}, \bar{y}, \bar{y}'). \]  
(52)

The function \( Q = Q(x, y, y') \) transforms in a rather complicated way into a new function \( \bar{Q} = \bar{Q}(\bar{x}, \bar{y}, \bar{y}'). \) But, using appropriate derivatives of \( Q \) one can construct functions which have nice transformation properties under transformations \( \bar{Q} \). In particular, the relative invariants of the equation \( \bar{Q} \) are such functions which, under transformations \( \bar{Q} \), scale by a factor. Their vanishing is the point invariant property of the equation. One of such relative invariants is

\[ a_0 = D^2Q_{pp} - 4DQ_{py} - 4Q_pQ_{pp} + 4Q_pQ_{py} - 3Q_{pp}Q_y + 6Q_{yy}, \]

the same function that appears in equations \( \bar{Q} \). This fact was already known to Sophus Lie \( \bar{Q} \). Elie Cartan \( \bar{Q} \) considered the problem of finding all point invariants of \( \bar{Q} \). He used his equivalence method which, enabled him to determine another relative invariant

\[ b_0 = Q_{pppp}. \]

Both \( a_0 \) and \( b_0 \) are of the same order and, it follows from the Cartan analysis, that the equation \( \bar{Q} \) has no more point invariants of order less than or equal to 4. Thus, according to Cartan, the second order ODEs modulo point transformations split into four major classes which are

\begin{enumerate}
  \item[i)] \( a_0 = b_0 = 0 \)
  \item[ii)] \( a_0 = 0 \) and \( b_0 \neq 0 \)
  \item[iii)] \( a_0 \neq 0 \) and \( b_0 = 0 \)
  \item[iv)] \( a_0 \neq 0 \) and \( b_0 \neq 0 \).
\end{enumerate}

Cases i)-ii) were analyzed by Cartan completely. In particular, he showed that if \( a_0 = 0 \) then with each point equivalence class of second order ODEs is associated a natural normal projective connection, whose curvature provides all the point invariants of the class. This connection equips the space of solutions of each of the equations from the equivalence class with a projective structure. It follows that the projective structures originating in this way from different equations from the same point equivalence class are equivalent. This distinguished projective structure associated with the class of equation \( \ddot{y} = Q(x, y, y') \) coincides with the structure \( \bar{Q} \) defined in the previous section.
