ATIYAH SEQUENCES AND CONNECTIONS ON PRINCIPAL BUNDLES OVER LIE GROUPOIDS AND DIFFERENTIABLE STACKS

INDRANIL BISWAS, SAIKAT CHATTERJEE, PRAPHULLA KOUSHIK, AND FRANK NEUMANN

Abstract. We construct and study both general and integrable connections on Lie groupoids and differentiable stacks, as well as on principal bundles over them using an Atiyah exact sequence of vector bundles associated to transversal tangential distributions.

1. Introduction

We develop a general theory of connections for principal bundles over Lie groupoids and differentiable stacks using Atiyah exact sequences associated to transversal tangential distributions. The constructions presented here are inspired by the classical work of Atiyah [At] on connections for fiber bundles in complex geometry.

Given a Lie groupoid $\mathcal{X} := [X_1 \xrightarrow{s} X_0]$ with both $X_0$ and $X_1$ smooth manifolds, such that the source map $s$ is a submersion, we introduce connections on $\mathcal{X}$ as a distribution $\mathcal{H} \subset TX_1$ transversal to the fibers of the source map $s$. Such a connection is said to be integrable or flat if, in addition, the corresponding distribution $\mathcal{H}$ is integrable. These connections (respectively, flat connections) also give rise to connections (respectively, flat connections) on differentiable stacks under certain compatibility conditions. For the particular case of Deligne–Mumford stacks, which are presented by étale Lie groupoids and include descriptions for orbifolds and foliations, such a connection always exists. Indeed, for a Deligne–Mumford stack a natural tangential distribution is given by the tangent bundle itself.

2010 Mathematics Subject Classification. Primary 53C08, Secondary 22A22, 58H05, 53D50.

Key words and phrases. Atiyah exact sequence, principal bundles, Lie groupoids, connections, differentiable stacks.
Now given a Lie group $G$ and a principal $G$-bundle over a Lie groupoid $X := [X_1 \rightrightarrows X_0]$ equipped with such a connection $\mathcal{H} \subset TX_1$, we can define the notion of a connection on the principal $G$-bundle. A principal $G$-bundle over the Lie groupoid $X$ is basically given by a principal $G$-bundle $\alpha : E_G \to X_0$ and some extra compatibility data reflecting the groupoid structure. More precisely, a connection for a principal $G$-bundle over $X$ corresponds to a splitting of the associated Atiyah exact sequence of vector bundles $[\text{At}]$

$$0 \to \text{ad}(E_G) \to \text{At}(E_G) \to TX_0 \to 0$$

which satisfies the condition of being compatible with the various data of the structures involved; the details are in Section 5. This then allows us to define the associated curvature and characteristic differential forms for connections on principal bundles over Lie groupoids.

Furthermore, using adequate groupoid presentations, these constructions extend to a framework that enables us to define and study connections and characteristic forms for principal $G$-bundles over differentiable stacks. In the particular case of Deligne-Mumford stacks, which are represented by étale Lie groupoids, we develop the theory of connections intrinsically and construct the Atiyah exact sequence out of the stack data. This relies on the fact that in the case of Deligne-Mumford stacks, the associated Atiyah exact sequence is again a sequence of vector bundles in a natural way. These constructions also corresponds to related ones in [BMW] for the algebraic geometrical context (compare also with [LM]). Though we will work throughout this article mainly in the differentiable setting, we remark that most of the concepts and constructions presented here also work equally well in the holomorphic and algebraic geometrical setting for the differential geometry of complex analytic and algebraic stacks. An associated Chern-Weil theory of characteristic classes for our setting is developed in a related article by the authors [BCKN]. Some of the constructions and results presented here were announced earlier in [BN].

Versions of connections and flat connections on differentiable, complex analytic, and algebraic stacks were also introduced using cofoliations on stacks by Behrend [Be]. Independently, Tang in [Ta] defined in a similar fashion flat connections for Lie groupoids, which he called étalizations. More recently, Arias Abad and Crainic in [AC] introduced general Ehresmann connections for Lie groupoids and relate them to their framework of homotopy representations of Lie groupoids. Connections for principal bundles over Lie groupoids using pseudo-connection forms were studied earlier also by Laurent-Gengoux, Tu, and Xu [LGTX]. They also describe the associated Chern-Weil theory. Herrera and Ortiz, [HO], have informed us that they are currently also developing a similar theory for principal 2-bundles over Lie groupoids involving Atiyah LA-groupoids. We refer the reader also to other related work on the differential geometry of Lie groupoids and differentiable stacks [FN, TXLG, CLW, Pi, Tr, DE].

Outline and organization of the article. In the first section (Section 2), we introduce the category of smooth spaces over which our stacks and groupoids are constructed and present the basic notions of fibered categories, stacks, and groupoids. We also discuss the relation between differentiable stacks on the one side and Lie groupoids on the other. In the following section (Section 3), we study principal bundles over differentiable stacks and Lie groupoids and their categorical interplay. In Section 4 we introduce notions and basic properties of connections on Lie groupoids and differentiable stacks using vertical tangential distributions and compare our constructions with other existing frameworks in
the literature. We also construct characteristic differential forms for our general connections. In the final section (Section 5), we define and study connections on Lie groupoids as splittings of associated Atiyah exact sequences. Finally, we apply the theory to study connections on principal bundles over differentiable stacks and give general characterizations for connections on principal bundles over Deligne-Mumford stacks, which corresponds to étale Lie groupoids.

2. Smooth spaces, groupoids, and stacks

In this section, we will recall the main notions and constructions needed for our set-up. For a background on the theory of stacks and its main properties we refer to [Be, BX, Pa, He, Ne].

2.1. Smooth spaces and fibered categories. We shall refer to any of

- the category of $C^\infty$-manifolds,
- the category of complex analytic manifolds, and
- the category of smooth schemes of finite type over the field of complex numbers,

as the category $\mathcal{S}$ of smooth spaces and smooth maps. The tangent bundle of any smooth space $X$ will be denoted by $TX$. A smooth space will mean an object in $\mathcal{S}$, and a smooth map will refer to a morphism in $\mathcal{S}$ which is a submersion, and by a submersion, we mean a smooth map whose differential restricted to $T_xX$ is surjective for every point $x$ of the domain $X$. An étale map is a smooth immersion in $\mathcal{S}$ (so it is also a submersion).

For a smooth space $X$, the structure sheaf of it will be denoted by $\mathcal{O}_X$. A vector bundle on $X$ will be identified with its sheaf of sections, which is a finitely generated locally free sheaf of $\mathcal{O}_X$-modules. The cotangent bundle of any smooth space $X$ will be denoted by $\Omega^1_X = T^*X$, and the $p$-th exterior power of $T^*X$ will be denoted by $\Omega^p_X := \bigwedge^p T^*X$. An integrable distribution on a smooth space $X$ is a subbundle $\mathcal{H} \subset TX$ of the tangent bundle of $X$ such that its annihilator $\mathcal{H}^\perp$ generates an ideal in $\bigoplus_{k \geq 0} \Omega^k_X$ which is preserved by the exterior differential of the de Rham complex; equivalently, $\mathcal{H}$ is closed under the Lie bracket operation on vector fields.

The big étale site $\mathcal{S}_{et}$ on the category $\mathcal{S}$ is given by the following Grothendieck topology on $\mathcal{S}$. We call a family $\{U_i \rightarrow X\}$ of morphisms in $\mathcal{S}$ with target $X$ a covering family of $X$, if all smooth maps $U_i \rightarrow X$ are étale and the total map from the disjoint union

$$\coprod_i U_i \rightarrow X$$

is surjective. This defines a pretopology on $\mathcal{S}$ generating a Grothendieck topology, which is known as the big étale topology on $\mathcal{S}$ (compare [SGA4, Exposé II] and [Vi]). If either or both of two morphisms $U \rightarrow X$ and $V \rightarrow X$ in $\mathcal{S}$ is a submersion, then their fiber product $U \times_X V \rightarrow X$ exists.

**Definition 2.1** (Groupoid fibration). A groupoid fibration over $\mathcal{S}$ is a category $\mathcal{X}$, together with a functor

$$\pi_\mathcal{X} : \mathcal{X} \rightarrow \mathcal{S}$$

satisfying the following axioms:
(i) For every morphism \( V \rightarrow U \) in \( \mathcal{G} \), and every object \( x \) of \( \mathcal{X} \) lying over \( U \), there exists an arrow \( y \rightarrow x \) in \( \mathcal{X} \) lying over \( V \rightarrow U \).

(ii) For every commutative triangle \( W \rightarrow V \rightarrow U \) in \( \mathcal{G} \) and all morphisms \( z \rightarrow x \) and \( y \rightarrow x \) in \( \mathcal{X} \) lying over \( W \rightarrow U \) and \( V \rightarrow U \) respectively, there exists a unique arrow \( z \rightarrow y \) in \( \mathcal{X} \) lying over \( W \rightarrow V \) such that the composition \( z \rightarrow y \rightarrow x \) is the morphism \( z \rightarrow x \).

The condition (ii) in Definition 2.1 ensures that the object \( y \) over \( V \), which exists by Definition 2.1(i), is unique up to a unique isomorphism. Any choice of such an object \( y \) is called a pullback of \( x \) via the morphism \( f : V \rightarrow U \). We will write as usual \( y = x|_V \) or \( y = f^*x \).

Let \( X \) be a groupoid fibration over \( \mathcal{G} \). The subcategory of \( \mathcal{X} \) consisting of all objects lying over a fixed object \( U \) of \( \mathcal{G} \) with the morphisms being those lying over the identity morphism \( \text{id}_U \) is called the fiber or category of sections of \( \mathcal{X} \) over \( U \). The fiber of \( \mathcal{X} \) over \( U \) will be denoted by \( \mathcal{X}(U) \).

Groupoid fibrations over \( \mathcal{G} \) form a 2-category in which fiber products exist (see [Gr, Vi]). For two groupoid fibrations \( \pi : \mathcal{X} \rightarrow \mathcal{G} \) and \( \pi : \mathcal{Y} \rightarrow \mathcal{G} \), the 1-morphisms from \( \mathcal{X} \) to \( \mathcal{Y} \) are given by functors \( \phi : \mathcal{X} \rightarrow \mathcal{Y} \) such that 
\[
\pi_Y \circ \phi = \pi_X .
\]
The 2-morphisms are given by natural transformations between these projection functor preserving functors.

**Example 2.2.** Let \( F : \mathcal{G} \rightarrow (\text{Sets}) \) be a presheaf, meaning a contravariant functor. We get a groupoid fibration \( \mathcal{X} \), where the objects are pairs of the form \((U, x)\), with \( U \) a smooth space and \( x \in F(U) \), while a morphism \((U, x) \rightarrow (V, y)\) is a smooth map \( f : U \rightarrow V \) such that \( x = y|_{F(U)} \), equivalently, \( x = F(f)(y) \). The projection functor is given by
\[
\pi : \mathcal{X} \rightarrow \mathcal{G} , \quad (U, x) \mapsto U .
\]
Therefore, any sheaf \( F : \mathcal{G} \rightarrow (\text{Sets}) \) gives a groupoid fibration over \( \mathcal{G} \). In particular, every smooth space \( X \) gives a groupoid fibration \( \underline{X} \) over \( \mathcal{G} \) as the sheaf represented by \( X \), in other words,
\[
\underline{X}(U) = \text{Hom}_{\mathcal{G}}(U, X) .
\]
To simplify notation, we will identify \( \underline{X} \) with the smooth space \( X \) without further clarification.

A category \( \mathcal{X} \) fibered in groupoids over \( \mathcal{G} \) is representable if there exists a smooth space \( X \) isomorphic to \( \mathcal{X} \) as groupoid fibrations over \( \mathcal{G} \). We call a morphism of groupoid fibrations \( \mathcal{X} \rightarrow \mathcal{Y} \) a representable submersion if for every smooth space \( U \) and every morphism \( U \rightarrow \mathcal{Y} \), the fiber product \( \mathcal{X} \times_{\mathcal{Y}} U \) is representable, and the induced morphism of smooth spaces \( \mathcal{X} \times_{\mathcal{Y}} U \rightarrow U \) is a submersion.
2.2. Stacks over smooth spaces. Now let us recall the definition of a stack \[\text{Be, BX}\]. We clarify that a stack \(\mathcal{X}\) here will always mean a stack over the big étale site \(\mathcal{S}_{et}\) of smooth spaces.

**Definition 2.3 (Stack).** A groupoid fibration \(\mathcal{X}\) over \(\mathcal{S}\) is a stack if the following gluing axioms hold with respect to the site \(\mathcal{S}\):

(i) Take any smooth space \(X\) in \(\mathcal{S}\), any two objects \(x, y\) in \(\mathcal{X}\) lying over \(X\) and any two isomorphisms

\[\phi, \psi : x \to y\]

over \(X\). If the condition \(\phi|_{U_i} = \psi|_{U_i}\) holds for all \(U_i\) in a covering \(\{U_i \to X\}\), then \(\phi = \psi\).

(ii) Take any smooth space \(X\) in \(\mathcal{S}\), any two objects \(x, y \in \mathcal{X}\) lying over \(X\) and any covering \(\{U_i \to X\}\) with isomorphisms

\[\phi_i : x|_{U_i} \to y|_{U_i}\]

for every \(i\). If the condition \(\phi_i|_{U_{ij}} = \phi_j|_{U_{ij}}\) holds for all \(i, j\), then there exists an isomorphism \(\phi : x \to y\) with \(\phi|_{U_i} = \phi_i\) for all \(i\).

(iii) For any smooth space \(X\) in \(\mathcal{S}\), any covering \(\{U_i \to X\}\), any family \(\{x_i\}\) of objects \(x_i\) in the fiber \(\mathcal{X}|_{U_i}\) and any family of morphisms \(\{\phi_{ij}\}\), where

\[\phi_{ij} : x_i|_{U_{ij}} \to x_j|_{U_{ij}}\]

satisfies the cocycle condition \(\phi_{jk} \circ \phi_{ij} = \phi_{ik}\) in \(\mathcal{X}(U_{ijk})\), there exists an object \(x\) lying over \(X\) with isomorphisms

\[\phi_i : x|_{U_i} \to x_i\]

such that \(\phi_{ij} \circ \phi_i = \phi_j\) in \(\mathcal{X}(U_{ij})\).

The isomorphism \(\phi\) in Definition 2.3(ii) is unique by Definition 2.3(i). Similarly, from Definition 2.3(i) and Definition 2.3(ii), it follows that the object \(x\) whose existence is asserted in Definition 2.3(iii) is unique up to a unique isomorphism. All pullbacks mentioned in Definition 2.3 are only unique up to isomorphism, but the properties do not depend on particular choices.

In order to be able to do geometry on stacks, we need to compare them with smooth spaces and extend the geometry to stacks. From now on, we will restrict ourselves to stacks over the category \(\mathcal{S}\) of \(C^\infty\)-manifolds, but we remark that we have incarnations of the analogue concepts and constructions for the category \(\mathcal{S}\) of complex analytic manifolds as well as smooth schemes of finite type over the complex numbers.

**Definition 2.4 (Differentiable stack).** A stack \(\mathcal{X}\) over the site \(\mathcal{S}_{et}\) is called differentiable if there exists a smooth space \(X\) in \(\mathcal{S}\) and a surjective representable submersion

\[x : X \to \mathcal{X},\]

i.e., there exists a smooth space \(X\) together with a morphism of stacks

\[x : X \to \mathcal{X},\]

such that for every smooth space \(U\) and every morphism of stacks \(U \to \mathcal{X}\), the following two hold:

1. the fiber product \(X \times_{\mathcal{X}} U\) is representable, and
the induced morphism of smooth spaces $X \times_{\mathcal{X}} U \to U$ is a surjective submersion.

If $\mathcal{X}$ is a differentiable stack, such a surjective representable submersion $x : X \to \mathcal{X}$ is called a presentation or atlas for the stack $\mathcal{X}$. It need not be unique, in other words, a differentiable stack can have different presentations.

**Definition 2.5.** A differentiable stack $\mathcal{X}$ is a (proper) Deligne–Mumford stack if it has a (proper) étale presentation.

Orbifolds correspond to proper Deligne–Mumford stacks (see [Be, LM]).

The incarnations of these concepts over the site $\mathcal{S}_{an}$ of complex analytic manifolds respectively, smooth schemes of finite type over $\mathbb{C}$ will be referred to as complex analytic stacks, respectively, algebraic stacks.

2.3. **Lie groupoids and differentiable stacks.** Differentiable stacks are also incarnations of Lie groupoids, as we will recall now in detail (see also [BX, dH]).

**Definition 2.6** (Lie groupoid). A Lie groupoid $\mathcal{X} = [X_1 \rightrightarrows X_0]$ is a groupoid internal to the category $\mathcal{S}$ of smooth spaces, meaning the space $X_1$ of arrows and the space $X_0$ of objects are objects of $\mathcal{S}$ and all structure morphisms

$$
s, t : X_1 \to X_0, \quad m : X_1 \times_{s,X_0,t} X_1 \to X_1,
$$

$$
i : X_1 \to X_1, \quad e : X_0 \to X_1
$$

are morphisms in $\mathcal{S}$ (so they are smooth maps). Here $s$ is the source map, $t$ is the target map, $m$ is the multiplication map, $e$ is the identity section, and $i$ is the inversion map of the groupoid. The source map $s$ is a submersion. Using $i$, this implies that the target map $t$ is also a submersion.

If $s$ and $t$ are étale, the groupoid $\mathcal{X} = [X_1 \rightrightarrows X_0]$ is called étale. If the anchor map

$$(s, t) : X_1 \to X_0 \times X_0$$

is proper, the groupoid is called a proper groupoid. If the

A Lie group $G$ is a Lie groupoid $[G \rightrightarrows \ast]$ with one object, meaning the space $X_0$ is just a point in $\mathcal{S}$.

Every Lie groupoid $\mathcal{X} = [X_1 \rightrightarrows X_0]$ gives rise to the associated tangent groupoid $T\mathcal{X} := [TX_1 \rightrightarrows TX_0]$.

**Example 2.7.** Let $X$ be a smooth space. The groupoid fibration $X$ is, in fact, a differentiable stack over $\mathcal{S}$. A presentation is given by the identity morphism $id_X$.

**Example 2.8** (Classifying stack). For a Lie group $G$, let $BG$ be the category which has as objects all pairs $(P, S)$, where $S$ is a smooth space of $\mathcal{S}$ and $P$ is a principal $G$-bundle over $S$; a morphism $(P, S) \to (Q, T)$ is a commutative diagram

$$
P \xrightarrow{\varphi} Q \\
\downarrow \quad \downarrow \\
S \to T$$
where $\varphi : P \to Q$ is a $G$-equivariant map. Note that the above diagram is Cartesian. Then $BG$ together with the projection functor

$$\pi : BG \to \mathcal{G}, \ (P, S) \mapsto S$$

is a groupoid fibration over $\mathcal{G}$. We note that $BG$ is in fact a differentiable stack, and it is known as the classifying stack of $G$ (see also Example 2.11 below). A presentation is given by the representable surjective submersion $\ast \to BG$ where $\ast$ is a “point” in $\mathcal{G}$.

**Definition 2.9.** Let $X = [X_1 \rightrightarrows X_0]$ be a Lie groupoid. A (left) $X$-space is given by an object $P$ of $\mathcal{G}$ together with a smooth map $\pi : P \to X_0$ and a map

$$\sigma : Q := X_1 \times_{s,X_0,\pi} P \to P, \ \sigma(\gamma, x) := \gamma \cdot x$$

such that,

(i) $\pi(\gamma \cdot x) = t(\gamma)$ for all $(\gamma, x) \in X_1 \times_{s,X_0,\pi} P$,

(ii) $e(\pi(x)) \cdot x = x$ for all $x \in X_1$, and

(iii) $(\delta \cdot \gamma) \cdot x = \delta \cdot (\gamma \cdot x)$ for all $(\gamma, \delta, x) \in X_1 \times_{s,X_0,t} X_1 \times_{s,X_0,\pi} P$.

Similarly, we can also define a (right) $X$-space.

Let $\mathcal{X}$ be a differentiable stack with a given presentation $x : X \to \mathcal{X}$. We can associate to $\mathcal{X}$ a Lie groupoid $\mathbb{X} = [X_1 \rightrightarrows X_0]$ as follows: Let $X_0 := X$ and $X_1 := X \times_{\mathcal{X}} X$ and the source and target morphisms

$$s, t : X \times_{\mathcal{X}} X \rightrightarrows X$$

of $\mathbb{X}$ being the first and second canonical projection morphisms. The composition of morphisms $m$ in $\mathbb{X}$ is given as projection to the first and third factor

$$X \times_{\mathcal{X}} X \times_{\mathcal{X}} X \cong (X \times_{\mathcal{X}} X) \times_{X} (X \times_{\mathcal{X}} X) \to X \times_{\mathcal{X}} X.$$

The morphism $X \times_{\mathcal{X}} X \to X \times_{\mathcal{X}} X$ that interchanges the two factors gives the inverse morphism $i$ for the groupoid, while the unit morphism $e$ is given by the diagonal morphism $X \to X \times_{\mathcal{X}} X$. As a presentation $x : X \to \mathcal{X}$ of a differentiable stack is a submersion, it follows that the source and target morphisms

$$s, t : X \times_{\mathcal{X}} X \rightrightarrows X,$$

being induced maps from the fiber product, are also submersions.

In the opposite direction, given a Lie groupoid $\mathbb{X}$ we can associate a differentiable stack $\mathcal{X}$ to it. Basically this is a generalization of associating to a Lie group $G$ its classifying stack $BG$ (see Example 2.8). For this we now define (compare also [BS]).

**Definition 2.10 (Torsors).** Let $\mathbb{X} = [X_1 \rightrightarrows X_0]$ be a Lie groupoid, and let $S$ be a smooth space. A (right) $\mathbb{X}$-torsor over $S$ is a smooth space $P$ together with a surjective submersion $\pi : P \to S$ and a right action of $\mathbb{X}$ on $P$ (see the second part of Definition 2.9) satisfying the condition that $\pi$ is $\mathbb{X}$-invariant, i.e., $\pi(\gamma \cdot p) = \pi(p)$ for all $(\gamma, x) \in X_1 \times_{s,X_0,a} P$ and the extra condition that for all $p, p' \in P$ with $\pi(p) = \pi(p')$, there exists a unique $x \in X_1$ such that $p \cdot x$ is defined and $p \cdot x = p'$. 

Let \( \pi : P \to S \) and \( \rho : Q \to T \) be \( \mathbb{X} \)-torsors. A \textit{morphism} of \( \mathbb{X} \)-torsors from the first one to the second one is given by a Cartesian diagram of smooth maps

\[
P \xrightarrow{\varphi} Q \\
\downarrow \downarrow \\
S \xrightarrow{\rho} T
\]

such that \( \varphi \) is a \( X_1 \)-equivariant map. Again, there is also a similar notion of a (left) \( \mathbb{X} \)-torsor over a smooth space \( S \).

Given a \( \mathbb{X} \)-torsor \( P \), the map \( a : P \to X_0 \) is called the \textit{anchor map} or \textit{momentum map}. The surjective submersion \( \pi : P \to S \) is called the \textit{structure map}.

For a Lie groupoid \( \mathbb{X} = [X_1 \rightrightarrows X_0] \), let \( \mathcal{B}X \) denote the category of \( \mathbb{X} \)-torsors, meaning the category whose objects are pairs \((P, S)\), where \( S \) is a smooth space and \( P \) a \( \mathbb{X} \)-torsor over \( S \). The morphisms \( (P, S) \to (Q, T) \) are given by Cartesian diagrams as in (2.1).

Then \( \mathcal{B}X \) is a groupoid fibration over \( S \) with a canonical projection functor \( \pi : \mathcal{B}X \to S \).

It turns out that \( \mathcal{B}X \) is, in fact, a differentiable stack, the \textit{classifying stack of \( \mathbb{X} \)-torsors}. The proof of [BX, Proposition 2.3] works in any of the three categories \( \mathcal{S} \).

\textbf{Example 2.11.} In the case where the Lie groupoid \( \mathbb{X} = [G \rightrightarrows \ast] \) is a Lie group, a \( \mathbb{X} \)-torsor over a smooth space \( S \) is simply a \( G \)-torsor or principal \( G \)-bundle over \( S \). The associated classifying stack is the classifying stack \( \mathcal{B}G \) of the Lie group \( G \).

As presentations for a given differentiable stack are not unique, the associated Lie groupoids might be different. In order to define algebraic and geometric invariants for differentiable stacks, like cohomology or differential forms, they should, however, be independent from the choice of a presentation for the given stack. Therefore, it is important to know under which conditions two different Lie groupoids give rise to isomorphic differentiable stacks.

\textbf{Definition 2.12.} Let \( \mathbb{X} = [X_1 \rightrightarrows X_0] \) and \( \mathbb{Y} = [Y_1 \rightrightarrows Y_0] \) be Lie groupoids. A \textit{morphism} of Lie groupoids is a functor \( \phi : \mathbb{X} \to \mathbb{Y} \) given by two smooth maps \( \phi = (\phi_1, \phi_0) \) with

\[
\phi_0 : X_0 \to Y_0, \quad \phi_1 : X_1 \to Y_1
\]

which commute with all structure morphisms of the groupoids.

A morphism \( \phi : \mathbb{X} \to \mathbb{Y} \) of Lie groupoids is an \textit{étale morphism}, if both maps \( \phi_0 : X_0 \to Y_0 \) and \( \phi_1 : X_1 \to Y_1 \) are étale.

A morphism \( \phi : \mathbb{X} \to \mathbb{Y} \) of Lie groupoids is a \textit{Morita morphism} or \textit{essential equivalence} if

\begin{enumerate}
  \item \( \phi_0 : X_0 \to Y_0 \) is a surjective submersion, and
  \item the diagram

\[
\begin{array}{ccc}
X_1 & \xrightarrow{(s,t)} & X_0 \times X_0 \\
\downarrow \phi_1 & & \downarrow \phi_0 \times \phi_0 \\
Y_1 & \xrightarrow{(s,t)} & Y_0 \times Y_0
\end{array}
\]

is Cartesian, or in other words, \( X_1 \cong Y_1 \times_{Y_0 \times Y_0} (X_0 \times X_0) \).
\end{enumerate}
Two Lie groupoids $X$ and $Y$ are *Morita equivalent*, if there exists a third Lie groupoid $W$ and Morita morphisms

$$X \xleftarrow{\phi} W \xrightarrow{\psi} Y.$$  

**Theorem 2.13 (Morita equivalence).** Let $X = [X_1 \rightrightarrows X_0]$ and $Y = [Y_1 \rightrightarrows Y_0]$ be Lie groupoids. Let $\mathcal{X}$ and $\mathcal{Y}$ be the associated differentiable stacks, i.e., $\mathcal{X}$ is the classifying stack $\mathcal{B}X$ of $X$-torsors and $\mathcal{Y}$ is the classifying stack $\mathcal{B}Y$ of $Y$-torsors. Then the following three statements are equivalent:

(i) The differentiable stacks $\mathcal{X}$ and $\mathcal{Y}$ are isomorphic.

(ii) The Lie groupoids $X$ and $Y$ are Morita equivalent.

(iii) there exists a smooth space $Q$ together with two smooth maps $f : Q \to X_0$ and $g : Q \to Y_0$ and (commuting actions) of $X_1$ and $Y_1$ in such a way that $Q$ is at the same time a left $X$-torsor over $Y_0$ via $g$ and a right $Y$-torsor over $X_0$ via $f$, in other words, $Q$ is a $X$-$Y$-bitorsor.

**Proof.** For the differentiable category of $C^\infty$-manifolds, this is [BX Theorem 2.2]. It is immediate to see that the proof works verbatim for any of the other categories $\mathcal{S}$ of smooth spaces, meaning for complex analytic as well as algebraic stacks. □

Therefore different presentations of the same differentiable stack are given by Morita equivalent Lie groupoids. Conversely, Morita equivalent Lie groupoids present isomorphic differentiable stacks. The case of étale groupoids presenting Deligne-Mumford stacks is of particular importance as these can be used naturally also to describe orbifolds and foliations [Co, CM, L].

### 3. Principal bundles over differentiable stacks and Lie groupoids

In this section, we will define the notion of a principal $G$-bundle over a differentiable stack and over a Lie groupoid.

**3.1. Principal bundles over differentiable stacks.** Let us start with the definition of principal bundles over differentiable stacks.

**Definition 3.1 (Principal bundle over differentiable stack).** Let $G$ be a Lie group and $\mathcal{X}$ a differentiable stack. A principal $G$-bundle or $G$-torsor $E_G$ over $\mathcal{X}$ is given by a differentiable stack $E_G$, a morphism of differentiable stacks $\pi : E_G \to \mathcal{X}$, and a 2-Cartesian diagram

$$
\begin{array}{ccc}
E_G \times G & \xrightarrow{\sigma} & E_G \\
\downarrow \text{p}_1 & & \downarrow \pi \\
E_G & \xrightarrow{\pi} & \mathcal{X}.
\end{array}
$$

such that for any submersion $f : U \to \mathcal{X}$ from a smooth space $U$, the pullback by $f$ in the above diagram defines a principal $G$-bundle on $U$. Morphisms $\rho : E_G \to \mathcal{F}_G$ between two principal $G$-bundles $E_G$ and $\mathcal{F}_G$ are defined in the obvious way.
Principal $G$-bundles over a differentiable stack $\mathcal{X}$ can also be defined directly by using a presentation or atlas. In other words, a principal $G$-bundle $E_G \to X$ over a differentiable stack $X$ is given by a principal $G$-bundle $E_G \to X_0$ for an atlas $X_0 \to \mathcal{X}$ together with an isomorphism of the pullbacks $p_1^*E_G \to p_2^*E_G$ on the fiber product $X_0 \times_{\mathcal{X}} X_0$. It turns out that for any submersion $f : U \to \mathcal{X}$, this datum defines a principal $G$-bundle $E_G \to U$ over $U$, because $X_0 \times_{\mathcal{X}} U \to U$ has local sections. Therefore we get a differentiable stack $E_G$ and the $G$-multiplication map glues and comes with a natural morphism of stacks $E_G \times G \to E_G$ (see [BMW, He, Ne]). We can reformulate all this more explicit also as follows: For each smooth atlas $u : U \to \mathcal{X}$ we are given a principal $G$-bundle $E_G, u$ over $U$, and for each 2-commutative diagram of the form

$$
\begin{array}{ccc}
U & \xrightarrow{\varphi} & V \\
\downarrow{u} & & \downarrow{v} \\
\mathcal{X} & \xrightarrow{\varphi} & \mathcal{X}
\end{array}
$$

(3.1)

with a 2-isomorphism $\alpha : u \Rightarrow v \circ \varphi$, where $u, v$ are smooth atlases, we are given an isomorphism

$$
\theta_{\varphi, \alpha} : E_G, u \cong \varphi^* E_G, v
$$

satisfying the cocycle condition which says that for each 2-commutative diagram of the form

$$
\begin{array}{ccc}
U & \xrightarrow{\varphi} & V & \xrightarrow{\psi} & W \\
\downarrow{u} & & \downarrow{v} & & \downarrow{w} \\
\mathcal{X} & \xrightarrow{\varphi} & \mathcal{X} & \xrightarrow{\psi} & \mathcal{X}
\end{array}
$$

with 2-isomorphisms $\alpha : u \Rightarrow v \circ \varphi$ and $\beta : v \Rightarrow w \circ \psi$ we have a commutative diagram

$$
\begin{array}{cccc}
E_G, u & \xrightarrow{\psi \circ \varphi \circ \beta \circ \alpha} & (\psi \circ \varphi)^* E_G, w \\
\theta_{\varphi, \alpha} \cong & & & \cong
\end{array}
$$

If $F_G$ is another principal $G$-bundle over $\mathcal{X}$, then a morphism $f : E_G \to F_G$ is given by a morphism $f_u : E_{G,u} \to F_{G,u}$ for each smooth atlas $u : U \to \mathcal{X}$ such that for any 2-commutative diagram of the form (3.1) we have a commutative diagram

$$
\begin{array}{cccc}
E_{G,u} & \xrightarrow{f_u} & F_{G,u} \\
\varphi^* E_{G,v} & \cong & \varphi^* F_{G,w}
\end{array}
$$

The category of principal $G$-bundles over a differentiable stack $\mathcal{X}$ forms in a natural way a groupoid fibration $\mathcal{B}un_G(\mathcal{X})$ over $\mathcal{G}$. In fact, we get the following characterization from the above (compare also [BMW, He])

**Proposition 3.2.** Let $\mathcal{X}$ be a differentiable stack and $G$ a Lie group with classifying stack $\mathcal{B}G$. Giving a principal $G$-bundle over $\mathcal{X}$ is equivalent to giving a morphism of
Stacks $\mathcal{X} \to BG$ and two principal $G$-bundles over $\mathcal{X}$ are isomorphic if and only if the corresponding morphisms of stacks $\mathcal{X} \to BG$ are 2-isomorphic.

We consider the groupoid fibration $\mathcal{B}un_G(\mathcal{X})$ over $\mathcal{S}$ whose objects over a smooth space $U$ are principal $G$-bundles $E_G$ over $\mathcal{X} \times U$ and whose morphisms are given by pullback diagrams of principal $G$-bundles. Given two differentiable stacks $\mathcal{X}$ and $\mathcal{Y}$, we also have the groupoid fibration $\mathcal{H}om(\mathcal{X}, \mathcal{Y})$ over $\mathcal{S}$, whose groupoid of sections over a smooth space $U$ is the groupoid of 1-morphisms or functors $\mathcal{H}om(\mathcal{X}, \mathcal{Y})(U) = \text{Hom}_U(\mathcal{X} \times U, \mathcal{Y} \times U)$. Let us remark that if in addition $\mathcal{X}$ is proper and $\mathcal{Y}$ of finite presentation, then $\mathcal{H}om(\mathcal{X}, \mathcal{Y})$ is again a differentiable stack and in particular if $\mathcal{Y}$ is a Deligne–Mumford stack, then the Hom stack $\mathcal{H}om(\mathcal{X}, \mathcal{Y})$ is also a Deligne–Mumford stack (compare [Ao], [Ol]). We can now make the following straightforward observation using Proposition 3.2 (compare with [BMW]).

**Proposition 3.3.** There is an equivalence of groupoid fibrations over $\mathcal{S}$

$$\mathcal{B}un_G(\mathcal{X}) \cong \mathcal{H}om(\mathcal{X}, BG).$$

### 3.2. Principal bundles over Lie groupoids.

Let us now recall the general notion of a principal $G$-bundle over a Lie groupoid (see [LGTX, TLG]).

Given a $\mathcal{X}$-space $\pi : P \to X_0$ for a Lie groupoid $\mathcal{X} = [X_1 \rightrightarrows X_0]$, we have for any $\gamma \in X_1$ a smooth isomorphism in $\mathcal{S}$

$$l_{\gamma} : \pi^{-1}(u) \to \pi^{-1}(v), \quad x \mapsto \gamma \cdot x,$$

where $u = s(\gamma)$ and $v = t(\gamma)$. Associated to this $\mathcal{X}$-space is a transformation groupoid $P = [Q = X_1 \times_{s,X_0} P \rightrightarrows P]$, where the source and target maps are given by $s(\gamma, x) = x$ and $t(\gamma, x) = \gamma \cdot x$. The multiplication map is given by

$$(\gamma, y) \cdot (\delta, x) = (\gamma \cdot \delta, x),$$

where $y = \delta \cdot x$. The first projection defines a strict homomorphism of Lie groupoids from $P = [Q \rightrightarrows P]$ to $\mathcal{X} = [X_1 \rightrightarrows X_0]$.

**Definition 3.4** (Principal bundle over Lie groupoid). Let $G$ be a Lie group and $\mathcal{X} = [X_1 \rightrightarrows X_0]$ a Lie groupoid. A principal $G$-bundle or $G$-torsor over $\mathcal{X}$, denoted by $E_G := [s^*E_G \rightrightarrows E_G]$, is given by a principal (right) $G$-bundle $\pi : E_G \to X_0$, which is also a $\mathcal{X}$-space such that for all $x \in E_G$ and all $\gamma \in X_1$ with $s(\gamma) = \pi(x)$, we have

$$(\gamma \cdot x) \cdot g = \gamma \cdot (x \cdot g) \quad \text{for all } g \in G.$$

Let $s^*E_G = X_1 \times_{s,X_0} E_G$ be the pullback along the source map $s$. Then $E_G = [s^*E_G \rightrightarrows E_G]$ is in a natural way a Lie groupoid, the transformation groupoid with respect to the $X_1$-action.

**Example 3.5.** Let $G$ and $H$ be Lie groups, and let $\mathcal{X} = [H \times X_0 \rightrightarrows X_0]$ be the transformation groupoid over a smooth space $X_0$. Then a principal $G$-bundle over $\mathcal{X}$ is an $H$-equivariant principal $G$-bundle over $X_0$. In particular, if $\mathcal{X} = [X_0 \rightrightarrows X_0]$ with both structure maps $s, t$ being the identity map $id_{X_0}$, then a principal $G$-bundle over $\mathcal{X}$ is just a principal $G$-bundle over $X_0$.

**Example 3.6.** Let $G, H$ be a pair of Lie groups, and $\mathcal{X} = [H \rightrightarrows *]$ the single object Lie groupoid associated to the Lie group $H$. Then a left-action of $H$ on $G$ satisfying $h \cdot (gg') = (h \cdot g)g'$ for all $h \in H$ and $g, g' \in G$ defines a principal $G$-bundle over $\mathcal{X}$, and vice versa.
Similarly, we can define vector bundles of rank $n$ over a Lie groupoid $\mathcal{X}$ and over a differentiable stack $\mathcal{X}$. They can be identified with the principal $\text{GL}_n$-bundles over $\mathcal{X}$ and $\mathcal{X}$ respectively.

The following theorem generalizes [BX, Proposition 4.1] for arbitrary principal bundles and the proof given below is a variation of the argument for $S^1$-bundles.

**Theorem 3.7.** Let $G$ be a Lie group, $\mathcal{X}$ be a differentiable stack and $\mathcal{X} = [X_1 \rightrightarrows X_0]$ be a Lie groupoid presenting $\mathcal{X}$. Then there is a canonical equivalence of categories:

$$
\mathcal{B}un_G(\mathcal{X}) \cong \mathcal{B}un_G(\mathcal{X}),
$$

where $\mathcal{B}un_G(\mathcal{X})$ is the category of principal $G$-bundles over $\mathcal{X}$ and $\mathcal{B}un_G(\mathcal{X})$ is the category of principal $G$-bundles over $\mathcal{X}$.

**Proof.** Let us first assume we have given a principal $G$-bundle $\pi : E_G \to \mathcal{X}$ over the differentiable stack $\mathcal{X}$. Let $E_G$ be the pullback of $X_0 \to \mathcal{X}$ via $\pi$, in other words, we have a 2-Cartesian diagram

$$
\begin{array}{ccc}
E_G & \to & X_0 \\
\downarrow & & \downarrow \\
\mathcal{E}_G & \xrightarrow{\pi} & \mathcal{X}
\end{array}
$$

This means that $E_G \to X_0$ is a principal $G$-bundle over $X_0$ and $E_G \to \mathcal{E}_G$ is a representable surjective submersion. Let $\mathcal{E}_G = [s^*E_G \rightrightarrows E_G]$ be the associated Lie groupoid, which comes with an induced morphism of Lie groupoids

$$
\mathcal{E}_G = [s^*E_G \rightrightarrows E_G] \to \mathcal{X} = [X_1 \rightrightarrows X_0]
$$

and gives rise to the Cartesian diagram

$$
\begin{array}{ccc}
s^*E_G & \to & X_1 \\
\downarrow & & \downarrow \\
E_G & \to & X_0
\end{array}
$$

In other words, we get a pullback diagram of smooth spaces in which the vertical maps are source maps. This implies that $s^*E_G \to E_G$ is a principal $G$-bundle, and the vertical maps are morphisms of $G$-bundle. Therefore, $X_1$ acts on $E_G$ and $E_G$ becomes an $\mathcal{X}$-space which actually turns $\mathcal{E}_G = [s^*E_G \rightrightarrows E_G]$ into a principal $G$-bundle over the groupoid $\mathcal{X} = [X_1 \rightrightarrows X_0]$.

In fact, we get a functor $\Psi : \mathcal{B}un_G(\mathcal{X}) \to \mathcal{B}un_G(\mathcal{X})$, which associates the principal $G$-bundle $\mathcal{E}_G = [s^*E_G \rightrightarrows E_G]$ over the Lie groupoid $\mathcal{X}$ to the given principal $G$-bundle $\mathcal{E}_G \to \mathcal{X}$.

Now let us assume conversely, that we have given a principal $G$-bundle $\mathcal{E}_G = [s^*E_G \rightrightarrows E_G]$ over the Lie groupoid $\mathcal{X} = [X_1 \rightrightarrows X_0]$. This means that we have a principal $G$-bundle $\pi : E_G \to X_0$, which is also a $\mathcal{X}$-space satisfying the conditions given in Definition 3.3.

Recall that

$$
s^*E_G = X_1 \times_{s,X_0,\pi} E_G
$$

is the pullback along the source map $s$, and $\mathcal{E}_G = [s^*E_G \rightrightarrows E_G]$ is in a natural way a Lie groupoid. It follows also that $s^*E_G$ becomes in a natural way a $G$-bundle over $X_1$, and we
have a morphism of Lie groupoids
\[ \mathcal{E}_G = [s^*E_G \rightrightarrows E_G] \to X \]
which respects the $G$-bundle structures of $\tau: s^*E_G \to X_1$ and $\pi: E_G \to X_0$. Let $\mathcal{E}_G := \mathcal{B}E_G$ be the associated differentiable stack of $E_G$-torsors. The morphism of Lie groupoids $E_G \to X$ induces a morphism between the associated differentiable stacks $\mathcal{E}_G \to \mathcal{X}$, which is representable, as its pullback to $X_0$ is the map $\pi: E_G \to X_0$ between smooth spaces:
\[
\begin{array}{ccc}
E_G & \longrightarrow & \mathcal{E}_G \\
\downarrow & & \downarrow \\
X_0 & \longrightarrow & X \\
\end{array}
\]
Furthermore, it follows that the pullback of the morphism of stacks $\mathcal{E}_G \to \mathcal{X}$ along any morphism $U \to X$ from a smooth space $U$ is a principal $G$-bundle. Therefore $\mathcal{E}_G$ is a principal $G$-bundle over the differentiable stack $X$.

Finally, we get a functor in the opposite direction $\Phi: \mathcal{B}un_G(X) \to \mathcal{B}un_G(X)$, which associates the principal $G$-bundle $E_G \to X$ to the given principal $G$-bundle $E_G = [s^*E_G \rightrightarrows E_G]$ over the Lie groupoid $X$. It is easy to see that the functors $\Psi$ and $\Phi$ are mutually inverse and give the desired equivalence of categories. □

The following definition allows for yet another alternative description of principal $G$-bundles over Lie groupoids.

**Definition 3.8.** Let $X = [X_1 \rightrightarrows X_0]$ be a Lie groupoid and $G$ a Lie group. A principal $G$-groupoid over $X$ is a Lie groupoid $\mathcal{P} = [Q \rightrightarrows P]$ together with a groupoid morphism
\[
\begin{array}{ccc}
G & \longrightarrow & Q \\
\downarrow & \sim & \downarrow \\
P & \longrightarrow & \mathcal{P} \\
\end{array}
\]
\[
\begin{array}{ccc}
G & \longrightarrow & Q \\
\sim & \downarrow & \sim \\
P & \longrightarrow & \mathcal{P} \\
\end{array}
\]
such that both $G \to Q \xrightarrow{\tau} X_1$ and $G \to P \xrightarrow{\pi} X_0$ are principal $G$-bundles, and, furthermore, the following conditions hold:

1. the source and target maps $\bar{s}$ and $\bar{t}$ on $Q$ are $G$-equivariant,
2. the identity section $\bar{e}: P \to Q$ is $G$-equivariant,
3. the inversion map $\bar{i}: Q \to Q$ satisfies the identity $\bar{i}(zg) = \bar{i}(z)g^{-1}$ for all $z \in Q$ and $g \in G$, and
4. the multiplication map $Q \times_{s,X_0,t} Q \to Q$ is $G$-equivariant for the diagonal action of $G$ on $Q \times_{s,X_0,t} Q$.

There is an obvious notion of a morphism between principal $G$-groupoids, and we can speak of the category $\mathcal{B}un_{G,X}$ of principal $G$-groupoids over $X$, which yields the following equivalent characterization of the category of principal $G$-bundles over a given Lie groupoid $X$.

**Proposition 3.9.** Let $G$ be a Lie group and $X = [X_1 \rightrightarrows X_0]$ a Lie groupoid. Then there is a canonical equivalence of categories
\[ \mathcal{B}un_G(X) \cong \mathcal{B}un_{G,X}, \]
where \( \text{Bun}_G(\mathcal{X}) \) is the category of principal \( G \)-bundles over \( \mathcal{X} \), and \( \text{Bun}_{G,\mathcal{X}} \) is the category of principal \( G \)-groupoids over \( \mathcal{X} \).

**Proof.** The proof for the differentiable category given in [LGTX, Lemma 2.5] and works equally well in the complex analytic and algebraic context. □

**Remark 3.10.** It can be shown that principal \( G \)-bundles over a Lie groupoid \( \mathcal{X} = [X_1 \rightrightarrows X_0] \) are also equivalent to generalized homomorphisms from \( \mathcal{X} \) to the Lie groupoid \( \mathbb{B}G = [G \rightrightarrows s] \), which is Morita equivalent to the gauge groupoid \( \mathbb{P}_{\text{Gauge}} := [P \times P/G \rightrightarrows X_0] \). In [LGTX, Prop. 2.13, Prop. 2.14 and Thm 2.15] this is discussed in the differentiable setting, but this makes sense again in any of the categories \( \mathcal{S} \) of smooth spaces.

### 4. Connections on Lie groupoids and differentiable stacks

In this section, we define and study the notion of connections on Lie groupoids and differentiable stacks.

#### 4.1. Connections on Lie groupoids and differentiable stacks

Let us start with the general definition of a connection on a Lie groupoid.

Let \( (\mathcal{X} = [X_1 \rightrightarrows X_0], s, t, m, e, i) \) be a Lie groupoid. Let

\[
\mathcal{K} := \text{kernel}(ds) \subset TX_1
\]

be the vertical tangent bundle for \( s \). Since the source map \( s : X_1 \rightarrow X_0 \) is a submersion, \( \mathcal{K} \) is a subbundle of \( TX_1 \). Fix a distribution on \( X_1 \) given by a subbundle \( \mathcal{H} \subset TX_1 \) such that the natural homomorphism

\[
\mathcal{K} \oplus \mathcal{H} \rightarrow TX_1
\]

is an isomorphism, so \( \mathcal{H} \) is a complement of \( \mathcal{K} \). Let

\[
d\mathcal{H}s := (ds)|_{\mathcal{H}} : \mathcal{H} \rightarrow s^*TX_0
\]

be the restriction of \( ds \) to \( \mathcal{H} \). Note that \( d\mathcal{H}s \) is an isomorphism because the homomorphism in (4.2) is an isomorphism.

Let \( dt : TX_1 \rightarrow t^*TX_0 \) be the differential of the map \( t \). Consider the homomorphism

\[
\theta := dt \circ (d\mathcal{H}s)^{-1} : s^*TX_0 \rightarrow t^*TX_0.
\]

For any \( y \in X_1 \), let

\[
\theta_y := \theta|_{(s^*TX_0)_y} : T_{s(y)}X_0 \rightarrow T_{t(y)}X_0
\]

be the restriction of \( \theta \) to the fiber \( (s^*TX_0)_y = T_{s(y)}X_0 \).

We can then define generally

**Definition 4.1** (Connection on a Lie groupoid). A **connection** on a Lie groupoid \( \mathcal{X} = [X_1 \rightrightarrows X_0] \) is a distribution \( \mathcal{H} \subset TX_1 \) given by a subbundle complementing \( \mathcal{K} \) such that

(i) for every \( x \in X_0 \), the image of the differential

\[
de(x) : T_xX_0 \rightarrow T_{e(x)}X_1
\]

coincides with the subspace \( \mathcal{H}_{e(x)} \subset T_{e(x)}X_1 \), and
(ii) for every \( y, z \in X_1 \) with \( t(y) = s(z) \), the homomorphism
\[
\theta_{m(y,z)} : T_{s(y)}X_0 \rightarrow T_{t(z)}X_0
\]
coincides with the composition \( \theta_z \circ \theta_y \) (see (4.4)).

A connection on \( X \) is said to be flat (or integrable) if the distribution \( \mathcal{H} \subset TX_1 \) defining the connection is integrable.

Henceforth we will denote \( m(y,z) = y \circ z \). Similarly for the pairs \( (y,v), (z,w) \in TX_1 \) such that \( s(y) = t(z), dt_y(v) = ds_z(w) \), the composition \( dm \) \( ((y,v), (z,w)) \) in the induced tangent Lie groupoid \( T\mathcal{X} = [TX_1 \rightrightarrows TX_0] \) will be denoted as \( (y \circ z, v \circ w) \).

We will now discuss some functoriality properties for our notion of connection on Lie groupoids.

**Proposition 4.2.** Let \( X = [X_1 \rightrightarrows X_0] \) and \( Y = [Y_1 \rightrightarrows Y_0] \) be Lie groupoids, and let
\[
\phi = (\phi_1, \phi_0) : X \rightarrow Y
\]
be a Morita morphism. Let
\[
\mathcal{H} \subset TY_1
\]
be a distribution that defines a connection on the groupoid \( Y \). Then \( \mathcal{H} \) induces a connection on the groupoid \( X \).

**Proof.** Recall from Definition 2.12(i) that the map \( \phi_0 : X_0 \rightarrow Y_0 \) is a surjective submersion. Hence from Definition 2.12(ii) it follows that
\[
\phi_1 : X_1 \rightarrow Y_1
\]
is also a surjective submersion. Let
\[
d\phi_1 : TX_1 \rightarrow TY_1
\]
be the differential of the map \( \phi_1 \). Let \( \mathcal{H} \subset TY_1 \) be the distribution inducing a connection on the groupoid \( Y \). Now define
\[
\tilde{\mathcal{H}} := (d\phi_1)^{-1}(\phi_1^*\mathcal{H}) \subset TX_1.
\]
Since \( \phi_1 \) is a surjective submersion, it follows that \( \tilde{\mathcal{H}} \subset TX_1 \) is a distribution and therefore defines a connection on the groupoid \( X \). \( \square \)

Similarly, as in [Be], we can study functorial behaviour with respect to horizontal morphisms of Lie groupoids.

**Definition 4.3.** Let \( X = [X_1 \rightrightarrows X_0] \) and \( Y = [Y_1 \rightrightarrows Y_0] \) be Lie groupoids and \( \phi = (\phi_1, \phi_0) : X \rightarrow Y \) be a morphism. Suppose that \( \mathcal{H} \subset TX_1 \) defines a connection on \( X \) and \( \mathcal{L} \subset TY_1 \) a connection on \( Y \). The morphism \( \phi \) is called horizontal if the differential \( d\phi_1 : TX_1 \rightarrow TY_1 \) maps \( \mathcal{H} \) into \( \mathcal{L} \).

**Proposition 4.4.** Let \( X \) and \( Y \) be Lie groupoids together with an étale morphism \( \phi = (\phi_1, \phi_0) : X \rightarrow Y \). Then any connection \( \mathcal{L} \) on \( Y \) induces a unique connection \( \mathcal{H} \) on \( X \) such that \( \phi \) is a horizontal morphism. If the connection \( \mathcal{L} \) is integrable, then also the induced connection \( \mathcal{H} \) is integrable.

**Proof.** Given a connection \( \mathcal{L} \) on the groupoid \( Y \), the unique connection \( \mathcal{H} \) on the groupoid \( X \) is given by the fiber product \( \mathcal{H} := \mathcal{L} \times_{TY_1} TX_1 \). \( \square \)
In particular, a connection (respectively, flat connection) on an étale groupoid induces then a connection (respectively, flat connection) on the associated Deligne-Mumford stack \( \mathcal{B}X \), the classifying stack of \( X \)-torsors.

**Example 4.5.** Let \( X = [X \rightrightarrows X] \) be the Lie groupoid associated to a smooth space \( X \). Then \( \text{kernel}(ds) = \{0\} \) and the map \( x \mapsto \mathcal{H}_xX := T_xM, \ x \in X \), defines an integrable connection \( \mathcal{H}_X \subset TX \) on \( X \).

**Example 4.6.** More generally, for an étale Lie groupoid \( X = [X_1 \rightrightarrows X_0] \), since the differential \( ds : TX_1 \rightarrow s^*TX_0 \) is an isomorphism, the distribution \( \mathcal{H}_X = TX_1 \) is an integrable connection on the Lie groupoid \( X \).

**Example 4.7.** Let \( \pi : E \rightarrow X \) be a finite rank vector bundle over a smooth space \( X \). We get a Lie groupoid \( X = [E \rightrightarrows X] \) with the source and target maps both being \( \pi \). Then any two composable morphisms belong to the same fibre, and the composition can be defined as addition of vectors in that fibre. Any connection on the vector bundle \( \pi : E \rightarrow X \) smoothly splits \( E \) into the horizontal component and \( \text{kernel}(ds) \). This gives a connection on the associated Lie groupoid \( X = [E \rightrightarrows X] \). Integrability of one connection implies integrability of the other.

**Example 4.8.** Let \( G \) be a Lie group. Given a principal \( G \)-bundle \( \pi : P \rightarrow X \) over a smooth space \( X \), one defines the Atiyah or gauge groupoid \( P_{\mathrm{Gauge}} := [P \times P \rightrightarrows X] \) by building the quotient of the groupoid \( [P \times P \rightrightarrows P] \) with respect to the diagonal action of \( G \) on \( P \times P \). A connection \( \omega \) on the principal bundle \( \pi : P \rightarrow X \) gives a \( G \)-invariant horizontal distribution \( \mathcal{H} \subset TP \) complementing the kernel. We define a connection \( \mathcal{H}_{P_{\mathrm{Gauge}}} \) on the Lie groupoid \( P_{\mathrm{Gauge}} \) by

\[
\mathcal{H}_{[p,q]} := \frac{\mathcal{H}_p \oplus T_qP}{T_{p,q}(p,q) \cdot G} \subset \frac{T_pP}{G},
\]

where \( (p, q) \cdot G \subset P \times P \) is the orbit of the element \( (p, q) \in P \times P \). Integrability of the connection \( \omega \) implies integrability of \( \mathcal{H}_{P_{\mathrm{Gauge}}} \).

**Remark 4.9.** Related constructions of connections and flat connections on groupoids and on stacks in the algebro-geometric, differentiable and holomorphic context were also studied by Behrend in [Be]. Flat connections in the differentiable setting for Lie groupoids were also independently introduced as étalifications by Tang [Ta]. These constructions give all rise to subgroupoids of the associated tangent groupoid \( TX \) of a groupoid \( X \), which in the differentiable category is equivalent to the horizontal paths forming a subgroupoid of the path groupoid of \( X \). This is used by Laurent-Gengoux, Stiénon and Xu in [LGSX] to define connections in the general framework of non-abelian differentiable gerbes via Ehresmann connections on Lie groupoid extensions. They also appear as multiplicative distributions on Lie groupoids in recent work by Drummond, and Egea [DE] and Trentinaglia [Tr]. Another definition of a general Ehresmann connection for Lie groupoids was more recently also given and discussed by Arias Abad and Crainic [AC].

We will now point out some additional properties of our constructions of connections for Lie groupoids to highlight the relation with other constructions existing in the literature and here in particular with those in [Be, AC].

Let \( \mathcal{H} \subset TX_1 \) be a connection on a Lie groupoid \( X = [X_0 \rightrightarrows X_1] \). The connection defines a groupoid \( [s^*TX_0 \rightrightarrows TX_0] \) as follows. Without loss of any information we denote
an element \((\gamma, s(\gamma), v)\) of \(s^*TX_0\) by \((\gamma, v)\), where \(v \in T_{s(\gamma)}X_0\). The source, target and composition maps are then respectively given by

\[
\begin{align*}
s : (\gamma, v) &\mapsto (s(\gamma), v), \quad \gamma \in X_1, v \in T_{s(\gamma)}X_0, \\
t : (\gamma, v) &\mapsto (t(\gamma), \theta_s(v)), \\
(\gamma_2, v_2) \circ (\gamma_1, v_1) &= (\gamma_2 \circ \gamma_1, v_1).
\end{align*}
\]

(4.5)

The inversion and unit maps are obvious. Note that the composition is well defined because of condition (ii) in Definition 4.1. Similarly \([t^*TX_0 \Rightarrow TX_0]\) is a groupoid with the corresponding structure maps given as:

\[
\begin{align*}
s : (\gamma, u) &\mapsto (s(\gamma), \theta_{s^{-1}}(u)), \quad \gamma \in X_1, u \in T_{t(\gamma)}X_0, \\
t : (\gamma, u) &\mapsto (t(\gamma), u), \\
(\gamma_2, u_2) \circ (\gamma_1, u_1) &= (\gamma_2 \circ \gamma_1, u_2).
\end{align*}
\]

(4.6)

In fact

\[
\theta : (\gamma, v) \mapsto (\gamma, d_{H}s_{\gamma}^{-1}(v)) \mapsto (\gamma, dt_\gamma \circ d_{H}s_{\gamma}^{-1}(v))
\]

\[
\xymatrix{ s^*TX_0 \ar[r]^-\theta & t^*TX_0 \\
TX_0 \ar[u] \ar[r]^-{\text{id}} & TX_0 \ar[u] }
\]

(4.7)

Moreover, the condition (ii) in Definition 4.1 implies that

\[
d_{H}s_{\gamma_2 \circ \gamma_1}^{-1}(v) - d_{H}s_{\gamma_2}^{-1}(\theta_{\gamma_1}(v)) \circ d_{H}s_{\gamma_1}^{-1}(v) \in \ker(dt_{\gamma_2 \circ \gamma_1})
\]

(4.8)

for any pair of composable \(\gamma_1, \gamma_2 \in X_1\) and \(v \in T_{s(\gamma_1)}X_0\). We denote the corresponding element in \(\ker(dt_{\gamma_2 \circ \gamma_1})\) by

\[
\mathcal{R}(\gamma_2, \gamma_1, v) := d_{H}s_{\gamma_2 \circ \gamma_1}^{-1}(v) - d_{H}s_{\gamma_2}^{-1}(\theta_{\gamma_1}(v)) \circ d_{H}s_{\gamma_1}^{-1}(v).
\]

The outcome of the above observation is the following lemma.

Lemma 4.10. \((d_{H}s^{-1}, \text{id}) : [s^*TX_0 \Rightarrow TX_0] \rightarrow [TX_1 \Rightarrow TX_0]\) defines an essentially surjective, faithful functor if and only if \(\mathcal{R}(\gamma_2, \gamma_1, v)\) vanishes for all pairs of composable arrows \(\gamma_1, \gamma_2 \in X_1\) and \(v \in T_{s(\gamma_1)}X_0\).

Proof. That it is essentially surjective is evident. Now we have:

\[
d_{H}s^{-1}((\gamma_2, v_2) \circ (\gamma_1, v_1)) = d_{H}s^{-1}((\gamma_2 \circ \gamma_1, v_1)) = (\gamma_2 \circ \gamma_1, d_{H}s_{\gamma_2 \circ \gamma_1}^{-1}(v_1)).
\]

On the other hand, we get:

\[
d_{H}s^{-1}((\gamma_2, v_2)) \circ d_{H}s^{-1}((\gamma_1, v_1)) = (\gamma_2, d_{H}s_{\gamma_2}^{-1}(v_2)) \circ (\gamma_1, d_{H}s_{\gamma_1}^{-1}(v_1))
\]

\[
= (\gamma_2 \circ \gamma_1, d_{H}s_{\gamma_2}^{-1}(v_2) \circ d_{H}s_{\gamma_1}^{-1}(v_1)).
\]

Then functoriality is now immediate from the vanishing of the left hand side in (4.8). Since \(d_{H}s^{-1}\) is injective, the functor is also faithful. \(\square\)
Remark 4.11. From the above we see that \( \mathcal{H}(\gamma_2, \gamma_1, v) \) gives an obstruction for the groupoid \([\mathcal{H} \rightrightarrows TX_0]\) to be a subgroupoid of the tangent groupoid \([TX_1 \rightrightarrows TX_0]\). Indeed vanishing of the element in (4.8) is equivalent to the necessary and sufficient condition for a splitting as in (4.2) to yield a subgroupoid, mentioned in Lemma 2.13 of [AC]. Moreover (4.7) implies that both diagrams

\[
\begin{array}{ccc}
\mathcal{H} & \rightrightarrows & TX_0 \\
\downarrow & & \downarrow \\
X_1 & \rightrightarrows & X_0
\end{array}
\]

are Cartesian and thus we arrive at the definition of a connection on a Lie groupoid as given in [Be, Def. 2.1]. In conclusion, we see that our definition of a connection on a Lie groupoid is more general than the one in [Be], but more strict than the definition in [AC]. In fact, a partition of unity argument shows that any Lie groupoid admits a connection in the sense of [AC]. If such a connection satisfies in addition the conditions (i) and (ii) of Definition 4.1, then we obtain a connection as defined in this article.

4.2. Making \( TX_0 \) a vector bundle over \( X \). We will now state another useful geometric interpretation. Let \( \mathcal{H} \) be a connection on a given Lie groupoid \( X = [X_1 \rightrightarrows X_0] \), and let \( \tau : TX_0 \longrightarrow X_0 \) be the natural projection. Consider the fiber product

\[
Y_1 := X_1 \times_{s,X_0,\tau} TX_0.
\]

Let \( s' : Y_1 \longrightarrow TX_0 \) be the projection to the second factor. Define the morphism

\[
t' : Y_1 \longrightarrow TX_0, \quad (x, v) \longmapsto \theta_x(v) \in T_{t(x)}X_0,
\]

where \( \theta_x \) is constructed as in (4.4). Furthermore, let

\[
p : Y_1 = X_1 \times_{s,X_0,\tau} TX_0 \longrightarrow X_1
\]

be the projection to the first factor. For any \( z, y \in Y_1 \) with \( t'(y) = s'(z) \), define

\[
m'(z, y) := (m(p(z), p(y)), s'(y)).
\]

Note that \( s(p(z)) = t(p(y)) \), so \( m(p(z), p(y)) \) is defined. Let \( e' \) be the morphism

\[
e' : TX_0 \longrightarrow Y_1, \quad v \longmapsto (e(\tau(v)), v).
\]

Finally, let

\[
i' : Y_1 \longrightarrow Y_1, \quad (z, v) \longmapsto (i(z), \theta_z(v))
\]

be the involution. It is straightforward to check that \( ([Y_1 \rightrightarrows TX_0], s', t', m', e', i') \) is a Lie groupoid. In other words, \( TX_0 \) is a vector bundle over the groupoid \( X \).

4.3. Characteristic differential forms for connections on \( X \). We will now study the behaviour and interpretation of connections on Lie groupoids in terms of differential forms. Let \( \mathcal{H} \) be a connection on the Lie groupoid \( X = [X_1 \rightrightarrows X_0] \). Using the canonical decomposition of the tangent space

\[
TX_1 = \mathcal{H} \oplus \ker(ds),
\]

we get a projection

\[
\wedge^jTX_1 \longrightarrow \wedge^j\mathcal{H} \hookrightarrow \wedge^jTX_1.
\]
The composition $\wedge^j T X_1 \to \wedge^j T X_1$ gives by duality an endomorphism of the space of $j$-forms on $X_1$.

For a differential form $\omega$ on $X_1$, the differential form on $X_1$ induced by the above endomorphism for the given connection $\mathcal{H}$ will be denoted by $H(\omega)$.

**Definition 4.12.** A differential $j$-form on the Lie groupoid $[X_1 \rightrightarrows X_0]$ is a differential $j$-form $\omega$ on $X_0$ such that $H(s^*\omega) = H(t^*\omega)$.

Induced differential forms for an integrable distribution observe the following basic property.

**Proposition 4.13.** Let $\mathcal{H}$ be a connection on a Lie groupoid $\mathcal{X} = [X_1 \rightrightarrows X_0]$ and assume that the distribution $\mathcal{H} \subset TX_1$ is integrable. Let $\omega$ be a differential form on $X_0$ such that $H(s^*\omega) = H(t^*\omega)$. Then $H(s^*d\omega) = H(t^*d\omega)$.

**Proof.** Take a point $x \in X_1$. Let $\mathcal{L}$ be the locally defined leaf of $\mathcal{H}$ passing through $x$. Let $\iota : \mathcal{L} \hookrightarrow X_1$ be the inclusion map. Since $H(s^*\omega) = H(t^*\omega)$, it follows immediately that $\iota^*s^*\omega = \iota^*t^*\omega$. Therefore we have,

$$\iota^*s^*(d\omega) = dt^*s^*\omega = dt^*t^*\omega = \iota^*t^*(d\omega).$$

But this implies that $H(s^*(d\omega))(x) = H(t^*(d\omega))(x)$ and so we conclude that $H(s^*(d\omega)) = H(t^*(d\omega))$, which finishes the proof. \qed

5. Connections on principal bundles over Lie groupoids and differentiable stacks

We will now study in detail the notion and interplay of connections on principal $G$-bundles over Lie groupoids and differentiable stacks.

5.1. Connections on principal $G$-bundles over Lie groupoids. Let us start with the groupoid picture. Let $(\mathcal{X} = [X_1 \rightrightarrows X_0], s, t, m, e, i)$ be a Lie groupoid and $G$ a Lie group. The Lie algebra of $G$ will be denoted by $\mathfrak{g}$. We shall consider $\mathfrak{g}$ as a $G$-module using the adjoint action. Let

$$\alpha : E_G \to X_0$$

be a principal $G$-bundle over $X_0$. The adjoint vector bundle for $E_G$

$$\text{ad}(E_G) := E_G \times^G \mathfrak{g} \to X_0$$

is the bundle associated to $E_G$ for the adjoint action of $G$ on $\mathfrak{g}$. The action of $G$ on $E_G$ induces an action of $G$ on the direct image $\alpha_*TE_G$, where $\alpha$ is the projection as given in \((5.1)\).

**Definition 5.1.** The *Atiyah bundle* for a principal $G$-bundle $E_G$ over $X_0$ is the invariant direct image

$$\text{At}(E_G) := (\alpha_*TE_G)^G \subset \alpha_*TE_G.$$
Therefore, we have \( \text{At}(E_G) = (T_E G)/G \) (see also [Al] for the classical and analogue notion of the Atiyah bundle in the complex analytic context).

Let 
\[
q_E : T_E G \longrightarrow (T_E G)/G = \text{At}(E_G)
\]
be the quotient map.

Let \( T_{\text{rel}} \subset T_E G \) be the relative tangent bundle for the projection \( \alpha \) in (5.1). It fits into the short exact sequence of vector bundles
\[
0 \longrightarrow T_{\text{rel}} \overset{\iota_0}{\longrightarrow} T_E G \overset{d\alpha}{\longrightarrow} \alpha^* T X_0 \longrightarrow 0 ,
\]
where \( d\alpha \) is the differential of \( \alpha \). Using the action of \( G \) on \( E_G \), the vector bundle \( T_{\text{rel}} \rightarrow E_G \) gets identified with the trivial vector bundle \( E_G \times g \rightarrow E_G \). Therefore, we see that
\[
\text{ad}(E_G) = (\alpha_\ast T_{\text{rel}})^G ,
\]
and so \( \text{ad}(E_G) = (\alpha_\ast T_{\text{rel}})/G \). The map of quotients \( T_{\text{rel}}/G \longrightarrow (T_E G)/G \) induced by the inclusion \( T_{\text{rel}} \hookrightarrow T_E G \) makes \( \text{ad}(E_G) \) a subbundle of \( \text{At}(E_G) \). The differential of \( d\alpha \) in (5.4) being \( G \)-equivariant therefore produces a homomorphism
\[
(d\alpha)' : \text{At}(E_G) \longrightarrow T X_0 .
\]
Combining these we obtain the Atiyah exact sequence (see [Al]):
\[
0 \longrightarrow \text{ad}(E_G) \longrightarrow \text{At}(E_G) \overset{(d\alpha)'}{\longrightarrow} T X_0 \longrightarrow 0 .
\]
This exact sequence is the quotient of the exact sequence in (5.4) by the action of \( G \). Now we can define the general notion of a connection on a principal \( G \)-bundle (compare [Al])

**Definition 5.2.** A connection on a principal \( G \)-bundle \( E_G \) over \( X_0 \) is a splitting of the Atiyah exact sequence
\[
0 \longrightarrow \text{ad}(E_G) \longrightarrow \text{At}(E_G) \overset{(d\alpha)'}{\longrightarrow} T X_0 \longrightarrow 0 .
\]

Giving a splitting of the exact sequence in (5.6) is evidently equivalent to giving a \( G \)-equivariant splitting of the exact sequence in (5.4). Therefore, a connection on \( E_G \) is a homomorphism
\[
D_{E_G} : T E_G \longrightarrow T_{\text{rel}}
\]
such that
\[
\begin{align*}
\bullet & \quad D_{E_G} \text{ is } G\text{-equivariant, and} \\
\bullet & \quad D_{E_G} \circ t_0 = \text{Id}_{T_{\text{rel}}}, \text{ where } t_0 \text{ is the homomorphism in (5.3)}.
\end{align*}
\]
Recall that \( T_{\text{rel}} = E_G \times g \). Therefore, any homomorphism \( D_{E_G} : T E_G \longrightarrow T_{\text{rel}} \) satisfying the above two conditions is a \( g \)-valued 1-form \( \widehat{D}_{E_G} \) on \( E_G \) such that the corresponding homomorphism
\[
\widehat{D}_{E_G} : T E_G \longrightarrow g
\]
is \( G \)-equivariant for the adjoint action of \( G \) on \( g \).

Now we equip \( E_G \) with the structure of a principal \( G \)-bundle on the fixed Lie groupoid \( \mathbb{X} = [X_1 \rightrightarrows X_0] \). First we shall use the description of a principal \( G \)-bundle over \( \mathbb{X} \) given
in Definition 3.8. So we have a Lie groupoid $E_G = [Q \rightrightarrows P]$ together with a groupoid morphism

$$
\begin{array}{ccc}
G & \xrightarrow{r} & Q \\
\downarrow{t} & & \downarrow{s} \\
G & \xrightarrow{\pi} & E_G \\
\downarrow{\tilde{t}} & & \downarrow{\tilde{s}} \\
& & X_1 \\
\end{array}
$$

(5.9)

such that both $Q \xrightarrow{r} X_1$ and $E_G \xrightarrow{\pi} X_0$ are principal $G$-bundles, and the four conditions in Definition 3.8 are satisfied.

Let $\nabla$ be a connection on the principal $G$-bundle $E_G \to X_0$. Let

$$
\hat{\nabla} : T E_G \to g
$$

(5.10)

be the $G$-equivariant $g$-valued 1-form on $E_G$ as in (5.8) corresponding to $\nabla$.

**Definition 5.3** (Connection on a principal bundles over a Lie groupoid). A connection on a principal $G$-bundle $E_G = [Q \rightrightarrows E_G]$ over the Lie groupoid $X = [X_1 \rightrightarrows X_0]$ is a connection $\nabla$ on the principal $G$-bundle $E_G \to X_0$ such that the two $g$-valued 1-forms $\tilde{t}^*\hat{\nabla}$ and $\tilde{s}^*\hat{\nabla}$ on $Q$ coincide, where $\hat{\nabla}$ is the 1-form $\hat{\nabla} : T E_G \to g$ associated to the connection $\nabla$.

Now we adopt Definition 3.4. Let

$$
E_G := [s^* E_G \rightrightarrows E_G]
$$

be a principal $G$-bundle over $X$ as in Definition 3.4. Let $\hat{s} : s^* E_G \to E_G$ and $\hat{t} : s^* E_G \to E_G$ respectively be the source map and the target map.

The following definition is then evidently equivalent to Definition 5.3.

**Definition 5.4.** A connection on the principal $G$-bundle $E_G = [s^* E_G \rightrightarrows E_G]$ over the Lie groupoid $X = [X_1 \rightrightarrows X_0]$ is a connection $\nabla$ on the principal $G$-bundle $E_G \to X_0$ such that the two $g$-valued 1-forms $\hat{s}^*\hat{\nabla}$ and $\hat{t}^*\hat{\nabla}$ on $s^* E_G$ coincide, where $\hat{\nabla}$ is the 1-form $\hat{\nabla} : T E_G \to g$ associated to the connection $\nabla$.

**Definition 5.5.** Let $\hat{\nabla}$ be a connection on a principal $G$-bundle $E_G = [s^* E_G \rightrightarrows E_G]$ over the Lie groupoid $X = [X_1 \rightrightarrows X_0]$ given by a connection $\nabla$ on $E_G$. The curvature of $\hat{\nabla}$ is defined to be the curvature of $\nabla$. In particular, the connection $\hat{\nabla}$ is called flat if $\nabla$ is integrable.

**Proposition 5.6.** Let $X = [X_1 \rightrightarrows X_0]$ and $Y = [Y_1 \rightrightarrows Y_0]$ be Lie groupoids, and let $\phi : X \to Y$ be a morphism given by maps

$$
\phi_0 : X_0 \to Y_0, \quad \phi_1 : X_1 \to Y_1
$$

(see Definition 2.12). Let

$$
E_G := [s^* E_G \rightrightarrows E_G]
$$

be a principal $G$-bundle on $Y$ equipped with a connection $\hat{\nabla}$ given by a connection $\nabla$ on the principal $G$-bundle $E_G \to Y_0$. Then the pulled back connection $\phi_0^* \hat{\nabla}$ on $\phi^* E_G \to X_0$ is a connection on the principal $G$-bundle $\phi^* E_G$ over the Lie groupoid $X$. 
Proof. Let \( s \) and \( s' \) (respectively, \( t \) and \( t' \)) be the source maps (respectively, target maps) of \( X \) and \( Y \) respectively. The two maps \( s' \circ \phi_1 \) and \( \phi_0 \circ s \) from \( X_1 \) to \( Y_0 \) coincide. Similarly, the two maps \( t' \circ \phi_1 \) and \( \phi_0 \circ t \) from \( X_1 \) to \( Y_0 \) also coincide.

Using this, it is straightforward to check that the connection \( \phi_0^* \nabla \) on \( \phi^* E_G \rightarrow X_0 \) is a connection on the principal \( G \)-bundle \( \phi^* E_G \) over the groupoid \( X \).

Example 5.7. A connection on a principal \( G \)-bundle \( E_G = [Q \rightrightarrows E_G] \) over the Lie groupoid \( X = [X \rightrightarrows X] \) is the same as a connection on the (ordinary) principal \( G \)-bundle \( E_G \rightarrow X \) over the smooth space \( X \).

Example 5.8. Let \( \pi_0 : E \rightarrow X_0 \) be a vector bundle and \( \pi_G : E_G \rightarrow X_0 \) a principal \( G \)-bundle over \( X_0 \). Let \( X := \{E \rightrightarrows X_0\} \) be the Lie groupoid introduced in Example 4.7. Then \( E_G \) is an \( X \)-space with respect to the map \( (v, p) \mapsto p \), for all \( (v, p) \in E \times E_G \) satisfying \( \pi_0(v) = s(v) = \pi_G(p) \). The action of \( X \) is obviously compatible with the action of \( G \) on \( E_G \), and thus we obtain a principal \( G \)-bundle over \( X \). Then any connection on the (ordinary) principal \( G \)-bundle \( E_G \rightarrow X_0 \) defines a connection on the principal \( G \)-bundle over \( X \).

Example 5.9. Let \( E_G \rightarrow X_0 \) be an \( H \)-equivariant principal \( G \)-bundle over \( X_0 \). Let \( X = [H \times X_0 \rightrightarrows X_0] \) be the transformation groupoid. As in Example 5.7 consider \( E_G \rightarrow X_0 \) to be a \( G \)-bundle over \( X \). Then a connection on the (ordinary) principal \( G \)-bundle \( E_G \rightarrow X_0 \) defines a connection on the principal \( G \)-bundle over \( X \).

Remark 5.10. The definition of a connection on a principal \( G \)-bundle over a Lie groupoid given in this article is less rigid than the one by Laurent-Gengoux, Tu and Xu [LGTX, Def. 3.5], the difference between our approach and the one in [LGTX] becomes clear when comparing the associated de Rham complexes and Chern-Weil maps, which is discussed in our follow-up article [BCKN, Sect. 5 & 6]. In particular, it is not hard to see that the two definitions coincide in the case of principal \( G \)-bundles over an étale Lie groupoid \( X = [X_1 \rightrightarrows X_0] \) with integrable distribution \( \mathcal{H} = TX_1 \).

The space of connections on a principal \( G \)-bundle \( E_G \) over the Lie groupoid \( X \) is an affine space for the space of all \( \text{ad}(E_G) \)-valued 1-forms on the groupoid.

Henceforth, given a Lie groupoid \( X = [X_1 \rightrightarrows X_0] \) we will assume that there exist a given integrable distribution \( \mathcal{H} \subset TX_1 \), in other words, we have given a flat connection on the Lie groupoid \( X \).

Consider now again the Atiyah exact sequence as constructed in [5.6]. The Lie bracket of vector fields defines a Lie algebra structure on the sheaves of sections of all three vector bundles. The Lie algebra structure on the sheaf of sections of \( \text{ad}(E_G) \) is linear with respect to the multiplication by functions on \( X_0 \), or in other words, the fibers of \( \text{ad}(E_G) \) are Lie algebras.

Let \( g \) be again the Lie algebra for the Lie group \( G \). Recall that \( \text{ad}(E_G) = (E_G \times g)/G \) is the vector bundle on \( X_0 \) associated to principal \( G \)-bundle \( E_G \) for the adjoint action of \( G \) on \( g \). Since this adjoint action of \( G \) preserves the Lie algebra structure of \( g \), it follows that the fibers of \( \text{ad}(E_G) \) are Lie algebras identified with \( g \) up to conjugations.

Given any splitting of the Atiyah exact sequence [5.6]

\[
D : TX_0 \rightarrow \text{At}(E_G),
\]
the obstruction for $D$ to be compatible with the Lie algebra structure is given by a section 
\[ K(D) \in H^0(X_0, \text{ad}(E_G) \otimes \Omega^2_{X_0}), \]
which is an $\text{ad}(E_G)$-valued 2-form on the groupoid $X$.

**Definition 5.11.** For a principal $G$-bundle $E_G = [s^*E_G \rightarrow E_G]$ over a Lie groupoid $X = [X_1 \Rightarrow X_0]$ with a connection $D$, the section $K(D)$ is called the curvature of the connection $D$.

The above constructions readily imply now the following result, which allows for the development of a general Chern-Weil theory and the construction of characteristic classes. This will be discussed systematically in [BCKN].

**Theorem 5.12.** For any invariant form $\nu \in (\text{Sym}^k(g^*))^G$, the evaluation $\nu(K(D))$ on the curvature $K(D)$ is a closed $2k$-form on the Lie groupoid $X$.

### 5.2. Connections on principal $G$-bundles over differentiable stacks

Finally, we shall turn to the stacky picture and study connections for principal $G$-bundles on a differentiable stack (compare also [BMW]).

**Definition 5.13 (Connection on principal bundle over differentiable stack).** Let $E_G$ be a principal $G$-bundle on a differentiable stack $\mathcal{X}$. A connection $\nabla$ on $E_G$ consists of the data of a connection $\nabla_u$ on each principal $G$-bundle $E_{G,u}$, where $u : U \rightarrow \mathcal{X}$ is a smooth atlas for $\mathcal{X}$, which pulls back naturally with respect to each 2-commutative diagram of the form

\[
\begin{array}{ccc}
U & \xrightarrow{\varphi} & V \\
\downarrow u & & \downarrow v \\
\mathcal{X} & \xrightarrow{\phi} & \mathcal{X}
\end{array}
\]

A connection $\nabla$ on $E_G$ is flat or integrable if it is in addition integrable on each principal $G$-bundle $E_{G,u}$.

Let us unravel this definition with more details. We can realize the connections for each atlas $u$ in terms of $g$-valued 1-forms such that $\omega_{E_{G,u}} \in H^0(E_{G,u}, \Omega^1_{E_{G,u}} \otimes g)$ is the corresponding 1-form for the connection $\nabla_u$ on $E_{G,u}$. From the Cartesian diagram

\[
\begin{array}{ccc}
U & \xrightarrow{\varphi^*} & E_{G,v} \\
\downarrow & & \downarrow \\
\mathcal{X} & \xrightarrow{\phi^*} & \mathcal{X}
\end{array}
\]

we get a connection $\phi^*\omega_{E_{G,u}}$ on $\varphi^*E_{G,v}$. The condition for the existence of a connection is then given as follows

\[ \omega_{E_{G,u}} = \theta_{\varphi,u}^*\omega_{E_{G,v}}. \]

From now on, we will assume that $\mathcal{X}$ is a Deligne–Mumford stack, which in particular means that the tangent stack $T\mathcal{X}$ gives rise to a vector bundle $T\mathcal{X} \rightarrow \mathcal{X}$ over $\mathcal{X}$. For a general differentiable stack, this is not always the case (see [Be], [LGTX], [Hp]).
Given a principal \( G \)-bundle \( \mathcal{E}_G \) over \( \mathcal{X} \), we define the associated Atiyah bundle \( \text{At}(\mathcal{E}_G) \) over \( \mathcal{X} \) by setting
\[
\text{At}(\mathcal{E}_G)_u := \text{At}(\mathcal{E}_{G,u}).
\]
for any étale morphism \( u : U \to \mathcal{X} \). In addition, for each 2-commutative diagram of the form
\[
\begin{array}{ccc}
U & \xrightarrow{\varphi} & V \\
\downarrow u & & \downarrow v \\
\mathcal{X} & \xrightarrow{\tau} & \mathcal{Y}
\end{array}
\]
where \( u, v, \varphi \) are étale morphisms, we can compose the isomorphism \( \text{At}(\mathcal{E}_{G,u}) \cong \text{At}(\mathcal{E}_{G,v}) \) with the isomorphism \( \varphi^* \text{At}(\mathcal{E}_{G,u}) \cong \text{At}((\varphi^*\mathcal{E}_{G,v}) \) to get an isomorphism
\[
\text{At}(\mathcal{E}_G)_u \cong \varphi^* \text{At}(\mathcal{E}_G)_v.
\]
Similarly, given a principal \( G \)-bundle \( \mathcal{E}_G \) over \( \mathcal{X} \), we can define the associated adjoint bundle \( \text{ad}(\mathcal{E}_G) \) over \( \mathcal{X} \) arising from the adjoint representation of \( G \) by setting (compare [BMW, Sect. 1.4])
\[
\text{ad}(\mathcal{E}_G)_u := \mathcal{E}_G \times^G \mathfrak{g},
\]
where \( \text{ad}(\mathcal{E}_G)_u = \text{ad}(\mathcal{E}_{G,u}) \). We then obtain a commutative diagram of vector bundles
\[
\begin{array}{cccccc}
& & 0 & \xrightarrow{=} \text{ad}(\mathcal{E}_G)_u & \xrightarrow{=} \text{At}(\mathcal{E}_G)_u & \xrightarrow{=} T\mathcal{X} & \xrightarrow{=} 0 \\
0 & \xrightarrow{=} \text{ad}(\mathcal{E}_G)_v & \xrightarrow{=} \varphi^* \text{At}(\mathcal{E}_G)_v & \varphi^* TV & \xrightarrow{=} 0
\end{array}
\]
which gives a well-defined short exact sequence of vector bundles over the Deligne–Mumford stack \( \mathcal{X} \), called the Atiyah exact sequence associated to the principal \( G \)-bundle \( \mathcal{E}_G \)
\[
0 \to \text{ad}(\mathcal{E}_G) \to \text{At}(\mathcal{E}_G) \to T\mathcal{X} \to 0.
\]

**Remark 5.14.** In the situation of a general differentiable stack \( \mathcal{X} \), similarly as for the tangent stack, \( \text{At}(\mathcal{E}_G) \) and \( \text{ad}(\mathcal{E}_G) \) will generally not give vector bundles over \( \mathcal{X} \).

From the constructions and considerations above, it follows now

**Proposition 5.15.** A principal \( G \)-bundle \( \mathcal{E}_G \) over a Deligne–Mumford stack \( \mathcal{X} \) admits a connection if and only if its associated Atiyah exact sequence has a splitting.

Finally, we have the following comparison theorem for the existence of a connection of a principal \( G \)-bundle over a Deligne–Mumford stack:

**Theorem 5.16.** Giving a connection (respectively, flat connection) on a principal \( G \)-bundle \( \mathcal{E}_G \) over a Deligne–Mumford stack \( \mathcal{X} \) with étale atlas \( x : X_0 \to \mathcal{X} \) is equivalent to giving a connection (respectively, flat connection) on the associated principal \( G \)-bundle \( \mathcal{E}_G \) over the groupoid \( \mathcal{X} = [X_1 \rightrightarrows X_0] \). Giving a connection (respectively, flat connection) on a principal \( G \)-bundle \( \mathcal{E}_G = [s^* \mathcal{E}_G \rightrightarrows \mathcal{E}_G] \) over an étale Lie groupoid \( \mathcal{X} = [X_1 \rightrightarrows X_0] \) is equivalent to giving a connection (respectively, flat connection) on the associated principal \( G \)-bundle \( \mathcal{E}_G \) of \( \mathcal{E}_G \)-torsors over the classifying stack \( \mathcal{B}\mathcal{X} \) of \( \mathcal{X} \)-torsors.
Proof. This follows from the categorical equivalence of Theorem 3.7 between the category \( \mathcal{B}un_G(X) \) of principal \( G \)-bundles over \( X \) and the category \( \mathcal{B}un_G(X) \) of principal \( G \)-bundles over the associated Lie groupoid \( X = [X_1 \rightrightarrows X_0] \) and the fact that a splitting of the Atiyah exact sequence of associated vector bundles over the stack \( X \)

\[
0 \longrightarrow \text{ad}(E_G) \longrightarrow \text{At}(E_G) \longrightarrow T\mathcal{X} \longrightarrow 0
\]
corresponds to a splitting of the Atiyah exact sequence of associated vector bundles over the smooth space \( X_0 \)

\[
0 \longrightarrow \text{ad}(E_G) \longrightarrow \text{At}(E_G) \longrightarrow TX_0 \longrightarrow 0
\]
and vice versa involving the 2-Cartesian diagram and unraveling the explicit constructions of associated bundles as given in the proof of Theorem 3.7. □

Let us now consider the classifying stack \( \mathcal{B}\nabla G \) of principal \( G \)-bundles with connections. The objects are triples \((P, \omega, S)\) where \( S \) is a smooth space of \( \mathcal{G} \) and \( P \) is a principal \( G \)-bundle over \( S \) and \( \omega \in \Omega^1(S, g)^G \) a connection 1-form. A morphisms \((P, \omega, S) \longrightarrow (P', \omega', S')\) is given by a commutative diagram

\[
P \xrightarrow{\varphi} P' \\
\downarrow \quad \downarrow \\
S \xrightarrow{} S'
\]
where \( \varphi : P \longrightarrow P' \) is a \( G \)-equivariant map and \( \varphi^* \omega' = \omega \). Then \( \mathcal{B}\nabla G \) together with the projection functor

\[
\pi : \mathcal{B}\nabla G \longrightarrow \mathcal{G}, \ (P, \omega, S) \longmapsto S
\]
is a groupoid fibration over \( \mathcal{G} \). We note that \( \mathcal{B}\nabla G \) is, in fact, a stack as principal \( G \)-bundles glue and connection 1-forms on the principal bundles glue as well (compare also [CLM]).

Remark 5.17. It is not clear in general if and under which conditions \( \mathcal{B}\nabla G \) is actually a differentiable or Deligne–Mumford stack and not just a stack over \( \mathcal{G} \).

The above constructions now allow us to characterize principal \( G \)-bundles over differentiable stacks equivalently as follows.

Proposition 5.18. Let \( \mathcal{X} \) be a differentiable stack. Giving a principal \( G \)-bundle with connection over \( \mathcal{X} \) is equivalent to giving a morphism of stacks \( \mathcal{X} \longrightarrow \mathcal{B}\nabla G \) and two principal \( G \)-bundles with connections over \( \mathcal{X} \) are isomorphic if and only if the corresponding morphisms of stacks \( \mathcal{X} \longrightarrow \mathcal{B}\nabla G \) are 2-isomorphic.

Similarly, as before, we can consider the groupoid fibration \( \mathcal{B}un_G(\mathcal{X}) \) over \( \mathcal{G} \) whose objects over a smooth space \( U \) are principal \( G \)-bundles \( E_G \) over \( \mathcal{X} \times U \) with connections and whose morphisms are given by pullback diagrams of principal \( G \)-bundles with connections as above. From Proposition 5.18 we get therefore the following:
Proposition 5.19. There is an equivalence of groupoid fibrations over $\mathcal{S}$
\[
\mathcal{B}un_G^\nabla(X) \cong \mathcal{H}om(X, \mathcal{B}^\nabla G).
\]

Collier–Lerman–Wolbert [CLW, Theorem 6.4] proved a similar result involving holonomy and parallel transport for principal $G$-bundles over stacks.
