Abstract

A simple proof is given for a generalized form of a theorem of Soshnikov. The latter states that the Janossy densities for multilevel determinantal ensembles supported on measurable subspaces of a set of measure spaces are constructed by dualization of bases on dual pairs of \( N \)-dimensional function spaces with respect to a pairing given by integration on the complements of the given measurable subspaces. The generalization extends this to dualization with respect to measures modified by arbitrary sets of weight functions.

1. Multilevel determinantal ensembles.

Let \( \{ (\Gamma_j, d\mu_j) \}_{j=1 \ldots m} \) be a set of measure spaces and \( \{ \tilde{H}_j := L^2(\Gamma_j, d\mu_j) \}_{j=1 \ldots m} \) the Hilbert spaces of square integrable functions on them. Let \( \{ f_a \}_{a=1 \ldots N} \) and \( \{ h_a \}_{a=1 \ldots N} \) be bases for a pair of \( N \)-dimensional subspaces \( H_1 \subset \tilde{H}_1, H_m \subset \tilde{H}_m \), respectively. Suppose we are given \( m-1 \) functions \( \{ g_{j+1,j} \}_{j=1 \ldots m-1} \) on the product spaces \( \Gamma_{j+1} \times \Gamma_j \), such that the corresponding integral operators

\[
g_{j+1,j} : \tilde{H}_j \rightarrow \tilde{H}_{j+1}
\]

\[
g_{j+1,j}(f)(x_{j+1}) := \int_{\Gamma_j} g_{j+1,j}(x_{j+1}, x_j) f(x_j) d\mu_j(x_j),
\]

(1.1)

together with their transposes

\[
g_{j+1,j}^* : \tilde{H}_{j+1} \rightarrow \tilde{H}_j
\]

\[
g_{j+1,j}^*(f)(x_j) := \int_{\Gamma_{j+1}} g_{j+1,j}(x_{j+1}, x_j) f(x_{j+1}) d\mu_j(x_{j+1}),
\]

(1.2)

are well defined injective maps on a sequence of dense subspaces \( \tilde{H}_1 \subset \tilde{H}_1, \tilde{H}_2 = g_{21}(\tilde{H}_1) \subset \tilde{H}_2, \ldots, \tilde{H}_m = g_{m,m-1}(\tilde{H}_{m-1}) \subset \tilde{H}_m \), as are their composites:

\[
g_{kj} := g_{k,k-1} \circ \ldots \circ g_{j+1,j}.
\]

(1.3)
We assume that $H_1 \subset \hat{H}_1$, $H^m \subset \hat{H}_m$, and denote the respective images as $H_2 := g_{21}(H_1), \ldots$, $H_m := g_{m,m-1}(H_{m-1})$ and $H^{m-1} := g_{m,m-1}(H^m), \ldots$, $H^1 := g_{2,1}(H^2)$. Assuming furthermore that the $N \times N$ matrix:

$$A_{ab} := \int_{\Gamma_1} f_a(x_1)g_m^b(h_b)(x_1)d\mu_1(x_1) = \int_{\Gamma_m} g_m^1(f_a(x_m))(h_b)(x_m)d\mu_m(x_m) \quad (1.4)$$

is nonsingular, it follows that the pairs of spaces $\{H_j, H^j\}$ may be viewed as mutually dual, and identified through the $d\mu_j$ integration pairings. Making a $PLU$ decomposition of $A$

$$A := PLU, \quad (1.5)$$

where $L$ and $U$ are, respectively, lower and upper triangular matrices, normalized, e.g., with equal diagonal entries (unique up to $2^N$ sign ambiguities on the diagonal), and $P$ a permutation matrix, we may form bases:

$$\psi_a^{(1)} := \sum_{b=1}^{N} (PL)^{-1}_{ab} f_b, \quad \phi_a^{(m)} := \sum_{b=1}^{N} U^{-1}_{ba} h_b \quad (1.6)$$

for the spaces $H_1$ and $H^m$, respectively, as well as for the sequence of dual spaces $\{H_j, H^j\}$ through composition with $g_{j1}$ and $g_{m_j}^{*}$:

$$\{\psi_a^{(j)} := g_{j1}(\psi_a^{(1)})\}_{a=1 \ldots N}, \quad \{\phi_a^{(j)} := g_{m_j}^{*}(\phi_a^{(m)})\}_{a=1 \ldots N}. \quad (1.7)$$

These are, by construction, mutually dual,

$$\int_{\Gamma_j} \psi_a^{(j)}(x_j)\phi_b^{(j)}(x_j)d\mu_j(x_j) = \delta_{ab}. \quad (1.8)$$

An example of the above construction consists of choosing the sets $\Gamma_j$ to be intervals on the real line, with Lebesgue measure, and the functions $f_a, h_a$, and $\{g_{j,j-1}\}$ of the form:

$$f_a(x_1) := x_1^{a-1}e^{-\frac{1}{a}V_1(x_1)}, \quad h_a(x_m) := x_m^{a-1}e^{-\frac{1}{a}V_m(x_m)},$$

$$g_{j,j-1}(x_j, x_{j-1}) := e^{x_{j-1}x_j - \frac{1}{2}(V_{j-1}(x_{j-1}) + V_j(x_j))}, \quad (1.9)$$

where the $V_j(x_j)$’s are suitably defined functions for which the integrals involved are convergent (e.g., polynomials of even degree with real, positive leading coefficients). This case arises in the study of random multimatrix chains models [EM, BEH1, BEH2]. The reduced probability density for eigenvalues $\{x_a^{(j)}\}_{j=1 \ldots m, a=1 \ldots N}$ is given by the determinantal formula

$$P_N^m(x_a^{(j)}) = \frac{1}{Z_{N,m}} \det(\psi_a^{(1)}(x_b^{(1)}))\det(\phi_a^{(m)}(x_b^{(m)})) \prod_{j=1}^{m-1} \det(g_{j+1,j}(x_a^{(j+1)}, x_b^{(j)})) \quad (1.10)$$
where the partition function $Z_{N,m}$ is defined so as to normalize this to a probability measure.

More generally, let us suppose that the functions $f_a, h_a, g_{j,j-1}$ are chosen so that the expression (1.10) defines a probability measure on the ensemble $\prod_{j=1}^{m} (\Gamma_j)^N$. Such ensembles are sometimes referred to as “determinantal ensembles” [BS, S]; other examples include, e.g., “polynuclear growth” models [PS, J].

Define the following set of functions on the product spaces $\Gamma_i \times \Gamma_j$:

$$K_{ij}(x_i, x_j) := \sum_{a=1}^{N} \psi_a^{(i)}(x_i) \phi_a^{(j)}(x_j)$$

and

$$\tilde{K}_{ij}(x_i, x_j) := K_{ij}(x_i, x_j) - g_{ij}(x_i, x_j),$$

where $g_{ij}(x_i, x_j) := 0$ if $i \leq j$. It may then be shown [EM] that the probability density (1.10) may equivalently be expressed in the form:

$$P_{N,m}(x_a^{(j)}) = \det(\tilde{K}_{ij}(x_a^{(i)}, x_b^{(j)})),$$

where $\tilde{K}_{ij}(x_a^{(i)}, x_b^{(j)})$ is viewed as the $((i, a), (j, b))$ element of a matrix of dimension $Nm \times Nm$, labelled by pairs of double indices $1 \leq i, j \leq m$, $1 \leq a, b \leq N$. By integrating (1.13) over a part of the variables, it follows [EM] that the correlation function giving the probability density for finding $k_j$ elements in $\Gamma_j$ at the points $\{x_1^{(j)}, \ldots, x_{k_j}^{(j)}\}$ for $j = 1, \ldots, m$ is similarly expressed by the $\sum_{j=1}^{m} k_j \times \sum_{j=1}^{m} k_j$ determinant

$$\rho_{k_1, \ldots, k_m}(\{x_1^{(j)}, \ldots, x_{k_j}^{(j)}\}) = \det(\tilde{K}_{ij}(x_a^{(i)}, x_b^{(j)})) \bigg|_{1 \leq a \leq k_i}^{1 \leq b \leq k_j}.$$  (1.14)

The functions $K_{ij}$ may also be viewed as kernels of integral operators

$$K_{ij} : \tilde{H}_j \rightarrow \tilde{H}_i$$

$$K_{ij}(f)(x_i) := \int_{\Gamma_j} K_{ij}(x_i, x_j) f(x_j) d\mu_j(x_j)$$

which, again, map the finite dimensional spaces $\{H_j\}$ to each other. Note that the various $K_{ij}$’s may all be obtained from $K_{1m}$ by composition on the left and right with operators $g_{ij}$:

$$K_{ij} = g_{i1} \circ K_{1m} \circ g_{mj},$$

and that, in particular, adjacent ones are related by

$$K_{ij} = g_{i,i-1} \circ K_{i-1,j} = K_{i,j+1} \circ g_{j+1,j}.$$  (1.17)
It follows from (1.8) that, when restricted to \( H_j \) and \( H^j \), \( K_{jj} \) and \( K_{jj}^* \) act as identity operators
\[
K_{jj}(\psi) = \psi, \quad \psi \in H_j, \quad K_{jj}^*(\phi) = \phi, \quad \phi \in H^j.
\] (1.18)

In the following, we denote by \( \hat{K} \), \( g \) and \( \hat{K} \) the \( m \times m \) matrices of integral operators acting on the direct sum
\[
\hat{H} := \oplus_{j=1}^{m} \hat{H}_j,
\] (1.19)
with matrix entries \( K_{ij} \), \( g_{ij} \) and \( \hat{K}_{ij} \) acting on the component spaces \( \hat{H}_j \).

Let \( \{I_j \subset \Gamma_j\}_{j=1}^{m} \) be measurable subsets of the spaces \( \Gamma_j \), and let \( \chi_j \) denote the characteristic function of \( I_j \subset \Gamma_j \). Denote by \( \chi_I \) the direct sum of these functions, viewed as an operator on \( \hat{H} \), acting by multiplication by the various \( \chi_j \)'s on the component spaces \( \hat{H}_j \)'s, and assume that this leaves \( \hat{H} \) invariant. Let
\[
\hat{K}^{\chi_I} := \hat{K} \circ \chi_I
\] (1.20)
denote the composition of these operators, also a matrix integral operator, and let
\[
R^{\chi_I} := (I - \hat{K}^{\chi_I})^{-1} \circ \hat{K}^{\chi_I}
\] (1.21)
be its Fredholm resolvent. Then the matrix components of this resolvent, denoted \( R_{ij} \), are operators with integral kernels \( R_{ij}(x_i, x_j) \). These also define certain correlation functions, on the product \( \prod_{j=1}^{m} I_j^N \), the so-called Janossy densities, given by a formula similar to (1.14), namely:
\[
\rho^{I}_{k_1...k_m} (\{x^{(j)}_1, \ldots, x^{(j)}_{k_j}\}_{j=1...m}) = C^{N,m}_{I} \det(R_{ij}(x^{(i)}_a, x^{(j)}_b))_{1 \leq a \leq k_i, 1 \leq b \leq k_j},
\] (1.22)
where the normalization constant \( C^{N,m}_{I} \) is defined to be the Fredholm determinant:
\[
C^{N,m}_{I} := \det(I - \hat{K}^{\chi_I})
\] (1.23)
(which equals the probability, under the original distribution (1.10), of having no elements within the subset \( I = \prod_{j=1}^{m} I_j^N \)). The correlation functions (1.22) give the probability density of finding, for \( j = 1 \ldots m \), exactly \( k_j \) elements in \( I_j \) at the points \( \{x^{(j)}_1, \ldots, x^{(j)}_{k_j}\}_{j=1...m} \).

A theorem of Soshnikov [S] expresses this distribution in terms of a new set of functions \( \{\tilde{\psi}^{(j)}, \tilde{\phi}^{(j)}, \tilde{g}_{ij}\} \), analogous to \( \{\psi^{(j)}, \phi^{(j)}, g_{ij}\} \). To define these functions, one begins by defining, as in (1.3), integral operators
\[
\tilde{g}_{kj} := g_{k,k-1} \circ_{k-1} \cdots \circ_{j+1} g_{j+1,j}
\] (1.24)
where the symbol $\circ_{I_j}$ denotes composition of integral operators by integration only over the domain $I_j^c$ complementary to $I_j$ within $\Gamma_j$. (Note that $\tilde{g}_{j+1,j} = g_{j+1,j}$.) Analogously to (1.4), we define the pairing matrix

$$A_{ab}^I := \int_{I^c_i} f_a(x_1)\tilde{g}^*_m(x_1) d\mu_1(x_1) = \int_{I^m_m} \tilde{g}_m f_a(x_m)(h_b)(x_m) d\mu_m(x_m),$$

(1.25)

and again assume it to be nonsingular. Once again, making a $PLU$ decomposition of $A^I$

$$A^I := P^I L^I U^I,$$

(1.26)

we may form new bases

$$\tilde{\psi}_a^{(1)} := \sum_{b=1}^N (P^I L^I)^{-1}_{ab} f_b \quad \tilde{\phi}_a^{(m)} := \sum_{a=1}^N (U^I)^{-1}_{ba} h_a$$

(1.27)

for the spaces $H_1$ and $H^m$, as well as bases for the sequence of dual pairs of spaces obtained by composition with $\tilde{g}_{j1}$ and $\tilde{g}_{mj}$:

$$\tilde{\psi}_a^{(j)} := \tilde{g}_{j1}(\tilde{\psi}_a^{(1)}), \quad \tilde{\phi}_a^{(j)} := \tilde{g}_{mj}(\tilde{\phi}_a^{(m)}).$$

(1.28)

These are mutually dual in the sense that

$$\int_{I^c_j} \tilde{\psi}_a^{(j)}(x_j)\tilde{\phi}_b^{(j)}(x_j) d\mu_j(x_j) = \delta_{ab}.$$  

(1.29)

Define, as before, a set of integral kernels:

$$\tilde{K}_{ij}(x_i, x_j) := \sum_{a=1}^N \tilde{\psi}_a^{(j)}(x_i)\tilde{\phi}_a^{(j)}(x_j)$$

(1.30)

and

$$\tilde{K}_{ij}(x_i, x_j) := \tilde{K}_{ij}(x_i, x_j) - \tilde{g}_{ij}(x_i, x_j),$$

(1.31)

where again, $\tilde{g}_{ij}(x_i, x_j) := 0$ if $i \leq j$, and denote by $\tilde{K}_{ij}$, $\tilde{g}_{ij}$ and $\tilde{K}_{ij}$ the corresponding integral operators mapping $\hat{H}_j \to \hat{H}_i$. The associated $m \times m$ matrix integral operators acting on $\hat{H}$ are similarly denoted $\tilde{K}$, $\tilde{g}$ and $\tilde{K}$, with

$$\tilde{K} := \tilde{K} - \tilde{g}.$$  

(1.32)

Then Soshnikov’s theorem states that the resolvent operator $R^{\chi_I}$ entering in the definition of the Janossy distribution coincides with the operator $\tilde{K}^{\chi_I} := \tilde{K} \circ \chi_I$ so constructed.
Theorem 1:

\[ R^{x^l} = \tilde{K}^{x^l}. \] (1.33)

A proof of this theorem is given in [S], based on decomposition of the spaces into various subspaces, and an inductive construction, but it is rather long and intricate. In the following section, a very simple direct proof will be given.

Since no further effort is required, we will actually prove an obvious generalization that reduces to the above result as a special case. Namely, instead of choosing measurable subsets \( I_j \subset \Gamma_j \) and their characteristic functions \( \chi_j \), we may replace the latter by any set of square integrable functions \( \{ w_j \in L^2(\Gamma_j, d\mu_j) \}_{j=1,...,m} \), and generalize the definition of the matrix \( A^l \) and the functions \( \{ \tilde{\psi}^{(j)}, \tilde{\phi}^{(j)}, \tilde{g}_{ij} \} \) accordingly to:

\[
A_w^{ab} := \int_{\Gamma_1} f_a(x_1) \tilde{g}^*_m(h_b)(x_1)(1 - w_1(x_1))d\mu_1(x_1)
= \int_{\Gamma_m} \tilde{g}_m(f_a)(x_m)(h_b)(x_m)(1 - w_m(x_m))d\mu_m(x_m),
\] (1.34)

with \( PLU \) decomposition

\[
A^w := P^w L^w U^w,
\] (1.35)

where, denoting by \( \circ v_j \) the operation of multiplication by a function \( v_j \) in \( L^2(\Gamma_j, d\mu_j) \) followed by composition, we replace the definition of \( \tilde{g}_{k,j} \) in (1.24) by

\[
\tilde{g}_{kj} := g_{k,k-1} \circ_{1-w_{k-1}} \circ \cdots \circ_{1-w_{j+1}} \circ g_{j+1,j}.
\] (1.36)

Then

\[
\tilde{\psi}^{(1)}_a := \sum_{a=1}^N (P^w L^w)^{-1}_{ab} f_a \quad \tilde{\phi}^{(m)}_a := \sum_{b=1}^N (U^w)^{-1}_{ba} h_a,
\] (1.37)

define bases for the spaces \( H_1 \) and \( H^m \), respectively, while bases for the sequence of dual spaces obtained by composition with \( \tilde{g}_{j,1} \) and \( \tilde{g}_{m,k}^* \), as defined in (1.36), are again given by (1.28), with the dualization pairing given by

\[
\int_{\Gamma_j} \tilde{\psi}^{(j)}_a(x_j) \tilde{\phi}^{(j)}_b(x_j)(1 - w_j(x_j))d\mu_j(x_j) = \delta_{ab}.
\] (1.38)

Replacing the characteristic functions \( \chi_l = (\chi_1 \ldots \chi_m) \) by the set of weight functions \( w := (w_1, \ldots w_m) \), the definitions of the integral operators and kernels \( \tilde{K}, \tilde{g}, \tilde{K} \) retain the same form and the theorem becomes

Theorem 2:

\[ R^w = \tilde{K}^w := \tilde{K} \circ w. \] (1.39)
where

\[ R^w := (1 - \tilde{K}^w)^{-1} \circ \tilde{K}^w \quad (1.40) \]

is the Fredholm resolvent of

\[ \tilde{K}^w := \tilde{K} \circ w. \quad (1.41) \]

Such a generalization is of use in multimatrix models, since it allows us to replace, for example, the characteristic functions \( \chi_j \) on subintervals \( I_j \subset \Gamma_j \) by weighted characteristic functions \( \sum_{\alpha=1}^{k_j} \kappa_{\alpha,j} \chi_{\alpha,j} \) over unions of disjoint subintervals \( I_j = \bigcup_{\alpha=1}^{k_j} I_{\alpha,j} \). The corresponding Fredholm determinant (1.23), expanded as a power series in the coefficients \( \kappa_{\alpha,j} \) becomes a generating function for the probabilities of having given numbers of eigenvalues within the subintervals, as in the 1-matrix case [TW].

2. Proof of the theorem.

The equality (1.39) may equivalently be written as

\[ \tilde{K}^w \circ \tilde{K}^w = \tilde{K}^w - \tilde{K}^w, \quad (2.1) \]

or, explicitly,

\[ \sum_{j=1}^{m} \tilde{K}_{ij} \circ w_j \tilde{K}_{jk} = \tilde{K}_{ik} - \tilde{K}_{ik} \quad (2.2) \]

(\text{where composition on the right by } w \text{ is omitted, since the equality will be shown to hold without it}). Substituting (1.12) and (1.32) in (2.1), this is equivalent to

\[ K \circ_w \tilde{K} - g \circ_w \tilde{K} - K \circ_w \tilde{g} + g \circ_w \tilde{g} + \tilde{g} - g = \tilde{K} - K. \quad (2.3) \]

This relation follows as a consequence of four identities relating the various summands on the left, each of which is easily proved:

\[ g \circ_w \tilde{g} + \tilde{g} - g = 0 \quad (2.4) \]

\[ (K \circ_w \tilde{K})_{ij} = g_{i1} \circ \tilde{K}_{1j} + \delta_{i1} \tilde{K}_{1j} - K_{im} \circ_{1-w_m} \tilde{g}_{mj} - K_{im} \delta_{mj} \quad (2.5) \]

\[ (g \circ_w \tilde{K})_{ij} = g_{i1} \circ \tilde{K}_{1j} + \delta_{i1} \tilde{K}_{1j} - \tilde{K}_{ij} \quad (2.6) \]

\[ (K \circ_w \tilde{g})_{ij} = K_{ij} - K_{im} \circ_{1-w_m} \tilde{g}_{mj} - K_{im} \delta_{mj} \quad (2.7) \]

Proof of (2.4): From (1.3) and (1.36) we have, for \( k - 1 > j > i + 1, \)

\[ g_{kj} \circ_{w_j} \tilde{g}_{ji} = g_{kj} \circ \tilde{g}_{ji} - g_{kj} \circ_{1-w_j} \tilde{g}_{ji} \]

\[ = g_{kj} \circ \tilde{g}_{ji} - g_{k,j+1} \circ_{1-w_j} \tilde{g}_{ji+1} \]

\[ = g_{kj} \circ \tilde{g}_{ji} - g_{k,j+1} \circ \tilde{g}_{j+1,i}, \quad (2.8) \]
while for $j = k - 1$,
\[
g_{k,k-1} \circ w_{k-1} \tilde{g}_{k-1,i} = g_{k,k-1} \circ \tilde{g}_{k-1,i} - g_{k,k-1} \circ 1 \circ w_{k-1} \tilde{g}_{k-1,i} \\
= g_{k,k-1} \circ \tilde{g}_{k-1,i} - \tilde{g}_{ki},
\]
(2.9)
and for $j = i + 1$
\[
g_{k,i+1} \circ w_{i+1} \tilde{g}_{i+1,i} = g_{k,i+1} \circ \tilde{g}_{i+1,i} - g_{k,i+1} \circ 1 \circ w_{i+1} \tilde{g}_{i+1,i} \\
= \tilde{g}_{ki} - g_{k,i+2} \circ \tilde{g}_{i+2,i}.
\]
(2.10)

Summing over $j$ and cancelling all intermediate terms gives the result
\[
(g \circ w \tilde{g})_{ki} = \sum_{j=i+1}^{k-1} g_{kj} \circ w_{j} \tilde{g}_{ji} = \tilde{g}_{ki} - \tilde{g}_{ki}.
\]
(2.11)

(Note that this means that the integral operator $g^w$ is the Fredholm resolvent of $\tilde{g}^w$.)

Proof of (2.5): For $j \neq m$, we have
\[
K_{ij} \circ w_{j} \tilde{K}_{jk} = K_{ij} \circ \tilde{K}_{jk} - K_{ij} \circ 1 \circ w_{j} \tilde{K}_{jk} \\
= K_{ij} \circ \tilde{K}_{jk} - K_{i,j+1} \circ g_{j+1,j} \circ 1 \circ w_{j} \tilde{K}_{jk} \\
= K_{ij} \circ \tilde{K}_{jk} - K_{i,j+1} \circ \tilde{K}_{j+1,k}.
\]
(2.12)
Therefore, summing and cancelling the intermediate terms gives
\[
\sum_{j=1}^{m} K_{ij} \circ w_{j} \tilde{K}_{jk} = K_{i1} \circ \tilde{K}_{1k} - K_{im} \circ 1 \circ w_{j} \tilde{K}_{mk}.
\]
(2.13)

By (1.8) and (1.38), the operators $K_{11}$ and $(\tilde{K}_{mm} \circ (1 - w_{m}))^*$ act as the identity on the spaces $H_{1}$ and $H^{m}$, respectively, and hence
\[
K_{11} \circ \tilde{K}_{1k} = \tilde{K}_{1k}, \quad K_{im} \circ 1 \circ w_{j} \tilde{K}_{mk} = \tilde{K}_{im}.
\]
(2.14)
It follows from (1.16) and the corresponding relations
\[
\tilde{K}_{ij} = \tilde{g}_{i1} \circ 1 \circ w_{1} \tilde{K}_{im} \circ 1 \circ w_{m} \tilde{g}_{mj}
\]
(2.15)
for the $\tilde{K}_{ij}$'s that, for $i \neq 1, j \neq m$,
\[
K_{i1} \circ \tilde{K}_{1k} = g_{i1} \circ \tilde{K}_{ik}, \quad K_{im} \circ 1 \circ w_{m} \tilde{K}_{mj} = K_{im} \circ 1 \circ w_{m} \tilde{g}_{mj}.
\]
(2.16)
Combining these relations with (2.13) leads to (2.5).
Janossy densities and Fredholm resolvents

Proof of (2.6): For $j < i - 1$, we have

$$g_{ij} \circ w_j \tilde{K}_{jk} = g_{ij} \circ \tilde{K}_{jk} - g_{ij} \circ 1 - w_j \tilde{K}_{jk}$$

$$= g_{ij} \circ \tilde{K}_{jk} - g_{i,j+1} \circ 1 - w_j \tilde{K}_{jk}$$

$$= g_{ij} \circ \tilde{K}_{jk} - g_{i,j+1} \circ \tilde{K}_{j+1,k},$$

while for $j = i - 1$,

$$g_{i,i-1} \circ w_{i-1} \tilde{K}_{i-1,k} = g_{i,i-1} \circ \tilde{K}_{i-1,k} - g_{i,i-1} \circ 1 - w_{i-1} \tilde{K}_{i-1,k}$$

$$= g_{i,i-1} \circ \tilde{K}_{i-1,k} - \tilde{K}_{ik},$$

Again, summing and cancelling the intermediate terms gives:

$$\sum_{j=1}^{m} g_{ij} \circ w_j \tilde{K}_{jk} = \sum_{j=1}^{i-1} g_{ij} \circ w_j \tilde{K}_{jk} = g_{i1} \circ \tilde{K}_{1k} - \tilde{K}_{ik},$$

which is (2.6) (the case $i = 1$ being trivially satisfied).

Proof of (2.7): For $m > j > k + 1$, we have

$$K_{ij} \circ w_j \tilde{g}_{jk} = K_{ij} \circ \tilde{g}_{jk} - K_{ij} \circ 1 - w_j \tilde{g}_{jk}$$

$$= K_{ij} \circ \tilde{g}_{jk} - K_{i,j+1} \circ 1 - w_j \tilde{g}_{jk}$$

$$= K_{ij} \circ \tilde{g}_{jk} - K_{i,j+1} \circ \tilde{g}_{j+1,k},$$

while for $j = k + 1$,

$$K_{i,k+1} \circ w_{k+1} \tilde{g}_{k+1,k} = K_{i,k+1} \circ \tilde{g}_{k+1,k} - K_{i,k+1} \circ 1 - w_{k+1} \tilde{g}_{k+1,k}$$

$$= K_{ik} - K_{i,k+2} \circ \tilde{g}_{k+2,k},$$

Again, summing and cancelling the intermediate terms gives:

$$\sum_{j=1}^{m} K_{ij} \circ w_j \tilde{g}_{jk} = \sum_{j=k+1}^{m} K_{ij} \circ w_j \tilde{g}_{jk} = K_{ik} - K_{im} \circ 1 - w_m \tilde{g}_{mk},$$

which is (2.7) (the case $j = m$ again being trivially satisfied).

Combining the four relations (2.4), (2.5), (2.6) and (2.7) gives (2.3), hence proving the theorem.

Remark. Although this theorem has been formulated with respect to probability measures and Hilbert spaces of functions on them, it may clearly be extended to more general cases involving, e.g., complex measures, provided all the integrals appearing are convergent, and the related integral operators and their composites are well-defined.

Acknowledgements. The author would like to thank M. Bertola and A. Soshnikov for helpful discussions. This research was supported in part by the Natural Sciences and Engineering Research Council of Canada.
