Topological strings on elliptic fibrations

Murad Alim and Emanuel Scheidegger

We study topological string theory on elliptically fibered Calabi–Yau manifolds using mirror symmetry. We compute higher genus topological string amplitudes and express these in terms of polynomials of functions constructed from the special geometry of the deformation spaces. The polynomials are fixed by the holomorphic anomaly equations supplemented by the expected behavior at special loci in moduli space. We further expand the amplitudes in the base moduli of the elliptic fibration and find that the fiber moduli dependence is captured by a finer polynomial structure in terms of the modular forms of the modular group of the elliptic curve. We further find a recursive equation which captures this finer structure and which can be related to the anomaly equations for correlation functions.

1. Introduction

Mirror symmetry and topological string theory are a rich source of insights in both mathematics and physics. The A- and B-model topological string theories probe Kähler and complex structure deformation families of two
mirror Calabi–Yau (CY) threefolds $Z$ and $Z^*$ and are identified by mirror symmetry. The B-model is more accessible to computations since its deformations are the complex structure deformations of $Z^*$ which are captured by the variation of Hodge structure. Mirror symmetry is established by providing the mirror maps, which are a distinguished set of local coordinates in a given patch of the deformation space. These provide the map to the A-model, since they are naturally associated with deformations of an underlying superconformal field theory and its chiral ring [1].

At special loci in the moduli space, the A-model data provides enumerative information of the CY $Z$. This is contained in the Gromov–Witten invariants which can be resumed to give integer multiplicities of BPS states in a five-dimensional theory obtained from an $M$-theory compactification on $Z$ [2, 3]. Moreover, the special geometry governing the deformation spaces allows one to compute the prepotential $F_0(t)$ which governs the exact effective action of the four-dimensional theories obtained from compactifying type IIA(IIB) string theory on $Z(Z^*)$, respectively.

The prepotential is the genus zero free energy of topological string theory, which is defined perturbatively in a coupling constant governing the higher genus expansion. The partition function of topological string theory indicating its dependence on local coordinates in the deformation space has the form:

$$Z(t, \bar{t}) = \exp \left( \sum_g \lambda^{2g-2} F^{(g)}(t, \bar{t}) \right).$$

In [4, 5], Bershadsky, Cecotti, Ooguri and Vafa (BCOV) developed the theory and properties of the higher genus topological string free energies putting forward recursive equations, the holomorphic anomaly equations along with a method to solve these in terms of Feynman diagrams. For the full partition function, these equations take the form of a heat equation [5, 6] and can be interpreted [6] as describing the background independence of the partition function when the latter is interpreted as a wave function associated with the geometric quantization of $H^3(Z^*)$.

The higher genus free energies of the topological string can be furthermore interpreted as giving certain amplitudes of the physical string theory.\footnote{See [7] for a review.}
The full topological string partition function conjecturally also encodes the information of 4d BPS states [8]. It is thus natural to expect the topological string free energies to be characterized by automorphic forms of the target space duality group. The modularity of the topological string amplitudes was used in [5] to fix the solutions of the anomaly equation. The modularity of the amplitudes is most manifest whenever the modular group is SL(2, \mathbb{Z}) or a subgroup thereof. The higher genus generating functions of the Gromov–Witten invariants for the elliptic curve were expressed as polynomials [9, 10] where the polynomial generators were the elements of the ring of almost holomorphic modular forms $E_2$, $E_4$ and $E_6$ [11]. Polynomials of these generators also appear whenever SL(2, \mathbb{Z}) is a subgroup of the modular group, as for example in [12–15]. The relation of topological strings and almost holomorphic modular forms was further explored in [16] (see also [17, 18]).

Using the special geometry of the deformation space a polynomial structure of the higher genus amplitudes in a finite number of generators was proven for the quintic and related one parameter deformation families [19] and generalized to arbitrary target CY manifolds [20]. The polynomial structure supplemented by appropriate boundary conditions enhances the computability of higher genus amplitudes. Moreover, the polynomial generators are expected to bridge the gap towards constructing the appropriate modular forms for a given target space duality group which is reflected by the special geometry of the CY manifold.

In this work we use the polynomial construction to study higher genus amplitudes on elliptically fibered CY. The higher genus amplitudes are expressed in terms of a finite number of generators which are constructed from the special geometry of the moduli space of the CY. Expanding the amplitudes of the elliptic fibration in terms of the base moduli allows us to further express the parts of the amplitudes depending on the fiber moduli in terms of the modular forms of SL(2, \mathbb{Z}). Together with this refinement of the polynomial structure we find a refined recursion which is the analog of an equation discovered in the context of BPS state counting of a non-critical string [12, 21, 22] and which was conjectured to hold for higher genus topological strings [13, 14].

We write the topological string amplitudes for elliptic fibrations in the A–model as an expansion:

$$F^{(g)}(t_E, t_B) = \sum_{n \in \mathbb{Z}} f_n^{(g)}(t_E) q_B^n,$$
where $t_E, t_{B,a}, a = 1, \ldots, b = \dim H^2(B, \mathbb{Z})$ denote the special coordinates corresponding to the Kähler parameters of the fiber and base of the elliptic fibration, respectively. We set $q_E = e^{2\pi i t_E}, q_{B,a} = e^{2\pi i t_{B,a}}$. Then we can formulate one of our main results as a conjecture:

**Conjecture 1.1.**

1. In the main example which we consider in this work (for which $b = 1$), the expansion coefficients $f_n^{(g)}$ can be written as

$$f_n^{(g)} = P_n^{(g)}(E_2, E_4, E_6) \frac{q_E^{3n/2}}{\eta^{36n}}.$$

Here $P_n^{(g)}$ denotes a quasi-homogeneous polynomial in the Eisenstein series $E_2, E_4, E_6$ of degree $2g - 2 + 18n$.

2. Furthermore, the expansion coefficients $f_n^{(g)}$ satisfy the following recursion:

$$\frac{\partial f_n^{(g)}}{\partial E_2} = -\frac{1}{24} \sum_{h=0}^{g} \sum_{s=1}^{n-1} s(n - s) f_s^{(h)} f_{n-s}^{(g-h)} + \frac{n(3-n)}{24} f_n^{(g-1)}.$$

3. Similar formulas hold for other elliptic fibrations with $b \leq 2$.

The outline of this work is as follows. In Section 2, we review some elements of mirror symmetry that allow us to set the stage for our discussion. We present and further develop techniques to identify the flat coordinates on the deformation spaces. In particular, we exhibit a systematic procedure to determine these coordinates at an arbitrary point in the boundary of the moduli space. We proceed in Section 3 with reviewing the holomorphic anomaly equations and how these can be used together with a polynomial construction to solve for higher genus topological string amplitudes. In Section 4, we present the results of the application of the techniques and methods described earlier to an example of an elliptically fibered CY. The dependence on the moduli of the elliptic fiber can be further organized in terms of polynomials of $E_2, E_4$ and $E_6$ order by order in an expansion in the base moduli. We find a recursion (1.2) which captures this structure and relate it to the anomaly equation for the correlation functions of the full geometry. We show that such recursions hold for several examples of elliptic fibrations. We proceed with our conclusions in Section 5.
2. Mirror symmetry

In this section, we review some aspects of mirror symmetry which we will be using in the following.\(^2\) To be able to fix the higher genus amplitudes we need a global understanding of mirror symmetry and how it matches expansion loci in the moduli spaces of the mirror manifolds \(Z\) and \(Z^*\). We will also review and further develop some methods and techniques on the B-model side along [29–36] to identify the special set of coordinates which allows an identification with the physical parameters and hence with the A-model side.

2.1. Mirror geometries

The mirror pair of CY 3-folds \((Z, Z^*)\) is given as hypersurfaces in toric ambient spaces \((W, W^*)\). The mirror symmetry construction of [24] associates the pair \((Z, Z^*)\) to a pair of integral reflexive polyhedra \((\Delta, \Delta^*)\).

The A-model geometry. The polyhedron \(\Delta^*\) is characterized by \(k\) relevant integral points \(\nu_i\) lying in a hyperplane of distance one from the origin in \(\mathbb{Z}^5\), \(\nu_0\) will denote the origin following the conventions of [24, 25]. The \(k\) integral points \(\nu_i(\Delta^*)\) of the polyhedron \(\Delta^*\) correspond to homogeneous coordinates \(u_i\) on the toric ambient space \(W\) and satisfy \(n = h^{1,1}(Z)\) linear relations:

\[
\sum_{i=0}^{k-1} l_i^a \nu_i = 0, \quad a = 1, \ldots, n.
\]

The integral entries of the vectors \(l^a\) for fixed \(a\) define the weights \(l_i^a\) of the coordinates \(x_i\) under the \(\mathbb{C}^*\) actions

\[
u_i \rightarrow (\lambda_a)^{l_i^a} u_i, \quad \lambda_a \in \mathbb{C}^*.
\]

The \(l_i^a\) can also be understood as the \(U(1)_a\) charges of the fields of the gauged linear sigma model (GLSM) construction associated with the toric variety [37]. The toric variety \(W\) is defined as \(W \simeq (\mathbb{C}^k - \Xi)/(\mathbb{C}^*)^n\), where

\(^2\)See [23–25] for foundational material as well as the review book [26] for general background on mirror symmetry. Some of the exposition in this section will follow [27, 28].
Ξ corresponds to an exceptional subset of degenerate orbits. To construct compact hypersurfaces, \( W \) is taken to be the total space of the anti-canonical bundle over a compact toric variety. The compact manifold \( Z \subset W \) is defined by introducing a superpotential \( W_Z = u_0 p(u_i) \) in the GLSM, where \( x_0 \) is the coordinate on the fiber and \( p(u_i) \) a polynomial in the \( u_{i>0} \) of degrees \( -l_a^0 \). At large Kähler volumes, the critical locus is at \( u_0 = p(u_i) = 0 \) [37].

An example of an elliptic fibration is the compact geometry given by a section of the anti-canonical bundle over the resolved weighted projective space \( \mathbb{P}(1, 1, 1, 6, 9) \). Mirror symmetry for this model has been studied in various places following [25, 38]. The charge vectors for this geometry are given by:

\[
\begin{align*}
(l^1) &= (-6 \ 3 \ 2 \ 1 \ 0 \ 0 \ 0), \\
(l^2) &= (0 \ 0 \ 0 \ -3 \ 1 \ 1 \ 1).
\end{align*}
\]

**The B-model geometry.** The B-model geometry \( Z^* \subset W^* \) is determined by the mirror symmetry construction of [24, 39] as the vanishing locus of the equation

\[
p(Z^*) = \sum_{i=0}^{k-1} a_i y_i = \sum_{\nu \in \Delta} a_i X^{\nu_i},
\]

where \( a_i \) parameterize the complex structure of \( Z^* \), \( y_i \) are homogeneous coordinates [39] on \( W^* \) and \( X_m, m = 1, \ldots, 4 \) are inhomogeneous coordinates on an open torus \( (\mathbb{C}^*)^4 \subset W^* \) and \( X^{\nu_i} := \prod_m X_m^{\nu_{im}} \) [40]. The relations (2.1) impose the following relations on the homogeneous coordinates:

\[
\prod_{i=0}^{k-1} y_i^{\nu_{ia}} = 1, \quad a = 1, \ldots, n = h^{2,1}(Z^*) = h^{1,1}(Z).
\]

The important quantity in the B-model is the holomorphic \((3,0)\) form which is given by:

\[
\Omega(a_i) = \text{Res}_{p=0} \frac{1}{p(Z^*)} \prod_{i=1}^{4} \frac{dX_i}{X_i}.
\]

Its periods

\[
\pi_\alpha(a_i) = \int_{\gamma^\alpha} \Omega(a_i), \quad \alpha = 0, \ldots, 2h^{2,1} + 1
\]
are annihilated by an extended system of Gelfand, Kapranov and Zelevinsky (GKZ) [41] differential operators

\begin{equation}
\mathcal{L}(l) = \prod_{l_i > 0} \left( \frac{\partial}{\partial a_i} \right)^{l_i} - \prod_{l_i < 0} \left( \frac{\partial}{\partial a_i} \right)^{-l_i}
\end{equation}

(2.6)

\begin{equation}
Z_k = \sum_{i=0}^{k-1} \nu_{i,j} \theta_i, \quad j = 1, \ldots, 4. \quad Z_0 = \sum_{i=0}^{k-1} \theta_i + 1, \quad \theta_i = a_i \frac{\partial}{\partial a_i},
\end{equation}

(2.7)

where \( l \) can be any positive integral linear combination of the charge vectors \( l^a \). The equation \( \mathcal{L}(l) \pi_0(a_i) = 0 \) follows from the definition (2.5). The equations \( Z_k \pi_\alpha(a_i) = 0 \) express the invariance of the period integral under the torus action and imply that the period integrals only depend on special combinations of the parameters \( a_i \)

\begin{equation}
\pi_\alpha(a_i) \sim \pi_\alpha(z_a), \quad z_a = (-)^{l_\alpha} \prod_{i} a_i^{l_a},
\end{equation}

(2.8)

the \( z_a, a = 1, \ldots, n \) define local coordinates on the moduli space \( \mathcal{M} \) of complex structures of \( Z^* \).

In our example, there is an additional symmetry on \( \mathcal{M} \). Its origin is the fact that the polytope \( \Delta^* \) has further integral points on facets [25, 38]. They correspond to nonlinear coordinate transformations of the ambient toric variety \( W \). These coordinate transformations can be compensated by transforming the parameters \( a_i \). This yields the symmetry on \( \mathcal{M} \)

\begin{equation}
I : (z_1, z_2) \mapsto \left( \frac{1}{432} - z_1, -\frac{z_1^3 z_2}{(\frac{1}{432} - z_1)^3} \right).
\end{equation}

(2.9)

The charge vectors defining the A-model geometry in Equation (2.2) give the following Picard–Fuchs (PF) operators annihilating \( \tilde{\pi}_\alpha(z_i) = a_0 \pi_\alpha(a_i) \):

\begin{equation}
\mathcal{L}_1 = \theta_1 (\theta_1 - 3 \theta_2) - 12 z_1 (6 \theta_1 + 1)(6 \theta_1 + 5),
\end{equation}

(2.10)

\begin{equation}
\mathcal{L}_2 = \theta_2^3 + z_2 \prod_{i=0}^{2} (3 \theta_2 - \theta_1 + i), \quad \theta_a := z_a \frac{\partial}{\partial z_a}.
\end{equation}

(2.11)

The discriminants of these operators are

\begin{equation}
\Delta_1 = (1 - 432 z_1)^3 - (432 z_1)^3 27 z_2,
\end{equation}

(2.12)

\begin{equation}
\Delta_2 = 1 + 27 z_2,
\end{equation}

\begin{equation}
\Delta_2 = 1 + 27 z_2,
\end{equation}
Furthermore, we label the function

\[ \Delta_3 = 1 - 432 z_1. \]

Note, that \( \Delta_1 \circ I = (432 z_1)^3 \Delta_2 \) and \( \Delta_2 \circ I = \frac{\Delta_1}{\Delta_3^3} \), hence the vanishing loci of \( \Delta_1 \) and \( \Delta_2 \) are exchanged under the symmetry \( I \).

A further important ingredient of mirror symmetry are the Yukawa couplings which are identified with the genus zero correlators of three chiral fields of the underlying topological field theory. In the B-model, these are defined by: \(^3\)

\[ C_{ijk}(x) := \int_{Z^*} \Omega \wedge \partial_i \partial_j \partial_k \Omega, \quad \partial_i := \frac{\partial}{\partial x^i}. \]

For the example above, these can be computed using the PF operators [25]:

\[ C_{111}(z) = \frac{9}{z_1^3 \Delta_1}, \]
\[ C_{112}(z) = \frac{3 \Delta_3}{z_1^2 z_2 \Delta_1}, \]
\[ C_{122}(z) = \frac{\Delta_3^2}{z_1 z_2^2 \Delta_1}, \]
\[ C_{222}(z) = \frac{9 \left( \Delta_3^3 + (432 z_1)^3 \right)}{z_2^2 \Delta_1 \Delta_2}. \]

\[ 2.2. \text{Variation of Hodge structure} \]

The PF equations capture the variation of Hodge structure which describes the geometric realization on the B-model side of the deformation of the \( \mathcal{N} = (2,2) \) superconformal field theory and its chiral ring [29], see also ref [32] for a review. Choosing one member of the deformation family of CY threefold \( Z^* \) characterized by a point in the moduli space \( \mathcal{M} \) of complex structures there is a unique holomorphic \( (3,0) \) form \( \Omega(x) \) depending on local coordinates in the deformation space.

\(^3\)We use \( x^i, i = 1, \ldots h^{2,1} \) to denote arbitrary coordinates on the moduli space of complex structures and denote a dependence on these collectively by \( x \). We make the distinction to the coordinates defined in Equation (2.8) which will be identified with the coordinates centered around the large complex structure limiting point in the moduli space.
A variation of complex structure induces a change of the type of the reference \((3, 0)\) form \(\Omega(x)\). This change is captured by the variation of Hodge structure. \(H^3(Z^*)\) is the fiber of a complex vector bundle over \(\mathcal{M}\) equipped with a flat connection \(\nabla\), the Gauss–Manin connection. The fibers of this vector bundle are constant up to monodromy of \(\nabla\). The Hodge decomposition

\[
H^3 = \bigoplus_{p=0}^{3} H^{3-p,p},
\]

varies over \(\mathcal{M}\) as the type splitting depends on the complex structure. A way to capture this variation holomorphically is through the Hodge filtration \(F^p\)

\[
(2.16) \quad H^3 = F^0 \supset F^1 \supset F^2 \supset F^3 \supset F^4 = 0, \quad F^p = \bigoplus_{q \geq p} H^{q,3-q} \subset H^3,
\]

which define holomorphic subbundles \(F^p \rightarrow \mathcal{M}\) whose fibers are \(F^p\). The Gauss–Manin connection on these subbundles has the property \(\nabla F^p \subset F^{p-1} \otimes T^* \mathcal{M}\) known as Griffiths transversality. This property allows us to identify derivatives of \(\Omega(x) \in F^3\) with elements in the lower filtration spaces. The whole filtration can be spanned by taking multiderivatives of the holomorphic \((3, 0)\) form. Fourth-order derivatives can then again be expressed by the elements of the basis, which is reflected by the fact that periods of \(\Omega(x)\) are annihilated the PF system of differential equations of fourth order. The dimensions of the spaces \((F^3, F^2/F^3, F^1/F^2, F^0/F^1)\) are \((1, h^{2,1}, h^{2,1}, 1)\). Elements in these spaces can be obtained by taking derivatives of \(\Omega(x)\) w.r.t. the moduli. For the example, we are discussing a section of the filtration is given by the following vector \(w(x)\) which has \(2h^{2,1} + 2 = 6\) components:

\[
(2.17) \quad w(x) = (\Omega(x), \theta_1 \Omega(x), \theta_2 \Omega(x), \theta_1 \theta_2 \Omega(x), \theta_2^2 \Omega(x), \theta_1 \theta_2^2 \Omega(x))^t.
\]

where \(\theta_i = x^i \frac{\partial}{\partial x^i}\). Using \(w(x)\) we can define the period matrix

\[
(2.18) \quad \Pi(x)^\alpha_\beta = \int_{\gamma^\alpha} w_\beta(x), \quad \gamma^\alpha \in H_3(Z^*), \quad \alpha, \beta = 0, \ldots, 2h^{2,1} + 1,
\]
the first row of which corresponds to the periods of $\Omega(x)$. The periods are annihilated by the PF operators. We can identify solutions of the PF operators with the periods of $\Omega(x)$. In our example, near the point of maximal unipotent monodromy $z = (z_1, z_2)$, the solutions are given in Appendix A.

**Polarization.** The variation of Hodge structure of a family of CY threefolds in addition comes with a polarization, i.e., a non-degenerate integral bilinear form $Q$ which is antisymmetric. This form is defined by $Q(\varphi, \psi) = \int_{Z^*} \varphi \wedge \psi$ for $\varphi, \psi \in H^3$. The polarization satisfies

$$Q(F^p, F^{4-p}) = 0, \quad Q(C\varphi, \varphi) > 0 \text{ for } \varphi \neq 0,$$

where $C$ acts by multiplication of $i^{p-q}$ on $H^{p,q}$. Hence, $Q$ is a symplectic form.

Since the space of periods can be identified with the space of solutions to the PF equations, the symplectic form on $H^3(Z^*)$ should be expressible in terms of a bilinear operator acting on the space of solutions. This approach has been developed in [36]. We will review and employ these techniques in the following.

We want to express the symplectic form $Q$ in terms of the basis (2.17). For this purpose, we define an antisymmetric linear bidifferential operator on the space of solutions of the PF equation as

$$D_1 \wedge D_2(f_1, f_2) = \frac{1}{2} (D_1 f_1 D_2 f_2 - D_2 f_1 D_1 f_2),$$

where $D_1$ and $D_2$ are arbitrary differential operators with respect to $x$. Then we can write $Q$ as an antisymmetric bidifferential operator

$$Q(x) = \sum_{k,l} Q_{k,l}(x) D_k(\theta) \wedge D_l(\theta),$$

where $D_k, D_l$ run over the basis of multiderivatives in $\theta = (\theta_1, \ldots, \theta_{h^{1,1}})$ used to define the vector $w(x)$ spanning the Hodge filtration, see (2.17). The condition that $Q(x)$ is constant over the moduli space, i.e.,

$$\theta_i Q(x) = 0, \quad i = 1, \ldots, h^{2,1},$$

imposes constraints on the coefficients $Q_{k,l}(x)$. These lead to a system of algebraic and differential equations for the $Q_{k,l}(x)$. At this point, we need
to express the higher-order differential operators in terms of the basis (2.17) using the relations such as (A.2) and (A.3). Then this system can be solved up to an overall constant.

In our example, near the point of maximal unipotent monodromy $z = (z_1, z_2)$, we find

\[
Q(z) = \frac{1}{3} \Delta_2 \Delta_3 \left( \theta_1 \wedge \theta_2^2 + \theta_2 \wedge \theta_1 \theta_2 \right) - \Delta_2 \theta_2 \wedge \theta_2^2 - \frac{a_9}{3 \Delta_3} \theta_1 \wedge \theta_1 \theta_2
- \frac{\Delta_1}{3 \Delta_3^2} 1 \wedge \theta_1 \theta_2^2 + \frac{a_{10}}{\Delta_3^2} 1 \wedge \theta_1 \theta_2 + \frac{a_4}{3 \Delta_3^2} 1 \wedge \theta_1 + \frac{20 z_1 a_9}{\Delta_3^2} 1 \wedge \theta_2.
\]

where $a_4$, $a_9$ and $a_{10}$ are given in (A.6). In the basis of periods (A.7) we then obtain

\[
\begin{pmatrix}
0 & 0 & 0 & 0 & 0 & 1/2 \\
0 & 0 & 0 & 0 & -1/2 & 0 \\
0 & 0 & 0 & -1/2 & 0 & 0 \\
0 & 0 & 1/2 & 0 & 0 & 0 \\
0 & 1/2 & 0 & 0 & 0 & 0 \\
-1/2 & 0 & 0 & 0 & 0 & 0
\end{pmatrix}
\]

Moreover, the invariant definition of the B-model prepotential is given in terms of the natural symplectic form $Q$ on $H^3(Z^*, \mathbb{Z})$. Let $\varpi_i(x)$ be a basis for the periods, then

\[
F^{(0)}(x) = \frac{1}{2} \sum_{i > j} Q(\varpi_i(x), \varpi_j(x))^{-1} \varpi_i(x) \varpi_j(x).
\]

**2.3. The Gauss–Manin connection and flat coordinates**

*The Gauss–Manin connection.* The PF operators (2.10) are equivalent to a first-order equation for the period matrix. Using linear combinations of the operators and derivatives thereof, the system can be cast in the form

\[
(\theta_i - A_i(x)) \Pi(x)_\beta^\alpha = 0, \quad i = 1, \ldots, h^{2,1},
\]
which defines the Gauss–Manin connection $\nabla$. For our example, the matrices $A_i(x)$ near the point of maximal unipotent monodromy are given in the appendix.

There are limiting points in the moduli space of complex structure $\mathcal{M}$ at which the Hodge structure degenerates [26, 42]. These points are of particular interest in the expansion of the topological string amplitudes. In order to describe these limiting points, we assume that there exists a smooth compactification $\overline{\mathcal{M}}$ of $\mathcal{M}$ such the boundary consists of a finite set $I$ of normal crossing divisors $\overline{\mathcal{M}} \setminus \mathcal{M} = \bigcup_{i \in I} D_i$. Along these divisors, the Gauss–Manin connection can acquire regular singularities. This means that, at a point $p \in \cap_{i=1}^{h^{2,1}} D_i$, the connection matrix has at worst a simple pole along $D_i$. Note that since we defined $A_i$ in (2.25) with $\theta_i$ instead of $\partial_i$ this means that matrix $A_i(z)$ is holomorphic along $D_i$.

At a regular singularity described by a divisor $D_i = \{y_i = 0\}$ we therefore define:

\begin{equation}
\text{Res}_{D_i}(\nabla) = A_i(y)|_{y_i = 0}.
\end{equation}

This residue matrix gives the following useful information. The eigenvalues of the monodromy $T$ are $\exp(2\pi i \lambda)$ as $\lambda$ ranges over the eigenvalues of Res($\nabla$). Furthermore, $T$ is unipotent if and only if Res($\nabla$) has integer eigenvalues. Finally, if no two distinct eigenvalues of Res($\nabla$) differ by an integer, then $T$ is conjugate to $S = \exp(-2\pi i \text{Res}(\nabla))$. These properties allow us to extract the relevant information about the monodromy of $\nabla$ around these boundary divisors. We will see later that this allows us to easily obtain the solutions to the PF equations at the various boundary points.

The monodromies $T_i$ for all the divisors $D_i$ in the boundary form a group, the monodromy group $\Gamma$ of the Gauss–Manin connection. This group is a subgroup of $\text{Aut}(H^3(Z^*, Z))$ preserving the symplectic form $Q$. Hence, $\Gamma$ is a subgroup of $\text{Sp}(2h^{2,1} + 2, Z)$. The topological string amplitudes $\mathcal{F}^{(g)}$ are expected to be automorphic with respect to this group.

The point $p$ in the boundary which has been studied usually so far, is the point of maximal unipotent monodromy, also known as the large complex structure limit. From the connection matrices $A_i(x)$ of our example we can

\footnote{We will denote local coordinates near an intersection point of boundary divisors by $y$, still reserving $z$ for the point of maximal unipotent monodromy.}
immediately get information on the monodromy matrices around the divisors $D_{(1,0)} = \{ z_1 = 0 \}$ and $D_{(0,1)} = \{ z_2 = 0 \}$. (For the notation on the divisors see Section 4.2.) We simply consider the matrices $\text{Res}_{\{z_i=0\}} = A_i(z) \mid_{z_i=0}$ and bring them into Jordan normal form. This yields

$$
\begin{pmatrix}
0 & 1 & 0 & 0 & 0 & 0 \\
0 & 0 & 1 & 0 & 0 & 0 \\
0 & 0 & 0 & 1 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0
\end{pmatrix},
$$

(2.27)

$$
\begin{pmatrix}
0 & 1 & 0 & 0 & 0 & 0 \\
0 & 0 & 1 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 1 \\
0 & 0 & 0 & 0 & 0 & 1 \\
0 & 0 & 0 & 0 & 0 & 0
\end{pmatrix}.
$$

From this we read off that the corresponding monodromy matrices $T_{D_{(1,0)}}$ and $T_{D_{(0,1)}}$ satisfy

$$(T_{D_{(1,0)}} - 1)^4 = 0, \quad (T_{D_{(0,1)}} - 1)^3 = 0.$$

(2.28)

It can be checked that these monodromy matrices satisfy the conditions for a point of maximal unipotent monodromy [26, 38].

**Flat coordinates.** We proceed by discussing a special set of coordinates on the moduli space of complex structure which permit an identification with the physical deformations of the underlying theory. These coordinates are defined within special geometry which was developed studying moduli spaces of $\mathcal{N} = 2$ theories, we follow [1, 23, 29–32, 43, 44]. Choosing a symplectic basis of 3-cycles $A^I, B_J \in H_3(Z^*)$ and a dual basis $\alpha_I, \beta^J$ of $H^3(Z^*)$ such
that
\[ A^I \cap B_J = \delta^I_J = -B_J \cap A^I, \quad A^I \cap A^J = B_I \cap B_J = 0, \]
\[ \int_{A^I} \alpha_J = \delta^I_J, \quad \int_{B_J} \beta^I = \delta^I_J, \quad I, J = 0, \ldots, h^{2,1}(Z^*), \]
(2.29)
the (3,0) form $\Omega(x)$ can be expanded in the basis $\alpha_I, \beta^J$:
\[ \Omega(x) = X^I(x)\alpha_I - F_J(x)\beta^J. \]
(2.30)
The periods $X^I(x)$ can be identified with projective coordinates on $\mathcal{M}$ and $\mathcal{F}_J$ with derivatives of a function $\mathcal{F}(X^I)$, $\mathcal{F}_J = \frac{\partial \mathcal{F}(X^I)}{\partial X^J}$. In a patch where $X^0(x) \neq 0$ a set of special coordinates can be defined
\[ t^a = \frac{X^a}{X^0}, \quad a = 1, \ldots, h^{2,1}(Z^*). \]

The normalized holomorphic (3,0) form $\nu_0 = (X^0)^{-1}\Omega(t)$ has the expansion:
\[ \nu_0 = \alpha_0 + t^a \alpha_a - \beta^b F_b(t) - (2F_0(t) - t^c F_c(t))\beta^0, \]
(2.31)
where
\[ F_0(t) = (X^0)^{-2}\mathcal{F} \quad \text{and} \quad F_a(t) := \partial_a F_0(t) = \frac{\partial F_0(t)}{\partial t^a}. \]

$F_0(t)$ is the prepotential. We define further
\[ \nu_a = \alpha_a - \beta^b F_{ab}(t) - (F_a(t) - t^b F_{ab}(t))\beta^0, \]
(2.32)
\[ \nu^a_D = -\beta^a - t^a \beta^0, \]
(2.33)
\[ \nu^0 = \beta^0. \]
(2.34)
The Yukawa coupling in special coordinates is given by
\[ C_{abc} := \partial_a \partial_b \partial_c F_0(t) = \int_{Z^*} \nu_0 \wedge \partial_a \partial_b \partial_c \nu_0. \]
(2.35)
where now $\partial_a = \frac{\partial}{\partial t^a}$. We further define the vector with $2h^{2,1} + 2$ components:
\[ v = (\nu_0, \nu_a, \nu^a_D, \nu^0)^t. \]
(2.36)
We have then by construction:

\begin{equation}
(\partial_a \left( \begin{array}{c} v_0 \\ v_b \\ v_D \\ v^0 \end{array} \right) = \left( \begin{array}{cccc} 0 & \delta^c_a & 0 & 0 \\ 0 & 0 & C_{abc} & 0 \\ 0 & 0 & 0 & \delta^b_a \\ 0 & 0 & 0 & 0 \end{array} \right) \left( \begin{array}{c} v_0 \\ v_c \\ v_D \\ v^0 \end{array} \right), \right)
\end{equation}

which defines the \((2h^{2,1} + 2) \times (2h^{2,1} + 2)\) matrices \(C_a\), in terms of which we can write the equation in the form:

\begin{equation}
(\partial_a - C_a) v = 0.
\end{equation}

The entries of \(v\) correspond to elements in the different filtration spaces discussed earlier. As in Equations (2.25) and (2.38) defines the Gauss–Manin connection, now in special coordinates. The upper triangular structure of the connection matrix reflects the effect of the charge increment of the elements in the chiral ring upon insertion of a marginal operator of unit charge. Since the underlying superconformal field theory is isomorphic for the A- and the B-models, this set of coordinates describing the variation of Hodge structure is the good one for describing mirror symmetry and provide thus the mirror maps. The following discussion builds on [33–35].

In order to find the mirror maps starting from a set of arbitrary local coordinates on the moduli space of complex structure we study the relation between the vectors \(w\) of Equation (2.17) and \(v\) spanning the Hodge filtration, these are related by the following change of basis:

\begin{equation}
w(x(t)) = M(x(t))v(t).
\end{equation}

By the fact that this change of basis is filtration-preserving, the matrix \(M(x)\) must be lower block-triangular. For concreteness, we expose the discussion in the following for \(h^{2,1}(\mathcal{Z}^*) = 2:\)

\begin{equation}
M(x) = \begin{pmatrix}
  m_{11} & 0 & 0 & 0 & 0 & 0 \\
  m_{21} & m_{22} & m_{23} & 0 & 0 & 0 \\
  m_{31} & m_{32} & m_{33} & 0 & 0 & 0 \\
  m_{41} & m_{42} & m_{43} & m_{44} & m_{45} & 0 \\
  m_{51} & m_{52} & m_{53} & m_{54} & m_{55} & 0 \\
  m_{61} & m_{62} & m_{63} & m_{64} & m_{65} & m_{66}
\end{pmatrix}
\end{equation}
Imposing that the change of connection matrices yields the desired result requires the vanishing of the following matrix:

\[ N_a(t) = C_a(t) - \sum_i J_{ia} M(x)^{-1} (A_i(x) M(x) - \theta_i M(x)) \]  

Here \( J = (J_{ia}) \) is the Jacobian for the logarithmic derivative

\[ J_{ia} = \frac{1}{x^i} \frac{\partial x^i}{\partial t^a}. \]

The matrices \( N_a \) have the general block form

\[ N_a(x) = \begin{pmatrix} n_{a,11} & n_{a,12} & n_{a,13} & 0 & 0 & 0 \\ n_{a,21} & n_{a,22} & n_{a,23} & n_{a,24} & n_{a,25} & 0 \\ n_{a,31} & n_{a,32} & n_{a,33} & n_{a,34} & n_{a,35} & 0 \\ n_{a,41} & n_{a,42} & n_{a,43} & n_{a,44} & n_{a,45} & n_{a,46} \\ n_{a,51} & n_{a,52} & n_{a,53} & n_{a,54} & n_{a,55} & n_{a,56} \\ n_{a,61} & n_{a,62} & n_{a,63} & n_{a,64} & n_{a,65} & n_{a,66} \end{pmatrix}. \]

We set \( m_{11}(x) = X^0(x) \) since it will turn out that this quantity should be identified with one of the periods. The vanishing of the first column of the \( N_a \) allows us to express the \( m_{k1} \) in terms of \( X^0(x) \) and its derivatives. Moreover, it follows that \( m_{11} \) is a solution to the PF equations

\[ \mathcal{L}_r X^0(x) = 0. \]

Similarly, the vanishing of the second and third column of the \( N_a \) expresses the \( m_{k2} \) and \( m_{k3} \) in terms of \( m_{12} \) and \( m_{13} \) and their derivatives, respectively. In addition, they satisfy differential equations of the form

\[ \mathcal{D}_r(t_a X^0) = \mathcal{L}_r(t_a X^0) - t_a \mathcal{L}_r X^0 = 0. \]

Together with (2.44) we conclude that the products \( t_1 X^0 \) and \( t_2 X^0 \) must be solutions to the PF equations as well. In other words, the flat coordinates must be ratios of two periods. The differential Equations (2.45) form a system of nonlinear partial differential equation which determine the flat coordinates in terms of \( x \). In general, they are hard to solve, but one can transform this system into a system of linear partial differential equations of higher order along the lines of [45].
Next, we consider the blocks \( \begin{pmatrix} n_{a,24} & n_{a,25} \\ n_{a,34} & n_{a,35} \end{pmatrix} = 0 \). They can be solved for the functions \( C_{abc}(t) \). This yields expressions in terms of \( t_a \), their derivatives, and the functions \( m_{22}, m_{23}, m_{32}, m_{33}, m_{44}, m_{45}, m_{54}, m_{55} \). Taking into account the previous results, we need to express the latter four functions in terms of \( X^0 \).

The two conditions \( n_{a,46} = 0 \) can be used to express \( m_{44} \) and \( m_{45} \) in terms of \( t_a \), their derivatives, and \( m_{66} \). Similarly, \( n_{a,56} = 0 \) yield similar expression for \( m_{54} \) and \( m_{55} \). If we apply this to our example and again choose the point of maximal unipotent monodromy with local coordinates \( z \), then we obtain the following relations:

\[
\begin{align*}
m_{44}(z) &= \frac{3 \theta_2 t_2 - \Delta_3 \theta_1 t_2}{\Delta_3 \det J} m_{66}(z), \\
m_{45}(z) &= -\frac{3 \theta_2 t_2 - \Delta_3 \theta_1 t_1}{\Delta_3 \det J} m_{66}(z), \\
m_{54}(z) &= -\frac{(9 - 11664 z_1 + 5038848 z_1^2) \theta_1 t_2 - \Delta_3^2 \Delta_2^2 \theta_2 t_2}{\Delta_3^2 \Delta_2 \det J} m_{66}(z), \\
m_{55}(z) &= \frac{(9 - 11664 z_1 + 5038848 z_1^2) \theta_1 t_1 - \Delta_3^2 \Delta_2 \theta_2 t_1}{\Delta_3^2 \Delta_2 \det J} m_{66}(z).
\end{align*}
\]

The vanishing of \( n_{1,44} \) and \( n_{1,45} \) allows us to express \( m_{64} \) and \( m_{65} \) in terms of \( m_{42}, \ldots, m_{45}, t_a \), their derivatives and the \( C_{abc} \). Upon using the previous results, they can be expressed in terms of \( X^0, t_i \), their derivatives and \( m_{66}(z) \).

To determine the latter, we use the vanishing of the \( n_{a,66} \).

\[
\begin{align*}
432 z_1 \left( \Delta_1 + 30233088 z_1^2 z_2 \right) \frac{m_{66}(z)}{\Delta_1 \Delta_3} - \theta_1 m_{66}(z) \\
- \left( \theta_1 t_1 \right) m_{64}(z) x - \left( \theta_1 t_2 \right) m_{65}(z) = 0.
\end{align*}
\]

Substituting all the previous results leads to the following differential equation

\[
\begin{align*}
\Delta_1 \Delta_3 \left( m_{66}(z) \theta_1 X^0(z) + X^0(z) \theta_1 m_{66}(z) \right) \\
- 432 z_1 \left( \Delta_1 + 30233088 z_1^2 z_2 \right) m_{66}(z) X^0(z) = 0.
\end{align*}
\]
All the dependence on the \( t_i \) has canceled. We observe that the prefactor of \( m_{66}(z)X^0(z) \) can be written as

\[
\frac{\Delta_1^2}{\Delta_3} \theta_1 \left( \frac{\Delta_3^2}{\Delta_1} \right) = 432 z_1 (\Delta_1 + 30233088 z_1^2 z_2).
\]

Hence, the differential equation simplifies to

\[
\theta_1 \left( \frac{\Delta_3^2}{\Delta_1 m_{66}(z)X^0(z)} \right) = 0.
\]

Its solution is

\[
m_{66}(z) = f(z_2) \frac{\Delta_3^2}{\Delta_1 X^0(z)},
\]

where \( f(z_2) \) is an undetermined function that only depends on \( z_2 \). To fix this function we look at the vanishing of the \( n_{2,66} \). After all substitutions this yields the differential equation

\[
\theta_2(\Delta_1 m_{66}(z)X^0(z)) = \theta_2 \left( f(z_2)\Delta_3^2 \right) = 0.
\]

Since \( \Delta_3 \) does not depend on \( z_2 \), we conclude that \( f(z_2) \) must be a constant, which we set to 1.

We can now recursively express all the functions \( m_{ij} \) through the function \( X^0(z) \) which must be a solution of the PF equations. In particular, this yields the well known expression for the Yukawa couplings in flat coordinates

\[
C_{abc}(t) = \sum_{i,j,k} \frac{1}{(X^0(z(t)))^2} \frac{\partial z_i}{\partial t^a} \frac{\partial z_j}{\partial t^b} \frac{\partial z_k}{\partial t^c} C_{ijk}(z(t)).
\]

There are still a few conditions remaining, namely \( n_{a,64} = 0 \) and \( n_{a,65} = 0 \). These turn out to be very difficult to analyze. One can check that these conditions are implied by

\[
Q(X^0, t_1X^0) = 0, \quad Q(X^0, t_2X^0) = 0, \quad Q(t_1X^0, t_2X^0) = 0.
\]

where \( Q \) was determined in (2.22). In particular, not every ratio of solutions to the PF equations yields a flat coordinate. In general, we expect a weaker condition involving the left-hand sides of (2.54) to be equivalent to the vanishing of \( N_a \).
Solutions of the PF equations. As we have just seen, in order to determine the flat coordinates we need solutions of the PF equation which satisfy (2.54). It is well-known how to solve these equations at the point of maximal unipotent monodromy by observing that they form extended GKZ hypergeometric systems; see, e.g., [25, 46]. However, we will need the flat coordinates at other special loci in the moduli space. For this purpose, we need a systematic procedure to solve the system of PF equations at an arbitrary point in the boundary $\overline{\mathcal{M}} \setminus \mathcal{M}$ of the moduli space where it is in general no longer of extended GKZ hypergeometric type.

However, if the moduli space $\mathcal{M}$ is one-dimensional we have the following well-known result; see e.g., [47, 48]. Let

$$R = \text{Res}_{y=0} \nabla = A(y)|_{y=0}$$

be the residue matrix of the connection $\nabla$ at a regular singular point given by $y = 0$. $R$ is a constant matrix. If the eigenvalues of $R$ do not differ by positive integers, then there exists a fundamental system of solutions to (2.25) of the form

$$u(y) = y^R S(y)$$

with $S(y)$ a single-valued and holomorphic matrix. If some of the eigenvalues of $R$ do not differ by positive integers, then there is an algorithm for finding a non-constant change of basis such that an eigenvalue is shifted by 1. Then, (2.55) holds with $R$ replaced by the residue matrix $\tilde{R}$ in the new basis. Since any two fundamental systems are related by an invertible constant matrix, this form is independent of the choice of basis, and we can take for $R$ its Jordan normal form. This simplifies the computations enormously.

In the present case where the moduli space $\mathcal{M}$ is higher-dimensional, we can prove the following result: Let $p = \bigcap_{i=1}^{n} D_i$ be a point at the intersection of $h^{2,1}$ boundary divisors, where each of the divisors $D_i$ is given by an equation $y_i = 0$. Let

$$R_i = \text{Res}_{D_i} \nabla = A_i(y)|_{y_i=0}, \quad \forall i.$$ 

The matrices $R$ are in general not constant anymore. However, for the solutions near a point given by $y_i = 0, i = 1, \ldots, n$, we can set all $y_i$ to zero in
Then a fundamental system of solutions takes the form

\[ u(y) = \prod_{i=1}^{n} y_i^{R_i} S(y). \]

This follows by induction from the result in dimension 1 together with the fact that \([R_i, R_j] = 0\), a consequence of the flatness of \(\nabla\). In general, the \(R_i\) cannot be simultaneously brought into Jordan normal form. However, there exist constant matrices \(C_i\) such that the \(R_i\) can be brought into simultaneous triangular form \(T_i = C_i^{-1} R_i C_i\). Then we can bring \(u(y)\) into the form

\[ u(y) = \prod_{i=1}^{n} P_i y_i T_i S(y), \]

which considerably simplifies the explicit computation. In practice, the \(P_i\) are often permutation matrices.

**Elliptic fibrations.** Here, we discuss a few aspects of elliptic fibrations. Let \(Z\) be an elliptically fibered CY threefold \(\pi : Z \to B\), where the fiber \(\pi^{-1}(p) \cong E\) is a smooth elliptic curve, \(p \in B \setminus \Delta\), where the discriminant \(\Delta\) is a divisor in \(B\). We consider the variation of Hodge structure for the family of mirror CY threefolds \(f : Z^* \to M\) where \(M\) is the complex structure moduli space. We recall that the Gauss–Manin connection for this family has monodromy group \(\Gamma \in \text{Aut}(H^3(Z^*, \mathbb{Z}))\). Since \(Z\) is an elliptic fibration, there is a distinguished subgroup of \(\Gamma\) isomorphic to a subgroup \(\Gamma_{\text{ell}} \subset \text{SL}_2(\mathbb{Z})\) and the variation of Hodge structure contains a variation of sub-Hodge structures coming from the elliptic fiber.

In our example the monodromy group \(\Gamma\) is generated by two matrices \(A\) and \(T\) [38]. Consider the element \(T_\infty = (TA)^{-1} \in \Gamma\). Then \(A^3\) and \(T_\infty^3\) generate an \(\text{SL}_2(\mathbb{Z})\) subgroup as follows:

\[ A^3 t_1 = -\frac{1}{t_1 + 1}, \quad T_\infty^3 t_1 = t_1 + 1 \]

Hence, we expect \(t_1\) to be a modular parameter of an elliptic curve. In fact, in the limit \(z_2 \to 0\) the PF system reduces to the PF equation of the elliptic curve mirror to the elliptic fiber.
3. Higher genus recursion

In this section, we review the ingredients of the polynomial construction [19, 20], following [20] as well as the boundary conditions needed to supplement the construction to fix remaining ambiguities. To implement the boundary conditions it is necessary to be able to provide the good physical coordinates in every patch in moduli space. This can be done by exploiting the flat structure of the variation of Hodge structure on the B-model side.

3.1. Special geometry and the holomorphic anomaly

The deformation space $\mathcal{M}$ of topological string theory, parameterized by coordinates $x^i$, $i = 1, \ldots, \dim(\mathcal{M})$, carries the structure of a special Kähler manifold. The ingredients of this structure are the Hodge line bundle $L$ over $\mathcal{M}$ and the cubic couplings $C$ which are a holomorphic section of $L^2 \otimes \text{Sym}^3 T^* \mathcal{M}$. The metric on $L$ is denoted by $e^{-K}$ with respect to some local trivialization and provides a Kähler potential for the special Kähler metric on $\mathcal{M}$, $G_{ij} = \partial_i \bar{\partial}_j K$. Special geometry further gives the following expression for the curvature of $\mathcal{M}$:

\begin{equation}
R_{i_1 \ldots i_n j} = [\bar{\partial}_{i_1}, D_i]_{i_2 \ldots i_n j} = \bar{\partial}_i \Gamma^l_{i_2 \ldots i_n j} = \delta^l_i G_{j_1} + \delta^l_j G_{i_1} - C_{i_1 j_1} C_{i_2}^{kl}.
\end{equation}

The topological string amplitude or partition function $\mathcal{F}(g)$ at genus $g$ is a section of the line bundle $L^{2-2g}$ over $\mathcal{M}$. The correlation function at genus $g$ with $n$ insertions $\mathcal{F}^{(g)}_{i_1 \ldots i_n}$ is only non-vanishing for $(2g - 2 + n) > 0$. They are related by taking covariant derivatives as this represents insertions of chiral operators in the bulk, e.g., $D_i \mathcal{F}^{(g)}_{i_1 \ldots i_n} = \mathcal{F}^{(g)}_{i_1 \ldots i_n}$.

$D_i$ denotes the covariant derivative on the bundle $L^m \otimes \text{Sym}^n T^* \mathcal{M}$ where $m$ and $n$ follow from the context. $T^* \mathcal{M}$ is the cotangent bundle of $\mathcal{M}$ with the standard connection coefficients $\Gamma^l_{j_k} = G^{l_1} \partial_j G_{i_k}$. The connection on the bundle $L$ is given by the first derivatives of the Kähler potential $K_i = \partial_i K$.

---

5See [5, Section 2.3] for background material.
6The notation $D_i$ is also being used for the boundary divisors $D_i \in \overline{\mathcal{M}} \setminus \mathcal{M}$. It is clear from the context which meaning applies.
In [5, Section 3.2] it is shown that the genus $g$ amplitudes are recursively related to lower genus amplitudes by the holomorphic anomaly equations:

$$
\bar{\partial}_i F^{(g)}_{i_1 \ldots i_n} = \frac{1}{2} \bar{C}_i^{jk} \left( \sum_{r=0}^{g} \sum_{s=0}^{n} \frac{1}{s!(n-s)!} \sum_{\sigma \in S_n} D_j F^{(r)}_{\sigma(1) \ldots \sigma(s)} D_k F^{(g-r)}_{\sigma(s+1) \ldots \sigma(n)} + D_j D_k F^{(g-1)}_{i_1 \ldots i_n} \right) ,
$$

(3.2)

$$
-(2g - 2 + n - 1) \sum_{s=1}^{n} G_{i_s} F^{(g)}_{i_1 \ldots i_{s-1} i_{s+1} \ldots i_n} ,
$$

where

$$
\bar{C}_i^{ij} = \bar{C}_{ij} G^{(i} G^{j)} e^{2K} , \quad \bar{C}_{ijk} = \bar{C}_{ijk} .
$$

(3.3)

and where the sum $\sigma \in S_n$ is over permutations of the insertions and the formula is valid for $(g = 0, n \geq 4)$, $(g = 1, n \geq 2)$ and all higher genera and number of insertions. For $n = 0$ it reduces to the holomorphic anomaly for the free energies $F^g$:

$$
\bar{\partial}_i F^{(g)} = \frac{1}{2} \bar{C}_i^{jk} \left( \sum_{r=1}^{g-1} D_j F^{(r)} D_k F^{(g-r)} + D_j D_k F^{(g-1)} \right) .
$$

(3.4)

These equations, supplemented by Bershadsky et al.[4]

$$
\bar{\partial}_i F^{(1)} = \frac{1}{2} C_{jkl} \bar{C}_i^{kl} + (1 - \chi 24) G_{ji} ,
$$

(3.5)

and special geometry, determine all correlation functions up to holomorphic ambiguities. In Equation (3.5), $\chi$ is the Euler character of the manifold. A solution of the recursion equations is given in terms of Feynman rules [5, Section 6].

The propagators $S$, $S^i$, $S^{ij}$ for these Feynman rules are related to the three point couplings $C_{ijk}$ as

$$
\bar{\partial}_i S^{ij} = \bar{C}_i^{ij} , \quad \bar{\partial}_i S^j = G_{ii'} S^{ij} , \quad \bar{\partial}_i S = G_{ii'} S^i .
$$

(3.6)

By definition, the propagators $S$, $S^i$ and $S^{ij}$ are sections of the bundles $L^{-2} \otimes \text{Sym}^m T$ with $m = 0, 1, 2$. The vertices of the Feynman rules are given by the correlation functions $F^{(g)}_{i_1 \ldots i_n}$. The anomaly Equations (3.4) and (3.5), as well as the definitions in Equation (3.6), leave the freedom of adding holomorphic functions under the $\bar{\partial}$ derivatives as integration constants. This freedom is referred to as holomorphic ambiguities.
3.2. Polynomial structure of higher genus amplitudes

In [20] it was proven that the correlation functions $F^{(g)}_{i_1\cdots i_n}$ are polynomials of degree $3g - 3 + n$ in the generators $K_i, S^{ij}, S^i, S$ where a grading $1, 1, 2, 3$ was assigned to these generators, respectively. It was furthermore shown that by making a change of generators [20]

\begin{align}
\tilde{S}^{ij} &= S^{ij}, \\
\tilde{S}^i &= S^i - S^{ij} K_j, \\
\tilde{S} &= S - S^i K_i + \frac{1}{2} S^{ij} K_i K_j, \\
\tilde{K}_i &= K_i,
\end{align}

(3.7)

the $F^{(g)}$ do not depend on $\tilde{K}_i$, i.e., $\partial F^{(g)} / \partial \tilde{K}_i = 0$. We will henceforth drop the tilde from the modified generators.

The proof relies on expressing the first non-vanishing correlation functions in terms of these generators. At genus zero these are the holomorphic three-point couplings $F^{(0)}_{ijk} = C_{ijk}$. The holomorphic anomaly Equation (3.4) can be integrated using Equation (3.6) to

\begin{equation}
F^{(1)}_i = \frac{1}{2} C_{ijk} S^{jk} + (1 - \frac{\chi}{24}) K_i + f^{(1)}_i,
\end{equation}

(3.8)

with ambiguity $f^{(1)}_i$. As can be seen from this expression, the non-holomorphicity of the correlation functions only comes from the generators. Furthermore, the special geometry relation (3.1) can be integrated:

\begin{equation}
\Gamma^l_{ij} = \delta^l_i K_j + \delta^l_j K_i - C_{ijk} S^{kl} + s^l_{ij},
\end{equation}

(3.9)

where $s^l_{ij}$ denote holomorphic functions that are not fixed by the special geometry relation, this can be used to derive the following equations which show the closure of the generators carrying the non-holomorphicity under taking derivatives [20].

\begin{equation}
\partial_i S^{jk} = C_{imn} S^{mj} S^{nk} + \delta^i_j S^k + \delta^i_k S^j - s^i_{im} S^{mk} - s^i_{jm} S^{mj} + h^i_{jk},
\end{equation}

7These equations are for the tilded generators of Equation (3.7) and are obtained straightforwardly from the equations in [20].
\[
\partial_i S^j = C_{imn} S^m S^n + 2 \delta_i^j S - s^j_{im} S^m - h_{ik} S^{kj} + h^j_i,
\]
\[
\partial_i S = \frac{1}{2} C_{imn} S^m - h_{ij} S^j + h_i,
\]
\[
\partial_i K_j = K_i K_j - C_{ijm} S^m K_m + s^m_{ij} K_m - C_{ijk} S^k + h_{ij},
\]
(3.10)

where \(h^{jk}_{i}, h^j_{i}, h_{i}\) and \(h_{ij}\) denote holomorphic functions. All these functions together with the functions in Equation (3.9) are not independent. It was shown in ref. [49] (see also [50]) that the freedom of choosing the holomorphic functions in this ring reduces to holomorphic functions \(\mathcal{E}^{ij}, \mathcal{E}^j, \mathcal{E}\) which can be added to the polynomial generators

\[
\hat{S}^{ij} = S^{ij} + \mathcal{E}^{ij},
\]
\[
\hat{S}^j = S^j + \mathcal{E}^j,
\]
\[
\hat{S} = S + \mathcal{E}.
\]
(3.11)

All the holomorphic quantities change accordingly.

The topological string amplitudes now satisfy the holomorphic anomaly equations where the \(\bar{\partial}\) derivative is replaced by derivatives with respect to the polynomial generators [20].

\[
\frac{\partial F^{(g)}_{i_1 \ldots i_n}}{\partial S^{i_j}} - \frac{1}{2} \left( K_i \frac{\partial F^{(g)}_{i_1 \ldots i_n}}{\partial S^{j}} + K_j \frac{\partial F^{(g)}_{i_1 \ldots i_n}}{\partial S^{i}} \right) + \frac{1}{2} K_i K_j \frac{\partial F^{(g)}_{i_1 \ldots i_n}}{\partial S}
\]
\[
= \frac{1}{2} \sum_{r=0}^{g} \sum_{s=0}^{n} \frac{1}{s!(n-s)!} \sum_{\sigma \in S_n} D_j F^{(r)}_{i_{\sigma(1)} \ldots i_{\sigma(s)}} D_k F^{(g-r)}_{i_{\sigma(s+1)} \ldots i_{\sigma(n)}} + \frac{1}{2} D_j D_k F^{(g-1)}_{i_1 \ldots i_n}
\]
(3.12)

\[
\sum_i G_{ii} \frac{\partial F^{(g)}_{i_1 \ldots i_n}}{\partial K_i} = -(2g - 2 + n - 1) \sum_{s=1}^{n} G_{ii_s} F^{g}_{i_1 \ldots i_{s-1} i_s \ldots i_n}.
\]
(3.13)

This equation can be simplified by grouping powers of \(K_i\) [50].

### 3.3. Constructing the generators

The construction of the generators of the polynomial construction has been discussed in [49]. The starting point is to pick a local coordinate \(z_*\) on the moduli space such that \(C_{*ij}\) is an invertible \(n \times n\) matrix in order to rewrite
Equation (3.9) as
\begin{equation}
S_{ij} = (C^{-1})*^ik \left( \delta^j_k K + \delta^j_k K^* - \Gamma^j_{*k} + s^j_k \right).
\end{equation}

The freedom in Equation (3.11) can be used to choose some of the $s^k_{ij}$ [49]. The other generators are then constructed using Equation (3.10) [49]:
\begin{align}
S^i &= \frac{1}{2} \left( \partial_i S^{ii} - C_{imn} S^{mi} S^{ni} + 2s^{i}_{im} S^{mi} - h^{ii}_i \right), \\
S &= \frac{1}{2} \left( \partial_i S^i - C_{imn} S^m S^{ni} + s^{i}_{im} S^m + h_{im} S^{m} - h^i \right).
\end{align}

In both equations, there is no summation over the index $i$. The second equation holds for every value of $i$. The freedom in adding holomorphic functions to the generators of Equation (3.11) can again be used to make a choice for the functions $h^{ii}_i$ for all $i$ and $h^{i_0}_{i_0}$ for some $i_0$, the other ones are fixed by this choice and can be computed from Equation (3.10).

### 3.4. Boundary conditions

**Genus 1.** The holomorphic anomaly equation at genus 1 (3.5) can be integrated to give:
\begin{equation}
\mathcal{F}^{(1)} = \frac{1}{2} \left( 3 + h^{1,1} - \frac{\chi}{12} \right) K + \frac{1}{2} \log \det G^{-1} + \sum_i s_i \log z_i + \sum_a r_a \log \Delta_a,
\end{equation}
where $i = 1, \ldots, h^{2,1}$ and $a$ runs over the number of discriminant components. The coefficients $s_i$ and $r_a$ are fixed by the leading singular behavior of $\mathcal{F}^{(1)}$ which is given by [4]
\begin{equation}
\mathcal{F}^{(1)} \sim -\frac{1}{24} \sum_i \log z_i \int_Z c_2 J_i,
\end{equation}
for the algebraic coordinates $z_i$, for a discriminant $\Delta$ corresponding to a conifold singularity the leading behavior is given by
\begin{equation}
\mathcal{F}^{(1)} \sim -\frac{1}{12} \log \Delta.
\end{equation}

**Higher genus boundary conditions.** The holomorphic ambiguity needed to reconstruct the full topological string amplitudes can be fixed by imposing...
various boundary conditions for $\mathcal{F}(g)$ at the boundary of the moduli space. As in Section 2.3 we assume that the boundary is described by simple normal crossing divisors $M \setminus \mathcal{M} = \bigcup_{i \in I} D_i$ for some finite set $I$.

We can distinguish the various boundary conditions by looking at the monodromy $T_i$ of the Gauss–Manin connection $\nabla$ around a boundary divisor $D_i$. By the monodromy theorem [51] we know that $T_i$ must satisfy

$$ (T_i^m - 1)^n = 0 $$

for $n \leq \dim Z^* + 1$ and some positive integer $m$. The current understanding of the boundary conditions for $\mathcal{F}(g)$ seems to suggest that they can roughly be classified according to the value of $n$. In general, the finer structure by the Jordan decomposition of $T$ is relevant; see [60].

**The large complex structure limit.** A point in the boundary is a large complex structure limit or a point of maximal unipotent monodromy if $n = \dim Z^* + 1$ in (3.20) and if $N_i = \log T_i$ satisfies certain conditions described in detail in [26] and [38].

The leading behavior of $\mathcal{F}(g)$ at this point (which is mirror to the large volume limit) was computed in [2–5, 52, 53]. In particular, the contribution from constant maps is

$$ \mathcal{F}(g)|_{q_a=0} = (-1)^g \frac{\chi |B_{2g}B_{2g-2}|}{2g(2g-2)(2g-2)!}, \quad g > 1, $$

where $q_a$ denote the exponentiated mirror map at this point.

**Conifold-like loci.** A divisor $D_i$ in the boundary is of conifold type if $n = 2$ in (3.20). If $m = 1$ then $Z^*$ acquires a conifold singularity, if $m > 1$ the singularity is not of conifold type but the physics behaves similarly. This singularity is often called a strong coupling singularity [54]. Singularities of both types appear at the vanishing of the discriminant $\Delta$. A well-known example for the case $m > 1$ is the divisor given by the non-principal discriminant in the moduli space of the mirror of $\mathbb{P}(1, 1, 2, 2, 6)[12]$ for which $m = 2$.

The leading singular behavior of the partition function $\mathcal{F}(g)$ at a conifold locus has been determined in [2–5, 55, 56]

$$ \mathcal{F}(g)(t_c) = b \frac{B_{2g}}{2g(2g-2)t_c^{2g-2}} + O(1), \quad g > 1 $$
Here \( t_c \sim \Delta^{\frac{1}{m}} \) is the flat coordinate at the discriminant locus \( \Delta = 0 \). For a
conifold singularity \( b = 1 \) and \( m = 1 \). In particular, the leading singularity
in (3.22) as well as the absence of subleading singular terms follows from
the Schwinger loop computation of [2, 3], which computes the effect of the
extra massless hypermultiplet in the space-time theory [57]. The singular
structure and the “gap” of subleading singular terms have been also observed
in the dual matrix model [58] and were first used in [59, 60] to fix the
holomorphic ambiguity at higher genus. The space-time derivation of [2, 3]
is not restricted to the conifold case and applies also to the case \( m > 1 \)
singularities which give rise to a different spectrum of extra massless vector
and hypermultiplets in space-time. The coefficient of the Schwinger loop
integral is a weighted trace over the spin of the particles [56, 57] leading to
the prediction \( b = n_H - n_V \) for the coefficient of the leading singular term.
The appearance of the prefactor \( b \) in the case \( m > 1 \) has been discussed
in [49] for the case of the local \( \mathbb{F}_2 \) (see also [61]).

**Orbifold loci.** A divisor \( D_i \) in the boundary is of orbifold type if \( n = 1 \)
in (3.20). In this case, the monodromy is of finite order. The leading singular
behavior of the partition function \( \mathcal{F}(g) \) at a such a divisor is expected to be
regular [5, Section 7.2]

\[
(3.23) \quad \mathcal{F}(g)(t_o) = O(1), \quad g > 1.
\]

where \( t_o \) is the flat coordinate at the orbifold locus \( D_i \).

**The holomorphic ambiguity.** The singular behavior of \( \mathcal{F}(g) \) is taken into
account by the local ansatz

\[
(3.24) \quad \text{hol. ambiguity} \sim \frac{p^{(g)}(y_i)}{\Delta^{2g-2}},
\]

for the holomorphic ambiguity near \( \Delta = 0 \), where \( p(y_i) \) is a priori a series
in the local coordinates \( y_i \) near the singularity. Patching together the local
information at all the singularities with the boundary divisors with finite
monodromy, it follows however that the numerator \( p(z_i) \) is generically a
polynomial of low degree in the \( z_i \). Here \( z_i \) denote the natural coordinates
centered at large complex structure, \( z_i = 0 \ \forall i \), cf. Footnote 4. The finite
number of coefficients in \( p(z_i) \) is constrained by (3.22).
4. Higher genus amplitudes for an elliptic fibration

In this section, we use the polynomial construction together with the boundary conditions discussed previously to construct the higher genus topological string amplitudes for the example of the elliptic fibration which we discussed.

4.1. Setup of the polynomials

We start by setting up the polynomial construction as discussed in Section 3.2. This involves using the freedom in choosing the generators in order to fix the holomorphic functions appearing in the derivative relations (3.10). We fix the choice of the polynomial generators such that these functions are rational expressions in terms of the coordinates in the large complex structure patch of the moduli space. For the holomorphic functions in the following we multiply lower indices by the corresponding coordinates and divide by the coordinates corresponding to upper indices.

\[ A_i^j \rightarrow \frac{z_i}{z_j} A_i^j \]

With this convention we can express all the holomorphic functions appearing in the setup of the polynomial construction in terms of polynomials in the local coordinates. We start by fixing the choice of the generators \( S_{ij} \) in Equations (3.14) and (3.9):

\[
\begin{align*}
    s_{11}^1 &= -2, & s_{12}^1 &= -\frac{1}{3}, & s_{22}^1 &= 0, \\
    s_{11}^2 &= 0, & s_{12}^2 &= 0, & s_{22}^2 &= -\frac{4}{3}.
\end{align*}
\]

Such a simple choice is in general not possible.

Then the following quantities are chosen by fixing the choice of the generators \( S^i \) in Equation (3.15), i.e., of \( h_{11}^1, h_{22}^2 \), and the other quantities are then computed from Equation (3.10):

\[
\begin{align*}
    h_{11}^1 &= \frac{1}{9} - 48 z_1 + \frac{5}{6} z_2 - 540 z_1 z_2, \\
    h_{12}^1 &= -\frac{5}{108} - \frac{5}{4} z_2 + 20 z_1 + 540 z_1 z_2, \\
    h_{22}^1 &= -60 z_1 (1 - 27 z_2),
\end{align*}
\]
(4.6) \[ h_2^{11} = -60 z_1 z_2, \]
(4.7) \[ h_2^{12} = \frac{1}{9} + \frac{5}{12} z_2 - 48 z_1, \]
(4.8) \[ h_2^{22} = -\frac{23}{54} + 40 z_1 - \frac{5}{2} z_2 - 540 z_1 z_2. \]

We proceed by fixing the choice of the generator $S$ in Equation (3.15), i.e., of, say, $h_1^1$, and compute from Equation (3.10)

(4.9) \[ h_1^1 = \frac{155}{27} z_1 - \frac{25}{1296} z_2 + 50 z_1 z_2, \]
(4.10) \[ h_1^2 = 0, \]
(4.11) \[ h_2^1 = -\frac{5}{18} z_2 + 120 z_1 z_2, \]
(4.12) \[ h_2^2 = \frac{155}{27} z_1 + \frac{1055}{1296} z_2 + 50 z_1 z_2. \]

We further compute:

(4.13) \[ h^1 = \frac{25}{23328}, \quad h^2 = -\frac{50}{3} z_1 z_2, \]

and

(4.14) \[ h_{11} = \frac{5}{36}, \quad h_{12} = \frac{5}{108}, \quad h_{22} = 0. \]

With these choices the polynomial part of the higher genus amplitudes is entirely fixed by Equation (3.12). However, we need to supplement this polynomial part with the holomorphic ambiguities which are not captured by the holomorphic anomaly recursion and can be fixed by the boundary conditions discussed earlier. In order to implement the boundary conditions we make an ansatz for the ambiguities which will be discussed in Section 4.4. We then expand the polynomial part and the ansatz in the local special coordinates in the different patches of moduli space. In order to do this for the present example we first proceed by discussing the moduli space and its various boundary components.

### 4.2. Moduli space and its compactification

To obtain a nice and useful description of the moduli space of complex structures, we first need the secondary fan of the variety $W$. This is obtained
from the columns of the Mori generators (2.2) which are (taking the primitive lattice vectors in $\mathbb{Z}^2$)

\[(4.15) \quad b_1 = (1, 0), \quad b_2 = (0, 1), \quad b_3 = (1, -3), \quad b_4 = (-1, 0).\]

These vectors define the weighted projective space $\mathbb{P}(1, 1, 3)$ blown up in one point, with toric divisors $D_{(1,0)}$, $D_{(0,1)}$, $D_{(1,-3)}$, $D_{(-1,0)}$, respectively. (The divisor $D_{(1,-3)}$ does not lie on the boundary of the moduli space [38] and will be neglected in the following.) This space is still singular, and we will discuss the resolution of the singularities in the next subsection.

We still have to remove the set where the hypersurface is singular, i.e., the discriminant locus. This is also given in terms of the data of toric geometry as follows: if $\theta$ is any face of the polytope $\Delta^*$, we define $f_\theta(x) = \sum_{\nu_i \in \theta \cap \mathbb{Z}^4} a_i \prod_i x^{\nu_i}$. The polynomial is degenerate if for any face $\theta \subset \Delta^*$, the system of polynomial equations

\[(4.16) \quad f_\theta = X_1 \frac{\partial f}{\partial X_1} = \cdots = X_4 \frac{\partial f}{\partial X_4} = 0\]

has no solution in the toric variety. This yields that the discriminant locus is given by the divisors

\[(4.17) \quad D_1 = \{\Delta_1 = 0\}, \quad D_2 = \{\Delta_2 = 0\}\]

with $\Delta_1$ and $\Delta_2$ given in (2.12).

In the following, we will use the following abbreviations:

\[(4.18) \quad \bar{z}_1 = 432z_1, \quad \bar{z}_2 = -27z_2.\]

These divisors intersect each other as follows. From $\Delta_1 = (1 - \bar{z}_1)^3 - \bar{z}_1^3 \bar{z}_2$, we see that there is a tangency of order 3 between $D_{(1,0)}$ and $D_1$ at the point $(1,0)$. Writing $\Delta_1 = (1 - 3\bar{z}_1 + 3\bar{z}_1^2) + \bar{z}_1^3 \Delta_2$ we see that $D_1$ and $D_2$ intersect transversally in the two points $(\bar{z}_1, \bar{z}_2) = (c_\pm, 1)$ with $c_\pm = \frac{1}{2} \left( 1 \pm \frac{i\sqrt{3}}{3} \right)$. By changing to the variables to $w_1 = \frac{1}{\bar{z}_1}$ we write $\Delta_1 = -w_1 (3 - 3w_1 + w_1^2) + \Delta_2$ and we have a triple intersection of $D_1$, $D_2$ and $D_{(-1,0)}$ in $(w_1, \bar{z}_2) = (0, 1)$.

Resolution of singularities. We want a compactification of the complex structure moduli space by divisors with normal crossings. To achieve this
we must resolve the singularities of $\mathbb{P}(1,1,3)$ and resolve all non-normal crossings of $D_1$ and $D_2$ with any of the other divisors. Moreover, we will need a set of local coordinates near each normal crossing.

The singularities of $\mathbb{P}(1,1,3)$ can be taken care of by toric geometry. Resolving them amounts to subdividing the secondary fan and this introduces three further generators $b_5 = (1, -1), b_6 = (1, -2)$ and $b_7 = (0, -1)$, and the corresponding toric divisors $D_{(1,-1)}, D_{(1,-2)}$ and $D_{(0,-1)}$. Toric geometry also provides us with the local coordinates near each intersection point of the toric divisors. They are determined by the generators of the cone dual to the maximal cone spanned by the corresponding generators. E.g. the dual cone to $\langle 0, b_5, b_6 \rangle$ is spanned by the vectors $(2, 1)$ and $(-1, -1)$, hence the corresponding local coordinates are $(\bar{z}_1 \bar{z}_2, \bar{z}_1 z_2)$. A summary can be found in Table 1.

In order to obtain normal crossings with $D_1$ and $D_2$ we first consider the resolution of the singularity of the hypersurface $W = x^3 - y^4 = 0$ in $(0,0)$. The choice of this hypersurface singularity is motivated by the fact that during the resolution process both a triple intersection and a tangency of order 3 appear. Their resolutions therefore serve as a local model for the resolutions of the non-normal crossings involving $D_1$ and $D_2$.

We view the hypersurface $W = 0$ as a divisor $D$ in $\mathbb{C}^2$. The resolution can be performed in terms of four blow-ups. At the first blow-up, we introduce a $\mathbb{P}^1$ with homogeneous coordinates $(u_0 : v_0)$ such that $u_0 x - v_0 y = 0$. We denote this exceptional divisor by $E_0$. In the coordinate patch $u_0 = 1$ we have $x = v_0 y$ and the singularity becomes $W = y^3(v_0^3 - y). W = 0$ now consists of the components $E_0 = \{y = 0\}$ and $D = \{v_0^3 - y = 0\}$ which do not intersect transversely in $(v_0,y) = (0,0)$. On the other hand, in the coordinate patch $v_0 = 1$, we have $y = u_0 x$ and the singularity becomes $W = x^3(1 - u_0^4 x)$, $W = 0$ consists of the components $E_0 = \{x = 0\}$ and $D = \{1 - u_0^4 x = 0\}$ which do not intersect at all. Hence, we focus on the patch $u_0 = 1$ with local coordinates $(v_0, y)$ and resolve further.

At the second blow-up, we introduce a $\mathbb{P}^1$ with homogeneous coordinates $(u_1, v_1)$ such that $u_1 v_0 - v_1 y = 0$. We denote this exceptional divisor by $E_1$. In the coordinate patch $u_1 = 1$, we have $v_0 = v_1 y$ and the singularity becomes $W = y^4(v_1^3 y^2 - 1)$. $W = 0$ now consists of the components $E_1 = \{y = 0\}$ and $D = \{v_1^2 y^2 - 1 = 0\}$ which do not intersect. On the other
Table 1: xxx.

| Crossing                         | Local coordinates               |
|----------------------------------|--------------------------------|
| $D_{(1,0)} \cap D_{(0,1)}$      | $(\bar{z}_1, \bar{z}_2)$      |
| $D_{(1,0)} \cap D_{(1,-1)}$     | $(\bar{z}_1 \bar{z}_2, \bar{z}_2^{-1})$ |
| $D_{(1,0)} \cap D_2$            | $(\bar{z}_1, 1 - \bar{z}_2)$ |
| $D_{(1,-2)} \cap D_{(1,-1)}$    | $((\bar{z}_1 \bar{z}_2)^{-1}, \bar{z}_1^2 \bar{z}_2)$ |
| $D_2 \cap E_0$                  | $(\bar{z}_1 (1 - \bar{z}_2), \frac{1}{\bar{z}_1})$ |
| $D_{(-1,0)} \cap D_{(0,-1)}$    | $(\bar{z}_1^{-1}, \bar{z}_2^{-1})$ |
| $D_{(-1,0)} \cap D_{(0,1)}$     | $(\bar{z}_1^2, \bar{z}_2)$    |
| $D_{(-1,0)} \cap E_0$           | $\left(\frac{1}{\bar{z}_1(1 - \bar{z}_2)}, 1 - \bar{z}_2\right)$ |
| $(D_1 \cap D_2)_+$               | $\left(1 - \frac{\bar{z}_1}{c_1}, \frac{1 - \bar{z}_2}{c_2}\right)$ |
| $(D_1 \cap D_2)_-$               | $\left(1 - \frac{\bar{z}_1}{c_1}, \frac{1 - \bar{z}_2}{c_2}\right)$ |
| $D_1 \cap E_0$                   | $\left(\frac{(1 - \bar{z}_1)^3 + \bar{z}_1^3 \bar{z}_2}{\bar{z}_1^3}, \frac{1}{\bar{z}_1}\right)$ |
| $E_3 \cap E_2$                   | $\left(-\frac{\bar{z}_1^3 \bar{z}_2}{(1-\bar{z}_1)^2}, \frac{(1-\bar{z}_1)^3}{\bar{z}_1^3 \bar{z}_2}\right)$ |
| $E_3 \cap D_{(0,1)}$            | $\left(1 - \bar{z}_1, -\frac{\bar{z}_1^3 \bar{z}_2}{(1-\bar{z}_1)^2}\right)$ |
| $E_3 \cap D_1$                   | $\left(1 - \bar{z}_1, 1 + \frac{\bar{z}_1^3 \bar{z}_2}{(1-\bar{z}_1)^2}\right)$ |
| $E_1 \cap E_2$                   | $\left(-\frac{\bar{z}_1^3 \bar{z}_2}{1-\bar{z}_1}, -(1-\bar{z}_1)^2\right)$ |

On the other hand, in the coordinate patch $v_1 = 1$, we have $y = u_1 v_0$ and the singularity becomes $W = u_1 v_0^4 (v_0^2 - u_2)$. $W = 0$ consists of the components $E_1 = \{v_0 = 0\}$, $E_0 = \{u_1 = 0\}$ and $D = \{v_0^2 - u_1 = 0\}$ which do not intersect transversely in $(v_0, u_1) = (0, 0)$. Hence, we focus on the patch $v_1 = 1$ with local coordinates $(v_0, u_1)$ and resolve further.

At the third blow-up, we introduce a $\mathbb{P}^1$ with homogeneous coordinates $(u_2 : v_2)$ such that $u_2 v_0 - v_2 u_1 = 0$. We denote this exceptional divisor by $E_2$. In the coordinate patch $u_2 = 1$, we have $v_0 = v_2 u_1$ and the singularity becomes $W = u_1^6 v_2^2 (u_1 v_2^2 - 1)$. $W = 0$ consists of the components $E_2 = \{u_1 = 0\}$, $E_1 = \{v_2 = 0\}$ and $D = \{u_1 v_2^2 - 1 = 0\}$ which do not intersect. On the other hand, in the coordinate patch $v_2 = 1$, we have $u_1 = u_2 v_0$.
and the singularity becomes \( W = u_2^3 v_0^6 (v_0 - u_2) \). \( W = 0 \) consists of the components \( E_2 = \{ v_0 = 0 \}, E_0 = \{ u_2 = 0 \} \) and \( D = \{ v_0 - u_2 = 0 \} \) which do not intersect transversely in \( (v_0, u_2) = (0, 0) \). Hence, we focus on the patch \( v_2 = 1 \) with local coordinates \( (v_0, u_2) \) and resolve further.

At the fourth and final blow-up, we introduce a \( \mathbb{P}^1 \) with homogeneous coordinates \( (u_3 : v_3) \) such that \( u_3 v_0 - v_3 u_2 = 0 \). We denote this exceptional divisor by \( E_3 \). In the coordinate patch \( u_3 = 1 \), we have \( v_0 = v_3 u_2 \) and the singularity becomes \( W = u_2^{10} v_3^6 (v_3 - 1) \). \( W = 0 \) consists of the components \( E_3 = \{ v_0 = 0 \}, E_2 = \{ v_3 = 0 \}, D = \{ v_3 - 1 = 0 \} \) which do not intersect. On the other hand, in the coordinate patch \( v_3 = 1 \), we have \( u_2 = u_3 v_0 \) and the singularity becomes \( W = u_3^3 v_0^{10} (1 - u_3) \). \( W = 0 \) consists of the components \( E_3 = \{ v_0 = 0 \}, E_0 = \{ u_3 = 0 \} \) and \( D = \{ 1 - u_3 = 0 \} \) which do intersect transversely in \( (u_3, v_0) = (0, 0) \). Hence, we have completely resolved the singularity.

We see that \( E_0 \cap E_3 = \{ v_0 = 0, u_3 = 0 \} \), \( E_3 \cap D = \{ v_0 = 0, u_3 = 1 \} = \{ u_2 = 0, v_3 = 1 \} \) and \( E_0 \cap D = \emptyset \). Moreover, in the other patch, \( E_3 \cap E_2 = \{ u_2 = 0, v_3 = 0 \}, E_2 \cap D = \emptyset \), and \( E_0 \cap E_2 = \emptyset \). Since \( E_1 \) does not appear anymore, \( E_3 \cap E_1 = \emptyset \), its intersections can only be seen in the previous patch with coordinates \( (u_1, v_2) \) and are \( E_0 \cap E_1 = \emptyset \) and \( E_1 \cap E_2 = \{ u_1 = 0, v_2 = 0 \} \).

Now, we apply this to the divisors in the moduli space of the mirror of \( \mathbb{P}(1, 1, 1, 6, 9) \). After the first blow-up \( W = v_0^3 - y \) describes a tangency of order 3 which locally can be identified with the tangency of \( D_1 \) and \( D_{(0,1)} \). This yields \( D = D_1, E_0 = D_{(0,1)} \) with local coordinates

\[
  v_0 = 1 - \bar{z}_1, \quad y = -\bar{z}_1^3 \bar{z}_2.
\]

From this we get

\[
  u_1 = \frac{y}{v_0} = -\frac{\bar{z}_1^3 \bar{z}_2}{1 - \bar{z}_1}, \quad v_1 = \frac{v_0}{y} = -\frac{1 - \bar{z}_1}{\bar{z}_1^3 \bar{z}_2}, \\
  u_2 = \frac{u_1}{v_0} = -\frac{\bar{z}_1^3 \bar{z}_2}{(1 - \bar{z}_1)^2}, \quad v_2 = \frac{v_0}{u_1} = -\frac{(1 - \bar{z}_1)^2}{\bar{z}_1^3 \bar{z}_2}, \\
  u_3 = \frac{u_2}{v_0} = -\frac{\bar{z}_1^3 \bar{z}_2}{(1 - \bar{z}_1)^3}, \quad v_3 = \frac{v_0}{u_2} = -\frac{(1 - \bar{z}_1)^3}{\bar{z}_1^3 \bar{z}_2}.
\]
With these identifications we find for the local coordinates near the four intersections of these divisors

\[
D_1 \cap E_3 : \left( 1 + \frac{\bar{z}_1^3 \bar{z}_2}{(1 - \bar{z}_1)^3}, 1 - \bar{z}_1 \right) \\
D_{(0,1)} \cap E_3 : \left( -\frac{\bar{z}_1^3 \bar{z}_2}{(1 - \bar{z}_1)^3}, 1 - \bar{z}_1 \right) \\
E_2 \cap E_3 : \left( -\frac{\bar{z}_1^3 \bar{z}_2}{(1 - \bar{z}_1)^2}, -\frac{(1 - \bar{z}_1)^3}{\bar{z}_1^3 \bar{z}_2} \right) \\
E_1 \cap E_2 : \left( -\frac{\bar{z}_1^3 \bar{z}_2}{1 - \bar{z}_1}, -\frac{(1 - \bar{z}_1)^2}{\bar{z}_1^3 \bar{z}_2} \right).
\]

Similarly, the triple intersection \( W = u_2 v_0 (v_0 - u_2) \) after the third blow-up locally can be identified with the triple intersection of \( D_1, D_2 \) and \( D_{(-1,0)} \). For this purpose, we set

\[
u_2 = 1 - \bar{z}_2, \quad v_0 = \alpha w_1,
\]

where \( w_1 = \frac{1}{\bar{z}_1} \) and \( \alpha = w_1^2 - 3w_1 + 3 \) which is nonzero at \( w_1 = 0 \). This yields \( D = D_1, E_0 = D_2 \) and \( E_2 = D_{(-1,0)} \). From this we get (neglecting factors of \( \alpha \))

\[
u_3 = \frac{u_2}{v_0} = \bar{z}_1(1 - \bar{z}_2), \quad v_3 = \frac{v_0}{u_2} = \frac{1}{\bar{z}_1(1 - \bar{z}_2)}.
\]

Relabeling the exceptional divisor \( E_3 \) by \( E_0 \) we find for the local coordinates near the two intersection points

\[
D_1 \cap E_0 : \left( \frac{1}{\bar{z}_1^2} \left( (1 - \bar{z}_1)^3 + \bar{z}_1^3 \bar{z}_2 \right), \frac{1}{\bar{z}_1} \right) \\
D_2 \cap E_0 : \left( \bar{z}_1(1 - \bar{z}_2), \frac{1}{\bar{z}_1} \right) \\
D_{(0,1)} \cap E_0 : \left( \frac{1}{\bar{z}_1(1 - \bar{z}_2)}, 1 - \bar{z}_2 \right).
\]

This concludes the construction of the compactification of the moduli space with normal crossing divisors. We summarize the local coordinates in table 1 where we have defined \( c_\pm = \frac{1}{2} \pm i \frac{\sqrt{3}}{6} \). We give a sketch for the compactification in figure 1. The divisor \( D_{(1,-3)} \) is drawn with a dashed line since it is
not in the boundary of the moduli space. Under the action of the symmetry $I$ given in (2.9), we have

\[
I(D_{1,-2}) = E_1, \quad I(D_{1,-1}) = E_2, \quad I(D_{1,0}) = E_3,
\]
\[
I(D_1) = D_2, \quad I(D_{0,1}) = D_{0,1}, \quad I(D_{0,-1}) = D_{0,-1},
\]
\[
I(D_{-1,0}) = D_{-1,0}, \quad I(E_0) = E_0.
\]

For a sketch of the compactification in coordinates in which this symmetry becomes manifest; see [38].

4.3. Periods and flat coordinates at the boundary points

Consider the intersection points $p$ of the boundary divisors listed in table 1. We again denote the local coordinates near one of these points $p$ by $y$. For each of the first nine intersections $p$ of (the remaining ones can be obtained by applying the symmetry $I$) we determine the Gauss–Manin connection. This can be done in two ways, starting from the results at the large complex structure point reviewed in Section 2. Either one performs the change of variables from $z$ to $y$ given in this table in the PF Equation (2.10) and then reads off the connection matrix as discussed in A, or one transforms the connection matrix using the gauge transformation law for this change.
of variables. In both cases, one needs to specify a basis for $H^3(Z^*)$ near the intersection $p$. We choose it to be the same everywhere and as in (2.17) and express it in terms of differential operators acting on a period as

$$1, \quad \theta_1, \quad \theta_2, \quad \theta_1\theta_2, \quad \theta_2^2, \quad \theta_1\theta_2^2,$$

where $\theta_i = y_i \frac{\partial}{\partial y_i}$.

Once we have the connection matrices $A_i(y)$, we can determine their residues. The residues are then used in two ways. First, they allow us to compute the index of the monodromy about the divisors intersecting $p$. Second, they enter into the solutions of the PF equations as discussed in Section 2. For the residues we find (the residues for $D_{(1,0)}$ and $D_{(0,1)}$ have been displayed in (2.27))

$$\text{Res}_{D_{(1,-1)}} \sim \begin{pmatrix} 0 & 1 & 0 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & \frac{1}{3} & 0 \\ 0 & 0 & 0 & 0 & 0 & \frac{2}{3} \end{pmatrix}, \quad \text{Res}_{D_2} \sim \begin{pmatrix} 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 2 & 0 & 0 & 0 & 0 \\ 0 & 0 & 1 & 1 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 1 \end{pmatrix},$$

$$\text{Res}_{D_{(1,-2)}} \sim \begin{pmatrix} 0 & 1 & 0 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & \frac{2}{3} & 0 \\ 0 & 0 & 0 & 0 & 0 & \frac{1}{3} \end{pmatrix}, \quad \text{Res}_{E_0} \sim \begin{pmatrix} 1 & 0 & 0 & 0 & 0 & 0 \\ 0 & \frac{1}{6} & 0 & 0 & 0 & 0 \\ 0 & 0 & \frac{5}{6} & 0 & 0 & 0 \\ 0 & 0 & 0 & \frac{7}{6} & 0 & 0 \\ 0 & 0 & 0 & 0 & \frac{11}{6} & 0 \\ 0 & 0 & 0 & 0 & 0 & 1 \end{pmatrix},$$

$$\text{Res}_{D_{(-1,0)}} \sim \begin{pmatrix} \frac{1}{6} & 0 & 0 & 0 & 0 & 0 \\ 0 & \frac{5}{6} & 0 & 0 & 0 & 0 \\ 0 & 0 & \frac{1}{6} & 0 & 0 & 0 \\ 0 & 0 & 0 & \frac{5}{6} & 0 & 0 \\ 0 & 0 & 0 & 0 & \frac{1}{6} & 0 \\ 0 & 0 & 0 & 0 & 0 & \frac{5}{6} \end{pmatrix}, \quad \text{Res}_{D_{(0,-1)}} \sim \begin{pmatrix} \frac{1}{18} & 0 & 0 & 0 & 0 & 0 \\ 0 & \frac{5}{18} & 0 & 0 & 0 & 0 \\ 0 & 0 & \frac{7}{18} & 0 & 0 & 0 \\ 0 & 0 & 0 & \frac{11}{18} & 0 & 0 \\ 0 & 0 & 0 & 0 & \frac{13}{18} & 0 \\ 0 & 0 & 0 & 0 & 0 & \frac{17}{18} \end{pmatrix}.$$
We note that the monodromy matrices $\text{Res}_{D_1}$, $\text{Res}_{D_2}$ appear at the various intersection points always with an eigenvalue 1 of multiplicity 3, but the multiplicities of the eigenvalues 0 and 2 are different at different points of intersection. This does not matter here, and can easily be remedied by multiplying the basis elements (4.24) with appropriate powers of $y_i$ and taking linear combinations. We have summarized the behavior of the various monodromy matrices in Table 2. (This has first been obtained in [38]. The monodromies about $D_{(1,-1)}$ and $D_{(1,-2)}$ can be related to the one about $D_{(1,0)}$ through the local toric geometry of the compactification $\mathcal{M}$ [62].) We note here that by [38] the generators of the monodromy group $\Gamma$ are $D_{(0,-1)}$ and $D_1$. The generators of the monodromy subgroup $\Gamma_{\text{ell}}$ corresponding to the elliptic fiber are $D_{(1,0)}$ and $D_{(0,-1)}^3$.

For the solutions of the PF equations, we only give an example, for the other points the results are analogous. The local coordinates at the intersection $D_{(1,0)} \cap D_{(1,-1)}$ read

\begin{equation}
\begin{aligned}
y_1 &= -11664 \, z_1 z_2, \\
y_2 &= -\frac{1}{27} \, z_2.
\end{aligned}
\end{equation}
The residue matrices at $y_i = 0$ have been displayed in (4.25). The solutions of the PF operators take the form

\begin{align*}
\pi_0(y) &= s_0(y), \\
\pi_1(y) &= s_0 \log \left( y_1 y_2^{\frac{2}{3}} \right) + s_1(y), \\
\pi_2(y) &= s_0 \log \left( y_1 y_2^{\frac{2}{3}} \right)^2 + 2 s_1(y) \log \left( y_1 y_2^{\frac{2}{3}} \right) + s_2(y), \\
\pi_3(y) &= s_0 \log \left( y_1 y_2^{\frac{2}{3}} \right)^3 + 3 s_1(y) \log \left( y_1 y_2^{\frac{2}{3}} \right)^2 + 3 s_2(y) \log \left( y_1 y_2^{\frac{2}{3}} \right) + s_3(y), \\
\pi_4(y) &= y_2^{\frac{1}{3}} s_4(y), \\
\pi_5(y) &= y_2^{\frac{2}{3}} s_5(y),
\end{align*}

with

\begin{align*}
s_0(y) &= 1 + \frac{5}{36} y_1 y_2 + O \left( y^4 \right), \\
s_1(y) &= \frac{31}{36} y_1 y_2 + O \left( y^4 \right), \\
(4.28) \quad s_2(y) &= \frac{5}{18} y_1 y_2 + O \left( y^4 \right), \\
s_3(y) &= -y_2 + \left( -\frac{9}{40} y_2^2 - \frac{5}{6} y_1 y_2 \right) + O \left( y^3 \right),
\end{align*}

Table 2: xxx.

| $D_{(1,0)}$ | $(T - 1)^4 = 0$ |
| $D_{(0,1)}$ | $(T - 1)^3 = 0$ |
| $D_{(1,-1)}$ | $(T^3 - 1)^4 = 0$ |
| $D_{(1,-2)}$ | $(T^3 - 1)^4 = 0$ |
| $D_{(0,-1)}$ | $T^{18} - 1 = 0$ |
| $D_{(-1,0)}$ | $T^6 - 1 = 0$ |
| $D_1$ | $(T - 1)^2 = 0$ |
| $D_2$ | $(T - 1)^2 = 0$ |
| $E_0$ | $T^6 - 1 = 0$ |
| $E_1$ | $(T^3 - 1)^4 = 0$ |
| $E_2$ | $(T^3 - 1)^4 = 0$ |
| $E_3$ | $(T - 1)^4 = 0$ |
\[ s_4(y) = 1 + \frac{1}{24} y_2 + \left( \frac{4}{315} y_2^2 + \frac{5}{12} y_1 y_2 \right) + O \left( y^3 \right), \]
\[ s_5(y) = 1 + \left( -\frac{5}{18} y_1 + \frac{2}{15} y_2 \right) + O \left( y^2 \right). \]

We obtain the symplectic form \( Q \) at \( p \) in the same way as the connection matrices \( A_i \), by changing the variables in (2.22). Then, inserting the solutions \( \pi_i(y) \) yields the intersection form

\[ Q(\pi_i(y), \pi_j(y)) = \begin{pmatrix}
0 & 0 & 0 & \frac{1}{9} & 0 & 0 \\
0 & 0 & -\frac{1}{27} & 0 & 0 & 0 \\
0 & \frac{1}{27} & 0 & 0 & 0 & 0 \\
-\frac{1}{9} & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & \frac{1}{27} & 0 \\
0 & 0 & 0 & 0 & 0 & -\frac{1}{27}
\end{pmatrix}. \]

This allows us to choose the flat coordinates as follows:

\[ t_1(y) = \frac{\pi_1(y)}{\pi_0(y)} = \log \left( y_1 y_2^{\frac{5}{3}} \right) + \frac{31}{36} y_1 y_2 + O \left( y^4 \right), \]
\[ t_2(y) = \frac{\pi_4(y)}{\pi_0(y)} = y_2^{\frac{1}{3}} \left( 1 + \frac{1}{24} y_2 + O \left( y^2 \right) \right). \]

### 4.4. The partition function for small genus

Having the flat coordinates at all the intersections points \( p \) at the boundary at hand, we can proceed to apply the boundary conditions discussed in Section 3. In genus 1, we use \( c_2 J_1 = 102 \) and \( c_2 J_2 = 36 \) to fix the \( s_i \) in (3.17) to be \( s_1 = -\frac{15}{4} \), \( s_2 = -\frac{7}{6} \), and furthermore we find \( r_1 = r_2 = -\frac{1}{6} \).

For higher genus we proceed as follows. We first compute the propagators near each of the intersection points \( p \) using (3.14) and (3.15). For this purpose, we need to determine the various ingredients in these equations. Since \( C_{ijk} \) are known as a rational functions in \( z \), we can simply substitute the change of variables \( z = z(y) \). For the holomorphic limits of \( K_i \) and \( \Gamma^k_{ij} \) we use the expressions in terms of the periods at \( p \):

\[ \hat{K}(y) = -\log \pi_0(y), \quad \hat{\Gamma}^k_{ij}(y) = -\frac{\partial y_k}{\partial t_l} \frac{\partial^2 t_l}{\partial y_i y_j}. \]
where $\pi_0(y)$ is the period that appears in the denominator of the mirror map; see e.g., (4.30). Since we do not know the analytic continuation of the periods from the point of maximal unipotent monodromy $z = (0,0)$ to $p$ in general, we pull the Christoffel symbols and $K_i$ from $p$ back to $(0,0)$, still expressing them as functions of $y$, i.e.,

$$K_i(y) = z_i(y) \frac{\partial y_k}{\partial z_i} \frac{\partial}{\partial y_k} \hat{K}(y),$$

(4.32)

$$\Gamma^k_{ij}(y) = \frac{z_i(y) z_j(y)}{z_k(y)} \left( \frac{\partial z_k}{\partial y_n} \frac{\partial y_l}{\partial z_i} \frac{\partial y_m}{\partial z_j} \hat{\Gamma}^n_{lm}(y) - \frac{\partial z_k}{\partial y_l} \frac{\partial z_i}{\partial y_m} \frac{\partial z_j}{\partial y_n}(y) \right).$$

The ambiguities are simply obtained by substituting $z = z(y)$ in the rational functions determined in Section 4.1. This yields all the information needed to determine the propagators at all the intersection points $p$.

In the next step, we make an ansatz for $F^{(g)}$, $g \geq 2$, as a polynomial of degree $3g - 3$ in formal variables $S^{ij}, S^i, S, K_i$ with weights $1, 2, 3, 1$, respectively. Then we compute both sides of the holomorphic anomaly equation (3.12) and compare the coefficients of $1, K_i, K_i K_j$. This yields equations for the coefficients in the ansatz of the polynomial $F^{(g)}$. The solution to this overdetermined system of equations is unique up to a constant which can be absorbed into the holomorphic ambiguity (3.24). To determine the latter, we make an ansatz for the numerator $p^{(g)}(z)$ as a series in $z$, i.e., near the point of maximal unipotent monodromy. Then we run through all the intersection points $p \in \bigcap_{j \in J} D_j, J \subset I, |J| = \dim \mathcal{M}$. In our example, these are the first nine intersection points in Table 1. For each of these points we substitute the propagators computed in the previous paragraph for the variables $S^{ij}, S^i, S, K_i$ into the polynomial expression of $F^{(g)}$. Finally, we compute the expansion in terms of the flat coordinates $t = t(y)$ at each point $p$:

$$F^{(g)}(t) = \frac{1}{\pi_0(y(t))^2} F^{(g)}(y(t)), \quad \text{(4.33)}$$

where $\pi_0(t)$ is again the period that appears in the denominator of the definition of the flat coordinates. To each of these expansions we then apply our discussion of the boundary conditions in Section 3.4.

In our example, we see from Table 2 that $D_{(0,-1)}, D_{(-1,0)},$ and $E_0$ are of orbifold type, while $D_1$ and $D_2$ are of conifold type. The condition that $F^{(g)}$ be regular at a divisor with finite monodromy, i.e., at $D_{(0,-1)}$, and $D_{(-1,0)}$
ensures that the holomorphic function $p^{(g)}(z)$ is a polynomial. The degrees $(d_1, d_2)$ of its monomials are bounded by

\[(4.34) \quad d_1 \leq 7(g - 1), \quad d_2 \leq 6(g - 1) - 1, \quad 3d_2 - d_1 \leq 9(g - 1).\]

In addition, regularity at $D_{(1,-1)}$ fixes the coefficients of the monomials in $p^{(g)}(z)$ with degrees $3d_2 - d_1 > 3(2g - 2)$, while regularity at $D_{(-1,0)}$ fixes those with $d_1 > 6(g - 1)$. The divisor $E_0$ does not yield additional conditions. In particular, the holomorphic ambiguity takes now the form of a rational function, for which we can now substitute $z = z(y)$ if necessary.

Since $D_1$ and $D_2$ are of conifold type, we can use the expansion (3.22). In order to do so, we have to take into account that the flat coordinates $t_1, t_2$ obtained from process described in Section 4.3 are only determined up to normalization. Hence we expect relations $t_i = k_i t_{c,i}$, $i = 1, 2$, where $t_{c,i}$ are the flat coordinates in the expansion (3.22). The gap condition for this expansion yields an overdetermined system of relations among the remaining coefficients of $p^{(g)}(z)$. For low genus, this system has a unique solution depending only on the parameter $k_1$. This normalization factor could in principle be determined by an explicit analytic continuation of the periods $\pi(z)$ at the point of maximal unipotent monodromy to the periods $\pi(y)$ at $D_1 \cap D_2$, though this is highly complicated.

Finally, at the point of maximal unipotent monodromy $D_{(0,1)} \cap D_{(1,0)}$ we can apply the Gopakumar–Vafa (GV) expansion [3]:

$$\mathcal{F}(Z, t, \lambda) = \frac{c(t)}{\lambda^2} + l(t) + \sum_{\beta} \sum_{m > 0} \sum_{r \geq 0} \frac{1}{m} n^{(g)}_{\beta}(Z) \left(2 \sin \left(\frac{m\lambda}{2}\right)\right)^{2g-2} q^{m \beta},$$

where $c(t)$ and $l(t)$ are a cubic and linear polynomials, respectively, depending on topological invariants of $Z$. Using the fact that there are no degree 1 curves of genus 2 in the base, $n^{(2)}_{0,1} = 0$ allows us to determine $k_1$ as well. Moreover, the constant term of $\mathcal{F}^{(g)}$ is determined by (3.21).

For genus $g = 2, 3$ all these conditions lead to a unique solution for the coefficients in the ansatz of $p^{(g)}$. It turns out that considering all the divisors at all the intersection points yields a lot of redundant information. Unless we have better understanding of the boundary behavior of the $\mathcal{F}^{(g)}$ it is not clear how to improve this procedure to minimize the number of computations. The resulting GV invariants $n^{(g)}_{\beta}$ are listed in C. The resulting expressions
for the ambiguities $f^{(2)}(z)$ and $f^{(3)}(z)$ can be found in B. For $g > 3$ the computations turn out to be too involved. Moreover, we expect that the boundary conditions known so far will not be sufficient to fix the holomorphic ambiguity. We observe that the $F^{(g)}$ also show a particular behavior at the other boundary divisors $D_i$, however, it is not possible to give a precise formulation of this behavior just from the resulting series expansion.

4.5. Recursion in terms of modular forms of $\text{SL}(2, \mathbb{Z})$

Having computed the topological string partition function up to genus 3 we proceed in the following with exploring the manifestation of the $\text{SL}(2, \mathbb{Z})$ subgroup of the modular group. To do so we examine the large complex structure expansion of $F^{(g)}$ in terms of the special coordinates. We need further to choose a section of the corresponding line bundle $\mathcal{L}^{2-2g}$. We do so by fixing the gauge $\pi_0(z) = 1$, where $\pi_0$ is the analytic solution at large complex structure given in Equation (A.7). The special, flat coordinates in this patch of moduli space are given by

\begin{align}
t_E := t_1 &= \frac{\pi_1}{\pi_0}, & t_B := t_2 &= \frac{\pi_2}{\pi_0}, & q_E := q_1 &= e^{2\pi i t_1}, & q_B := q_2 &= e^{2\pi i t_2},
\end{align}

where the periods $\pi_i$ are given in A. We consider the functions

\begin{align}
F^{(g)}(t_E, t_B) = \pi_0(z(t))^{2g-2} F^{(g)}(z(t)),
\end{align}

and expand these in the exponentiated base modulus $q_B$:

\begin{align}
F^{(g)}(t_E, t_B) = \sum_n f_n^{(g)}(t_E) q_B^n = \sum_n \frac{1}{n!} \frac{\partial^n F^{(g)}}{\partial q_B^n} \bigg|_{q_B=0} q_B^n,
\end{align}

our Conjecture 1.1 then states that the $f_n^{(g)}$ can be written as

\begin{align}
f_n^{(g)} = P_n^{(g)}(E_2, E_4, E_6) \frac{q_E^{3n/2}}{\Delta^{3n/2}},
\end{align}

where $P_n^{(g)}$ denotes a quasi-modular form constructed out of the Eisenstein series $E_2, E_4, E_6$ of weight $2g + 18n - 2$. The structure and weights of this quasi-modular form was made as an ansatz guided by similar results for the
canonical bundle over the $\frac{1}{2}$ K3 surface in [13, 14]. The link between the geometries considered there and our example is the geometry of an elliptic fibration over a Hirzebruch surface $F_1$, which was considered in [63]. In that geometry, it is possible to take a limit in the Kähler moduli space which leads to the non-compact geometry of the canonical bundle over the $\frac{1}{2}$ K3, in a different limit, it is furthermore possible to extract expressions for the elliptic genera of a K3 surface [67], which are modular forms in $E_4$ and $E_6$. The compact elliptic fibration over $\mathbb{P}_2$, which we consider here, can be considered as another limit of the same geometry, where $F_1$ is blown down to $\mathbb{P}_2$. We confirm this ansatz by computing higher genus topological string amplitudes using their polynomial structure in terms of special geometry generators as discussed in Section 4.4. Expanding the resulting expressions as in Equation (4.37), we confirm our conjecture for all the $f^{(g)}_n$ which we computed. Some examples of these are given in Appendix (D.2). We furthermore find that the $f^{(g)}_n$ satisfy the following recursion:

$$
\frac{\partial f^{(g)}_n}{\partial E_2} = -\frac{1}{24} \sum_{h=0}^{g-1} \sum_{s=1}^{n-1} s(n-s)f^{(h)}_s f^{(g-h)}_{n-s} + \frac{n(3-n)}{24} f^{(g-1)}_n.
$$

This recursion is analogous to a recursion which was conjectured for higher genus in [13, 14]. The geometry considered in these works was that of a $\frac{1}{2}K_3$. The recursion at genus 0 was motivated by a recursion in the BPS state counting of the non-critical string [12, 21, 22] and its relation to the prepotential of the geometry used to construct these [63].

The recursion at genus zero can be verified explicitly either from the construction of the polynomial expressions from integrals of the underlying Seiberg–Witten-type curve [21, 22] or from the properties of the PF equations [13]. The higher genus version of the equation is verified for low genera by the explicit construction of the polynomials. In particular, the explicit knowledge of the holomorphic ambiguities $f^{(2)}$ and $f^{(3)}$ allow us to determine the $E_2$ independent part of the polynomials $P^{(g)}_n$ which is not determined by (4.38). Moreover, the higher genus version is conjectured to be equivalent to the BCOV anomaly equation [14, 50]. In the following, we want to relate qualitatively Equation (4.38) to the anomaly equations for the amplitudes with insertions in its polynomial form (3.12), and (3.13).

---

8More recently this geometry has also been studied in [68].
We work with the coordinates centered at large complex structure $z_1$ and $z_2$ and consider the free energy with $n$ insertions w.r.t $z_2$:

$$F_n^{(g)} := (\pi_0)^{2g-2} F^{(g)}_{\bar{z}_2 \ldots \bar{z}_2}$$

since $z_2$ is not the flat coordinate, the insertions are defined using covariant derivatives on $T^* M$. We will use however that $z_2 = q_2 + \cdots$ and hence to leading order derivatives w.r.t $q_2$ are captured by the amplitudes with insertions w.r.t $z_2$.

We are now interested in the appearance of $E_2$ in the $q_2 \to 0$ limit in the polynomial generators of the full problem, we find an occurrence in two of the generators:\footnote{Since $S^{22}$ is a section of $L^{-2}$ we fix a section by multiplying by $\pi_0^2$, we moreover have $\pi_0|_{q_2=0} = E_4^{1/4}$.}

\begin{align*}
(4.39) & \quad \left( \frac{S^{22}}{z_2^2} \right) |_{q_2=0} = -\frac{1}{12} E_2 + E_4^{1/2} + \frac{1}{12} E_6, \\
(4.40) & \quad K_1 |_{q_2=0} = \frac{E_4^{3/2}}{\Delta} (E_2 E_4 - E_6).
\end{align*}

We hence have

\begin{equation}
(4.41) \quad \left. \frac{\partial F_n^{(g)}}{\partial E_2} \right|_{q_2=0} = \left( \frac{\partial F_n^{(g)}}{\partial S^{22}} \frac{\partial S^{22}}{\partial E_2} + \frac{\partial F_n^{(g)}}{\partial K_1} \frac{\partial K_1}{\partial E_2} \right) |_{q_2=0},
\end{equation}

the two terms on the r.h.s can be computed from Equations (3.12) and (3.13). The second of which vanishes in this case due to the vanishing of the Kähler metric $G_{\bar{1}2}$ on the r.h.s of Equation (3.13) in the limit $q_2 \to 0$.

We therefore have from (3.12):

\begin{equation}
(4.42) \quad \frac{\partial F_n^{(g)}}{\partial S^{22}} = \frac{1}{2} \sum_{h=0}^{g} \sum_{s=0}^{n} D_2 F_s^{(h)} D_2 F_{n-s}^{(g-h)} + \frac{1}{2} D_2 D_2 F_n^{(g-1)}
\end{equation}

and furthermore:

\begin{equation}
(4.43) \quad \left. \frac{\partial F_n^{(g)}}{\partial E_2} \right|_{q_2=0} = -\frac{z_2^2}{24} \left( \sum_{h=0}^{g} \sum_{s=0}^{n} D_2 F_s^{(h)} D_2 F_{n-s}^{(g-h)} + D_2 D_2 F_n^{(g-1)} \right) |_{q_2=0}.
\end{equation}
We further compute 

\[ z_2 \Gamma_{22}^2 |_{q_2=0} = -1 \]

and note that

\[ z_2 D_2 F_n^{(g)} |_{q_2=0} = \left( \theta_2 F_n^{(g)} - n z_2 \Gamma_{22}^2 F_n^{(g)} \right) |_{q_2=0} = n \left( F_n^{(g)} \right) |_{q_2=0}. \]

Relating the \( f_n^{(g)} \sim F_n^{(g)} |_{q_2=0} \) it is possible to see the characteristic traits of Equation (4.38). Due to the multiplication with \( z_2^2 \) the non-vanishing contribution of the first term on the r.h.s of (4.43) is coming from the product of the connections with prefactor \( s(n - s) \), from the second term, a contribution of \( n(n + 1) \) is coming from the contribution of the product of the two connections. Further contributions come from derivatives acting on the connections. This completes our qualitative relation of refined recursion (4.38) to the polynomial form of the holomorphic anomaly equation with insertions (3.12). A more thorough matching of the two equations is beyond the scope of this work and will be discussed elsewhere.

### 4.6. Further examples

The expansion (4.38) also holds for other elliptic fibrations. We present here some more examples. The first is a section of the anti-canonical bundle over the resolved weighted projective space \( \mathbb{P}(1,1,1,3,6) \). The charge vectors for this geometry are given by:

\[
(l^1) = (-4, 2, 1, 1, 0, 0, 0),
\]

\[
(l^2) = (0, 0, 0, -3, 1, 1, 1).
\]

If we take the derivative with respect to \( E_2(2\tau) \) instead of \( E_2(\tau) \), then (4.38) holds with the first initial condition given as

\[
f_1^{(0)} = \frac{3}{8} F_2 G_2^3 \left( 16 F_2^4 - 51 F_2^2 G_2^2 + 51 G_2^4 \right) \Delta^{-3/2},
\]

where \( F_2 \) and \( G_2 \) are modular forms of weight 2 and generate the ring of modular forms for \( \Gamma(2) \). They can be expressed in terms of Jacobi theta functions as

\[
F_2(\tau) = \theta_2(\tau)^4 + \theta_3(\tau)^4,
\]

\[
G_2(\tau) = \theta_2(\tau)^4 - \theta_3(\tau)^4.
\]
The same is true, if we consider a section of the anti-canonical bundle over the resolved weighted projective space \( \mathbb{P}(1,1,1,3,3) \) whose charge vectors are

\[
(l^1) = (-3 \ 1 \ 1 \ 1 \ 0 \ 0 \ 0), \\
(l^2) = (0 \ 0 \ 0 \ -3 \ 1 \ 1 \ 1).
\]

Taking the derivative with respect to \( E_2(3\tau) \) instead of \( E_2(\tau) \), then (4.38) holds with initial condition

\[
f_1^{(0)} = 9 E_1 \left( E_1^6 - 87 F_3 E_1^3 + 2349 F_3^2 \right) \left( E_1^3 - 27 F_3 \right)^{3} \Delta^{-3/2},
\]

where \( E_1 \) and \( F_3 \) are modular forms of weight 1 and 3, respectively, and generate the ring of modular forms for \( \Gamma_1(3) \). They can be expressed in terms of the Dedekind eta functions as

\[
E_1(\tau) = \frac{(\eta(\tau)^{12} + 27\eta(3\tau)^{12})^{\frac{1}{3}}}{\eta(\tau)\eta(3\tau)}, \\
F_3(\tau) = \frac{\eta(3\tau)^9}{\eta(\tau)^3}.
\]

Another elliptic fibration whose associated congruence subgroup is \( \Gamma_1(3) \) is the degree \((3,3)\) hypersurface in \( \mathbb{P}^2 \times \mathbb{P}^2 \). Its charge vectors are

\[
(l^1) = (-3 \ -2 \ -2 \ 1 \ 1 \ 1 \ 1 \ 0 \ 0 \ 0 \ 0), \\
(l^2) = (0 \ 0 \ 0 \ 0 \ -3 \ 1 \ 1 \ 1 \ 1).
\]

and the first initial condition for the recursion is

\[
F_1^{(0)} = 27 E_1 \left( 7 E_1^3 + 54 F_3 \right) \Delta^{-1/2}.
\]

A similar example as (4.44) and (4.47) is a complete intersection of two sections of the anti-canonical bundle over the resolved weighted projective space \( \mathbb{P}(1,1,1,3,3,3) \) whose charge vectors are

\[
(l^1) = (-2 \ -2 \ -2 \ 1 \ 1 \ 1 \ 1 \ 0 \ 0 \ 0 \ 0 \ 0), \\
(l^2) = (0 \ 0 \ 0 \ 0 \ 0 \ -3 \ 1 \ 1 \ 1 \ 1).
\]
Taking the derivative with respect to $E_2(4\tau)$ instead of $E_2(\tau)$, then (4.38) holds with initial condition

$$f_1^{(0)} = 3E_1^3F_1^9 \left(4E_1^4 - 13E_1^2F_1^2 + 13F_1^4\right) \Delta^{-3/2},$$

where $E_1$ and $F_1$ are modular forms of weight 1, and generate the ring of modular forms for $\Gamma_1(4)$. They can be expressed in terms of the Dedekind eta functions as

$$E_1(\tau) = \frac{(\eta(\tau)^8 + 16\eta(4\tau)^8)^{1/2}}{\eta(2\tau)^2},$$

$$F_1(\tau) = \frac{\eta(\tau)^4}{\eta(2\tau)^2}.$$

The argument of the previous subsection also applies to elliptic fibrations over Hirzebruch surfaces $\mathbb{F}_n$, $n = 0, 1, 2$. They have more than one base modulus. For example, the elliptic fibration given by the charge vectors

$$\begin{align*}
(l^1) &= (-6 \ 3 \ 2 \ 1 \ 0 \ 0 \ 0 \ 0), \\
(l^2) &= (0 \ 0 \ 0 \ -2 \ 1 \ 1 \ 0 \ 0), \\
(l^3) &= (0 \ 0 \ 0 \ -2 \ 0 \ 0 \ 1 \ 1),
\end{align*}$$

has base $\mathbb{F}_0$. In this case, the recursion (4.38) takes the following form:

$$\frac{\partial f_{m,n}^{(g)}}{\partial E_2} = -\frac{1}{24} \left(2mn - 2m - 2n\right) f_{m,n}^{(g-1)}$$

$$+ \frac{1}{24} \sum_{h=0}^{g} \sum_{s=0}^{m} \sum_{t=0}^{n} \left(s(n-t) + t(m-s)\right) f_{s,t}^{(g-h)} f_{m-s,n-t}^{(h)}$$

with first initial condition

$$f_{0,1}^{(0)} = -2 \frac{E_4E_6}{\Delta}.$$
Next, we consider an elliptic fibration over the Hirzebruch surface $\mathbb{F}_1$ which has two phases. In the phase with charge vectors

\begin{align*}
(l^1) &= (-6 \ 3 \ 2 \ 1 \ 0 \ 0 \ 0 \ 0), \\
(l^2) &= (0 \ 0 \ 0 \ -2 \ 1 \ 1 \ 0 \ 0), \\
(l^3) &= (0 \ 0 \ 0 \ -1 \ 0 \ -1 \ 1 \ 1)
\end{align*}

the recursion turns out to be

\begin{align*}
\frac{\partial f_{m,n}^{(q)}}{\partial E_2} &= -\frac{1}{24} \left( 2mn - 2m - n - n^2 \right) f_{m,n}^{(q-1)} \\
&\quad + \frac{1}{24} \sum_{h=0}^{g} \sum_{s=0}^{m} \sum_{t=0}^{n} (2t(n-t) - s(n-t) - t(m-s)) f_{s,t}^{(q-h)} f_{m-s,n-t}^{(h)}
\end{align*}

with first initial conditions

\begin{align*}
f_{0,0}^{(0)} &= \frac{E_4}{\Delta^{1/2}}, \\
f_{1,0}^{(0)} &= -2 \frac{E_4 E_6}{\Delta}.
\end{align*}

In this case, the quasi-modular form $P_{m,n}^{(g)}(E_2, E_4, E_6)$ has weight $2g - 2 + 12m + 6n$. The modularity of $f_{0,1}^{(0)}$ has been analyzed in detail in [63].

Finally, for the elliptic fibration over $\mathbb{F}_2$ given by the charge vectors

\begin{align*}
(l^1) &= (-6 \ 3 \ 2 \ 1 \ 0 \ 0 \ 0 \ 0), \\
(l^2) &= (0 \ 0 \ 0 \ -2 \ 1 \ 1 \ 0 \ 0), \\
(l^3) &= (0 \ 0 \ 0 \ 0 \ 0 \ -2 \ 1 \ 1)
\end{align*}

we find that the recursion turns out to be

\begin{align*}
\frac{\partial f_{m,n}^{(q)}}{\partial E_2} &= -\frac{1}{24} \left( 2mn - 2m - 2n^2 \right) f_{m,n}^{(q-1)} \\
&\quad + \frac{1}{24} \sum_{h=0}^{g} \sum_{s=0}^{m} \sum_{t=0}^{n} (2t(n-t) - s(n-t) - t(m-s)) f_{s,t}^{(q-h)} f_{m-s,n-t}^{(h)}
\end{align*}
with first initial conditions

\begin{align}
\tag{4.63}
&f_{1,0}^{(0)} = -2 \frac{E_4 E_6}{\Delta}, \quad f_{0,1}^{(0)} = 0.
\end{align}

In this case, the quasi-modular form $P_{m,n}^{(g)}(E_2, E_4, E_6)$ has weight $2g - 2 + 12m$.

As last example, we consider Schoen’s CY, i.e., a complete intersection of two equations of degrees $(3, 1, 0)$ and $(0, 1, 3)$, respectively, in $\mathbb{P}^2 \times \mathbb{P}^1 \times \mathbb{P}^2$, i.e., the charge vectors are

\begin{align}
\tag{4.64}
(l_1) &= (-3, 0, 1, 1, 1, 0, 0, 0, 0, 0), \\
(l_2) &= (-1, -1, 0, 0, 0, 1, 1, 0, 0, 0), \\
(l_3) &= (0, -3, 0, 0, 0, 0, 0, 1, 1, 1).
\end{align}

This is an elliptic fibration over the rational elliptic surface dP$_9$ studied in detail in [64] (see also [65]). For simplicity, we have restricted the Kähler classes of the rational elliptic surface to the class of the fiber and the section. The recursion turns out to be

\begin{align}
\tag{4.65}
\frac{\partial f_{m,n}^{(g)}}{\partial E_2} &= -\frac{1}{24} \left( 9mn + 3n^2 - 3n \right) f_{m,n}^{(g-1)} \\
&\quad + \frac{1}{24} \sum_{h=0}^{g} \sum_{s=0}^{m} \sum_{t=0}^{n} \left( -s(n-t) - t(m-s) \right) f_{s,t}^{(g-h)} f_{m-s,n-t}^{(h)}
\end{align}

with first initial conditions

\begin{align}
\tag{4.66}
&f_{1,0}^{(0)} = 81 \frac{1}{\Delta_{1/6}}, \quad f_{0,1}^{(0)} = 0.
\end{align}

In this case, the quasi-modular form $P_{m,n}^{(g)}(E_2, E_1, F_1)$ for $\Gamma_1(3)$ has weight $2g - 2 + 2m$ with $E_1$ and $F_1$ given in (4.49). The modularity of $f_{1,0}^{(0)}$ has been proven in [66].
5. Conclusions

In this work, we studied topological string theory and mirror symmetry on an elliptically fibered CY. We computed higher genus amplitudes for this geometry using their polynomial structure and appropriate boundary conditions. The implementation of the boundary conditions required the use of techniques to single out the preferred coordinates on the deformation space of complex structures on the B-model side of topological strings. To do this we used the Gauss–Manin connection and the special, flat coordinates which could be found in various loci in the moduli space. At the large volume limiting point on the A-side which is mirror to the B-model large complex structure limit, the topological string free energies reduce to the Gromov–Witten generating functions allowing us thus to make predictions for these invariants at genus 2 and 3 in their resumed version giving the GV integer BPS degeneracies.

Having computed the higher genus topological string amplitudes we showed that these carry an additional interesting structure which exhibits the elliptic fibration. Namely the order by order expansion in terms of the moduli of the base of the elliptic fibration can be expressed in terms of the characteristic modular forms of $\text{SL}(2, \mathbb{Z})$ which is a subgroup of the full modular group due to the elliptic fibration. Along with this refined expansion in terms of $E_2, E_4$ and $E_6$ we found a refined anomaly equation which could be related to the holomorphic anomaly equations of BCOV for the correlation functions. This type of anomaly is the analog of an anomaly which was studied in the study of BPS states of exceptional non-critical strings [12, 21, 22] which are captured by the prepotential of the geometry used in their construction [63]. It was furthermore shown in [12] that this anomaly is related to an anomaly found in the study of partition functions of $\mathcal{N} = 4$ topological SYM theory [69]. The anomaly for the that latter theory on $\mathbb{P}^2$ found in [69] marks the first physical appearance of what became to be know as mock modular forms (see [70] for an introduction). The relation of the non-holomorphicity of mock modular forms and the recursion at genus 0 was further studied in [67, 71–73]. The recursion found in this work (4.38) is expected to shed more light on the higher rank $\mathcal{N} = 4$ topological SYM theory on $\mathbb{P}^2$, since the main example of this paper is an elliptic fibration over $\mathbb{P}^2$ and the elliptic fibration structure is the analogous setup to [12].
It would be furthermore interesting to give the higher genus amplitudes an interpretation in the SYM theory.

Acknowledgments

We would like to thank S. Hosono, D. van Straten, K. Wendland and Timm Wrase for helpful discussions. We would furthermore like to thank A. Klemm, J. Manschot and T. Wotschke for coordinating the submission of their work. M.A. would like to thank Michael Hecht, Dominique Länge and Peter Mayr for discussions and collaborations on related projects, where the recursion discussed in this paper was first observed. M.A. is supported by the DFG fellowship AL 1407/1-1.

Appendix A. Gauss–Manin connection matrices

The vector \( w(z) \) with \( 2h^{2,1} + 2 \) components:

\[
(A.1) \quad w(z) = (\Omega(z), \theta_1 \Omega(z), \theta_2 \Omega(z), \theta_1 \theta_2 \Omega(z), \theta_1^2 \Omega(z), \theta_2^2 \Omega(z))^t.
\]

was picked such that its entries span the filtration quotient groups \((F^3, F^2/F^3, F^1/F^2, F^0/F^1)\) of respective orders \((1, h^{2,1}, h^{2,1}, 1)\). Further multi-derivatives of \( \Omega(z) \) can be expressed in terms of the elements of this vector using the PF equations, derivatives and linear combinations thereof. We find the following relation for the remaining double derivative:

\[
(A.2) \quad \theta_1^2 = \frac{3 (\theta_2 \theta_1 + 144 z_1 \theta_1 + 20 z_1)}{\Delta_3},
\]

as well as relations for the triple derivatives, for example:

\[
\theta_1^3 = \frac{3 (164 z_1 \theta_1 + 53568 z_1^2 \theta_1 + 20 z_1 + 1296 \theta_2 \theta_1 z_1 + 8640 z_1^2 + 3 \theta_2^2 \theta_1 + 60 \theta_2 z_1)}{\Delta_3^2},
\]

\[
(A.3) \quad \theta_1^2 \theta_2 = \frac{3 \theta_2 (20 z_1 + 144 z_1 \theta_1 + \theta_1 \theta_2)}{\Delta_3}.
\]
The fourth-order derivatives can be expressed in terms of the Gauss–Manin connection acting on the period matrix:

\[(\theta_i - A_i(z)) \Pi(z)_{\beta}^\alpha = 0, \quad i = 1, \ldots, h^{2,1},\]

In the following, we give these matrices at the large complex complex structure limit for the example discussed in this work:

\[
A_1(z) = \begin{pmatrix}
0 & 1 & 0 & 0 & 0 & 0 \\
\frac{60z_1}{\Delta_3} & \frac{432z_1}{\Delta_3} & 0 & \frac{3}{\Delta_3} & 0 & 0 \\
0 & 0 & 0 & 1 & 0 & 0 \\
0 & 0 & \frac{60z_1}{\Delta_3} & \frac{432z_1}{\Delta_3} & 0 & \frac{3}{\Delta_3} \\
0 & 0 & 0 & 0 & 0 & 1
\end{pmatrix},
\]

\[
A_2(z) = \begin{pmatrix}
0 & 0 & 1 & 0 & 0 & 0 \\
0 & 0 & 0 & 1 & 0 & 0 \\
0 & 0 & 0 & 0 & 1 & 0 \\
0 & 0 & 0 & 0 & 0 & 1 \\
\frac{a_6}{\Delta_3^2 \Delta_2} & \frac{a_7}{\Delta_3^2 \Delta_2} & \frac{a_8}{\Delta_3^2 \Delta_2} & \frac{a_9}{\Delta_3^2 \Delta_2} & -\frac{27z_2}{\Delta_2} & \frac{a_9}{\Delta_3^2 \Delta_2} \\
\frac{a_1}{\Delta_1} & \frac{a_2}{\Delta_1} & \frac{a_3}{\Delta_1} & \frac{a_3}{\Delta_1} & \frac{60z_1a_9}{\Delta_1} & \frac{a_{10}}{\Delta_1}
\end{pmatrix}.
\]

with

\[
a_1 = 720 z_1^2 z_2 (5 + 91152 z_1),
\]
\[
a_2 = -12 z_2 z_1 (5 - 12960 z_1 - 35645184 z_1^2),
\]
\[
a_3 = 180 z_2 z_1 (1 - 2160 z_1 + 1679616 z_1^2),
\]
\[
a_4 = -36 z_2 z_1 (5 - 8640 z_1 - 71103744 z_1^2),
\]

(A.6)
\[ a_5 = 432 z_1 (\Delta_1(z) + 30233088 z_1^2 z_2), \]
\[ a_6 = -120 z_1 z_2 (1 - 864 z_1), \]
\[ a_7 = -2 z_2 (1 - 1266 z_1 + 546912 z_1^2), \]
\[ a_8 = -6 z_2 (1 - 804 z_1 + 147744 z_1^2), \]
\[ a_9 = 9 z_2 (1 - 1296 z_1 + 559872 z_1^2), \]
\[ a_{10} = 4353564672 z_1^3 z_2. \]

A fundamental solution is given by
\[ \pi_0(z) = s_0(z), \]
\[ \pi_1(z) = s_0(z) \log z_1 + s_1(z), \]
\[ \pi_2(z) = s_0(z) \log z_2 + s_2(z), \]
\[ \pi_3(z) = s_0(z) \left( \frac{9}{2} (\log z_1)^2 + 3 \log z_1 \log z_2 \right) + s_1(z) \log z_2 + s_2(z) \log z_1 + s_3(z), \]
\[ \pi_4(z) = s_0(z) \left( \frac{9}{2} (\log z_1)^2 + 3 \log z_1 \log z_2 + \frac{1}{2} (\log z_2)^2 \right) + s_2(z) (3 \log z_1 + \log z_2) + s_4(z), \]
\[ \pi_5(z) = s_0(z) \left( \frac{3}{2} (\log z_1)^3 + \frac{3}{2} (\log z_1)^2 \log z_2 + \frac{1}{2} \log z_1 (\log z_2)^2 \right) + \frac{s_1(z)}{2} (\log z_2)^2 + s_2(z) \left( \frac{3}{2} (\log z_1)^2 + \log z_1 \log z_2 \right) + s_3(z) \log z_2 + s_4(z) \log z_1 + s_5(z), \]

where
\[ s_0(z) = 1 + \frac{5}{36} z_1 + \frac{385}{5184} z_1^2 + O(z^3), \]
\[ s_1(z) = \frac{13}{18} z_1 - \frac{2}{27} z_2 + \frac{719}{1728} z_1^2 - \frac{5}{243} z_2^2 + \frac{5}{972} z_2 z_1 + O(z^3), \]
\[ s_2(z) = \frac{5}{12} z_1 + \frac{2}{9} z_2 + \frac{385}{1152} z_1^2 + \frac{5}{81} z_2^2 - \frac{5}{324} z_2 z_1 + O(z^3), \]
\[ s_3(z) = -\frac{1}{3} z_2 + \frac{13}{4} z_1^2 - \frac{47}{324} z_2^2 + O(z^3), \]
\[ s_4(z) = \frac{15}{4} z_1 + \frac{10183}{768} z_1^2 + O(z^3), \]
\[ s_5(z) = -\frac{15}{2} z_1 + \frac{2}{3} z_2 - \frac{965}{256} z_1^2 + \frac{13}{108} z_2^2 - \frac{5}{108} z_2 z_1 + O(z^3). \]
Appendix B. Holomorphic ambiguity

(B.1) \[ f^{(2)}(z) = \frac{1}{155520} \left( -111885 \, \bar{z}_1 + 25523 \, \bar{z}_2 + 671310 \, \bar{z}_1^2 + 111447 \, \bar{z}_2 \bar{z}_1 \right. \]

\[ - 56842 \, \bar{z}_2^2 - 1678275 \, \bar{z}_1^3 - 1204665 \, \bar{z}_2 \bar{z}_1^2 + 148602 \, \bar{z}_2^2 \bar{z}_1 + 29375 \, \bar{z}_2^3 \]

\[ + 2237700 \, \bar{z}_1^4 + 3455528 \, \bar{z}_2 \bar{z}_1^3 + 302070 \, \bar{z}_2^2 \bar{z}_1^2 - 136500 \, \bar{z}_2^3 \bar{z}_1 - 1678275 \, \bar{z}_1^5 - 5125329 \, \bar{z}_2 \bar{z}_1^4 - 1693290 \, \bar{z}_2^2 \bar{z}_1^3 + 202125 \, \bar{z}_2^3 \bar{z}_1^2 \]

Appendix D. Modular forms

D.1. Definitions

We summarize the definitions of the modular objects appearing in this work.

\( \eta(\tau) = q^{\frac{1}{24}} \prod_{n=1}^{\infty} (1 - q^n), \quad \Delta(\tau) = \eta(\tau)^{24} \) \hspace{1cm} (D.1)

and transforms according to

\( \eta(\tau + 1) = e^{i\frac{\pi}{12}} \eta(\tau), \quad \eta\left(-\frac{1}{\tau}\right) = \sqrt{\frac{\tau}{i}} \eta(\tau). \) \hspace{1cm} (D.2)

The Eisenstein series are defined by

\( E_k(\tau) = 1 - \frac{2}{B_k} \sum_{n=1}^{\infty} \frac{n^{k-1}q^n}{1 - q^n}, \) \hspace{1cm} (D.3)

where \( B_k \) denotes the \( k \)-th Bernoulli number. \( E_k \) is a modular form of weight \( k \) for \( k > 2 \) and even. The discriminant form is

\( \Delta(\tau) = \frac{1}{1728} (E_4(\tau)^3 - E_6(\tau)^2) = \eta(\tau)^{24}. \) \hspace{1cm} (D.4)

The modular completion of the holomorphic Eisenstein series \( E_2 \) has the form

\( \hat{E}_2(\tau) = E_2(\tau) - \frac{3}{\pi \text{Im} \tau}. \) \hspace{1cm} (D.5)

D.2. Expansions of \( f_n^{(g)} \)

\( f_1^{(0)} = \frac{1}{48} \Delta^{-\frac{3}{2}} E_4 \left(113 E_6^2 + 31 E_4^3\right), \) \hspace{1cm} (D.6)

\( f_2^{(0)} = \frac{1}{221184} \Delta^{-3} \left( E_4 E_6 \right. \right. \\
\left. \times \left( 196319 E_6^4 + 755906 E_6^2 E_4^3 + 208991 E_4^6 \right) \right. \\
