A dynamic systems approach to fermions and their relation to spins

Zoltán Zimborás1,2,3, Robert Zeier4*, Michael Keyl1,5 and Thomas Schulte-Herbrüggen4

Abstract
The key dynamic properties of fermionic systems, like controllability, reachability, and simulability, are investigated in a general Lie-theoretical frame for quantum systems theory. It just requires knowing drift and control Hamiltonians of an experimental set-up. Then one can easily determine all the states that can be reached from any given initial state. Likewise all the quantum operations that can be simulated with a given set-up can be identified. Observing the parity superselection rule, we treat the fully controllable and quasifree cases of fermions, as well as various translation-invariant and particle-number conserving cases. We determine the respective dynamic system Lie algebras to express reachable sets of pure (and mixed) states by explicit orbit manifolds.

Keywords: quantum simulation; control theory; fermionic systems; spin chains

1 Introduction
The vast experimental progress in implementing coherent control of ultra-cold gases including fermionic systems [1–6] has also great impact on quantum simulation (e.g., [7]) of quantum phase transitions [8, 9], pairing phenomena [10], and in particular for understanding phases in Hubbard models [11]. Moreover, digital quantum simulation of fermionic systems has come into focus [12–16]. For either way of quantum simulation, there are important algebraic aspects going beyond the standard textbook approach [17], some of which can be found in [18–21]. Here we set out for a unified picture of quantum systems theory in a Lie-algebraic frame following the lines of [22]. It paves the way for optimal-control methods to be applied to fermionic systems and leads to a plethora of new results presented here.

It is generally recognized that optimal control algorithms are key tools needed for further advances in experimentally exploiting these quantum systems for simulation as well as for computation [23–26]. In the implementation of these algorithms it is crucial to know before-hand to which extent the system can be controlled. For instance: which states can be reached from a given initial state under given controls? or likewise: which quantum operations can be simulated in a given set-up? The usual scenario (in coherent control) is that one is given a drift Hamiltonian and a set of control Hamiltonians with tunable strengths. The achievable operations will be characterized by their generators forming the system Lie algebra. Then the reachable sets of states can easily be given as the respective state orbits.
under the corresponding dynamic group. Dynamic Lie algebras and reachability questions have been intensively studied in the literature for qudit systems [22, 27–29]. However, in the case of fermions these questions have to be reconsidered mainly due to the presence of the parity superselection rule. Hence in a broader sense the present work on fermions can be envisaged also as a step towards quantum control theory for quantum simulation in the presence of superselection rules.

Apart from discussing the implications of the parity superselection rule we treat the cases of imposing translation-invariance or particle-number conservation. In particular, the experimentally relevant case of quasifree fermions (with and without translation invariance) is discussed in detail. Since we interrelate fermionic systems with the Lie-theoretical framework of quantum-dynamical systems, at times we will be somewhat more explicit and put known results into a new frame. The main results thus extend from general fermionic systems to the action of Hamiltonians with and without restrictions like quadratic interactions, translation invariance, reflection symmetry, or particle-number conservation.

The paper itself is structured as follows: In order to set a unified frame, we resume some basic concepts of Hamiltonian controllability of qudit systems in Section 2. Thus the dynamic systems approach is presented in a way to address a broader readership, who is enabled to make quick use of the key results summarized in the tables. These concepts are subsequently translated to their fermionic counterparts, starting with the discussion of general fermionic systems in Section 3.

Then the new results are presented in the following six sections: In Section 4 we obtain the dynamic system algebra for general fermionic systems respecting the parity superselection rule (see Theorem 4 in Section 4.1). An explicit example for a set of Hamiltonians that provides full controllability over the fermionic system is discussed in Section 4.2. Some general results on the controllability of fermionic and spin systems, such as Theorem 51, are relegated to Appendix A. Following the same line, in Section 5 we wrap up some known results on quasifree fermionic systems in a general Lie-theoretic frame by streamlining the derivation for the respective system algebra in Proposition 9 of Section 5. Corollary 16 provides a most general controllability condition of quasifree fermionic systems building on the tensor-square representation used in [22]. Furthermore, we develop methods for restricting the set of possible system algebras by analyzing their rank, see Theorem 13 as well as Appendices C and D. The structure and orbits of pure states in quasifree fermionic systems are analyzed in Section 6 leading to a complete characterization of pure-state controllability (Theorem 23). Sections 7 and 8 are devoted to translation-invariant systems. For spin chains we give in Theorem 25 the first full characterization of the corresponding system algebras and strengthen in Theorem 27 earlier results on short-range interactions in [19]. The system algebras for general translation-invariant fermionic chains are given in Theorem 30 of Section 7.3. We also identify translation-invariant fermionic Hamiltonians of bounded interaction length which cannot be generated from nearest-neighbor ones (see Theorem 33 of Section 7.4). The particular case of quadratic interactions (see Section 8.1) is settled in Theorem 34. Corollary 35 considers systems which additionally carry a twisted reflection symmetry (or equivalently have no imaginary hopping terms) as discussed in [19]. Furthermore, we provide a complete classification of all pure quasifree state orbits in Theorem 39 of Section 8.2. This leads to Theorem 41 of Section 8.3 presenting a bound on the scaling of the gap for a class of quadratic Hamiltonians which
are translation-invariant. Section 9 deals with fermionic systems conserving the number of particles. Their system algebras in the general case as well as in the quasifree case are derived in Proposition 42 and Proposition 43, respectively. Furthermore, a necessary and sufficient condition for quasifree pure-state controllability in the particle-number conserving setting is provided by Theorem 48.

In Section 10, we summarize the main results as given in Theorem 4, Corollary 16, as well as in Theorems 23, 25, 27, 30, 33, 34, 39, 41, and 48. We conclude leaving a number of details and proofs to the Appendices in order to streamline the presentation.

2 Basic quantum systems theory of $N$-level systems

As a starting point, consider the controlled Schrödinger (or Liouville) equation

\[
\dot{\rho}(t) = -\left[i H_u, \rho(t)\right] = -(i H_u \rho(t) - \rho(t) i H_u)
\]  

(1)

driven by the Hamiltonian $H_u := H_0 + \sum_{j=1}^{m} u_j(t) H_j$ and fulfilling the initial condition $\rho_0 := \rho(0)$. Here the drift term $H_0$ describes the evolution of the unperturbed system, while the control terms $\{H_j\}$ represent coherent manipulations from outside. Equation (1) defines a bilinear control system $\Sigma$ [30], as it is linear both in the density operator $\rho(t)$ and in the control amplitudes $u_j(t) \in \mathbb{R}$.

For a $N$-level system, the natural representation as Hermitian operators over $\mathbb{C}^N$ relates the Hamiltonians as generators of unitary time evolutions to the Lie algebra $\mathfrak{u}(N)$ of skew-Hermitian operators that generate the unitary group $U(N)$ of propagators. Let $L := \{i H_1, i H_2, \ldots, i H_m\}$ be a subset of Hamiltonians seen as Lie-algebra elements. Then the smallest subalgebra (with respect to the commutator $[A,B] := AB - BA$) of $\mathfrak{u}(N)$ containing $L$ is called the Lie closure of $L$ written as $\langle i H_1, i H_2, \ldots, i H_m \rangle_{\text{Lie}}$. Moreover, for any element $i H \in \langle i H_1, \ldots, i H_m \rangle_{\text{Lie}}$, there exist control amplitudes $u_j(t) \in \mathbb{R}$ with $j \in \{1, \ldots, m\}$ such that (and similarly with a drift term)

\[
\exp(-iH) = T \int_{t=0}^{1} \exp \left[ \sum_{j=1}^{m} -i u_j(t) H_j \right] \, dt, 
\]

(2)

where $T$ denotes time-ordering.

Now taking the Lie closure over the system Hamiltonian and all control Hamiltonians of a bilinear control system $\Sigma$ defines the dynamic system Lie algebra (or system algebra for short)

\[
\mathfrak{g}_{\Sigma} := \langle i H_0, i H_j \mid j = 1, 2, \ldots, m \rangle_{\text{Lie}}. 
\]

(3)

It is the key to characterize the differential geometry of a dynamic system in terms of its complete set of Hamiltonian directions forming the tangent space to the time evolutions. For instance, the condition for full controllability of bilinear systems can readily be adopted from classical systems [31–34] to the quantum realm such as to take the form of

\[
\langle i H_0, i H_j \mid j = 1, 2, \ldots, m \rangle_{\text{Lie}} = \mathfrak{u}(N) 
\]

(4)

saying that a $N$-level quantum system is fully controllable if and only if its system algebra is the full unitary algebra, which we will relax to $\mathfrak{su}(N)$ in a moment. This notion of con-
trollability is also intuitive (recalling that the exponential map is surjective for compact connected Lie groups), as it requires that all Hamiltonian directions can be generated.

So in fully controllable closed systems, to every initial state \( \rho_0 \) the reachable set is the entire unitary orbit \( \text{reach}_u(\rho_0) := \{ U\rho_0U^\dagger \mid U \in U(N) \} \). With density operators being Hermitian, this means any final state \( \rho(t) \) can be reached from any initial state \( \rho_0 \) as long as both of them share the same spectrum of eigenvalues (including multiplicities). Thus the reachable set of \( \rho_0 \) is the isospectral set of \( \rho_0 \).

**Remark 1** Interestingly, this notion is stronger than the requirement that from any given (normalized) pure state one can reach any other (normalized) pure state, since it is well known [27–29] that for \( N \) being even, all rank-one projectors are already on the unitary symplectic orbit

\[
\text{reach}(|\psi_0\rangle\langle\psi_0|) = \{ K|\psi_0\rangle\langle\psi_0|K^\dagger \mid K \in \text{Sp}(N/2) \} = \{ U|\psi_0\rangle\langle\psi_0|U^\dagger \mid U \in \text{SU}(N) \}
\]

and \( \text{Sp}(N/2) \) is a proper subgroup of \( \text{SU}(N) \).

In general, the reachable set to an initial state \( \rho_0 \) of a dynamic system (\( \Sigma \)) with system algebra \( g_{\Sigma} \) is given by the orbit of the dynamic (sub)group \( G_{\Sigma} := \exp(g_{\Sigma}) \subseteq U(N) \) generated by the system algebra

\[
\text{reach}_{\Sigma}(\rho_0) := \{ G\rho_0G^\dagger \mid G \in G_{\Sigma} = \exp(g_{\Sigma}) \}.
\]

Thus the system algebra \( g_{\Sigma} \) can be envisaged as the fingerprint encoding all the dynamic properties of a dynamic system \( \Sigma \). Via the respective reachable sets (see, e.g., [22]) it is easy to see that a coherently controlled dynamic system \( \Sigma_A \) can simulate the dynamics of another system \( \Sigma_B \) if and only if the system algebra \( g_{\Sigma_A} \) of the simulating system \( \Sigma_A \) encompasses the system algebra \( g_{\Sigma_B} \) of the simulated system \( \Sigma_B \),

\[
g_{\Sigma_A} \supseteq g_{\Sigma_B}.
\]

In [22], we have analyzed the possibility of quantum simulation with respect to the dynamic degrees of freedom and have given a number of illustrating worked examples.

Next we describe dynamic symmetries of bilinear control systems whose Hamiltonians are given by \( m := \{ iH_1 \} = \{ iH_0, iH_1, \ldots, iH_m \} \). The symmetry operators \( s \) are collected in the centralizer of \( m \) in \( u(N) \):

\[
\text{cent}(m) := \{ s \in u(N) \mid [s, iH] = 0 \text{ for all } iH \in m \}.
\]

More generally, let \( S' \) denote the commutant of a set \( S \) of matrices, i.e., the set of all complex matrices which commute simultaneously with all matrices in \( S \). By Jacobi’s identity \([a, b, c] + [b, c, a] + [c, a, b] = 0\) one gets two properties of the centralizer pertinent for our context: First, an element \( s \) that commutes with all Hamiltonians \( a, b \in m \) also commutes with their Lie closure \( g_{\Sigma} := \{ m \}_\text{Lie} \) (i.e. \( \text{cent}(m) \equiv \text{cent}(g_{\Sigma}) \)), as \([s, a] = 0 \) and \([s, b] = 0\) imply \([s, [a, b]] = 0\). Second, for any \( u \in u(N) \), \([s_1, u] = 0 \) and \([s_2, u] = 0\) imply \([s_1, s_2, u] = 0\), so the centralizer forms itself a Lie subalgebra to \( u(N) \) consisting of all symmetry operators.
Likewise the symmetries to a given set $\rho_{\Sigma}$ of states are given by its centralizer

$$\text{cent}(\rho_{\Sigma}) := \{ s \in u(N) \mid [s, \rho] = 0 \ \forall \rho \in \rho_{\Sigma} \} \equiv \text{cent}(\langle \rho_{\Sigma} \rangle_\mathbb{R}),$$

where $(\cdot)_\mathbb{R}$ denotes the real span. Clearly, $\text{cent}(\rho_{\Sigma}) \subseteq u(N)$ generates the stabilizer group to the state space $\rho_{\Sigma}$ of the control system ($\Sigma$).

Since in the absence of other symmetries the identity is the only and trivial symmetry of both any state space $\rho_{\Sigma}$ as well as any set of Hamiltonians and their respective system algebra $g_{\Sigma}$, one has $\text{cent}(g_{\Sigma}) = \text{cent}(\rho_{\Sigma}) = \{i\lambda \mathbb{1}_N \mid \lambda \in \mathbb{R}\} := u(1)$. So there is always a trivial stabilizer group $U(1) := \{ e^{i\phi} \mathbb{1}_N \mid \phi \in \mathbb{R}\}$. This explains why the time evolutions generated by two Hamiltonians $H_1$ and $H_2$ coincide for the set of all density operators if (and without other symmetries only if) $H_1 - H_2 = \lambda \mathbb{1}$. As is well known, by the same argument, in time evolutions

$$\rho(t) := U(t)\rho U(t)^{-1} = \text{Ad}_{U(t)}(\rho_0)$$

following from Eq. (1), one may take $U(t) := \exp(-itH)$ equally well from $U(N)$ or SU(N).

Thus henceforth we will only consider special unitaries (of determinant +1) generated by traceless Hamiltonians $iH_t \in u(N)$, since for any Hamiltonian $\hat{H}$ there exists an equivalent unique traceless Hamiltonian $H := \hat{H} - \frac{1}{N} \text{tr}(\hat{H}) \mathbb{1}_N$ generating a time evolution coinciding with the one of $\hat{H}$.

However, the above simple arguments are in fact much stronger, e.g., one readily gets the following statement:

**Lemma 2** Consider a bilinear control system with system algebra $g_{\Sigma}$ on a state space $\rho_{\Sigma}$. Let $iH_1 \in g_{\Sigma}$ and $iH_2 \in u(N)$ while assuming that $[H_1, \langle \rho_{\Sigma} \rangle_\mathbb{R}] \subseteq i\langle \rho_{\Sigma} \rangle_\mathbb{R}$ for all $iH_1 \in g_{\Sigma}$, i.e., operations generated by $g_{\Sigma}$ map the set $\langle \rho_{\Sigma} \rangle_\mathbb{R}$ into itself. Then the condition

$$e^{-itH_1} \rho e^{itH_2} = e^{-itH_1 + H_2} \rho e^{itH_1 + H_2} \text{ for all } t \in \mathbb{R}, \rho \in \rho_{\Sigma}$$

(11)

is equivalent to $iH_2 \in \text{cent}(\rho_{\Sigma})$.

**Proof** Using the formula $e^{A}Be^{-A} = \exp[\text{ad}_A(B)] = \sum_{k=0}^{\infty} \frac{t^k}{k!} \text{ad}_A^k(B)$ we show that Eq. (11) is equivalent to condition (a): $\text{ad}^k_{H_1}(\rho) = \text{ad}^k_{H_2}(\rho)$ for all non-negative integer $k$ and all $\rho \in \langle \rho_{\Sigma} \rangle_\mathbb{R}$. Moreover, (a) implies condition (b): $(\text{ad}_{H_2} \circ \text{ad}_{H_1})(\rho) = 0$ for all non-negative integer $k$ and all $\rho \in \langle \rho_{\Sigma} \rangle_\mathbb{R}$, as $[H_1, \text{ad}^{k-1}_{H_2}(\rho)] = [H_1 + H_2, \text{ad}^{k-1}_{H_2}(\rho)] = [H_1 + H_2, \text{ad}^{k-1}_{H_2}(\rho)] = \cdots = \text{ad}^k_{H_1 + H_2}(\rho)$. Applying $[H_1, \langle \rho_{\Sigma} \rangle_\mathbb{R}] \subseteq i\langle \rho_{\Sigma} \rangle_\mathbb{R}$ to (b) completes the proof. \hfill \Box

Therefore, let us consider a pair of Hamiltonians $iH_1, iH_2 \in g_{\Sigma}$ (fulfilling the conditions of Lemma 2) as equivalent on the state space $\rho_{\Sigma}$, if their difference $iH_2 := i(H_1 - H_2)$ falls into the centralizer $\text{cent}(\rho_{\Sigma})$.

Finally note that all unitary conjugations of type $\text{Ad}_{U}$ are elements of the projective special unitary group $\text{PSU}(N) = U(N)/U(1) \simeq \text{SU}(N)/\mathbb{Z}(N)$, where the centers of $U(N)$ and $\text{SU}(N)$ are respectively given by $U(1)$ and $\mathbb{Z}(N) := \{ e^{ir\mathbb{1}_N} \mid r \in \mathbb{R} \text{ with } rN \text{ mod } 2\pi = 0 \}$. 

Moreover, recall $\text{Ad}_{\text{exp}(-itH)} = e^{-it\text{ad}_H}$, where $\text{ad}_H := [H, \cdot]$ can be represented as a commutator superoperator $\text{ad}_H = \mathbb{1}_N \otimes H - H^\dagger \otimes \mathbb{1}_N$. Now, for any $H_1 - H_2 = \lambda \mathbb{1}_N$, one immediately obtains $\text{ad}_{H_1} = \text{ad}_{H_2}$, which also elucidates that the generators of the projective unitaries $\text{PSU}(N)$ are given by $\text{psu}(N) = \{ i \text{ad}_H \mid iH \in \mathfrak{u}(N) \}$.

### 3 Fermionic quantum systems

In this section, we fix our notation by recalling basic notions for fermionic systems. In the first subsection, we discuss the Fock space and different operators acting on it as given by the creation and annihilation operators as well as the Majorana operators. We point out how the Lie algebra $\mathfrak{u}(2^d)$ of skew-Hermitian matrices can be embedded as a real subspace in the set of the complex operators acting on the Fock space. In the second subsection, we focus on the parity superselection rule and how it structures a fermionic system.

#### 3.1 The Fock space and Majorana monomials

The complex Hilbert space of a $d$-mode fermionic system with one-particle subspace $\mathbb{C}^d$ is the Fock space

$$\mathcal{F}(\mathbb{C}^d) := \bigoplus_{i=0}^d \left( \bigwedge^i \mathbb{C}^d \right) = \mathbb{C} \oplus \mathbb{C}^d \oplus \wedge^2 \mathbb{C}^d \oplus \cdots \oplus (\wedge^d \mathbb{C}^d).$$

Given an orthonormal basis $\{e_i\}_{i=1}^{2d}$ of $\mathbb{C}^d$, the Fock vacuum $\Omega := 1(= 1 \oplus 1 \oplus \cdots \oplus 1)$ and the vectors of the form $e_{i_1} \wedge e_{i_2} \wedge \cdots \wedge e_{i_k}$ (with $i_1 < i_2 < \cdots < i_k$ and $1 \leq k \leq d$) form an orthonormal basis of $\mathcal{F}(\mathbb{C}^d)$. Note that $\mathcal{F}(\mathbb{C}^d)$ is a $2^d$-dimensional Hilbert space isomorphic to $\otimes_{i=1}^{2d} \mathbb{C}^2$ ($\equiv \mathbb{C}^{2^d}$).

The fermionic creation and annihilation operators, $f_p^\dagger$ and $f_p$, act on the Fock space in the following way: $f_p^\dagger \Omega = \delta_{pq} e_q \Omega = 0, f_p^\dagger e_q = e_p \wedge e_q$, and $f_p e_q = \delta_{pq} 1$; while in the general case of $1 \leq \ell \leq d$, their action is given by $f_p^\dagger(e_{q_1} \wedge e_{q_2} \wedge \cdots \wedge e_{q_k}) = (e_p \wedge e_{q_1} \wedge e_{q_2} \wedge \cdots \wedge e_{q_k})$ and $f_p(e_{q_1} \wedge e_{q_2} \wedge \cdots \wedge e_{q_k}) = \sum_{k=1}^{n} (-1)^{k-1} \delta_{pq_k} e_{q_1} \wedge \cdots \wedge e_{\delta(k-1)} \wedge e_{q(k+1)} \wedge \cdots \wedge e_{q_k}$. By their definition, these operators satisfy the fermionic canonical anticommutation relations

$$\{f_p^\dagger, f_q\} = \{f_p, f_q^\dagger\} = 0 \quad \text{and} \quad \{f_p, f_q^\dagger\} = \delta_{pq} 1,$$

where $\{A, B\} := AB + BA$ denotes the anticommutator. Moreover, every linear operator acting on $\mathcal{F}(\mathbb{C}^d)$ can be written as a complex polynomial in the creation and annihilation operators.

Another set of polynomial generators acting on the Fock space is given by the $2d$ Hermitian Majorana operators $m_{2p-1} := f_p + f_p^\dagger$ and $m_{2p} := if_p - f_p^\dagger$, which satisfy the relations $(k, \ell \in \{1, \ldots, 2d\})$

$$\{m_k, m_\ell\} = 2\delta_{k\ell} 1.$$

A product $m_{q_1} m_{q_2} \cdots m_{q_k}$ of $k \geq 0$ Majorana operators is called a Majorana monomial. The ordered Majorana monomials with $q_1 < q_2 < \cdots < q_k$ form a linearly independent basis of the complex operators acting on $\mathcal{F}(\mathbb{C}^d)$. Each Majorana monomial acting on $d$-mode
fermionic system can be identified with a complex operator acting on a chain of $d$ qubits via the Jordan-Wigner transformation \[35-38\] which is induced by

$$m_{2p-1} \mapsto Z \otimes \cdots \otimes Z \otimes X \otimes I \otimes \cdots \otimes I$$

and

$$m_{2p} \mapsto Z \otimes \cdots \otimes Z \otimes Y \otimes I \otimes \cdots \otimes I,$$

where the following notation for the Pauli matrices $X := \left( \begin{array}{cc} 0 & 1 \\ 1 & 0 \end{array} \right)$, $Y := \left( \begin{array}{cc} 0 & -i \\ i & 0 \end{array} \right)$, and $Z := \left( \begin{array}{cc} 1 & 0 \\ 0 & -1 \end{array} \right)$ is used.

Now we highlight the real subspace contained in the set of complex operators acting on the Fock space $\mathcal{F}(\mathbb{C}^d)$ which consists of all skew-Hermitian operators and which forms the real Lie algebra $u(2^d)$ closed under the commutator $[A, B] = AB - BA$ and real-linear combinations. More precisely, $u(2^d)$ is generated by all operators

$$L(M) := -\frac{1}{2} w(M) M,$$

where $M$ denotes any ordered Majorana monomial and

$$w(M) := \begin{cases} i & \text{if } [\deg(M) \mod 8] \in \{0, 1\}, \\ 1 & \text{if } [\deg(M) \mod 8] \in \{2, 3\}, \\ -i & \text{if } [\deg(M) \mod 8] \in \{4, 5\}, \\ -1 & \text{if } [\deg(M) \mod 8] \in \{6, 7\}. \end{cases}$$

Similarly, one obtains a basis of $su(2^d)$ by excluding $-\frac{i}{2} \mathbb{1}$.

### 3.2 Parity superselection rule

An additional fundamental ingredient in describing fermionic systems is the parity superselection rule. Superselection rules were originally introduced by Wick, Wightman, and Wigner \[39\] (see also \[40, 41\]). These rules, in the finite-dimensional definition of Piron \[42\], describe the existence of non-trivial observables that commute with all physical observables. The existence of such a commuting observable in turn implies that a superposition of pure states from different blocks of a block-diagonal decomposition w.r.t. the eigenspaces of this observable are equivalent to an incoherent classical mixture.

The parity superselection rule identifies among the operators acting on $\mathcal{F}(\mathbb{C}^d)$ the physical observables $\mathbb{1}_F$ as those that do commute with the parity operator

$$P := \mathbb{1}^d \prod_{k=1}^{2d} m_k,$$

where the adjoint action of $P$ on a Majorana monomial is given as

$$P m_{k_1} m_{k_2} \cdots m_{k_t} P^{-1} = (-1)^t m_{k_1} m_{k_2} \cdots m_{k_t}.$$

These physical operators are also exactly the ones that can be written as a sum of products of an even number of Majorana operators (as $P$ contains all Majorana operators whereof there exist an even number). They are therefore denoted as even operators for short. If the
parity is the only non-trivial symmetry, we obtain $\mathbb{H}_F' = \langle 1, P \rangle$, where the bracket stands for the complex-linear span.

Now we will discuss why the set of all physical fermionic states $\rho_F$ consists similarly of all density operators that commute with $P$, notably $\rho_F' = \langle 1, P \rangle$. As we will show, the parity superselection rule induces a decomposition into a direct sum of two irreducible state-space components exploiting $\mathbb{H}_F' \cap \rho_F' = \langle 1, P \rangle$. Recall that $P^2 = 1$ and the eigenspaces to the eigenvalues $+1$ and $-1$ are indeed of equal dimension, as there are exactly $2^{2d-1}$ even operators which map the vacuum state $\Omega_1$ into the $+1$ eigenspace of $P$. Note that $P e_{q_1} \wedge e_{q_2} \wedge \cdots \wedge e_{q_r} = (-1)^r e_{q_1} \wedge e_{q_2} \wedge \cdots \wedge e_{q_r}$. Thus the Fock space can be split up as a direct sum of two equal-dimensional eigenspaces of $P$, called the positive and negative parity subspaces:

$$\mathcal{F}(\mathbb{C}^d) = \bigoplus_{i \text{ even}} (\wedge^i \mathbb{C}^d) \oplus \bigoplus_{i \text{ odd}} (\wedge^i \mathbb{C}^d).$$

Note that for clarity we use this notation in contrast to the notation of even and odd subspaces (which is also used in the literature) in order to avoid any confusion with the even operators.

Now we may write $P^2 = 1 = P_+ + P_-$ with the orthogonal projections $P_+ := \frac{1}{2}(1 + P)$ and $P_- := \frac{1}{2}(1 - P)$ projecting onto the respective subspaces. Any physical observable (i.e., even operator) $A$ has a block-diagonal structure with respect to the above splitting, i.e., $A = P_+ A P_+ + P_- A P_-$. This follows, as the requirement $[A, P] = \frac{1}{2} [A, P_+] = -\frac{1}{2} [A, P_-] = 0$ enforces $P_+ A P_+ = P_- A P_- = 0$ for any operator $A = P_+ A P_+ + P_- A P_-$. We obtain

$$\text{Tr}(\rho A) = \text{Tr}(\rho P_+ A P_+ + \rho P_- A P_-) = \text{Tr}[(P_+ \rho P_+ + P_- \rho P_-)A].$$

Hence physical observables cannot distinguish between the density operator $\rho$ and its block-diagonal projection to $P_+ \rho P_+ + P_- \rho P_-$. (which is always an even density operator). In this sense, a physical linear combination (a formal superposition) of pure states from the positive and negative parity subspaces is equivalent to an incoherent classical mixture. Equation (15) also shows that without loss of generality we can restrict ourselves to even density operators and regard only those as physical.

Finally, we would like to recall three further aspects of the parity superselection rule. First, without the parity superselection rule, two noncommuting observables acting on two different and spatially-separated regions would exist which would allow for a violation of locality (e.g., by instantaneous signaling between the regions). Second, the parity superselection rule, of course, does not apply if one uses a spin system to simulate a fermionic system via the Jordan-Wigner transformation. This system respects locality, since the Majorana operators $m_k$ are—in this case—localized on the first $[(k + 1) \text{ div } 2]$ spins; two non-commuting Majorana operators are therefore not acting on spatially-separated regions. Third, the parity superselection rule also affects the concept of entanglement as has been pointed out and studied in detail in [43, 44].

4 Fully controllable fermionic systems

Here we derive a general controllability result for fermions obeying the parity superselection rule. We illustrate that full controllability for a fermionic system can be achieved
with quadratic Hamiltonians and a single fourth-order interaction term. For example, in a system with $d$ modes, the complete fermionic dynamical algebra $L_d \equiv su(2^{d-1}) \oplus su(2^{d-1})$ (see Theorem 4) can be generated by a quartic interaction between the first two modes $ih_{\text{int}} = i(2f_1^\dagger f_1 - 1)(2f_2^\dagger f_2 - 1) = -im_1m_2m_3m_4$ combined with three quadratic Hamiltonians: the nearest-neighbor hopping term

$$ih = -2i \sum_{p=1}^{d-1} f_p^\dagger f_{p+1}^\dagger f_p f_{p+1},$$

the on-site potential of the first site $ih_0 = i(2f_1^\dagger f_1 - 1) = m_1m_2$, and a pairing-hopping term between the first two modes $ih_{12} = i(f_1^\dagger f_2 - f_2^\dagger f_1)(f_1^\dagger f_2 - f_2^\dagger f_1) = m_2m_3$ (see Proposition 6). Finally, we provide a general discussion about when the commutant of a system algebra determines the algebra itself.

### 4.1 System algebra

In the case of qubit systems mentioned in Section 2, two Hamiltonians generate equivalent time evolutions if and only if they differ by a multiple of the identity. This condition can readily be modified for the fermionic case such as to match the parity-superselection rule as well.

**Corollary 3** Let $H_1$ and $H_2$ be two physical fermionic Hamiltonians, i.e., even Hermitian operators acting on $\mathcal{F}(\mathbb{C}^d)$. Then by Lemma 2 the equality $e^{-iH_2t} \rho e^{iH_1t} = e^{-iH_2t} \rho e^{iH_2t}$ holds for all even (physical) density operators $\rho$ with $\rho^\dagger = (\mathbb{1}, P)$ in the sense that $H_1$ and $H_2$ generate the same time-evolution, if and only if $H_2 - H_1 = \lambda \mathbb{1} + \mu P = (\lambda + \mu)P_+ + (\lambda - \mu)P_-$ with $\lambda, \mu \in \mathbb{R}$.

This also implies that for any physical fermionic Hamiltonian $H$, there exists a unique Hamiltonian

$$\hat{H} := H - \frac{\text{tr}(P_+ H P_+)}{\dim P_+} P_+ - \frac{\text{tr}(P_- H P_-)}{\dim P_-} P_-$$

that is traceless on both the positive and the negative parity subspaces, i.e.,

$$\text{tr}(P_+ \hat{H} P_+) = \text{tr}(P_- \hat{H} P_-) = 0,$$

and moreover, $\hat{H}$ and $H$ are equivalent and generate the same time evolution. If necessary, we can restrict ourselves to the set of Hamiltonians satisfying Eq. (16). These elements decompose as $H = H_+ \oplus H_-$, where $H_+$ and $H_-$ are generic traceless Hermitian operators each acting on a $2^{d-1}$-dimensional Hilbert space. We explicitly define the linear space $\mathbb{F}_d$ of physical fermionic Hamiltonians as generated by the basis of all even Majorana monomials without the operators $\mathbb{1}$ and $P$, ensuring that $\mathbb{F}_d$ is traceless both on $H_+$ and $H_-$.—We summarize our exposition on fully controllable fermionic systems in the following result:

**Theorem 4** The Lie algebra corresponding to the physical fermionic (and Hermitian) Hamiltonians $\mathbb{F}_d$ is $L_d := su(2^{d-1}) \oplus su(2^{d-1})$. The most general set of unitary transformations generated by $L_d$ is given as the block-diagonal decomposition $SU(2^{d-1}) \oplus$...
SU(2^{d-1}). Hence a set \{H_0, H_1, \ldots, H_m\} of Hermitian Hamiltonians defines a fully controllable fermionic system if \langle iH_0, iH_1, \ldots, iH_m \rangle_{\text{Lie}} = \text{su}(2^{d-1}) \oplus \text{su}(2^{d-1}).

Remark 5 For Lie algebras, \(t_1 + t_2\) will denote only an abstract direct sum without referring to any concrete realization. We reserve the notation \(t_1 \oplus t_2\) to specify a direct sum of Lie algebras which is (up to a change of basis) represented in a block-diagonal form \((t_1, t_2)\).

Proof of Theorem 4 It follows from Section 3 that \(F_d\) commutes with \(P\) and that the matrix representation of \(F_d\) splits into two blocks of dimension \(2^{d-1}\) corresponding to the + and – eigenspaces of \(P\). As the center of \(F_d\) is given by \(F_d' \cap F_d = \{1, P\} \cap F_d = \{0\}\), the Lie algebra \(F_d\) is semisimple. As there are exactly \(2^{2d-1} - 2\) linear-independent operators in \(F_d\), the system algebra could be \(\text{su}(2^{d-1}) \oplus \text{su}(2^{d-1})\). And indeed, all other system algebras are ruled out as the subalgebras acting on each of the two matrix blocks would have a smaller Lie-algebra dimension than \(\text{su}(2^{d-1})\).

\[\square\]

4.2 Examples and discussion

We start out with an example realizing a fully controllable fermionic system by adding only one quartic operator to the set of quadratic Hamiltonians which will be discussed in Section 5 below (cf. Theorem 11):

Proposition 6 Consider a fermionic quantum system with \(d > 2\) modes. The system algebra \(\mathcal{L}_d = \text{su}(2^{d-1}) \oplus \text{su}(2^{d-1})\) of a fully controllable fermionic system can be generated using the operators \(w_1 := L(v_1), w_2 := L(v_2), w_3 := L(v_3),\) and \(w_4 := L(v_4)\) with the map \(L\) as defined in Eqs. (12) and (13), where

\[
\begin{align*}
v_1 & := \sum_{p=1}^{d-1} -m_{2p-1}m_{2p+1} + m_{2p}m_{2p+2}, \\
v_2 & := m_1m_2, \quad v_3 := m_2m_3, \quad v_4 := m_1m_2m_3m_4.
\end{align*}
\]

Proof It follows from the independent Theorem 11 (see Section 5 below) that \(w_1, w_2,\) and \(w_3\) generate all quadratic Majorana monomials \(m_pm_q\). Consider an even Majorana monomial \(s_1 := L(\prod_{i \in \mathcal{I}} m_i)\) of degree \(2d\), where \(s_2\) is defined using the ordered index set \(\mathcal{I}\), and a quadratic operator \(s_2 := L(m_pm_q)\) with \(p \in \mathcal{I}\) and \(q \notin \mathcal{I}\). We can change any index \(p\) of \(s_1\) into \(q\) of using \(L(\prod_{j \in (\mathcal{I} \cup \mathcal{J}) \setminus \{q\}} m_j) = \pm[s_1, s_2]\). Therefore, we get from \(w_4\) and the quadratic operators all Majorana monomials of degree four.

Using the quartic Majorana monomials we can increase the degree of the monomials in steps of two: Consider the operators \(s_3 := L(\prod_{i \in \mathcal{J}} m_i)\) and \(s_4 := L(\prod_{i \in \mathcal{J}} m_i)\) which are defined using the ordered index sets \(\mathcal{I}\) and \(\mathcal{J}\) and have degrees \(2d' < 2(d - 1)\) and \(4\), respectively. Assuming that \(|\mathcal{I} \cap \mathcal{J}| = 1\), we can generate an operator \(L(\prod_{k \in \mathcal{K}} m_k) = \pm[s_3, s_4]\) of degree \(|\mathcal{K}| = 2(d'' + 1) < 2d\) where the corresponding ordered index set is given by \(\mathcal{K} := (\mathcal{I} \cup \mathcal{J}) \setminus (\mathcal{I} \cap \mathcal{J})\). By induction, we can now generate all even Majorana monomials except \(L(\prod_{q=1}^{2d} m_q)\). Note that \(L(\prod_{q=1}^{2d} m_q)\) cannot be obtained as \(\mathcal{I} \cap \mathcal{J} \subseteq \mathcal{K}\) holds by construction. Thus, we get all elements of \(\mathcal{L}_d\) (see Section 4.1) and the proposition follows.

\[\square\]

The proof also implies that all the operators generated commute with \(\prod_{q=1}^{2d} m_q = P/j^d\) (cf. Eq. (14)) and the identity operator \(1\). In addition, all operators commuting simultaneously
with all elements of $\mathcal{L}_d$ can be written as a complex-linear combination of $\mathbb{1}$ and $P$. We thus obtain a partial characterization of full controllability in fermionic systems:

**Lemma 7** Consider a fermionic quantum system with $d \geq 2$ modes. A necessary condition for full controllability of a given set of Hermitian Hamiltonians $H_v$ is that $[iH_v]' = (\mathbb{1}, P)$.

One can expect that the condition of Lemma 7 is not sufficient under any reasonable assumption by applying counterexamples from spin systems in [22]. These counterexamples could be lifted to fermionic systems by providing the explicit form of the embeddings from $su(2^{d-1})$ to the first and second component of the direct sum $\mathcal{L}_d = su(2^{d-1}) \oplus su(2^{d-1})$.

We guide the discussion in a different direction by emphasizing that the property $[iH_v]' = (\mathbb{1}, P)$ does not determine the system algebra uniquely. We define the centralizer of a set $B \subseteq su(k)$ in $su(k)$ (e.g. $k = 2^d$) as

$$\text{cent}_{su(k)}(B) := \{ g \in su(k) \mid [g, b] = 0 \text{ for all } b \in B \}.$$  

We consider the algebras $\mathcal{L}_d = su(2^{d-1}) \oplus su(2^{d-1})$ and $su(2^{d-1}) \oplus u(2^{d-1})$, where the latter algebra is isomorphic to $su(2^{d-1}) + su(2^{d-1}) + u(1)$ and contains the additional (non-physical) generator $L(\prod_{q=1}^{2d} m_q)$. Note that $\text{cent}_{su(k)}(\mathcal{L}_d) = \text{cent}_{su(k)}(su(2^{d-1}) \oplus u(2^{d-1})) = L(\prod_{q=1}^{2d} m_q)$, i.e., the centralizers of both algebras are equal. However $\text{cent}_{su(k)}(su(2^{d-1}) \oplus u(2^{d-1})) \neq su(2^{d-1}) \oplus su(2^{d-1})$. In particular, we have $\mathcal{L}_d \neq \text{cent}_{su(k)}(\text{cent}_{su(k)}(\mathcal{L}_d))$, and $\mathcal{L}_d$ does not fulfill the double-centralizer property. A more general incarnation of this effect in line with a discussion of double centralizers is given in Appendix A. It leads in the case of irreducible subalgebras to the following maximality result:

**Corollary 8** Let $g$ denote an irreducible subalgebra of $su(k)$, i.e. $\text{cent}_{su(k)}(g) = \{0\}$. Then one finds that $\text{cent}_{su(k)}(\text{cent}_{su(k)}(g)) = g$ if and only if $g = su(k)$.

To sum up, the symmetry properties of a Lie algebra $g \subseteq su(k)$, as given by its commutant w.r.t. a representation of $g$, do not determine the Lie algebra $g$ uniquely. Yet the commutant allows us to infer a unique maximal Lie algebra contained in $su(k)$, which is (up to an identity matrix) equal to the double commutant of $g$, but in general not to $g$ itself.

### 5 Quasifree fermions

Here we present the dynamic system algebras for fermions with quadratic Hamiltonians. For illustration, also the relation to spin chains is worked out in detail. In this context, we show by free fermionic techniques that a Heisenberg-XX Hamiltonian of Eq. (21) combined with the one-site term $ih_0 = iZ \otimes I \otimes \cdots \otimes I = m_1 m_2$ and the two-site interaction $ih_{12} = iX \otimes X \otimes I \otimes \cdots \otimes I = m_2 m_3$ gives rise to the system algebra $so(2d)$ (see Theorem 11), while the first two operators generate only the subalgebra $u(d)$ (see Theorem 13). Further results along this line are presented in Appendix C.

Finally, we arrive at a very useful general result: In order to decide if a set of operators generates the full quadratic algebra for $d$ modes, we characterize quadratic operators by a real skew-symmetric matrix $T$ whose entries are given via $-\frac{1}{2} \sum_{k,l} T_{s_k m_l m_l}$ (see Eq. (19)). Adapting our tensor-square criterion for full controllability from spin systems
to quasifree fermionic systems, a set of operators $T_\nu$ generates the full quadratic algebra $\mathfrak{so}(2d)$ if and only if the joint commutant of the operators $T_\nu \otimes 1_{2d} + 1_{2d} \otimes T_\nu$ has dimension three (see Corollary 16).

5.1 Quadratic Hamiltonians

A general quadratic Hamiltonian of a fermionic system can be written as (cf. [19, 45–48])

$$H = \sum_{pq=1}^{d} A_{pq} \left( f_p^\dagger f_q - \delta_{pq} \frac{\mathbb{1}}{2} \right) + \frac{1}{2} B_{pq} f_p^\dagger f_q - \frac{1}{2} B_{pq}^* f_p f_q,$$

where the coupling coefficients $A_{pq}$ and $B_{pq}$ are complex entries of the $d \times d$-matrices $A$ and $B$, respectively. The canonical anticommutation relations and the hermiticity of $H$ require that $A$ is Hermitian and $B$ is (complex) skew-symmetric. The terms corresponding to the non-zero matrix entries of $A$ and $B$ are usually referred to as hopping and pairing terms, respectively. Related parameterizations for quadratic Hamiltonians are discussed in Appendix B.

In the Majorana monomial basis, the quadratic Hamiltonian $H$ can be written as

$$-iH = \sum_{k,\ell=1}^{2d} T_{k\ell} \left[ -\frac{1}{2} m_k m_\ell \right],$$

with

$$T = \frac{1}{2} \left[ \Re(A) \otimes \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix} + \Re(B) \otimes \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix} \right] + \Im(A) \otimes \begin{pmatrix} -1 & 0 \\ 0 & -1 \end{pmatrix} + \Im(B) \otimes \begin{pmatrix} -1 & 0 \\ 0 & 1 \end{pmatrix}.$$

The properties of $A$ and $B$ directly imply that the matrix $T$ is real and skew-symmetric. Using the formula

$$[m_p m_q, m_r m_s] = -4(\delta_{pq} \delta_{rs} \mathbb{1} - \delta_{qs} \delta_{pr} \mathbb{1})$$

$$+ 2(\delta_{pq} m_q m_r - \delta_{pr} m_q m_s + \delta_{qs} m_p m_s - \delta_{qs} m_p m_r)$$

$$= \delta_{pq}(m_q m_r - m_r m_q) - \delta_{pr}(m_q m_s - m_s m_q)$$

$$+ \delta_{qs}(m_p m_s - m_s m_p) - \delta_{qs}(m_p m_r - m_r m_p),$$

one can easily verify that the space of quadratic Hamiltonians is closed under the commutator. To sum up, we have established the well-known Lie homomorphism from the system algebra generated by a set of quadratic Hamiltonians (whose control functions are given by the matrix entries of $A$ and $B$) onto the system algebra $\mathfrak{so}(2d)$ represented by the entries of $T$ (cf. pp.183-184 of [38]):

**Proposition 9** The maximal system algebra for a system of quasifree fermions with $d$ modes is given by $\mathfrak{so}(2d)$. 
Proof Let the map \( h \) transform the Majorana monomial \(-\frac{1}{2}(m_p m_q - m_q m_p)\) into the skew-symmetric matrix \( e_{pq} = -e_{qp} \) where \( e_{pq} \) has the matrix entries \( [e_{pq}]_{uv} := \delta_{pu}\delta_{qv} \). We show that \( h \) is a Lie-homomorphism assuming \( p \neq q \) and \( r \neq s \) in the following, while the case of \( p = q \) or \( r = s \) holds trivially. Note that \( \frac{1}{2}(m_p m_q - m_q m_p) = m_p m_q \). It follows from Eq. (20b) that
\[ h\left(\left[-\frac{1}{2}(m_p m_q - m_q m_p), -\frac{1}{2}(m_s m_t - m_t m_s)\right]\right) = [h\left(-\frac{1}{2}(m_p m_q - m_q m_p)\right), h\left(-\frac{1}{2}(m_s m_t - m_t m_s)\right)]. \]
\( \square \)

### 5.2 Examples and explicit realizations

We start by showing that the full system algebra \( \mathfrak{so}(2d) \) of quasifree fermions can be generated using only three quadratic operators, namely \( w_1 = L(v_1), w_2 = L(v_2), \) and \( w_3 = L(v_3) \) from Eqs. (17a) and (17b) where \( v_1 = \sum_{p=1}^{d-1} -m_{2p-1}m_{2p+1} + m_{2p}m_{2p+1}, v_2 = m_1m_2, \) and \( v_3 = m_2m_3 \). The Jordan-Wigner transformation maps these generators respectively to the Heisenberg-XX term
\[ iH_{XX} = -\frac{d}{2} \sum_{p=1}^{d-1} (X_pX_{p+1} + Y_pY_{p+1}), \]
\[ -\frac{1}{2}Z_1, \text{ and } -\frac{1}{2}X_1X_2, \] where operators as (e.g.) \( Z_i \) are defined as \( Z \otimes I \otimes \cdots \otimes I \).

**Lemma 10** Consider a fermionic quantum system with \( d \geq 2 \) modes. The system algebras \( \mathfrak{t}_1 \) and \( \mathfrak{t}_2 \) generated by the set of Lie generators \( \{w_1, w_2\} \) and \( \{w_1, w_2, w_3\} \) contain the elements \( L(a_p) \) with \( a_p := m_{2p-1}m_{2p} \) for all \( p \in \{1, \ldots, d-1\} \) as well as \( L(b_p) \) with \( b_p := -m_{2p-1}m_{2p+2} + m_{2p}m_{2p+1} \) and \( L(c_p) \) with \( c_p := m_{2p-1}m_{2p+1} + m_{2p}m_{2p+2} \) for all \( p \in \{1, \ldots, d-1\} \).

Note that the elements \( L(a_p), L(b_p), \) and \( L(c_p) \) are mapped by the Jordan-Wigner transformation to the spin operators \(-iZ_p/2, -i(X_pX_{p+1} + Y_pY_{p+1})/2, \) and \(-i(X_pY_{p+1} - Y_pX_{p+1})/2, \) respectively.

**Proof of Lemma 10** We compute the commutators \( w_4 := -L(c_1) = [w_2, w_1], w_5 := L(b_1) = [w_4, w_2], \) and \( w_6 := L(a_1) = [w_5, w_4] - w_2 \). We can now reduce the problem from \( d \) to \( d - 1 \) by subtracting \( w_5 \) from \( w_1 \). The cases of \( d \in \{2, 3, 4\} \) can be verified directly and the proof is completed by induction. \( \square \)

This proof also yields an explicit realization for the algebra \( \mathfrak{so}(2d) \) while providing a more direct line of reasoning as compared to our proof of Theorem 32 in [22].

**Theorem 11** Consider a fermionic quantum system with \( d \geq 2 \) modes. The system Lie algebra \( \mathfrak{t}_2 \) generated by \( \{w_1, w_2, w_3\} \) is given by \( \mathfrak{so}(2d) \).

**Proof** The cases of \( d \in \{2, 3, 4\} \) can be verified directly. We build on Lemma 10 and remark that \( \mathfrak{t}_2 \subseteq \mathfrak{so}(2d) \) as it is generated only by quadratic operators (see Proposition 9). We compute in the Jordan-Wigner picture \( w_7 := -i(Y_1Y_2 - Y_2Y_3)/2 = [w_3, [w_3, w_1]], \) and \( w_8 := -iX_2X_3/2 = L(b_2) - (w_5 - w_3 - w_7) \). This shows by induction that \( \mathfrak{so}(2d) \supseteq \mathfrak{t}_2 \supseteq \mathfrak{u}(1) + \mathfrak{so}(2d - 2) \). As \( \mathfrak{u}(1) + \mathfrak{so}(2d - 2) \) is a maximal subalgebra of \( \mathfrak{so}(2d) \) (see p.219 of [49] or Section 8.4 of [50]), one obtains that \( \mathfrak{t}_2 = \mathfrak{so}(2d) \). Alternatively, one can explicitly show that \( \mathfrak{t}_2 \) consists of all quadratic Majorana operators, which together with Proposition 9 also completes the proof. \( \square \)
Note that the generators $w_1$, $w_2$, and $w_3$ can be described using the Hamiltonian of Eq. (18) while keeping the control functions given by the matrix entries $A_{pq}$ and $B_{pq}$ in the real range, see Appendix B for details. This also provides a simplified approach to Theorem 32 in [22], where only the real case was considered:

**Corollary 12** (see Theorem 32 in [22]) Consider a control system given by the Hamiltonian components of Eq. (18). The control functions are specified by the matrix entries $A_{pq}$ and $B_{pq}$ which are assumed to be real. The resulting system algebra is $so(2d)$.

The relations between quasifree fermions and spin systems will be analyzed in Appendix C.—Next we treat the case of the algebra $u(d)$.

**Theorem 13** (see Lemma 36 in [22]) Consider a fermionic quantum system with $d \geq 2$ modes. The system Lie algebra $\mathfrak{t}_1$ generated by $\{w_1, w_2\}$ is given by $u(d)$.

Here we just sketch ideas for the proof of Theorem 13 while leaving the full details to Appendix D. Our methods exploit the detailed structure of the appearing Majorana operators while being more explicit than in [22] and avoiding obstacles of the spin picture. Building on the notation of Lemma 10, we show that the elements $L(a_p)$ with $1 \leq p \leq d$ together with the elements $L(b_p^{(i)})$ with $b_p^{(i)} := -m_{2p-1}m_{2p+2i} + m_{2p}m_{2p+2i-1}$ and $L(c_p^{(i)})$ with $c_p^{(i)} := m_{2p-1}m_{2p+2i-1} + m_{2p}m_{2p+2i}$ where $p, i \geq 1$ and $p + i \leq d$ form a basis of $\mathfrak{t}_1$. One obtains that $\dim(\mathfrak{t}_1) = d + (d - 1)d = d^2$. Furthermore, the elements $L(a_p)$ form a maximal abelian subalgebra and the rank of $\mathfrak{t}_1$ is equal to $d$. (The rank of a Lie algebra is defined as the dimension of its maximal abelian subalgebras.) We limit the possible cases further by showing that $\mathfrak{t}_1$ is a direct sum of a simple and a one-dimensional Lie algebra. A complete enumeration of all possible cases completes the proof.

**Remark 14** A spin chain equivalent to the fermionic system in Theorem 13 was also considered in [51], where it was shown how to swap pairs of fermions using the given Hamiltonians. As a consequence of Theorem 13, the Lie algebra in the spin chain of [51] can be identified as $u(d)$. Clearly, its size grows only linearly with the number of modes $d$. However, the addition of controlled-Z gates, as discussed in [51], already allows for scalable quantum computation.

### 5.3 Tensor-square criterion

Consider a control system of quasifree fermions which is represented by matrices $T_i$ in the form of Eq. (19). For more than two modes (i.e. $d \geq 3$), we can efficiently decide if the system algebra is equal to $so(2d)$. Recall that the alternating square $\text{Alt}^2(\phi)$ and the symmetric square $\text{Sym}^2(\phi)$ of a representation $\phi$ are defined as restrictions to the alternating and symmetric subspace of the tensor square $\phi \otimes \phi$.

**Theorem 15** Assume that $\mathfrak{t}$ is a subalgebra of $so(2d)$ with $d \geq 3$ and denote by $\Phi$ the standard representation of $so(2d)$. Then, the following statements are equivalent: (1) $\mathfrak{t} = so(2d)$. (2) The restriction of $\text{Alt}^2 \Phi$ to the subalgebra $\mathfrak{t}$ is irreducible and the restriction of $\text{Sym}^2 \Phi$ to $\mathfrak{t}$ splits into two irreducible components. Each irreducible component occurs only once. (3) The commutant of all complex matrices commuting with the tensor square $(\Phi|_{\mathfrak{t}}) \otimes \phi$ of $\mathfrak{t}$ has dimension three.
Proof Assuming (1), condition (2) follows from the formulas for the alternating and symmetric square of $so(2d)$ with $d \geq 3$ given in its standard representation $\phi_{(1,0,...,0)}$ [where $(1,0,...,0)$ denotes the corresponding highest weight]: The alternating square is given as $\text{Alt}^2 \phi_{(1,0,0)} = \phi_{(0,1,1)}$ for $so(6)$ and $\text{Alt}^2 \phi_{(1,0,0,...,0)} = \phi_{(0,1,0,...,0)}$ for $so(2d)$ in the case of $d \geq 3$ (cf. Table 6 in [52] or Table X in [22]). The symmetric square $\text{Sym}^2 \phi_{(1,0,...,0)} = \phi_{(2,0,...,0)} \otimes \phi_{(0,0,...,0)}$ for $so(2d)$ and $d \geq 3$ can be computed using Example 19.21 of [54]. We verify the dimension of the commutant and show that (3) is a consequence of (2) by applying Proposition 50 which says that the dimension of the commutant of a representation $\phi$ is given by $\sum m_i^2$ where the $m_i$ are the multiplicities of the irreducible components of $\phi$. For the rest of the proof we assume that condition (3) holds. We remark that the representation $\Phi|_T$ is irreducible as otherwise the dimension of the commutant would be larger than three. Thus, we obtain that $\ell$ is semisimple. The dimension of the commutant allows only two possibilities: one of the restrictions ($\text{Alt}^2 \Phi|_T$ or $\text{Sym}^2 \Phi|_T$) to the subalgebra $\mathfrak{t}$ has to be irreducible. We emphasize that $\mathfrak{t}$ is given in an orthogonal representation (i.e. a representation of real type) of even dimension, as $\mathfrak{t}$ is given in an irreducible representation obtained by restricting the standard representation of $so(2d)$. Therefore, we can use the list of all irreducible representations which are orthogonal or symplectic (i.e. of quaternionic type) and whose alternating or symmetric square is irreducible (Theorem 4.5 as well as Tables 7a and 7b of [52]): (a) for $su(2)$ the alternating square of the symplectic representation $\phi = (1)$ of dimension two, (b) for $so(3) \cong su(2)$ the alternating square of the orthogonal representation $\phi = (2)$ of dimension three, (c) for $so(2\ell + 1)$ with $\ell > 1$ the alternating square of the orthogonal representation $\phi = (1,0,...,0)$ of dimension $2\ell + 1$, (d) for $so(2\ell)$ with $\ell \geq 3$ the alternating square of the orthogonal representation $\phi = (1,0,...,0)$ of dimension $2\ell$, and (e) for $sp(\ell)$ with $\ell \geq 1$ the symmetric square of the symplectic representation $\phi = (1,0,...,0)$ of dimension $2\ell$. Only possibility (d) fulfills all conditions which proves (1).

Describing the matrices in the tensor square more explicitly along the lines of [22], we present a necessary and sufficient condition for full controllability in systems of quasifree fermions.

**Corollary 16** Consider a set of matrices $\{T_v \mid v \in \{0;1,...,m\}\}$ as given by Eq. (19) generating the system algebra $\mathfrak{t} \subseteq so(2d)$ with $d \geq 3$. We obtain $\mathfrak{t} = so(2d)$ if and only if the joint commutant of $\{T_v \otimes 1_{2d} + 1_{2d} \otimes T_v \mid v \in \{0;1,...,m\}\}$ has dimension three.

Along the lines of Eq. (19), one can apply Corollary 16 to the matrices $T$ corresponding to the generators of $so(2d)$ of Theorem 11. For $d \geq 3$ one can verify that the commutant of the tensor square has dimension three. But for $d = 2$ one computes a dimension of four as $so(4) = su(2) + su(2)$ is not simple.

For illustration, note that two elements in the commutant are trivial, to wit the identity and the generator for the swap-operation between the two tensor copies. The third element does not yet occur in the unitary case described in [22]: it is the projector $P_0$ onto the totally anti-symmetric state. To see this, recall that [55] implies that if the Hamiltonians $\{iH_v \mid v \in \{0;1,...,m\}\}$ generate a system algebra of orthogonal type, then there is an operator $S \in SL(N)$ satisfying

$$S H_v^+ + H_v S = 0$$  \hfill (22)
jointly for all \( v \in \{0; 1, \ldots, m\} \) as in [22]. Using Kronecker products and writing \( |S\rangle := \text{vec}(S) \) [56], one sees that \( |S\rangle \) is in the intersection of all the kernels of the tensor squares, so

\[
(H_v \otimes 1 + 1 \otimes H_v)|S\rangle = |0\rangle \iff (H_v \otimes 1 + 1 \otimes H_v)|S\rangle \langle S| = 0_N
\]

and thus \( P_S := |S\rangle \langle S| \in (H_v \otimes 1 + 1 \otimes H_v)' \) holds jointly for all \( v \in \{0; 1, \ldots, m\} \); \( 0_N \) denotes the zero matrix of degree \( N \).

6 Pure-state controllability for quasifree systems

In this section, we present a straightforward criterion for pure-state controllability of quasifree fermionic systems with \( d \) modes. A fermionic state is called quasifree if Majorana operators of odd degree map it to zero and even-degree ones map it to states which factorize into the Wick expansion form (see below). We obtain that quadratic Hamiltonians act transitively on pure quasifree states, i.e., every pure quasifree state can be transformed into any other pure quasifree state using only quadratic Hamiltonians (see Theorem 20).

In particular, within the Lie algebra of quadratic Hamiltonians a subalgebra isomorphic to \( u(d) \) provides the stabilizer of any pure quasifree state. Thus the set of pure quasifree states can be identified with a homogeneous space of the type \( \text{SO}(2d)/\text{U}(d) \). At first glance, this might suggest that for full pure-state controllability the system algebra has to be isomorphic to \( \text{so}(2d) \). However, the central result of this section shows that this is in general not necessary: a quasifree fermionic system (with \( d > 4 \) or \( d = 3 \)) is fully pure-state controllable iff its system algebra is isomorphic to \( \text{so}(2d) \) or \( \text{so}(2d – 1) \), see Theorem 23.

6.1 Quasifree states

A fermionic state \( \rho \) on \( F(C^d) \) is called quasifree or Gaussian if it vanishes on odd monomials of Majorana operators and factorizes on even monomials into the Wick expansion form

\[
\text{tr}(\rho m_{k_1} \cdots m_{k_{2d}}) = \sum_{\pi} \text{sgn}(\pi) \prod_{p=1}^d \text{tr}(\rho m_{k_{2p-1}} m_{k_{2p}}).
\]

Here the sum runs over all pairings of \( [1, \ldots, 2d] \), i.e., over all permutations \( \pi \) of \( [1, \ldots, 2d] \) satisfying \( \pi(2q-1) < \pi(2q) \) and \( \pi(2q-1) < \pi(2q+1) \) for all \( q \). The covariance matrix of \( \rho \) is defined as the \( 2d \times 2d \) skew-symmetric matrix with real entries

\[
G^\rho_{pq} = i[\text{Tr}(\rho m_p m_q) – \delta_{pq}].
\]

Due to the Wick expansion property, a quasifree state is uniquely characterized by its covariance matrix. (General references for this section include [20, 57–60] ) The following proposition resumes a known result on these covariance matrices (see, e.g., Lemma 2.1 and Theorem 2.3 in [58]), which will be useful in the later development:

**Proposition 17** The singular values of the covariance matrix of a \( d \)-mode fermionic state must lie between 0 and 1. Conversely, for any \( 2d \times 2d \) skew-symmetric matrix \( G^\rho \) with singular values between 0 and 1 there exists a quasifree state that has \( G^\rho \) as a covariance matrix.
6.2 Orbits and stabilizers of quasifree states under the action of quadratic Hamiltonians

The action of the time-evolution unitaries generated by quadratic Hamiltonians on quasifree states can be described by the next proposition (see Lemma 2.6 in [58]):

**Proposition 18** Consider a quasifree state $\rho_a$ corresponding to the (skew-symmetric) covariance matrix $G^a$. The quadratic Hamiltonian

$$H = i \sum_{p,q=1}^{2d} T_{pq} \left( -\frac{1}{2} m_p m_q \right)$$

is defined using the skew-symmetric matrix $T$ and generates the time-evolution of $\rho_a$. The time-evolved state (at unit time), $\rho_b = e^{-iH} \rho_a e^{iH}$ is again a quasifree state with a (skew-symmetric) covariance matrix $G^b = O_T G^a O_T^T$, where $O_T := e^{-iT} \in \text{SO}(2d)$.

Any skew-symmetric matrix $G$ can be brought into its canonical form

$$O_G G O_G^T = \begin{pmatrix} 0 & v_1 & & & & \\ -v_1 & 0 & & & & \\ & & 0 & v_2 & & \\ & & -v_2 & 0 & & \\ & & & & & \ddots & \\ & & & & & 0 & v_N \\ & & & & & -v_N & 0 \end{pmatrix}$$

using a (not necessarily unique) element $O_G \in \text{SO}(2d)$ where $\{v_i\}_{i=1}^N$ denotes the singular values of $G$. This means that a quasifree state can be reached from another one by the action of quadratic Hamiltonians if their covariance matrices share the same singular values (including multiplicities). Let us now recall another result related to the singular values of the covariance matrices of pure quasifree states (Theorem 6.2 in [58], and Lemma 1 in [60]):

**Proposition 19** A quasifree state $\rho$ is pure iff the following (equivalent) conditions hold for its covariance matrix $G^\rho$: (a) The rows (and columns) of $G^\rho$ are real unit vectors which are pairwise orthogonal to each other. (b) The singular values of $G^\rho$ are all $1$.

Applying this result together with Proposition 18, we obtain the next theorem:

**Theorem 20** The set of quadratic Hamiltonians acts transitively on pure quasifree states, and the corresponding stabilizer algebras are isomorphic to $\mathfrak{u}(d)$.

**Proof** We have already shown that the singular values of the covariance matrices (with multiplicities) form a separating set of invariants for the orbits generated by quadratic Hamiltonians over the set of quasifree states. This means, according to Proposition 19, that the pure quasifree states form a single orbit.

As the set of quadratic Hamiltonians generate a transitive action over the pure quasifree states, the corresponding stabilizer subalgebras are isomorphic to each other. Consider a
quadratic Hamiltonian $H$ with the coefficient matrices $A$ and $B$ as given in Eq. (18) and the Fock state $\rho_\Omega$, which is the projection onto the Fock vacuum vector $\Omega$. The state $\rho_\Omega$ is left invariant under the time evolution generated by $H$ ($\rho_\Omega = e^{-iHt} \rho_\Omega e^{iHt}$) iff $\Omega$ is an eigenvector of $H$. We obtain that

$$H\Omega = \left[ \sum_{p,q=1}^{d} A_{pq} \left( f_p^d f_q^d - \delta_{pq} \frac{1}{2} \right) + \frac{1}{2} B_{pq} f_p^d f_q^d - \frac{1}{2} B_{pq}^* f_p f_q \right] \Omega$$

$$= - \frac{1}{2} \sum_{p,q=1}^{d} A_{pq} \Omega + \sum_{p,q} B_{pq} f_p^d f_q^d \Omega.$$ 

By noting that $\Omega$ and $f_p^d f_q^d \Omega$ (with $p < q$) are linearly independent vectors, we can conclude that a quadratic Hamiltonian $H$ leaves the Fock vacuum invariant iff $H = \sum_{p,q=1}^{d} A_{pq} \left( f_p^d f_q^d - \delta_{pq} \frac{1}{2} \right)$. In Theorem 43 of Section 9 we will show that these operators form a Lie algebra isomorphic to $u(d)$.

**Corollary 21** Theorem 20 identifies the space of pure quasifree states with the quotient space $SO(2d)/U(d)$.

### 6.3 Conditions for quasifree pure-state controllability

According to Theorem 20, a set of quasifree control Hamiltonians $\{H_1, \ldots, H_m\}$ allows for quasifree pure-state controllability, if the corresponding Hamiltonians generate the full quasifree system algebra, i.e. if $\langle iH_1, \ldots, iH_m \rangle_{\text{Lie}} \cong \mathfrak{s} \mathfrak{o}(2d)$. It is natural to ask whether this condition is also a necessary. Remarkably, it turns out that this is not the case, which is shown by the following lemma:

**Lemma 22** Consider a quasifree fermionic system with $d > 1$ modes. Let $K$ be the subgroup of $SO(2d)$ which is isomorphic to $SO(2d-1)$ and stabilizes the first coordinate; its Lie algebra is denoted by $\mathfrak{k}$. Then (a) the group $K$ acts via its adjoint action transitively on the set of all skew-symmetric covariance matrices of pure quasifree states (whose singular values are all 1) and (b) the quasifree system is pure-state controllable if its system algebra is conjugate under $SO(2d)$ to $\mathfrak{k}$.

**Proof** We prove (a) by showing that all pure quasifree states can be transformed under $K$-conjugation to the same pure state. We employ an induction on $d$. The base case $d = 2$ can be directly verified. It follows from Proposition 19(b) that the skew-symmetric covariance matrix of a pure quasifree state can be written as $G^p = \left( \begin{array}{cc} 0 & v_1^d \\ -v_1 & A_1 \end{array} \right)$, where $v_1$ denotes a normalized $(2d-1)$-dimensional vector and $A_1$ denotes a $(2d-1) \times (2d-1)$-dimensional skew-symmetric matrix. We consider the action of a general orthogonal transformation $1 \oplus O_1$ with $O_1 \in SO(d-1)$:

$$\begin{pmatrix} 1 \\ O_1 \end{pmatrix} \begin{pmatrix} 0 & v_1^d \\ -v_1 & A_1 \end{pmatrix} \begin{pmatrix} 1 \\ O_1^t \end{pmatrix} = \begin{pmatrix} 0 & v_1^d O_1^t \\ -O_1 v_1 & O_1 A_1 O_1^t \end{pmatrix}.$$ 

Since any $(2d - 1)$-dimensional vector $v_1$ with unit length can be transformed by an orthogonal transformation to $(1, 0, 0, \ldots, 0)$, we can choose $O_1$ such that $v_1^d O_1^t = (1, 0, 0, \ldots, 0)$.
We have \((O_1 A_1 O_1^T)_{11} = 0\) as the transformed matrix is skew-symmetric. Again by Proposition 19(b) we obtain the transformed matrix as
\[
\begin{pmatrix}
0 & 1 \\
-1 & 0 \\
0 & v^T_2 \\
-v_2 & A_2
\end{pmatrix},
\]
where \(v_2\) is a \(2d - 3\) dimensional unit real vector and \(A_2\) is a \((2d - 3) \times (2d - 3)\) skew-symmetric matrix. Now the proof of (a) follows using the induction hypothesis. The statement (b) is a consequence of (a).

We relate Lemma 22 to what is known about transitive actions on the coset space \(\text{SO}(2d)/U(d)\). Only Lie groups isomorphic to \(\text{SO}(2d - 1)\) and \(\text{SO}(2d)\) can act transitively (i.e. in a pure-state controllable manner) on the homogeneous space \(\text{SO}(2d)/U(d)\) assuming \(d \geq 3\). The case \(d \geq 4\) is discussed in [61]. For \(d = 3\) we have \(\text{SO}(6) \cong \text{SU}(4)\) and \(\text{SU}(4)/U(3) = \text{CP}^3\) (where \(\text{CP}^3\) denotes the complex projective space in four dimensions), and it is known that only subgroups of \(\text{SU}(4)\) isomorphic to \(\text{SU}(4)\) or \(\text{Sp}(2) \cong \text{SO}(5)\) can act transitively on \(\text{CP}^3\) (see p.168 of [62] or p.68 of [63]; refer also to [64]).

In most cases the \(\mathfrak{so}(k - 1)\)-subalgebras of \(\mathfrak{so}(k)\) are conjugate to each other. More precisely, Lemma 7 of [65] states that for \(3 \leq k \notin \{4, 8\}\) all subalgebras of \(\mathfrak{so}(k)\) whose dimension is equal to \((k - 1)(k - 2)/2\) are conjugate to each other under the action of the group \(\text{SO}(k)\). In particular, it follows in these cases that all subalgebras of \(\mathfrak{so}(k)\) with dimension \((k - 1)(k - 2)/2\) are isomorphic to \(\mathfrak{so}(k - 1)\). Interestingly, the last statement holds also for \(k \in \{4, 8\}\) (see Lemma 3 of [65]); however not all of these subalgebras of \(\mathfrak{so}(k)\) are conjugate. We obtain the following theorem providing a necessary and sufficient condition for full quasifree pure-state controllability in the case of \(d > 4\) or \(d = 3\) modes:

**Theorem 23** A quasifree fermionic system with \(d > 4\) or \(d = 3\) modes is fully pure-state controllable iff its system algebra is isomorphic to \(\mathfrak{so}(2d)\) or \(\mathfrak{so}(2d - 1)\).

**Proof** “⇒”: Note that Theorem 20 identifies the space of pure quasifree states with the homogeneous space \(\text{SO}(2d)/U(d)\). Assuming \(d \geq 3\), we summarized above that a group acting transitively on this homogeneous space is isomorphic either to \(\text{SO}(2d)\) or \(\text{SO}(2d - 1)\). Thus only the full quasifree system algebra \(\mathfrak{so}(2d)\) or a system algebra isomorphic to \(\mathfrak{so}(2d - 1)\) can generate a transitive action on the space of pure quasifree states.

“⇐”: As discussed, all \(\mathfrak{so}(2d - 1)\)-subalgebras are conjugate to each other for \(d > 4\) and \(d = 3\). Lemma 22(b) then implies that any set of Hamiltonians generating a system algebra isomorphic to \(\mathfrak{so}(2d - 1)\) will allow for full quasifree pure-state controllability.

Note that the cases \(d = 2\) and \(d = 4\) are well-known pathological exceptions. The algebra \(\mathfrak{so}(4)\) breaks up into a direct sum of two \(\mathfrak{so}(3)\)-algebras which hence cannot be conjugate to each other. For \(d = 4\), there are three classes of non-conjugate subalgebras of type \(\mathfrak{so}(7)\) in \(\mathfrak{so}(8)\) where two classes are given by irreducible embeddings and the third one is conjugate to the reducible standard embedding fixing the first coordinate. (For details, refer to the discussions on the pp.57-58 of [66], on the pp.234-235 of [67], or on the pp.418-419 of [68]. In addition, this information can also be inferred from the tables on p.260 of [69].)
On a more general level, Theorem 23 can be seen as a fermionic variant of the pure-state controllability criterion for spin systems [27–29]. We note here that the result for spin systems has been recently generalized from the transitivity over a set of one-dimensional projections (i.e., pure states) to the transitivity over a set of projections of arbitrary fixed rank (i.e., over Grassmannian spaces) [64]. We will use exactly this generalization in Section 9.3 in order to find a necessary and sufficient pure-state controllability condition for particle-conserving quasifree systems.

7 Translation-invariant systems

We study system algebras generated by translation-invariant Hamiltonians of the type which arises approximately in experimental settings of, e.g., optical lattices. As the naturally occurring interactions are usually short-ranged, we pay particular attention to the case of Hamiltonians with restricted interaction length. For example, consider a $d$-site fermionic chain with Hamiltonians which are translation-invariant and are composed of nearest-neighbor (plus on-site) terms. All elements in its dynamic algebra can be written as linear combinations of six types of terms: the chemical potential

$$h_0 := \sum_{n=1}^{d} \left( f_n^+ f_n - \frac{1}{2} \right),$$

(25)

the real and complex hopping Hamiltonians

$$h_{\text{th}} := \sum_{n=1}^{d} \left( f_n^+ f_{n+1} + f_{n+1}^+ f_n \right) \quad \text{and} \quad h_{\text{ch}} := \sum_{n=1}^{d} i( f_n^+ f_{n+1} - f_{n+1}^+ f_n ),$$

(26)

the real and complex pairing terms

$$h_{\text{tp}} := \sum_{n=1}^{d} \left( f_n^+ f_{n+1}^+ + f_{n+1} f_n \right) \quad \text{and} \quad h_{\text{cp}} := \sum_{n=1}^{d} i( f_n^+ f_{n+1} - f_{n+1}^+ f_n ),$$

(27)

as well as a local density-density-type interaction

$$h_{\text{int}} := \sum_{n=1}^{d} \left( f_n^+ f_n f_{n+1}^+ f_{n+1} - \frac{1}{4} \right).$$

(28)

The corresponding dynamic system algebras (given in Table 1) were computed with the help of the computer algebra system MAGMA [70] for up to six modes while distinguishing nearest-neighbor interactions from arbitrary translation-invariant ones.

| $d$  | System algebra for (a) | System algebra for (b) |
|------|------------------------|------------------------|
| 2    | $\sum_{i=1}^{d} u(1)$  | $\sum_{i=1}^{d} u(1)$  |
| 3    | $\sum_{i=1}^{d} \text{su}(2) + \sum_{i=1}^{d} u(1)$ | $\sum_{i=1}^{d} \text{su}(2) + \sum_{i=1}^{d} u(1)$ |
| 4    | $\sum_{i=1}^{d} \text{su}(2) + \sum_{i=1}^{d} u(1)$ | $\sum_{i=1}^{d} \text{su}(2) + \sum_{i=1}^{d} u(1)$ |
| 5    | $\sum_{i=1}^{d} \text{su}(4) + \sum_{i=1}^{d} \text{su}(3) + \sum_{i=1}^{d} u(1)$ | $\sum_{i=1}^{d} \text{su}(4) + \sum_{i=1}^{d} \text{su}(3) + \sum_{i=1}^{d} u(1)$ |
| 6    | $\sum_{i=1}^{d} \text{su}(6) + \sum_{i=1}^{d} \text{su}(5) + \sum_{i=1}^{d} \text{su}(4) + \sum_{i=1}^{d} u(1)$ | $\sum_{i=1}^{d} \text{su}(6) + \sum_{i=1}^{d} \text{su}(5) + \sum_{i=1}^{d} \text{su}(4) + \sum_{i=1}^{d} u(1)$ |
In this context, two sets of natural questions arise: (a) How does the dimension of these dynamic system algebras scale with the number of modes? (b) How do the system algebras generated by the nearest-neighbor terms differ from the general translation-invariant ones? Can one characterize those elements that are translation-invariant yet not generated by nearest-neighbor Hamiltonians? Are there, for example, next-nearest-neighbor interactions of this type? In this section, we will answer these questions partially. We determine the system algebra for general translation-invariant fermionic Hamiltonians, and conclude that its dimension scales exponentially with the number of modes. We also provide translation-invariant fermionic Hamiltonians of bounded interaction length which cannot be generated by nearest-neighbor ones.

The structure of this section is the following: As the structure of system algebras for translation-invariant systems has only been studied sparsely even for simple scenarios of spin models, we start by examining this case first. In Sections 7.1 and 7.2, we determine the system algebras of all translation invariant spin-chain Hamiltonians with \( L \) qubits. In particular, we simplify and generalize results of [19] concerning finite-ranged interactions. Finally, we present the corresponding results for the fermionic case in Sections 7.3 and 7.4.

7.1 Translation-invariant spin chains

Consider a chain of \( L \) qubits with Hilbert space \( \mathbb{C}^{2^L} \). The translation unitary \( U_T \) is defined by its action on the canonical basis vectors as

\[
U_T |n_1, n_2, \ldots, n_L\rangle = |n_L, n_1, \ldots, n_{L-1}\rangle,
\]

where \( n_i \in \{0, 1\} \). We will determine the translation-invariant system algebra which is defined as the maximal Lie algebra of skew-Hermitian matrices commuting with the translation unitary \( U_T \).

**Lemma 24** The translation unitary can be spectrally decomposed as \( U_T = \sum_{\ell=0}^{L-1} \exp(2\pi i \ell / L) P_\ell \), and the rank \( r_\ell \) of the spectral projection \( P_\ell \) is given by the Fourier transform

\[
r_\ell := \frac{1}{L} \sum_{k=0}^{L-1} 2^{\gcd(L,k)} \exp(-2\pi i k \ell / L),
\]

where \( \gcd(L,k) \) denotes the greatest common divisor of \( L \) and \( k \).

**Proof** The eigenvalues of \( U_T \) are limited to \( \exp(2\pi i \ell / L) \) with \( \ell \in \{0, \ldots, L - 1\} \) as the order of \( U_T \) is \( L \), i.e. \( U_T^L = \mathbb{1} \). Hence, the corresponding spectral decomposition is given by \( U_T = \sum_{\ell=0}^{L-1} \exp(2\pi i \ell / L) P_\ell \). This induces a unitary representation \( D_T \) of the cyclic group \( \mathbb{Z}_L \) which maps the \( k \)th power of the generator \( g \in \mathbb{Z}_L \) of degree \( L \) to \( D_T(g^k) = U_T^k \). Note that \( D_T \) splits up into a direct sum \( D_T \cong \bigoplus_{\ell=0}^{L-1} (D_\ell)^{\oplus \dim(P_\ell)} \) containing \( \dim(P_\ell) \) copies of the one-dimensional representations satisfying \( D_\ell(g^k) = \exp(2\pi i k \ell / L) \). Therefore, we determine the rank of a projection \( P_\ell \) by computing the multiplicity of \( D_\ell \) using the character scalar product

\[
r_\ell = \frac{1}{L} \sum_{k=0}^{L-1} \text{tr}[D_T(g^k)] \text{tr}[D_\ell(g^k)]^* = \frac{1}{L} \sum_{k=0}^{L-1} \text{tr}[D_T(g^k)] \exp(-2\pi i k \ell / L).
\]
The trace of $D_T(g^k)$ is equal to the number of basis vectors left invariant since $D_T(g^k)$ is a permutation matrix in the canonical basis. From elementary combinatorial theory we know that a bit string $(n_1, n_2, \ldots, n_L)$ is left invariant under a cyclic shift by $k$ positions if and only if it is of the form

$$(n_1, n_2, \ldots, n_{\gcd(L,k)}, \ldots, n_1, n_2, \ldots, n_{\gcd(L,k)}).$$

It follows that the number of $U_T^2$-invariant basis vectors and—hence—the trace of $D_T(g^k) = U_T^2$ is equal to $2^{\gcd(L,k)}$. Thus, the multiplicities of $D_{tl}$ are given accordingly by

$$r_{\ell} = \frac{1}{L} \sum_{k=0}^{L-1} 2^{\gcd(L,k)} \exp(-2\pi i k/\ell).$$

Note that a Hamiltonian commutes with $U_T$ iff it commutes with all spectral projections $P_\ell$ of $U_T$. Combining this fact with Theorem 51 we obtain a characterization of the system algebra for translation-invariant spin systems:

**Theorem 25** The translation-invariant Hamiltonians acting on a $L$-qubit system generate the system algebra $t(L) := s(\bigoplus_{\ell=0}^{L-1} u(r_\ell)) \ni \bigoplus_{\ell=0}^{L-1} su(r_\ell) + \bigoplus_{\ell=0}^{L-1} u(1)$, where the numbers $r_\ell$ are defined in Eq. (30).

In complete analogy one can show that for a chain consisting of $L$ systems with $N$ levels, the system algebra is equal to $s(\bigoplus_{\ell=0}^{L-1} u(r_{N,\ell}))$, where $r_{N,\ell}$ denotes the Fourier transform of the function $N^{\gcd(L,k)}$.

7.2 Short-ranged spin-chain Hamiltonians

In many physical scenarios, we may only have direct control over translation-invariant Hamiltonians of limited interaction range. We will investigate in this section how the limitations on the interaction range constrain the set of reachable operations. In particular, we provide upper bounds for the system algebras with finite interaction range.

Let us denote the Lie algebra corresponding to Hamiltonians of interaction length less than $M$ by $t_M(t)$, or $t_M$ for short. In other words, $t_M(L)$ is the Lie subalgebra of $t(L)$ generated by the skew-Hermitian operators

$$i \sum_{q=0}^{L-1} U_T^q \left[ \bigotimes_{p=1}^{M} \mathbb{Q}_p \right] \otimes \mathbb{1}_{2^{L-M}} U_T^{-q}$$

for all combinations of $Q_p \in \{\mathbb{1}, X, Y, Z\}$ apart from the case when $Q_1 = \mathbb{1}$. In this way, $t_1(L)$ corresponds to the translation-invariant on-site Hamiltonians, while $t_2(L)$ is generated by the on-site terms and the nearest-neighbor interactions, and so on. Finally, we have $t_2(L) = t_2$.

We computed all the algebras $t_M(L)$ for $1 \leq L \leq 6$ and $1 \leq M \leq L$ using the computer algebra system Magma [70]. The results, shown in Table 2, suggest that for certain restrictions on the interaction length (e.g., nearest-neighbor terms), there will be some translation-invariant interactions that cannot be generated. This is in accordance with the result of Kraus et al. [19]. Building partly on their work, we analyze the properties of the algebras $t_M(L)$ for general $M$ and $L$ values, and then compare our theorems with Table 2.
Proposition 26 Let $M < L$ denote a divisor of $L$. Given two elements $iH_M \in \mathfrak{t}_M$ and $iH_{M+1} \in \mathfrak{t}_{M+1}$, we obtain that $\text{tr}(U^M_T H_M) = 0$ and $\text{tr}[(U^M_T - U^{qM}_T)H_{M+1}] = 0$ hold for any positive integer $q$.

Applying Proposition 26, we can present upper bounds for the system algebras with restricted interaction length.

Theorem 27 Let $M < L$ denote a divisor of the number of spins $L$, and define $R := L/M$. We obtain: (a) The algebra $\mathfrak{t}_M$ is isomorphic to a Lie subalgebra of $[\sum_{l=0}^{L-1} \text{su}(r)] + [\sum_{l=1}^{R-1} \text{su}(1)]$ and does not generate $\mathfrak{t}_L$. (b) The algebra $\mathfrak{t}_{M+1}$ is isomorphic to a Lie subalgebra of $[\sum_{l=0}^{L-1} \text{su}(r)] + [\sum_{l=1}^{L-1}(R/2) \text{su}(1)]$ and does not generate $\mathfrak{t}_L$. (c) In addition, $\mathfrak{t}_M \neq \mathfrak{t}_{M+1}$.

Proof (a) Since $M$ is a divisor of $L$, the equation

$$U^M_T = \sum_{\ell=0}^{L-1} \exp \left( \frac{2\pi i q M \ell}{L} \right) P_\ell = \sum_{\ell=0}^{L-1} \exp \left( \frac{2\pi i q \ell}{R} \right) P_\ell$$

holds for any integer $q$, and one can invert the equation as $\sum_{p=0}^{M-1} P_{pR+\ell'} = \frac{1}{R} \times \sum_{q=0}^{R-1} \exp(\frac{2\pi i q \ell'}{R}) U^M_T$. If $i\hbar \in \mathfrak{t}_M$, we obtain by applying Proposition 26 that

$$\text{tr} \left( i\hbar \sum_{p=0}^{M-1} P_{pR+\ell'} \right) = 0 \quad (31)$$

holds for $\ell' \in \{0, 1, \ldots, R-1\}$. It follows that $\mathfrak{t}_M$ is a subalgebra of the Lie algebra $\mathfrak{f}$ which consists of all skew-Hermitian matrices satisfying the condition in Eq. (31). Note that $\mathfrak{f}$ is isomorphic to $\bigoplus_{\ell'=0}^{R-1}(\bigoplus_{p=0}^{M-1} u(r_{pR+\ell'})) \cong [\sum_{l=0}^{L-1} \text{su}(r)] + [\sum_{l=1}^{L-1} \text{su}(1)]$, and part (a) follows.
(b) For elements \(ig \in t_{M+1}\), Proposition 26 and Eq. (31) imply that

\[
\text{tr} \left[ ig \sum_{p=0}^{M-1} (P_{pR+1} - P_{pR+L-1}) \right] = 0.
\] (32)

The maximal Lie algebra consisting of skew-Hermitian matrices which satisfy the condition in Eq. (32) is isomorphic to \([\sum_{i=1}^{L-1} su(r_i)] + [\sum_{i=1}^{L-1} u(1)]\). Let

\[
\text{ih} = i \sum_{q'=0}^{L-1} U_{q'}^T [X \otimes \frac{1}{2} \otimes M-1 \otimes X \otimes \frac{1}{2} \otimes L-M-1] U_{q'}^T.
\]

Obviously, \(ih \in t_{M+1}\) holds. Using the formula for \(F(1,M+1)\) in Appendix E.2, we obtain that \(\text{tr}(U_{q}^M \text{ih}) = i2L\) holds for every integer \(q\). Hence, \(ih \notin t_M\). □

In particular, this theorem implies that the algebra \(t(L) = t_2(L)\) of all translation-invariant Hamiltonians cannot be generated from the subclass of nearest-neighbor Hamiltonians, cf. also [19]. More precisely, one finds:

**Corollary 28** If \(L\) is even, \(t_2(L)\) is isomorphic to a Lie subalgebra of the Lie algebra \([\sum_{i=1}^{L-1} su(r_i)] + [\sum_{i=1}^{L/2} u(1)]\). For odd \(L \geq 3\), \(t_2(L)\) is isomorphic to a Lie subalgebra of the Lie algebra \([\sum_{i=1}^{L-1} su(r_i)] + [\sum_{i=1}^{(L-3)/2} u(1)]\).

Let us now compare our upper bounds with the results of Table 2. Theorem 27 restricts the possibilities for the \(M\)-local algebras \(t_M(L)\) only by some central elements \(u(1)\) when compared to the corresponding full translation-invariant algebra \(t(L)\). One can indeed identify in Table 2 some missing \(u(1)\)-parts for \(L \in \{3, \ldots, 6\}\). In general, the dimensions of the \(M\)-local algebras \(t_M(L)\) can be even smaller than predicted by the upper bounds of Theorem 27 as can be seen in Table 2 for \(L = 4\). Theorem 27 and Table 2 suggest that the prime decomposition of the chain length \(L\) will have strong implications on the dimension of \(t_M(L)\).

### 7.3 Translation-invariant fermionic systems

To determine the system algebra generated by all translation-invariant Hamiltonians of a fermionic chain, we can follow similar lines as in Section 7.1. Here, however, we additionally have to consider the parity superselection rule. We define the fermionic translation-invariant system algebra as the maximal Lie subalgebra of \(su(2^{d-1}) \oplus su(2^{d-1})\) [see Theorem 4] which contains only skew-Hermitian matrices commuting with the fermionic translation unitary \(U\), which is defined below such that it commutes with the parity operator \(P\) (see Eq. (14)). The standard orthonormal basis in the Fock space for a chain of \(d\) fermionic modes is given by

\[
|n_1, n_2, \ldots, n_d\rangle := (f_1^\dagger)^{n_1} (f_2^\dagger)^{n_2} \cdots (f_d^\dagger)^{n_d} |0\rangle
\] (33)

with \(n_i \in \{0, 1\}\). Note that for the purpose of unambiguously defining this basis, we order the operators \((f_i^\dagger)^{n_i}\) in Eq. (33) with respect to their site index \(i\). The fermionic translation
unitary $U$ is defined by its action

$$
U|n_1, n_2, \ldots, n_d\rangle = U(f_1^+)^{n_1} (f_2^+)^{n_2} \cdots (f_d^+)^{n_d} |0\rangle = (f_1^+)^{n_1} \cdots (f_d^+)^{n_d} |f_1^+)^{n_d} |0\rangle
$$

$$
= (-1)^{n_0(n_1+n_2+\cdots+n_d-1)} (f_1)^{n_0} \cdots (f_d)^{n_0-1} |f_1\rangle^n f_1|0\rangle
$$

$$
= (-1)^{n_0(n_1+n_2+\cdots+n_d-1)} |n_d, n_1, \ldots, n_d-1\rangle
$$

on the standard basis. The adjoint action of $U$ on the creation operators $f_1^+$ is then given by

$$
U f_1^+ U^\dagger = f_1^+^{(\ell + 1 \text{mod} d)}.
$$

The superselection rule for fermions splits the spectral decomposition of the translation unitary into two blocks corresponding to the positive and negative parity subspace. The translation unitary $U$ commutes with the parity operator $P$, and hence $U = U_+ + U_-$. The spectral decomposition of the reducible representation is given by

$$
\text{tr} \text{al decomposition is given by}
$$

$\text{Lemma 29}$ The unitary operators $U_{\pm} = \sum_{\ell=0}^{d-1} e^{2\pi i \ell/d} \times P^\pm_\ell$, where the rank $\hat{r}_\ell$ of the spectral projection $P^\pm_\ell$ is given by the Fourier transform

$$
\hat{r}_\ell := \frac{1}{d} \sum_{k=0}^{d-1} h(d, k) \exp(-2\pi i k \ell/d)
$$

of $h(d, k)$ where $\ell \in \{0, \ldots, d-1\}$ and

$$
h(d, k) := \begin{cases} 
0 & \text{if } d/ \gcd(d, k) \text{ is even}, \\
2^{\gcd(d, k)-1} & \text{if } d/ \gcd(d, k) \text{ is odd}.
\end{cases}
$$

**Proof** We determine the spectral decomposition of $U_+$ and $U_-$ along the lines of Lemma 24. Let $F_\ell(\mathbb{C}^d)$ denote the subspace spanned by those basis vectors of $\mathbb{C}^d$ for which $n = \sum_{i=1}^d n_i$ is even. Likewise, $F_\ell(\mathbb{C}^d)$ corresponds to the case of odd $n$. As $(U_{\pm})^d = 1_{F_\ell(\mathbb{C}^d)}$, the eigenvalues of $U_{\pm}$ are of the form $\exp(2\pi i \ell/d)$ with $\ell \in \{0, \ldots, d-1\}$. Hence, the spectral decomposition is given by $U_{\pm} = \sum_{\ell=0}^{d-1} \exp(2\pi i \ell/d) P_{\ell} \pm$. We define representations $D_{\pm}$ of the cyclic group $\mathbb{Z}_d$ which map the $k$th power of the generator $g \in \mathbb{Z}_d$ of degree $d$ to $D_{\pm}(g^k) := U_{\pm}^k$. Note that $D_{\pm}$ splits up into a direct sum $D_{\pm} \cong \bigoplus_{\ell=0}^{d-1} (D_{\ell} \otimes \text{dim}(P_{\ell}))$ containing $\text{dim}(P_{\ell})$ copies of the one-dimensional representations satisfying $D_{\ell}(g^k) \equiv \exp(2\pi i \ell k/d)$. The rank $r_{k}^\pm$ of the projection $P_{\ell}^\pm$ is equal to the multiplicity of $D_{\ell}$ in the decomposition of the reducible representation $D_{\pm}$. This multiplicity can be computed as the character scalar product

$$
r_{k}^\pm = \frac{1}{d} \sum_{k=0}^{d-1} \text{tr}[D_{\pm}(g^k)] \text{tr}[D_{\ell}(g^k)]^* = \frac{1}{d} \sum_{k=0}^{d-1} \text{tr}[D_{\pm}(g^k)] \exp(-2\pi i k/d).
$$

In the standard basis, all matrix entries of $D_{\pm}(g^k) = U_{\pm}^k$ are elements of the set $\{0, 1, -1\}$. It follows by repeated applications of Eq. (34) that $U_k$ maps the basis vectors $|n_1, n_2, \ldots, n_d\rangle$
to \( s|n_{\pi(1)}, n_{\pi(2)}, \ldots, n_{\pi(d)}\rangle \) where \( \pi \) is a cyclic shift by \( k \) positions and the sign \( s \) is given by

\[
S := (-1)^{\sum_{\ell=1}^{d-k} n_{\ell}} \sum_{j=d-k+1}^{d} n_{j}.
\]

Recall from the proof of Lemma 24 that a bit string \((n_{1}, n_{2}, \ldots, n_{N})\) is left invariant under a cyclic shift by \( k \) positions iff it is of the form

\[
(n_{1}, n_{2}, \ldots, n_{\text{gcd}(d, k)}), \ldots, n_{1}, n_{2}, \ldots, n_{\text{gcd}(d, k)}).
\]

If \( d/\text{gcd}(d, k) \) is even, the sum \( \tilde{n} = \sum_{i=1}^{d} n_{i} \) is even for all of the \( 2^{\text{gcd}(d, k)} \) bit strings invariant under a cyclic shift by \( k \) positions. It follows that all the diagonal entries of \( U_{k}^{+} \) are zero, while \( U_{k}^{-} \) has \( 2^{\text{gcd}(d, k)} \) non-zero diagonal entries. The non-zero diagonal entries of \( U_{k}^{-} \) are given by the number \( s \) of Eq. (36). Note that \( s \) is +1 if \( \sum_{i=1}^{d-k} n_{i} \) is even; and –1 otherwise.

Hence the frequencies of +1 and –1 in the set of diagonal entries are equal. In summary,

\[
\text{tr}(U_{k}^{\pm}) = 0 \text{ if } d/\text{gcd}(d, k) \text{ is even.}
\]

Assume now that \( d/\text{gcd}(d, k) \) is odd. The sum \( \tilde{n} \) is odd for half of the \( 2^{\text{gcd}(d, k)} \) bit strings and even for the other half. Applying again Eq. (36), we obtain always a positive sign. Hence, both traces \( \text{tr}(U_{k}^{\pm}) \) are equal to \( 2^{\text{gcd}(d, k)-1} \). This completes the proof. \( \square \)

Lemma 29 together with Theorem 51 implies the following characterization of the system algebra for a translation-invariant fermionic system:

**Theorem 30** Let the translation-invariant Hamiltonians act on a fermionic system with \( d \) modes. The corresponding system algebra \( \mathcal{A} \) is given by

\[
\mathcal{A} \cong \bigoplus_{\ell=0}^{d-1} \mathfrak{u}(\mathfrak{r}_{\ell}) \oplus \bigoplus_{\ell=0}^{d-1} \mathfrak{u}(\mathfrak{r}^{-}_{\ell}) \oplus \left[ \sum_{\ell=0}^{d-1} \mathfrak{su}(\mathfrak{r}_{\ell}) + \mathfrak{su}(\mathfrak{r}^{-}_{\ell}) \right] \oplus \sum_{\ell=1}^{2d-2} \mathfrak{u}(1),
\]

where the numbers \( \mathfrak{r}_{\ell} \) are defined in Eq. (35).

**Remark 31** Note that \( \mathfrak{r}_{0} \geq \mathfrak{r}_{\ell} \) holds for any \( \ell \) and that \( \sum_{\ell=0}^{d} \mathfrak{r}_{\ell} = 2^{d-1} \). It follows that \( \mathfrak{r}_{0} \geq (2^{d-1} - 1)/d \) and hence that the dimension of the system algebra in Theorem 30 scales exponentially with \( d \).

**Remark 32** Assuming that the number of modes is given by a prime number \( p \), we can explicitly determine the numbers \( \mathfrak{r}_{\ell} \) from Eq. (35). The corresponding system algebras are

\[
\sum_{i=1}^{2} \mathfrak{su}(F_{i} + 1) + \sum_{i=1}^{2p-2} \mathfrak{su}(F_{i}) + \sum_{i=1}^{2p-2} \mathfrak{u}(1),
\]

where \( F_{p} = (2^{p-1} - 1)/p \) is guaranteed to be an integer by Fermat’s little theorem.

### 7.4 Fermionic nearest-neighbor Hamiltonians

For spin systems (see Section 7.2) we verified that the translation-invariant nearest-neighbor interactions together with the on-site elements will never generate all translation-invariant operators, i.e. \( t_{1} \neq t_{2} \) (if the number of spins \( L \) is greater than two). This
means that there exist certain translation-invariant elements which cannot be generated by nearest-neighbor interactions and on-site elements, but we could not identify the explicit form of these translation-invariant elements for general \(L\). In particular, it would be interesting to know if \(t_M \neq t_2\) holds for interaction lengths less than \(M (2 < M < L)\), where \(M\) is independent of \(L\).

In the case of fermionic systems, we can provide a result in this direction due to the restriction imposed by the parity superselection rule, which strongly limits the set of nearest-neighbor Hamiltonians. As we have discussed at the beginning of this section, the fermionic translation-invariant Hamiltonians of nearest-neighbor type are spanned by only six elements: \(h_0\), \(h_{\text{hh}}\), \(h_{\text{hp}}\), \(h_{\text{cp}}\), and \(h_{\text{int}}\) as defined in Eqs. (25)-(28). We can show that there exist next-nearest-neighbor or third-neighbor interactions for odd \(d \geq 5\) which cannot be generated by these six Hamiltonians, while for even \(d \geq 6\) we provide a fourth-neighbor element.

Let \(t_M^f\) denote the subalgebra of \(t^f\) (see Theorem 30) which is generated by all elements of interaction length less than \(M\). In particular, \(t_2^f\) is generated by nearest-neighbor and on-site elements. The result of this subsection is summarized in the following theorem:

**Theorem 33** Let us consider the Hamiltonian \(h_o := \sum_{n=1}^{d} i(f_n^d f_{n+3}^d - f_{n+3}^d f_n^d)\), and fourth-neighbor Hamiltonian

\[
h_e := \sum_{n=1}^{d} \left( f_n^d f_{n+1}^d f_{n+2}^d f_{n+3}^d f_{n+4}^d - \frac{1}{32} \mathbb{1} \right). \]

The generator \(i h_o \in t_4^f\) is not contained in the system algebra \(t_2^f\) generated by nearest-neighbor interactions and on-site elements if \(d \geq 5\) is odd, while the element \(i h_e \in t_4^f\) is not contained in \(t_2^f\) if \(d \geq 6\) is even. Hence \(t_2^f \neq t_4^f\) (when \(d \geq 5\)).

8 Quasifree fermionic systems satisfying translation-invariance

We continue the discussion of translation-invariant fermionic systems from Section 7 by narrowing the scope to quadratic Hamiltonians. In Section 8.1, we derive the dynamic algebras for systems with and without (twisted) reflection symmetry. Both of these cases are summarized for quasifree fermionic systems in Table 3: the system algebras were computed using the computer algebra system MAGMA [70] for cases with low number of modes, while the complete picture is provided by Theorem 34 and Corollary 35. Section 8.2 yields a classification of the orbit structure of pure translation-invariant quasifree states. This allows us to present an application to many-body physics in Section 8.3, where we bound the scaling of the gap for a class of quadratic Hamiltonians.

8.1 Translation-invariant quadratic Hamiltonians

A quadratic Hamiltonian \(H\) is translation-invariant (i.e. \([H, \mathcal{U}] = 0\)) iff the coefficient matrices \(A\) and \(B\) in Eq. (18) are cyclic (i.e. \(A_{nm} - A_{n+1,m+1} = B_{nm} - B_{n+1,m+1} = 0\)). To study such
Hamiltonians, it is useful to rewrite them in terms of the Fourier-transformed annihilation and creation operators

\[ \tilde{f}_k := \frac{1}{\sqrt{d}} \sum_{p=1}^{d} f_p e^{-2\pi ip k/d} \quad \text{and} \quad \tilde{f}_k^\dagger := \frac{1}{\sqrt{d}} \sum_{p=1}^{d} f_p^* e^{2\pi ip k/d}, \]

with \( k \in \{0, 1, \ldots, d - 1\} \), which satisfy the canonical anticommutation relations

\[ \{ \tilde{f}_k, \tilde{f}_k' \} = \{ \tilde{f}_k, \tilde{f}_k^\dagger \} = 0 \quad \text{and} \quad \{ \tilde{f}_k^\dagger, \tilde{f}_k' \} = \delta_{kk'} \mathbb{1}. \]

A Hamiltonian from Eq. (18) with cyclic \( A \) and \( B \) can now be rewritten as

\[ H = \sum_{k=0}^{d-1} \tilde{A}_k \left( \tilde{f}_k^\dagger \tilde{f}_k - \frac{\mathbb{1}}{2} \right) + \frac{1}{2} \tilde{B}_k \left( \tilde{f}_k^\dagger \tilde{f}_d - \tilde{f}_d^\dagger \tilde{f}_k \right) - \frac{1}{2} \tilde{B}_k^* \tilde{f}_k^\dagger \tilde{f}_d \]

(40)

applying \( \tilde{A}_k := \sum_{p=1}^{d} A_{ip} \exp(-2\pi ip k/d) \) and \( \tilde{B}_k := \sum_{p=1}^{d} B_{ip} \exp(-2\pi ip k/d) \), as well as the notation \( \tilde{f}_d = f_0 \). The hermiticity of \( A \) and the skew-symmetry of \( B \) translates into the properties \( \tilde{A}_k = \tilde{A}_{d-k}^* \) and \( \tilde{B}_k = -\tilde{B}_{d-k} \). This allows us to decompose the Hamiltonian into a four-part sum

\[ H = \sum_{k=1}^{[(d-1)/2]} \Im(\tilde{A}_k) \ell_k^X + \sum_{k=1}^{[(d-1)/2]} \Re(\tilde{B}_k) \ell_k^X / 2 + \sum_{k=1}^{[(d-1)/2]} \Im(\tilde{B}_k) \ell_k^Y / 2 + \sum_{k=0}^{[d/2]} \Re(\tilde{A}_k) \ell_k^Z, \]

(41)

where one has the following definitions

\[ \ell_k^X := i(\tilde{f}_k^\dagger \tilde{f}_d - \tilde{f}_d^\dagger \tilde{f}_k), \quad \ell_k^Y := (\tilde{f}_k^\dagger \tilde{f}_d + \tilde{f}_d^\dagger \tilde{f}_k), \]

\[ \ell_k^Z := i(\tilde{f}_d^\dagger \tilde{f}_k - \tilde{f}_k^\dagger \tilde{f}_d), \quad \ell_k^Z := (\tilde{f}_d^\dagger \tilde{f}_d + \tilde{f}_d^\dagger \tilde{f}_d - 1/2) \]

with \( k \in \{1, \ldots, [(d-1)/2]\} \) as well as

\[ \ell_{d/2}^Z := (\tilde{f}_{d/2}^\dagger \tilde{f}_{d/2} - 1/2) \quad \text{for } d \text{ even}, \quad \ell_0^Z := (\tilde{f}_0^\dagger \tilde{f}_0 - 1/2). \]

(42)

(43)
Note that the operators $\ell_d^a$ (for $d$ even), $\ell_d^x$, $\ell_d^y$, $\ell_d^z$, and $\ell_d^t$ are linearly independent and span the $(|d - 1| + d)$-dimensional space of all translation-invariant quadratic Hamiltonians. For notational convenience we also introduce the dummy operators $\ell_0^Q := 0$ (assuming $d$ is even) and $\ell_0^Q := 0$ for $Q \in \{1, X, Y\}$.

With these stipulations, we can characterize the system algebra:

**Theorem 34** Let $q_d$ denote the system algebra on a fermionic system with $d$ modes which corresponds to the set of Hamiltonians that are translation-invariant and quadratic. Then the Lie algebra $q_d$ is isomorphic to $[\sum_{i=1}^{(d-1)/2} u(2)] + u(1)$ for odd $d$ and to $[\sum_{i=1}^{(d-2)/2} u(2)] + u(1) + u(1)$ for even $d$.

**Proof** If $d = 2m - 1$ is odd, the generators $it_d^a$, $it_d^x$, $it_d^y$, $it_d^z$, and $it_d^t$ can be partitioned into $m$ pairwise-commuting sets, which each span linear subspaces as

$$L_0 := \{it_d^a\}_{\mathbb{R}} \quad \text{and} \quad L_k := \{it_d^X, it_d^Y, it_d^Z\}_{\mathbb{R}}$$

with $k \in \{1, \ldots, m - 1\}$. The commutation properties $[L_k, L_{k'}] = 0$ (with $k \neq k'$) follow from Eq. (39). Moreover, $L_0$ is one-dimensional and forms a $u(1)$-algebra. Using Eq. (39), the relations $[\hat{f}_d^a, \hat{f}_d^{a'}] = [\hat{f}_d^X, \hat{f}_d^{X'}] = [\hat{f}_d^Y, \hat{f}_d^{Y'}] = [\hat{f}_d^Z, \hat{f}_d^{Z'}] = 0$ and $[\hat{f}_d^a, \hat{f}_d^{a'}] = \hat{f}_d^{a'} \hat{f}_d^a - 1$ can be deduced for $a \neq b$. Substituting $k$ and $d - k$ into $a$ and $b$ in the previous formula, one can verify directly that the correspondence

$$it_d^a \mapsto i\mathbb{1}, \quad it_d^X \mapsto iX, \quad it_d^Y \mapsto iY, \quad it_d^Z \mapsto iZ$$

provides an explicit Lie isomorphism between $L_k$ and $u(2)$. If $d = 2m$ is even, the system algebra consists of the above-described generators supplemented with the element $it_d^t$. This additional element commutes with all the other generators and—therefore—provides an additional $u(1)$.

The isomorphism between $L_k$ and $u(2)$ as given in the proof leads to a compact formula for the time evolution (in the Heisenberg picture) of the elements of $L_k$. Since the operators $\ell_d^X, \ell_d^Y, \ell_d^Z$, and $\ell_d^t$ (with $k \in \{1, \ldots, (|d - 1|/2)\}$) satisfy the same commutation relations as the Pauli matrices $X, Y, Z,$ and $\mathbb{1}$, their time-evolution generated by the Hamiltonian $H$ in Eq. (41) can be straightforwardly related to a qubit time-evolution

$$e^{iHt}(a d^a \ell_d^a + a X \ell_d^X + a Y \ell_d^Y + a Z \ell_d^Z) e^{-iHt}$$

$$= i a_d \ell_d^a + \sum_{Q \in \{X, Y, Z\}} i a_Q \ell_d^Q \text{tr}(e^{iHt} Q e^{-iHt} Q),$$

where $H_s = \Re(\hat{A} X) + \Re(\hat{B} Y) + 3 \Re(\hat{B} Y) / 2$.

The twisted reflection symmetry plays an important role in translation-invariant quasifree fermionic systems. It is defined by the unitary

$$\mathcal{R}|n_1, n_2, \ldots, n_d\rangle = |\sum_{i=1}^d n_i^2 |n_{d-d-1}, \ldots, n_1\rangle$$

whose adjoint action on creation operators and their Fourier transforms is given by

$$\mathcal{R} \ell_d^a \mathcal{R}^\dagger = i \ell_d^{(-a)} \quad \text{and} \quad \mathcal{R} \ell_d^\dagger \mathcal{R}^\dagger = \ell_d^\dagger$$

(46)
A given translation-invariant quasifree Hamiltonian is $\mathcal{R}$-symmetric (i.e. $[\mathcal{R}, H] = 0$) iff the coefficient matrix is restricted to be real. In our language, these Hamiltonians are exactly the ones for which $\Im m(\tilde{A}_k) = 0$, i.e., the corresponding generators are spanned by the operators $i\tilde{Z}_{d/2}$ (for $d$ even), $i\tilde{Z}_0$, $i\tilde{Z}_k$, and $i\tilde{Y}_k$. From the proof of Theorem 34 one can immediately deduce the corresponding system algebra:

**Corollary 35** Consider a fermionic system with $d$ modes and the set of quadratic Hamiltonians which are translation-invariant and $\mathcal{R}$-symmetric. The corresponding system algebra $q^R_d$ is isomorphic to $[\sum_{i=1}^{(d-1)/2} \text{su}(2)] + u(1)$ for odd $d$ and to $[\sum_{i=1}^{(d-2)/2} \text{su}(2)] + u(1) + u(1)$ for even $d$.

Given the system algebras $q_d$ and $q^R_d$, we investigate the subalgebras generated by short-range Hamiltonians. It will be useful to introduce for $p \in \{1, \ldots, [(d - 1)/2]\}$ the Hamiltonians

\[
\begin{align*}
h^X_p &:= \frac{1}{2} \sum_{\ell=1}^{d} i(f^{\dagger}_\ell f_{\ell+p} - f_{\ell+p} f^{\dagger}_\ell) = \sum_{k=0}^{[(d-1)/2]} \sin\left(\frac{2\pi kp}{d}\right) \ell^2_k, \\
h^Y_p &:= \frac{1}{2} \sum_{\ell=1}^{d} (f^{\dagger}_\ell f_{\ell+p} + f_{\ell+p} f^{\dagger}_\ell) = \sum_{k=0}^{[(d-1)/2]} \sin\left(\frac{2\pi kp}{d}\right) \ell^1_k, \\
h^Z_p &:= \frac{1}{2} \sum_{\ell=1}^{d} (\ell f^{\dagger}_\ell f_{\ell+p} + f_{\ell+p} f^{\dagger}_\ell) = \sum_{k=0}^{[(d-2)/2]} \cos\left(\frac{2\pi kp}{d}\right) \ell^0_k, \\
h^Z_{d/2} &:= \frac{1}{2} \sum_{\ell=1}^{d} (\ell f^{\dagger}_\ell f_{\ell+p} + f_{\ell+p} f^{\dagger}_\ell - \frac{d}{2}) = \sum_{k=0}^{[d/2]} \ell^Z_k,
\end{align*}
\]

as well as the additional ones ($h^Z_{d/2}$ only for even $d$)

\[
\begin{align*}
h^Z_0 &:= \frac{1}{2} \sum_{\ell=1}^{d} (f^{\dagger}_\ell f_{\ell} + f^{\dagger}_\ell f_{\ell} - \frac{d}{2}) = \sum_{k=0}^{[d/2]} \ell^Z_k, \\
h^Z_{d/2} &:= \frac{1}{2} \sum_{\ell=1}^{d} (f^{\dagger}_\ell f_{\ell+p} + f^{\dagger}_\ell f_{\ell+p}) = \sum_{k=0}^{[d/2]} (-1)^k \ell^Z_k.
\end{align*}
\]

In these definition we used cyclic indices, e.g., $f_{d+a} = f_a$. The operators $h^Z_{d/2}$ (for $d$ even), $h^Z_0$, $h^Z_p$, $h^X_p$, and $h^Y_p$ span $q_d$ linearly. Using the identities above, the commutation relations of the $\ell^k$ operators, and some trigonometric identities, we obtain

\[
\begin{align*}
[h^X_p, h^Y_p] &= [ih^X_p, ih^Y_p] = [ih^X_p, ih^Y_p] = 0, \\
[h^X_p, ih^Y_p] &= -\frac{i}{2} (h^X_{(a+b) \mod \lfloor d/2 \rfloor} - h^X_{(a-b) \mod \lfloor d/2 \rfloor}), \\
[h^Y_p, ih^Z_p] &= -\frac{i}{2} [\text{sgn}(d - a - b)h^X_{(a+b) \mod \lfloor d/2 \rfloor} - \text{sgn}(a - b)h^X_{(a-b) \mod \lfloor d/2 \rfloor}], \\
[h^Z_p, ih^X_p] &= -\frac{i}{2} [\text{sgn}(d - a - b)h^Y_{(a+b) \mod \lfloor d/2 \rfloor} - \text{sgn}(a - b)h^Y_{(a-b) \mod \lfloor d/2 \rfloor}].
\end{align*}
\]
for \(a, b \in \{0, \ldots, [d/2]\}\). In [19] it was shown that already the nearest-neighbor Hamiltonians of \(q^R_d\) generate the whole \(q^R_d\). Now we are in the position to provide a more systematic proof of their result:

**Lemma 36** The system algebra \(q^R_d\) can be generated using the one-site-local operator \(ih_0^Q\) and a nearest-neighbor element \(i(\alpha_1 h_1^2 + \alpha_2 h_1^2 + \alpha_3 h_1^2)\) with \(\alpha_i \in \mathbb{R}\) assuming that \(\alpha_2 \neq 0\) or \(\alpha_3 \neq 0\) for odd \(d\) and additionally requiring \(\alpha_1 \neq 0\) for even \(d\).

**Proof** (1) From Eqs. (48a)–(48d) we know that \(ih_0^Q, ih_1^2, ih_1^X\), and \(ih_1^Y\) would generate the whole \(q^R_d\). (2) Suppose that \(\alpha_1 \neq 0\) and \(\alpha_2^2 + \alpha_3^2 \neq 0\). From \(2[2ih_0^Q, i(\alpha_1 h_1^2 + \alpha_2 h_1^2 + \alpha_3 h_1^2)] = \alpha_2^2 h_1^2 - \alpha_3 h_1^X + 2ih_1^2, \alpha_2 i h_1^2 - \alpha_3 i h_1^2 = -\alpha_2 i h_1^2 - \alpha_3 i h_1^2\) it follows that one can generate \(ih_0^Q, ih_1^2, ih_1^X\), and \(ih_1^Y\). Hence according to observation (1), the whole \(q^R_d\) is generated. (3) Suppose now that \(\alpha_1 = 0\), \(d\) is odd, and \(\alpha_2^2 + \alpha_3^2 \neq 0\). From \(2[2ih_0^Q, i(\alpha_2 h_1^2 + \alpha_3 h_1^2)] = \alpha_2^2 h_1^2 - \alpha_3 h_1^X + 2ih_1^2, \alpha_2 i h_1^2 - \alpha_3 i h_1^2\) one can generate \(ih_0^Q, ih_1^Z\), \(ih_1^X\), and \(ih_1^Y\). From Eqs. (48a)–(48d) it follows that these generators in turn generate all \(ih_{2p+1}^Q\). Since \(d\) is odd, \(ih_1^Z\) is also generated. Hence we obtain \(ih_0^Q, ih_1^2, ih_1^X\), and \(ih_1^Y\), and according to (1), the algebra \(q^R_d\) is generated. \(\Box\)

For the more general \(q_d\), we obtain a slightly larger system algebra when we do not assume \(\mathcal{R}\)-symmetry:

**Proposition 37** The elements of \(q_d\) with interaction length less than \(M\) (where \(2 \leq M \leq \lfloor d/2 \rfloor\) and \(d \geq 3\)) generate a system algebra which is isomorphic to \([\sum_{i=1}^{d-1/2} su(2)] + \sum_{i=1}^{M} u(1)\) for odd \(d\) and to \([\sum_{i=1}^{d-2/2} su(2)] + \sum_{i=1}^{M+1} u(1)\) for even \(d\).

**Proof** From Lemma 36 we know that the operators \(h_0^Q\) with \(Q \in \{X, Y, Z\}\) already generate \(q^R_d\) which is isomorphic to \([\sum_{i=1}^{d-1/2} su(2)] + u(1)\) for odd \(d\) and to \([\sum_{i=1}^{d-2/2} su(2)] + u(1) + u(1)\) for even \(d\). We have \(M-1\) additional operators \(h_q^a\) with \(q \in \{1, \ldots, M-1\}\) which are linearly independent and commuting. These generate the other parts corresponding \(\sum_{i=1}^{M+1} u(1)\). \(\Box\)

We illustrate Lemma 36 and Proposition 37 with a fermionic ring of \(d = 6\) modes. Suppose that the drift Hamiltonian of this system is the nearest-neighbor hopping Hamiltonian \(ih_0^Q = \frac{1}{2} \sum_{i=1}^{d/2} (f_i f_{i+1} + f_{i+1} f_i)\), and that one can additionally control the on-site potential \(ih_1^Z = \frac{1}{2} \sum_{i=1}^{d/2} (f_i^2 - \frac{1}{2})\), the pairing strength \(ih_1^X = \frac{1}{2} \sum_{i=1}^{d/2} (f_i f_{i+1}^\dagger + f_{i+1} f_i)\), and the magnetic flux \(ih_1^Y = -\frac{1}{2} \sum_{i=1}^{d/2} (f_i f_{i+1}^\dagger - f_{i+1} f_i)\) in the ring. Lemma 36 implies that the first three Hamiltonians generate the Lie algebra \(q^R_d\) of all Hamiltonians which are simultaneously \(\mathcal{R}\)-invariant, translation-invariant, and quadratic. The magnetic flux term \(ih_1^Y\) commutes with all elements of \(q^R_d\) and contributes only an additional \(u(1)\) to the system algebra. Thus, the system algebra generated by all nearest-neighbor quadratic Hamiltonians that are translation-invariant is given by \(q^R_d \cong su(2) + su(2) + u(1) + u(1)\). In order to achieve full controllability for a translation-invariant and quasifree fermionic system (which corresponds to the Lie algebra \(q_6 \cong su(2) + su(2) + u(1) + u(1) + u(1)\)), one has to add a next-nearest neighbor Hamiltonian as \(ih_2^Z = -\frac{1}{2} \sum_{i=1}^{d/2} (f_i f_{i+2} - f_{i+2} f_i)\).

### 8.2 Orbits of pure translation-invariant quasifree states

We characterize now the orbits of pure translation-invariant quasifree states under the action of translation-invariant quadratic Hamiltonians. Since the operators \(\ell_k^a = i[\tilde{f}_k^a, \tilde{f}_k^a -\)

\[ \tilde{f}_d \tilde{f}_{d-k} \] commute with all the other translation-invariant quadratic Hamiltonians (as discussed in Section 8.1), their expectation values stay invariant under the considered time evolutions. At the end of the section, we show that these invariant expectation values even form a separating set of invariants for the orbits of pure translation-invariant quasifree states.

Let us recall that a quasifree state is fully characterized by its Majorana covariance matrix, defined in Eq. (24). The translation unitary \( U \) acts on the Majorana operators by conjugation as
\[
U m_p U^\dagger = m_{p+2\text{mod}2d}.
\]
It follows that a quasifree state \( \rho \) is translation-invariant (i.e. \( [\rho, U] = 0 \)) iff its covariance matrix \( G_{pq} \) is doubly-cyclic, i.e.
\[
G_{pq} = G_{(p+2\text{mod}2d),(q+2\text{mod}2d)}.
\]
The double-cyclicity of \( G \) implies that it can be expressed as a block-Fourier transform of a block-diagonal matrix, i.e.
\[
\tilde{G} = U_F G U_F^\dagger, \tag{49}
\]
where \( U_F := \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix} \otimes W \) with \( W_{pq} := \exp(2\pi i/d)^{p-q} \) and \( \tilde{G} = \bigoplus_{k=0}^{d-1} \tilde{g}(k) \) with \( \tilde{g}(k) \) being \( 2 \times 2 \)-matrices. The matrices \( \tilde{g}(k) \) can be calculated by the inverse block-Fourier transform
\[
\tilde{g}(k) = -i \sum_{\ell=1}^d e^{2\pi i k\ell/d} \begin{pmatrix} G_{1,2\ell-1} & G_{1,2\ell} \\ G_{2,2\ell-1} & G_{2,2\ell} \end{pmatrix}. \tag{50}
\]
The fact that \( G \) is skew-symmetric and real implies
\[
\tilde{g}(d-k) = -\tilde{g}^T(k). \tag{51}
\]
Moreover, due to Eq. (49) the set of eigenvalues of all the matrices \( \tilde{g}(k) \) equals the one of \(-iG\) (including multiplicities). Combining these observations with Proposition 17 and Proposition 19, we obtain the following characterization of pure translation-invariant quasifree states:

**Lemma 38** A set of \( 2 \times 2 \) matrices \( \tilde{g}(k) \) (with \( k \in \{0, \ldots, d-1\} \)) defines a covariance matrix of a pure quasifree state through Eq. (49) if and only if they satisfy Eq. (51) and their eigenvalues are in the set \( \{1, -1\} \).

The entries of \( \tilde{g}(k) \) and the expectation values of the \( \ell_k \) operators defined in Eq. (42) can be related by
\[
\tilde{g}(k) = 1_2(\ell_k^x) + X(\ell_k^x) + Y(\ell_k^y) + Z(\ell_k^z) \tag{52}
\]
using Eq. (50) and the definitions for \( \ell_k^x, \ell_k^y, \ell_k^y, \) and \( \ell_k^z \). Now we can prove the main theorem of this subsection:

**Theorem 39** Two pure quasifree states \( \rho_1 \) and \( \rho_2 \) can be connected through the action of a translation-invariant quadratic Hamiltonian if and only if \( \text{tr}(\rho_1 \ell_k^x) = \text{tr}(\rho_2 \ell_k^x) \) holds for all \( \ell_k^x \) with \( k \in \{0, \ldots, \lfloor (d-1)/2 \rfloor \} \).

**Proof** First, we consider the ‘if’-case: Let \( H \) be a translation-invariant quadratic Hamiltonians for which \( \rho_1 = e^{-iHt} \rho_2 e^{iHt} \) holds. Since the operators \( \ell_k^x \) commute with any
translation-invariant Hamiltonian, we have $\text{tr}(\rho_1 \ell^2_k) = \text{tr}(e^{-iHt}\rho_2 e^{iHt} \ell^2_k) = \text{tr}(\rho_2 e^{iHt} \ell^2_k e^{-iHt}) = \text{tr}(\rho_1 \ell^2_k)$. Second, we treat the ‘only if’-case: Let $\tilde{g}_1(k)$ and $\tilde{g}_2(k)$ denote the Fourier-transformed Majorana two-point functions (defined as in Eq. (50)) of $\rho_1$ and $\rho_2$, respectively. The action of a translation-invariant Hamiltonian, $\rho_a \mapsto e^{-iHt}\rho_a e^{iHt}$ is represented by the map

$$\tilde{g}_a(k) \mapsto U(k)\tilde{g}_a(k)U(k)^\dagger,$$

(53)

where $U(k)$ is given by $\exp[-i\Re(\tilde{A}_k)Z - i\Im(\tilde{B}_k)X/2 - i\Im(\tilde{B}_k)Y/2]$. Using Eq. (52), we obtain $\text{tr}(\rho_a \ell^2_k) = i\text{tr}(\tilde{g}_a(k))$ for $a \in \{1, 2\}$. These expectation values have to be in the set $\{-2, 0, 2\}$, since the eigenvalues of $\tilde{g}_1(k)$ and $\tilde{g}_2(k)$ are in the set $\{-1, 1\}$. Then, it follows from $\text{tr}(\rho_1 \ell^2_k) = \text{tr}(\rho_2 \ell^2_k)$ that the expectation values of $\tilde{g}_1(k)$ and $\tilde{g}_2(k)$ coincide. Thus, we obtain from Eq. (53) that $\rho_1$ and $\rho_2$ can be transformed into each other. \hfill $\Box$

Finally, we turn to the $\mathcal{R}$-symmetric setting, as introduced in Section 8.1, and determine the orbit structure of quasifree pure states which are translation-invariant and $\mathcal{R}$-symmetric under the action of operators in $q_d^{\mathcal{R}}$.

**Proposition 40** The unitaries generated by the Lie algebra $q_d^{\mathcal{R}}$ act transitively on the set of quasifree pure states which are translation-invariant and $\mathcal{R}$-symmetric.

**Proof** Since $\mathcal{R} \ell^2_k \mathcal{R}^{-1} = -\ell^2_k$, the expectation value of these operators in $\mathcal{R}$-symmetric states must vanish as $\text{tr}(\rho \ell^2_k) = -\text{tr}(\mathcal{R} \rho \ell^2_k \mathcal{R}^{-1}) = -\text{tr}(\mathcal{R}^{-1} \rho \mathcal{R} \ell^2_k) = -\text{tr}(\rho \ell^2_k)$. Moreover, by Theorem 39 we know that two pure translation-invariant states are on the same $q_d$-orbit iff the expectation values of the $\ell^2_k$ operators coincide for all $k \in \{0, \ldots, \lfloor (d-1)/2 \rfloor \}$. Hence the translation-invariant $\mathcal{R}$-symmetric states lie on the same $q_d$-orbit. As Eq. (53) implies that the $q_d$-orbits are equivalent to $q_d^{\mathcal{R}}$-orbits, we have proved the proposition. \hfill $\Box$

### 8.3 An application to many-body physics

In many-body physics, one of the important characteristics of quantum criticality is the *closing of the gap*. This means that the energy difference between the ground state and the first excited state goes to zero in the thermodynamic limit, when the number of spins or fermionic modes goes to infinity. Quasifree fermionic models can display both gapped and gapless behavior. Using the techniques developed in the previous subsections, we will prove that the gap always disappears (i.e. closes) for translation-invariant quasifree models if the coefficient matrix $A$ of Eq. (18) is purely imaginary while $B$ is an arbitrary, complex skew-symmetric matrix. Different cases have been considered in [71].

To formalize this statement, let us consider a set $a$, of fixed (finite) real numbers with $r \in \{1, \ldots, M - 1\}$ and a set $b$, of fixed complex numbers (of finite modulus) with $r \in \{1, \ldots, M - 1\}$. With these stipulations, we define for any $d \geq 2M$ the cyclic $d \times d$ matrices $A_d$ and $B_d$ (or $A$ and $B$ for short) by specifying their entries

$$A_{pq} := \begin{cases} ia_{q-p} & \text{if } q - p \in \{1, \ldots, M - 1\}, \\ -ia_{p-q} & \text{if } p - q \in \{1, \ldots, M - 1\}, \\ 0 & \text{otherwise} \end{cases},$$

(54)
and

\[ B_{pq} := \begin{cases} b_{q-p} & \text{if } q - p \in \{1, \ldots, M-1\}, \\ -b_{p-q} & \text{if } p - q \in \{1, \ldots, M-1\}, \\ 0 & \text{otherwise.} \end{cases} \tag{55} \]

By applying these definitions to Eq. (18) we obtain:

**Theorem 41** Given the positive integers \(d\) and \(M\) with \(d \geq 2M\), consider the corresponding translation-invariant quasifree Hamiltonian

\[ H_d = \sum_{p,q=1}^{d} A_{pq} \left( f^d_p f^d_q - \delta_{pq} \frac{1}{2} \right) + \frac{1}{2} B_{pq} f^d_p f^d_q - \frac{1}{2} B^*_{pq} f^d_p f^d_q, \]

where \(A\) and \(B\) are defined in Eqs. (54) and (55). Assume that \(H_d\) has a unique ground state. Then the gap \(\Delta_d\) of \(H_d\) is bounded by \(\Delta_d \leq \frac{8\pi (M-1)}{d} \left( \sum_{p=1}^{M-1} (|a_p| + |b_p|) \right)\), i.e. the gap closes algebraically in the thermodynamic limit of \(d\) going to infinity.

**Proof** Since \(H_d\) is translation-invariant and its coefficient matrix is imaginary, it can be decomposed into terms of the operators \(\ell^Q_k\) with \(Q \in \{1, X, Y\}\) and \(k \in \{1, \ldots, \lfloor (d-1)/2 \rfloor \}\) as

\[ H_d = \sum_{k=1}^{\lfloor (d-1)/2 \rfloor} \tilde{a}_k \ell^1_k + \frac{1}{2} \tilde{b}^X_k \ell^X_k + \frac{1}{2} \tilde{b}^Y_k \ell^Y_k, \]

using \(\tilde{a}_k := -\sum_{p=1}^{M-1} a_p \sin(-2\pi pk/d)\), \(\tilde{b}^X_k := -\Re \left[ \sum_{p=1}^{M-1} b_p \sin(-2\pi pk/d) \right]\), as well as \(\tilde{b}^Y_k := -\Im \left[ \sum_{p=1}^{M-1} b_p \sin(-2\pi pk/d) \right]\). Let \(\rho_d\) be a pure quasifree state, and let \(\tilde{g}_d(k)\) denote its Fourier-transformed Majorana two-point functions (see Eq. (50)). From Eq. (44) we know that \(\rho_d\) is an eigenstate of \(H_d\) iff \([\tilde{b}^X_k \ell^X_k + \tilde{b}^Y_k \ell^Y_k, \tilde{g}_d(k)] = 0\). The eigenvalue of \(H_d\) corresponding to this state is given by

\[ \text{tr}(\rho_d H_d) = \sum_{k=1}^{\lfloor (d-1)/2 \rfloor} \text{tr} \left( \tilde{g}_d(k) \left( \tilde{a}_k \ell^1 + \frac{1}{2} \tilde{b}^X_k \ell^X + \frac{1}{2} \tilde{b}^Y_k \ell^Y \right) \right). \tag{56} \]

Let us emphasize that the proof builds on the fact that \(M\) is fixed and finite, while \(d\) goes to infinity in the thermodynamic limit. Among the eigenstates of \(H_d\), consider the (unique) ground state \(\rho^d_{gs}\), whose Fourier-transformed Majorana two-point functions (see Eq. (50)) will be denoted by \(\tilde{g}^d_{gs}(k)\). From this ground state let us construct another quasifree state \(\rho^d_e\) which is defined through its Majorana two-point functions

\[ \tilde{g}^d_e(1) := \begin{cases} \mathbb{1}_2 & \text{if } \tilde{g}^d_{gs}(1) \neq -\mathbb{1}_2, \\ -\mathbb{1}_2 & \text{otherwise,} \end{cases} \]

while for general \(k \neq 1\) we assign \(\tilde{g}^d_e(k) := \tilde{g}^d_{gs}(k)\).

The corresponding pure quasifree state \(\rho^d_e\) is an eigenstate of \(H_d\), since according to Eq. (53) its Fourier-transformed Majorana two-point function stays invariant during the
time-evolution generated by \( H_d \). Using Eq. (56), we can calculate the difference between the energies corresponding to \( \rho^{d}_{gs} \) and \( \rho^d_c \) as

\[
\Delta_d := \text{tr}[\rho^{d}_{gs}(H_d - \rho^d_c)H_d] = \sum_{k=1}^{(d-1)/2} \text{tr}\left( (\hat{g}^{d}_{gs}(k) - \hat{g}^d_c(k)) \left( \hat{a}_k \hat{1} + \frac{1}{2} \hat{b}_k^\dagger \hat{b}_k^\dagger \right) \right)
\]

\[
= \text{tr}\left( \left( \hat{g}^{d}_{gs}(1) - \hat{g}^d_c(1) \right) \left( \hat{a}_1 \hat{1} + \frac{1}{2} \hat{b}_1^\dagger \hat{b}_1^\dagger \right) \right)
\]

\[
\leq 2 \left\| \left( \hat{g}^{d}_{gs}(1) - \hat{g}^d_c(1) \right) \left( \hat{a}_1 \hat{1} + \frac{1}{2} \hat{b}_1^\dagger \hat{b}_1^\dagger \right) \right\| \leq 4 \left| \hat{a}_1 \right| + \frac{1}{2} \left| \hat{b}_1^\dagger \right| + \frac{1}{2} \left| \hat{b}_1^\dagger \right|
\]

\[
\leq 4 \left[ \sum_{p=1}^{M-1} a_p \sin(2\pi p/d) \right] + 4 \left[ \sum_{p=1}^{M-1} b_p \sin(2\pi p/d) \right] \leq \frac{8\pi(M-1)}{d} \sum_{p=1}^{M-1} (|a_p| + |b_p|).
\]

This completes the proof of the theorem. \( \square \)

### 9 Particle-number conserving systems

Finally, we treat fermionic systems whose particle-number is conserved. The corresponding system algebras are given both in the general case as well as in the quasifree case. Furthermore, a necessary and sufficient condition for quasifree pure-state controllability in this setting is provided.

#### 9.1 The system algebra of particle-number conserving Hamiltonians

Let \( P_n \) denote the orthogonal projection from the Fock space \( \mathcal{F}(\mathbb{C}^d) = \bigoplus_{n=0}^d \wedge^n \mathbb{C}^d \) onto the \( n \)-particle subspace \( \wedge^n \mathbb{C}^d \subset \mathcal{F}(\mathbb{C}^d) \) of dimension \( \binom{d}{n} \). The particle-number operator \( \hat{n} \) of a fermionic system is defined as \( \hat{n} := \sum_{n=0}^d nP_n \). Note that \( \sum_{p=1}^d f_p f_p^\dagger \psi_n = n\psi_n \) holds for any \( \psi_n \in \wedge^n \mathbb{C}^d \). Hence, the particle number operator can also be expressed as \( \hat{n} = \sum_{p=1}^d f_p f_p^\dagger \). A fermionic Hamiltonian \( H \) is called particle-number conserving if it commutes with \( \hat{n} \). Using the general Theorem 51 of Appendix A, one directly obtains the corresponding system algebra.

**Proposition 42** The system algebra of particle-number conserving fermionic interactions with \( d \) modes is \( s(\bigoplus_{n \text{ even}} \mathfrak{u}(\binom{d}{n})) \oplus s(\bigoplus_{n \text{ odd}} \mathfrak{u}(\binom{d}{n})) \).

#### 9.2 Quadratic Hamiltonians

A quadratic Hamiltonian \( H \) is particle-number conserving iff its coefficient matrix \( B \) of Eq. (18) is zero, i.e., iff \( H = \sum_{p=1}^d A_{pq} f_p^\dagger f_q - \frac{1}{2} \) where \( A \) denotes any Hermitian matrix. The corresponding system algebra is given by the following proposition:

**Proposition 43** The system algebra of the particle-number conserving quadratic \( d \)-mode Hamiltonians is isomorphic to \( \mathfrak{u}(d) \).

**Proof** Let \( \iota \) denote the \( \mathbb{R} \)-linear mapping from the \( d \)-mode Hamiltonians which are quadratic and particle-number conserving to the \( d \times d \) skew-Hermitian matrices. We define \( \iota \) using \( (\iota(f_p^\dagger f_q + f_q^\dagger f_p) = \frac{1}{2}) = \iota(e_{pq} + e_{qp}) \) and \( \iota(f_p^\dagger f_q - f_q^\dagger f_p) = e_{pq} - e_{qp} \), where \( e_{pq} \) denotes a matrix with entries \( [e_{pq}]_{uv} := \delta_{p+q,u+v} \). Note that the canonical anticommutation relations
Consider a particle-number conserving quasifree state \( \rho \).

Proposition 44

Obviously, the map \( \iota \) is a homomorphism as

\[
i((\kappa_+ f_\rho f_\delta f_\rho f_\delta - \delta_\rho \frac{2}{2})) = \kappa_+ (f_\rho f_\delta f_\rho f_\delta - \delta_\rho \frac{2}{2})
\]

Thus, \( \iota \) is a homomorphism as \( \iota((\kappa_+ f_\rho f_\delta f_\rho f_\delta - \delta_\rho \frac{2}{2})) = \kappa_+ (f_\rho f_\delta f_\rho f_\delta - \delta_\rho \frac{2}{2}) \) equals \( \kappa_+ (f_\rho f_\delta f_\rho f_\delta - \delta_\rho \frac{2}{2}) \), \( \kappa_+ (f_\rho f_\delta f_\rho f_\delta - \delta_\rho \frac{2}{2}) \), \( \kappa_+ (f_\rho f_\delta f_\rho f_\delta - \delta_\rho \frac{2}{2}) \), where \( \kappa_+ = 1 \) and \( \kappa_- = 1 \).

The map \( \iota \) is even an isomorphism as its kernel is trivial. The proposition follows as the Lie algebra \( \mathfrak{u}(d) \) is isomorphic to the Lie algebra of \( d \times d \) skew-Hermitian matrices.

\[\square\]

Remark 44

Obviously, the map \( \iota \) from the previous proof establishes an isomorphism \( \iota : \sum_{\rho=1}^{d} A_\rho(f_\rho f_\delta f_\rho f_\delta - \delta_\rho \frac{2}{2}) \) from the algebra \( \mathfrak{h}(\rho), \ldots, \mathfrak{h}(\rho) \) to the algebra \( \mathfrak{a}(\rho), \ldots, \mathfrak{a}(\rho) \) for any set \( \mathfrak{a}(\rho), \mathfrak{a}(\rho) \) of \( d \times d \) Hermitian matrices.

9.3 Quasifree pure-state controllability in the particle-number conserving setting

We presented in Section 6.3 a necessary and sufficient condition for quasifree pure-state controllability. Here, we provide an analogous result in the particle-number conserving setting using a Lie-theoretic result of [64].

A quasifree state \( \rho_F \) is called particle-number conserving if \( [\rho_F, P_n] = 0 \) holds for all \( n \in \{0, \ldots, d\} \). As discussed in Section 6.1, quasifree states are uniquely characterized by the expectation values of the \( m_n m_n \) operators. We obtain in the number-conserving case that \( \text{tr}(\rho_F f_\rho f_\rho) = 0 \) as the condition \( [\rho_F, P_n] = 0 \) implies \( \sum_{n=0}^{d} P_n \rho_F P_n = \rho_F \) as well as \( \text{tr}(\rho_F f_\rho f_\rho) = \sum_{n=0}^{d} \text{tr}(P_n \rho_F P_n f_\rho f_\rho) = \sum_{n=0}^{d} \text{tr}(\rho_F P_n f_\rho f_\rho P_n) = 0 \) similarly, one can prove \( \text{tr}(\rho_F f_\rho f_\rho f_\rho) = 0 \). It follows that \( \rho_F \) is uniquely determined by the \( d \times d \) Hermitian matrix \( M_{\rho_F} = \text{tr}(\rho_F f_\rho f_\rho) \).

In the literature, this matrix is usually called the one-particle density matrix of \( \rho_F \). (Note that in some papers the one-particle density matrix is defined as \( M/\text{tr}(M) \).) Let us shortly summarize three well-known statements about one-particle density matrices of quasifree states (see [12, 58]):

Proposition 45

Consider a particle-number conserving quasifree state \( \rho_F \) of a fermionic system, and let \( M \) denote its one-particle density matrix. The following statements hold:

(a) The eigenvalues of \( M \) lie between 0 and 1. (b) \( \rho_F \) is pure if \( M \) is a projection. (c) If \( \rho_F \) is pure, then \( \text{tr}(M) = n \) is an integer, and \( \rho_F \) is supported on the \( n \)-particle subspace \( \wedge^n \mathbb{C}^d \) of the Fock space, i.e.

\[
P_k \rho_F P_k = \begin{cases} 
\rho_F & \text{if } k = n, \\
0 & \text{if } k \neq n.
\end{cases}
\]

(57)

The dynamics of particle-number conserving quasifree fermions can also be represented using the one-particle density matrices (see [12, 58]):

Proposition 46

Consider a particle-number conserving quasifree state \( \rho_a \) corresponding to the one-particle density matrix \( M_a \). Assume that the quadratic Hamiltonian \( H = \sum_{\rho q=1}^{d} A_\rho f_\rho f_\rho - \delta_\rho \frac{2}{2} \), which is defined by the Hermitian matrix \( A \), generates the time-evolution of \( \rho_a \). The time-evolved state (at unit time), \( \rho_b = e^{-iH} \rho_a e^{iH} \) is again a number-conserving quasifree state with a one-particle density matrix \( M_b = U_A M_a U_A^\dagger \), where \( U_A = e^{-iA} \in U(d) \).
A particle-number conserving pure quasifree state $\rho_F$ with $\text{tr}(M) = n$ is sometimes called an $n$-particle pure quasifree state, since according to Proposition 45 its state is supported on the $n$-particle subspace $\mathbb{C}^d$. We will denote the set of such quasifree pure states by $QF_n$. A system of number-conserving quadratic Hamiltonians $S = \{ih_1, \ldots, ih_n\}$ is said to provide quasifree pure-state controllability for a fixed particle number $n$ if there exists an $iH \in \langle S \rangle_{\text{Lie}}$ for any $\rho_\alpha, \rho_\beta \in QF_n$ such that $\rho_\beta = e^{-ith}\rho_\alpha e^{ith}$. To find a necessary and sufficient conditions for this type of controllability, let us invoke a Theorem 4.1 of [64]:

**Theorem 47** Consider the Lie algebra $s_\Sigma$ generated by the traceless $d \times d$ skew-Hermitian matrices $iB_1, \ldots, iB_l$ and let $\mathcal{P}(d, n)$ denote the set of all projections acting on $\mathbb{C}^d$ whose rank $n$ lies between 1 and $d - 1$. The Lie group corresponding to $s_\Sigma$ acts naturally via the adjoint action on $\mathcal{P}(d, n)$. This action is transitive if and only if either (a) $s_\Sigma$ is isomorphic to $su(d)$ or (b) $d$ is even, $n \in [1, d - 1]$, and $s_\Sigma$ is isomorphic to $sp(d/2)$.

The theorem implies the following necessary and sufficient condition:

**Theorem 48** Consider the set $S = \{ih_1, \ldots, ih_l\}$ corresponding to number-conserving quadratic Hamiltonians of a fermionic system with $d \geq 2$ modes. The set $S$ generates a particle-number conserving system giving rise to full quasifree pure-state controllability on the $n$-particle subspace with $1 \leq n \leq d - 1$, if and only if either (a) $S_{\text{Lie}}$ is isomorphic to $su(d)$ or (b) $d$ is even, $n \in [1, d - 1]$ and $S_{\text{Lie}}$ is isomorphic to $u(d)$, $su(d)$, $u(1) + sp(d/2)$, or $sp(d/2)$.

**Proof** We consider the set $A = \{iA^{(1)}, iA^{(2)}, \ldots, iA^{(l)}\}$ of skew-Hermitian matrices which correspond to the generators in $S$, i.e. $ih_k = i \sum_{pq=1}^d A^{(k)}_{pq} f^q pf_q - \delta_{pq} 1/2$. We apply Remark 44 and obtain that $\langle S \rangle_{\text{Lie}}$ is isomorphic to $\langle A \rangle_{\text{Lie}}$. We combine this result with Propositions 45 and 46: There exists an $iA_{ab} \in \langle S \rangle_{\text{Lie}}$ for each pair $\rho_\alpha, \rho_\beta \in QF_n$ such that $e^{-ith} \rho_\alpha e^{ith} = \rho_\beta$, if there exist an $iA_{ab} \in \langle A \rangle_{\text{Lie}}$ for each pair $M_\alpha, M_\beta \in \mathcal{P}(d, n)$ such that $e^{-ith}M_\alpha e^{ith} = M_\beta$. Thus we have to find necessary and sufficient conditions under which $\langle A \rangle_{\text{Lie}}$ generates a transitive action on $\mathcal{P}(d, n)$ for a given $d$ and $n$. For any skew-Hermitian $iA$ and $M \in \mathcal{P}(d, n)$, we have that $\exp(-iA)M\exp(iA) = \exp[-i(A - \text{tr}(A)\mathbb{1}/d)M]\exp[i(A - \text{tr}(A)\mathbb{1}/d)]$. Hence we can infer that $\langle A \rangle_{\text{Lie}}$ generates a transitive action iff the system algebra generated by the set $A' := \{i(A^{(1)} - \text{tr}(A^{(1)})\mathbb{1}/d), \ldots, i(A^{(l)} - \text{tr}(A^{(l)})\mathbb{1}/d)\}$ also gives rise to a transitive action. Since $A'$ contains only traceless skew-Hermitian operators, we know from Theorem 47 that it can act transitively on $\mathcal{P}(d, n)$ if and only if either $\langle A' \rangle_{\text{Lie}}$ is isomorphic to $su(d)$, or $d$ is even, $n \in [1, d - 1]$, and $\langle A' \rangle_{\text{Lie}}$ is isomorphic to $sp(d/2)$.

On the other hand, if $\langle A' \rangle_{\text{Lie}} = su(d)$ or $\langle A' \rangle_{\text{Lie}} = sp(d/2)$ then $\langle A' \rangle_{\text{Lie}}$ is a simple irreducible Lie subalgebra of $su(d)$. It follows that $\langle A \rangle_{\text{Lie}}$ is either isomorphic to $\langle A' \rangle_{\text{Lie}}$ if $\text{tr}(A^{(k)}) = 0$ for all $k \in \{1, \ldots, l\}$ or to $u(1) + \langle A' \rangle_{\text{Lie}}$ if there exists a $k$ such that $\text{tr}(A^{(k)}) \neq 0$. This proves the theorem.

**10 Conclusion**

We set out to answer the questions (1) which states can be reached from a given initial state under given controls and (2) which quantum operations can be simulated in a given Hamiltonian set-up for fermionic quantum systems in a plethora of scenarios imposing various superselection rules.
Table 4  System algebras for $d$-mode fermionic systems

| Symmetries | System algebra | Details |
|------------|----------------|---------|
| General systems: | $\text{su}(2^{d-1}) \oplus \text{su}(2^{d-1})$ | Theorem 4 |
| $\{T\}$ | $s(\bigoplus_{n=0}^{d-1} u(\tau_n)) \oplus s(\bigoplus_{n=0}^{d-1} u(\tau_n))$ | Theorem 30 |
| $\{N\}$ | $s(\bigoplus_{n=0}^{d-1} u(\tau_n)) \oplus s(\bigoplus_{n=0}^{d-1} u(\tau_n))$ | Proposition 42 |
| Quasifree systems: | $\text{so}(2^{d})$ | Proposition 9 |
| $\{T\}, d$ odd | $\left(\sum_{i=1}^{(d-1)/2} u(2)\right) + u(1)$ | Theorem 34 |
| $\{T\}, d$ even | $\left(\sum_{i=1}^{(d-2)/2} u(2)\right) + u(1) + u(1)$ | Theorem 34 |
| $\{T, R\}, d$ odd | $\left(\sum_{i=1}^{(d-1)/2} u(2)\right) + u(1)$ | Corollary 35 |
| $\{T, R\}, d$ even | $\left(\sum_{i=1}^{(d-2)/2} u(2)\right) + u(1) + u(1)$ | Corollary 35 |
| $\{N\}$ | $u(2)$ | Proposition 43 |

$^a$Besides parity superselection rule $P$ we have translation-invariance $T$, twisted reflection symmetry $R$, and particle-number conservation $N$.

$^b$The orthogonal algebra is represented as direct sum of two equal copies given as irreducible blocks of dimension $2^{d-1}$; the system algebra $\text{so}(2^{d})$ itself was determined already, e.g., in [38].

Therefore we have put dynamic systems theory of coherently controlled fermions into a Lie-algebraic frame in order to answer problems of controllability, reachability, and simulability in a unified picture. As summarized in Table 4, to this end we have determined the dynamic system Lie algebras in a comprehensive number of cases, illustrated by examples with and without confinement to quadratic interactions (quasifree particles) as well as with and without symmetries such as translation invariance, twisted reflection symmetry, or particle-number conservation. Once having established the system algebras, the group orbits of a given (pure or mixed) initial quantum state determine the respective reachable sets of all states a system can be driven into by coherent control. Here different types of pure-state reachability and their relation to coset spaces have been treated with particular attention.

There are illuminating analogies and differences between spin and fermionic systems. For quasifree systems, this has been discussed in Section 5 and in Appendix C, while the translation-invariant case is addressed in Section 7. In particular, translation-invariant Hamiltonians which cannot be generated from nearest-neighbor ones appear both for spin systems (Section 7.2) and for fermionic systems (Section 7.4). Moreover, for fermionic systems some of these Hamiltonians have bounded interaction length. It is an open question if the same also holds for spin systems.

On a general scale, the system algebras determined serve as a dynamic fingerprint. Their application to quantum simulation has been elucidated in a plethora of paradigmatic settings. Hence we anticipate the comprehensive findings presented here will find a broad scope of use.

Appendix A: Discussion of double centralizers
Motivated by Section 4.2, in this appendix we discuss how the form of the double centralizer of a Lie algebra $\mathfrak{g} \subset \text{su}(k)$ limits the possibilities for $\mathfrak{g}$:

**Proposition 49**  Let $\mathfrak{g}$ denote a subalgebra of $\text{su}(k)$. There exists a set $A \subset \text{su}(k)$ such that $\mathfrak{g} = \text{cent}_{\text{su}(k)}(A)$, if and only if $\text{cent}_{\text{su}(k)}(\text{cent}_{\text{su}(k)}(A)) = \mathfrak{g}$.

**Proof**  First, assume that $A$ exists. As $\text{cent}_{\text{su}(k)}(\text{cent}_{\text{su}(k)}(\text{cent}_{\text{su}(k)}(A))) = \text{cent}_{\text{su}(k)}(A)$ holds for any set $A$, which can also be inferred from [72, Proposition 6.1.3.1(iii)], we obtain
cent_{su(k)}(cent_{su(k)}(g)) = g. Second, we assume that cent_{su(k)}(cent_{su(k)}(g)) = g holds. We choose \( A := cent_{su(k)}(g) \) and verify its existence.

To further analyze the influence of symmetry properties on the system algebra, we recall some elementary representation theory (see, e.g., Theorem 1.5 of [73]):

**Proposition 50** Consider a completely reducible complex matrix representation \( \Phi(g) \) of a group \( G \), where \( k \) is the degree of \( \Phi \). Let \( \text{comm}(\Phi) = \Phi' \) denote the commutant algebra of all complex \( k \times k \)-matrices simultaneously commuting with \( \Phi(g) \) for \( g \in G \). Then, \( \Phi(g) \) is equivalent to \( \bigoplus_{j=1}^{w}[1_{\phi_j} \otimes \Phi_j(g)] \), where \( \phi_j \) denote for \( j \in \{1, \ldots, w\} \) distinct inequivalent irreducible complex matrix representations of \( G \) with degree \( k_j \), occurring with multiplicity \( e_j \) in \( \Phi \). In particular, (a) \( \dim \text{comm}(\Phi) = \sum_{j=1}^{w} e_j^2 \), (b) \( \dim \text{cent}(\text{comm}(\Phi)) = w \), (c) \( k = \sum_{j=1}^{w} k_j e_j \).

Obviously, the same is true for representations of a compact Lie group or its Lie algebra. Given a subalgebra \( \mathfrak{g} \) of \( su(k) \) (or respectively of \( u(k) \)) and a representation \( \Phi \) of \( g \) with degree \( k \), we discuss the easiest case of Proposition 50 where \( w = 1 \) and \( e_1 = 1 \). Hence, \( \Phi \) is irreducible and \( \mathfrak{g} \) is an irreducible subalgebra of \( su(k) \) (or respectively of \( u(k) \)). But \( g \) is not necessarily equal to \( su(k) \) (or respectively to \( u(k) \)). Irreducible simple subalgebras of \( su(k) \) were studied extensively in this regard in [22]. Note that the irreducible subalgebras of \( u(k) \) are of the form \( \mathfrak{g} \) or \( \mathfrak{g} + u(1) \) where \( g \) denotes any irreducible subalgebra of \( su(k) \) (cf. pp.27-28 and p.321 of [50]).—A slight generalization is given by the case of an abelian commutant algebra, i.e. \( \dim \text{comm}(\Phi) = \dim \text{cent}(\text{comm}(\Phi)) \) and \( e_j = 1 \) for all \( j \in \{1, \ldots, w\} \). One may thus apply the spectral theorem (see, e.g., [74–76]) simultaneously to all the elements of the commutant algebra:

**Theorem 51** Consider a Lie algebra \( \mathfrak{g} \subseteq su(k) \) and its representation \( \Phi \) of degree \( k \). Assume that the corresponding commutant algebra \( \mathcal{C} = \text{comm}(\Phi) \) is abelian. One obtains that \( \mathfrak{g} \) is a subalgebra of \( s[\bigoplus_{j=1}^{\dim C} u(k_j)] \) and it is equivalent to \( s[\bigoplus_{j=1}^{\dim C} \mathfrak{g}_j] \), where \( k = \sum_{j=1}^{\dim C} k_j \) and \( \mathfrak{g}_j \) are irreducible subalgebras of \( u(k_j) \). Furthermore, one finds \( k_j = \dim(P_j) \), where \( P_j \) are the orthogonal projection operators given by the joint spectral decomposition of \( \mathcal{C} \) with \( \sum_{j=1}^{\dim C} P_j = I_k \) and \( P_i P_j = 0 \) for \( i \neq j \). If \( \mathfrak{g} \) is the maximal Lie algebra with these properties, then \( \mathfrak{g} = s[\bigoplus_{j=1}^{\dim C} u(k_j)] \).

Using Proposition 50 one can directly characterize a maximal Lie algebra \( \mathfrak{g} \) contained in \( su(k) \) which is defined by all its symmetries including cases where the commutant to \( g \) is not necessarily abelian. Observe the notation of Remark 5 and the one of Proposition 50.

**Theorem 52** Consider a Lie algebra \( \mathfrak{g} \subseteq su(k) \) and its representation \( \Phi \) of degree \( k \). Let \( \mathcal{C} = \text{comm}(\Phi) \) denote the commutant of \( \mathfrak{g} \). If \( \mathfrak{g} \) is the maximal Lie algebra with these properties, then \( \mathfrak{g} = s[\sum_1^\omega u(k_j)] \) where \( \omega = \dim(\text{cent}(\mathcal{C})) \) and \( \sum_1^\omega k_j \leq k \).

**Proof** Using Proposition 50 (and its notation) one obtains that \( g \) is equivalent to \( \bigoplus_{j=1}^{w}[1_{\phi_j} \otimes \phi_j(g)] \). Therefore, \( \mathfrak{g} \) is a subalgebra of \( s[\sum_1^\omega u(k_j)] \) with \( \sum_1^\omega k_j \leq k \). The maximality of \( \mathfrak{g} \) completes the proof.
In a dual approach, one could start from a set $S$ of symmetries of $\mathfrak{g}$. Due to the maximality of $\mathfrak{g}$, the set $S$ has to comprise all symmetries of $\mathfrak{g}$. Next, one can apply Proposition 50 to the subalgebra of $\mathfrak{su}(k)$ generated by the linear span intersected with $\mathfrak{su}(k)$, i.e. $(S) \cap \mathfrak{su}(k)$. The theorem then follows directly using Schur’s lemma and the maximality of $\mathfrak{g}$.

The reader familiar with the double-commutant theorem in algebraic quantum mechanics will wonder about the different power of symmetries for characterizing algebras of observables on the one hand and Lie algebras on the other: a von-Neumann algebra $\mathcal{A}$ is entirely determined by its commutant $\mathcal{A}'$, since $\mathcal{A}'' = \mathcal{A}$ [77, 78]. In this sense, there is a duality between the algebra $\mathcal{A}$ and its commutant $\mathcal{A}'$ encapsulating all symmetries. On the other hand, consider the illustrative case of an irreducible Lie subalgebra $\mathfrak{g}$ of $\mathfrak{su}(k)$, which is semisimple (or even simple) and whose centralizer $\text{cent}_{\mathfrak{su}(k)}(\mathfrak{g})$ is trivial (i.e. zero). This centralizer is shared with all irreducible Lie subalgebras of $\mathfrak{su}(k)$. So in turn, the double centralizer in $\mathfrak{su}(k)$ to all these subalgebras is $\mathfrak{su}(k)$ itself. We thus obtain the following corollary to Proposition 49 and Theorem 51, where the double centralizer gives a maximality criterion ensuring that an irreducible subalgebra $\mathfrak{g}$ of $\mathfrak{su}(k)$ is in fact fulfilling $\mathfrak{g} = \mathfrak{su}(k)$.

(Note that the condition $\text{cent}_{\mathfrak{su}(k)}([0]) = \mathfrak{g}$ is not easily tested using only a set of generators of $\mathfrak{g}$.)

**Corollary 8** Let $\mathfrak{g}$ denote an irreducible subalgebra of $\mathfrak{su}(k)$, i.e. $\text{cent}_{\mathfrak{su}(k)}(\mathfrak{g}) = [0]$. Then one finds that $\text{cent}_{\mathfrak{su}(k)}(\text{cent}_{\mathfrak{su}(k)}(\mathfrak{g})) = \mathfrak{g}$ if and only if $\mathfrak{g} = \mathfrak{su}(k)$.

Note that Corollary 8 can be readily generalized: Let $\mathfrak{g}, \mathfrak{h}$ denote two irreducible subalgebras of $\mathfrak{su}(k)$ with $\mathfrak{g} \subseteq \mathfrak{h} \subseteq \mathfrak{su}(k)$ so that $\text{cent}_{\mathfrak{h}}(\mathfrak{g}) = [0] = \text{cent}_{\mathfrak{h}}(\mathfrak{h})$. Then one finds $\text{cent}_{\mathfrak{h}}(\text{cent}_{\mathfrak{h}}(\mathfrak{g})) = \mathfrak{g}$ if and only if $\mathfrak{g} = \mathfrak{h}$.

Summarizing the general case, the symmetry properties of a Lie algebra $\mathfrak{g} \subseteq \mathfrak{su}(k)$, as given by its commutant w.r.t. a representation of $\mathfrak{g}$, do not determine the Lie algebra $\mathfrak{g}$ uniquely. Yet the commutant allows us to infer a unique maximal Lie algebra contained in $\mathfrak{su}(k)$, which is (up to an identity matrix) equal to the double commutant of $\mathfrak{g}$, but in general not to $\mathfrak{g}$ itself. Although all representations of compact Lie algebras, such as $\mathfrak{su}(k)$ and its semisimple subalgebras, are completely reducible, the situation for Lie algebras also differs from the case of associative algebras: here complete reducibility of a representation implies the double-commutant theorem (see Theorem (3.5.D) of [79] or Theorem 4.1.13 of [80]), whereas the double-commutant theorem does not apply to Lie algebras as discussed above.

**Appendix B: Parameterizations of quadratic Hamiltonians**

In this appendix, we discuss various parameterizations of quadratic Hamiltonians related to the one of Eq. (18) in Section 5. We start with the parametrization

$$H := \sum_{p,q=1}^{d} C_{pq} f_p f_q + D_{pq} f_p f_q^\dagger + E_{pq} f_p^\dagger f_q + F_{pq} f_p^\dagger f_q^\dagger$$

by complex $d \times d$-matrices $C, D, E$, and $F$. Hermiticity of $H$ requires $C = F^\dagger$, $D = D^\dagger$, and $E = E^\dagger$, while the (anti-)commutator relations enforce $C = -C^\dagger$, $D = -E^\dagger$, and $F = -F^\dagger$. 
Setting \( A := 2E \) and \( B := -2C^* \), we recover the notation of Eq. (18) and obtain

\[
H = \frac{1}{2} \sum_{pq=1}^{d} -B_{pq} f_p f_q - A_{pq} f_p f_q^\dagger + A_{pq} f_q f_p^\dagger + B_{pq} f_q f_p^\dagger
\]

\[
= \frac{1}{2} \sum_{pq=1}^{d} -B_{pq} f_p f_q + 2A_{pq} \left( f_p f_q - \delta_{pq} \frac{n}{2} \right) + B_{pq} f_q f_p^\dagger
\]

\[
= \frac{1}{2} \sum_{pq=1}^{d} \Re(B_{pq})(f_q f_q - f_p f_p) + \Re(A_{pq})(f_p f_q - f_q f_p)
\]

\[
+ \Im(B_{pq})(f_q f_p + f_p f_q) + \Im(A_{pq})(f_q f_q + f_p f_p).
\]

Note \( \Re(A) = \Re(A)^\dagger \), \( \Im(A) = -\Im(A)^\dagger \), \( \Re(B) = -\Re(B)^\dagger \), and \( \Im(B) = -\Im(B)^\dagger \) which is a consequence of \( A = A^\dagger \) and \( B = -B^\dagger \). We rewrite the Hamiltonian using Majorana operators such that

\[
-iH = -\frac{1}{2} \left[ \sum_{p=1}^{d} -\Re(A_{pp})m_{2p-1}m_{2p} + \sum_{pq=1+p>q} \Re(V_{pq}) \right],
\]

where \( V_{pq} = -\Re(B_{pq})[m_{2p-1}m_{2q} - m_{2q-1}m_{2p}] - \Re(A_{pq})[m_{2p-1}m_{2q} + m_{2q-1}m_{2p}] - \Im(B_{pq}) \times \left[ m_{2p-1}m_{2q-1} - m_{2q}m_{2p} \right] - \Im(A_{pq}) \times \left[ m_{2p-1}m_{2q-1} + m_{2q}m_{2p} \right] \). By applying the Jordan-Wigner transformation we obtain the Hamiltonian for the corresponding spin system (for better readability, the tensor-product symbol is omitted, e.g., \( IXY := I \otimes X \otimes Y \)) as

\[
-iH = -\frac{i}{2} \sum_{p=1}^{d} -\Re(A_{pp})\prod_{q=1}^{p-1} X_{q} \cdot I \cdot \prod_{d-p}^{d-1} Z + \sum_{pq=1+p>q} \Re(W_{pq})
\]

where \( W_{pq} := [\Re(B_{pq}) + \Im(A_{pq})](\alpha_{pq} - \beta_{pq}) + [\Re(A_{pq}) - \Im(B_{pq})](\alpha_{pq} + \beta_{pq}) \),

\[
\alpha_{pq} := \prod_{q=1}^{p-1} I \cdot X \cdot Z \cdot \prod_{d-p}^{d-1} X \cdot I \cdot \prod_{d-p}^{d-1} Z
\]

\[
\beta_{pq} := \prod_{q=1}^{p-1} I \cdot Y \cdot Z \cdot \prod_{d-p}^{d-1} Z \cdot Y \cdot I \cdot \prod_{d-p}^{d-1} I.
\]

**Appendix C: Applications of quasifree fermions to spin systems**

Here we take new fermionic approaches to exhaustively prove and improve some results of [22], where some proofs were still sketchy—thereby also filling a desideratum voiced in [81].

**C.1 A spin system with system algebra \( so(2n + 1) \)**

**Proposition 53** (see Proposition 27 in [22]) *Consider a Heisenberg-XX chain with the drift Hamiltonian \( H_d = XX \cdots II + YY \cdots II + \cdots + II \cdots XX + II \cdots YY \) on \( n \) spin- \( \frac{1}{2} \) qubits with \( n \geq 2 \). Assume that one end qubit is individually locally controllable. The system algebra is isomorphic to \( so(2n + 1) \) and irreducibly embedded in \( su(2^n) \).*

**Proof** We use the fermionic picture where the number of modes \( d \) equals the number of spins \( n \). The generators are given by \( w_1 = L(v_1) \) with \( v_1 = \sum_{p=1}^{d-1} -m_{2p-1}m_{2p+2} + m_{2p}m_{2p+1} \).
\( L(m_1) \) and \( L(m_2) \). Obviously, the element \( w_2 = L(v_2) \) with \( v_2 = m_1 m_2 \) can also be generated. One can verify that exactly all Majorana operators of degree one or two can be obtained: One can reason using Lemma 10 together with the commutation relations \([L(m_{2p-1}), L(b_p)] = L(m_{2p-2}) \) and \([L(m_{2p}), L(b_p)] = -L(m_{2p+1}) \) to show that all degree-one operators can be generated. This immediately gives all quadratic operators as well, while operators of higher degree are not attainable. Therefore, the dimension of the system algebra is \( 2d^2 + d \). Note that the operators \( L(m_{2p-1} m_{2p}) \) form a maximal abelian subalgebra which proves that the system algebra has rank \( d \). In the spin picture, we can directly verify that \( a = \langle -i Z_1/2, \ldots, -i Z_n/2 \rangle_{\text{Lie}} \) by computing the centralizer \( c_a := \langle -\frac{1}{2} \prod_{j \in S} Z_j \mid S \neq \emptyset \rangle_{\text{Lie}} \) of \( a \) in \( su(2^n) \). Let us compute the centralizer \( c_b \) of \( b = \langle m_{2p} m_{2p+1}, -m_{2p-1} m_{2p+2} \mid p \in \{1, \ldots, d - 1\} \rangle_{\text{Lie}} \) in \( su(2^n) \). Note that the generators of \( b \) are given in the spin picture by \(-iX_p X_{p+1}/2 \) and \(-iY_p Y_{p+1}/2 \). One can readily show by induction that \( c_b = \langle -\frac{1}{2} \prod_{j=1}^n X_j - \frac{1}{2} \prod_{j=1}^n Y_j - \frac{1}{2} \prod_{j=1}^n Z_j \rangle_{\text{Lie}} \). It follows that the centralizer \( \epsilon \) of the full system algebra in \( su(2^n) \) has to be contained in \( c_a \cap c_b = \langle -\frac{1}{2} \prod_{j=1}^n Z_j \rangle_{\text{Lie}} \). One can now easily prove that the centralizer of the full system algebra in \( su(2^n) \) is trivial and that the system algebra is irreducibly embedded in \( su(2^d) \). As the coupling graph of the spin system is connected, we conclude with Theorem 6 of [22] that the system algebra is simple. Listing all simple (and compact) Lie algebras with the correct dimension and rank, we obtain (a) \( so(2d + 1) \) for \( d \geq 1 \), (b) \( sp(d) \) for \( d \geq 1 \), (c) \( su(2) \cong so(3) \) for \( d = 1 \), and (d) \( \epsilon_b \) for \( d = 6 \). As the system algebra contains also all quadratic operators, it has a subalgebra \( so(2d) \) which is of maximal rank. This rules out the cases (b) and (d) (see p.219 of [49] or Section 8.4 of [50]) for \( d \neq 2 \). But the case (b) agrees with (a) for \( d = 2 \). For \( d = 1 \), the cases (a) and (c) coincide. This completes the proof.}

\( \square \)

Note that with our fermionic approach one can readily determine the dimension and rank of the system algebra. Likewise, we establish that all fermionic operators act irreducibly from which we can infer that the system algebra is simple. The rest of the proof follows by an exhaustive enumeration.—In more general terms, as in Theorem 34 and Corollary 35 of [22], we connect a spin system with a fictitious fermionic system:

**Corollary 54** Consider a fictitious fermionic system with \( d \) modes which consists of all linear and quadratic operators and whose generators can, e.g., be chosen as all Majorana operators of type \( L(m_{2p-1}) \) combined with the Hamiltonian from Eq. (18) where the control functions \( A_{pq} \) and \( B_{pq} \) can be assumed to be real. This fictitious fermionic system and the spin system of Proposition 53 with \( n = d \) spins can simulate each other. In particular, both can simulate a general quasifree fermionic system with \( d \) modes and system algebra \( so(2d) \) as presented in Proposition 9 and Theorem 11.

**C.2 A spin system with system algebra \( so(2n + 2) \)**

**Proposition 55** (see Proposition 28 in [22]) Consider a Heisenberg-XX chain with the drift Hamiltonian \( H_d = XX \cdots II + YY \cdots II + \cdots + II \cdots XX + II \cdots YY \) on \( n \) spin- \( \frac{1}{2} \) qubits with \( n \geq 2 \). Assume that each of the two end qubits is individually locally controllable. The system algebra is given as the subalgebra \( so(2n + 2) \) which is irreducibly embedded in \( su(2^n) \).

**Proof** We switch to a fermionic picture where the number of modes \( d \) equals the number of spins \( n \). The generators are \( w_1 = L(v_1) \) with \( v_1 = \sum_{p=1}^{d-1} -m_{2p-1} m_{2p+2} + m_{2p} m_{2p+1} \),...
L(m_1), L(m_2), L(m_{2d-1} \prod_{p=1}^{d-1} m_{2p-1} m_{2p}), and L(m_{2d} \prod_{p=1}^{d-1} m_{2p-1} m_{2p}). One can verify by explicit computations that exactly all Majorana operators of degree one, two, 2d – 1, and 2d can be generated. Therefore, the dimension of the system algebra is 2d^2 + 3d + 1. Using a similar argument as in the proof of Proposition 53, we conclude that the operators L(m_{2p-1} m_{2p}) together with the operator L(\prod_{p=1}^{d} m_{2p-1} m_{p}) form a maximal abelian subalgebra which proves that the system algebra has rank d + 1. One can also show that the system algebra is irreducibly embedded in su(2^d). As the coupling graph of the spin system is connected, we conclude with Theorem 6 of [22] that the system algebra is simple. The proof is completed by listing all simple (and compact) Lie algebras with the correct dimension and rank, i.e. (a) so(2d + 2) for d \geq 1 and (b) su(4) \cong so(6) for d = 2.

**Principle Remark** Now we have established a setting that allows for exploiting the powerful general results of [65] on the structure of orthogonal groups that provide a second avenue to Proposition 53 assuming we have already established Proposition 55: Lemmata 3 and 4 of [65] show that for k \geq 3 any subalgebra of so(k) with dimension (k – 1)(k – 2)/2 is isomorphic to so(k – 1); moreover so(k – 1) is a maximal subalgebra of so(k). Thus, by proving that the system algebra has dimension 2d^2 + d with d \geq 1, it can be identified as the subalgebra so(2d + 1) of so(2d + 2). We emphasize that this particular proof technique should be widely applicable in quantum systems theory.

Relying on the proof of Proposition 55 and building on Theorem 32 as well as Corollary 34 of [22], we obtain connections between a spin system, a quasi-free fermionic system, and a fictitious fermionic system:

**Corollary 56** The following control systems all have the system algebra so(2k + 2) and can simulate each other: (a) the spin system of Proposition 55 with k spins, (b) the quasi-free fermionic system with k + 1 modes as presented in Proposition 9 and Theorem 11, and (c) a fictitious fermionic system with k modes which contains all Majorana operators of degree one, two, 2k – 1, and 2k, and whose generating Hamiltonian can be chosen from Eq. (18) where the control functions A_{pq} and B_{pq} can be assumed to be real.

**Appendix D: Proof of Theorem 13**

The cases of d \in \{2, 3, 4\} can be verified directly and we assume in the following that d \geq 5 holds. We build on Lemma 10 and obtain a basis of \(\mathfrak{t}_1\) consisting of \(L(a_p)\) with 1 \leq p \leq d as well as \(L(b_p^{(i)})\) with \(b_p^{(i)} := -m_{2p-1} m_{2p+2i} + m_{2p} m_{2p+2i-1}\) and \(L(c_p^{(i)})\) with \(c_p^{(i)} := m_{2p-1} m_{2p+2i-1} + m_{2p} m_{2p+2i}\) where \(p, i \geq 1\) and \(p + i \leq d\). One can systematically enlarge the index (i) starting from the elements \(L(b_p^{(1)}) = L(b_p) \in \mathfrak{t}_1\) and \(L(c_p^{(1)}) = (c_p) \in \mathfrak{t}_1\) and generate all \(L(b_p^{(i)})\) and \(L(c_p^{(i)})\) by combining the commutator relations \([L(c_p), L(b_p^{(i)})] = -L(b_p^{(i+1)})\) and \([L(c_p), L(b_p^{(i)})] = L(b_p^{(i+1)})\) with the commutator relations \([L(a_p), L(b_p^{(i)})] = -L(c_p^{(i)})\) and \([L(a_p), L(c_p^{(i)})] = L(b_p^{(i)})\). It is straightforward to check that no further elements are generated by commutators starting from the elements \(L(a_p), L(b_p^{(i)})\), and \(L(c_p^{(i)})\). We obtain that \(\dim(\mathfrak{t}_1) = d + (d – 1)d = d^2\). Furthermore, the elements \(L(a_p)\) form a maximal abelian subalgebra of \(\mathfrak{t}_1\) and the rank of \(\mathfrak{t}_1\) is \(d\). It follows that \(\mathfrak{t}_1\) is a subalgebra of maximal rank in so(2d). We now show that the center of \(\mathfrak{t}_1\) is one-dimensional and is generated by \(L(c)\) with \(c := \sum_{p=1}^{d} a_p\). Combining the commutator relations \([L(a_p), L(b_p^{(i)})] = L(c_p^{(i)})\) and \([L(a_p) + L(b_p^{(i)}), L(c_p^{(i)})] = -L(b_p^{(i)})\) with the ones for \(L(a_p)\) mentioned above, we conclude that
\[ L(a_p + a_{p+1}), L(b_p^{(0)}) = [L(a_p + a_{p+1}), L(c_p^{(0)}) = 0 \] in addition, we obtain \[ L(a_i), L(b_p^{(0)}) = [L(a_i), L(c_p^{(0)}) = 0 \] if \( p \neq j \neq p + i \). It follows that \( L(c), L(b_p^{(0)}) = [L(c), L(c_p^{(0)}) = 0 \) and that \( L(c) \) commutes with all elements of \( t_1 \). We rule out the existence of further elements in the center by explicitly computing the semisimple part \( s := \{t_1, t_2\} \). By applying \( [L(b_p^{(0)}), L(c_p^{(0)})]/2 = L(a_{p+i} - a_p) \) combined with previously mentioned commutator relations, we can fix a basis of \( s \) consisting of the elements \( L(b_p^{(0)}), L(c_p^{(0)}) \), and \( L(a_p - a_{p+1}) \) where \( 1 \leq p \leq d - 1 \) and \( 1 \leq i \leq d - p \). We proceed to prove in the following that \( s \) is actually simple by showing that \( s \) is not abelian (which obviously holds) and that any non-zero ideal of \( s \) is equal to \( s \). Starting from \( (ad_s^2(L(a_p)))L(b_p^{(0)}) = -L(b_p^{(0)}) \) and \( (ad_s^2(L(a_p)))L(c_p^{(0)}) = -L(c_p^{(0)}) \) for \( q = p \) or \( q = p + i \), we deduce that \( ad_s^2(L(a_p)) + ad_s^4(L(a_p)) = 0 \). Likewise, \( \gamma_p^{(0)} := [ad_s^2(L(a_p - a_{p+i})) + ad_s^4(L(a_p - a_{p+i}))]/12 \) annihilates all basis elements of \( s \) except for \( L(b_p^{(0)}) \) and \( L(c_p^{(0)}) \) which are left invariant. Using the definition \( x_p^{(0)} := [ad_s^2(L(b_p^{(0)})) - ad_s^2(L(c_p^{(0)}))]/4 \) and verifying \( x_p^{(0)} L(a_p) = x_p^{(0)} L(a_{p+i}) = 0 \), we can infer that \( x_p^{(0)} L(a_q - a_{q+i}) = 0 \) holds for all valid \( q \) and \( j \). Furthermore, we have \( x_p^{(0)} L(b_q^{(0)}) = x_p^{(0)} L(c_q^{(0)}) = 0 \) for all valid \( q \) and \( j \) unless when \( q = p \) and \( j = i \) hold. We obtain \( x_p^{(0)} L(b_p^{(0)}) = L(b_p^{(0)}) \) and \( x_p^{(0)} L(c_p^{(0)}) = -L(c_p^{(0)}) \) in this exceptional case. As \( s \) is semisimple, it cannot be abelian and has to contain an element which is supported on some \( L(b_p^{(0)}) \) or \( L(c_p^{(0)}) \). Relying on the ideal property \( [s, i] \subseteq i \) and the operators \( x_p^{(0)} \) and \( y_p^{(0)} \), we conclude that \( L(b_p^{(0)}) \in i \) or \( L(c_p^{(0)}) \in i \). Obviously, the conditions \( L(b_p^{(0)}) \in i \), \( L(c_p^{(0)}) \in i \), and \( L(a_p - a_{p+i}) \in i \) are equivalent. By applying previously mentioned commutator relations, we can verify that \( L[b_p^{(0)}] \in i \) holds for all \( p \leq q \) and \( j + p \leq q + i \). In particular, \( L(b_p^{q-1}) \in i \). Using the commutator relations \( [L(c_p), L(b_p^{(0)})] = L(b_p^{(q-1)}) \) and \( [L(c_p+1), L(b_p^{(0)})] = -L(b_p^{(q-1)}) \) where \( i > 1 \), we can reach the conclusion that \( L(b_p^{(0)}) \in i \) for all valid \( q \) and \( j \). Thus, we have shown that \( i = s \) and \( s \) has to be simple. We summarize that \( t_1 \) has dimension \( d^2 \), has rank \( d \), and is a subalgebra of maximal rank in \( so(2d) \). In addition, it is a direct sum of a simple subalgebra and a one-dimensional abelian subalgebra. We list all compact, simple Lie algebras \( s \) of rank \( k := d - 1 \geq 4 \); \( su(k + 1) \) has dimension \( k^2 + 2k \), \( so(2k + 1) \) has dimension \( 2k^2 + k \), \( sp(k) \) has dimension \( 2k^2 + k \), \( so(2k) \) has dimension \( 2k^2 - k \), and \( al(2k) \) has dimension \( 2k^2 - k \), as well as the exceptional ones. Note that the exceptional cases \( g_2, f_4, e_6, e_7, \) and \( e_8 \) are ruled out by their respective ranks \( 2, 4, 6, 7, \) and \( 8 \) as well as dimensions \( 14, 52, 78, 133, \) and \( 248 \). We obtain \( s \cong su(d) \) and \( t_1 \cong u(d) \).

Appendix E: Proof of Proposition 26

Here, a proof for the Proposition 26 of Section 7.2 is provided. We start in Section E.1 by generalizing a key observation of [19] (where the particular case of Proposition 57 when \( K \) divides \( L \) was already considered). This generalization is then applied in Section E.2 to the proof of Proposition 26.

E.1 Generalizing a key observation of [19]

Proposition 57 The trace of the product of \( U_T^K \) with a tensor product of Pauli operators \( Q \in \{I_2, X, Y, Z\} \) can be computed as

\[
\text{tr} \left[ U_T^K \left( \bigotimes_{i=1}^{L} Q_i \right) \right] = \prod_{p=1}^{L-1} \text{tr} \left[ \prod_{q=0}^{L-1} Q_{(qK + p) \mod L} \right], \quad \text{where} \quad c := \gcd(K, L). \tag{58}
\]

Proof To simplify our calculations, let us introduce the notation \( v(\ell) = (K + \ell) \mod L \), note that \( (v \circ v)(\ell) = v(v(\ell)) = (2K + \ell) \mod L \), or more generally \( v^{p\ell}(\ell) = (pK + \ell) \mod L \). The desired}
\( \ell \) mod \( L \). We can now write the action of \( U_T^{qK} \) on an arbitrary standard basis vector as \( U_T^{qK}(n_1, \ldots, n_{\ell}, \ldots, n_L) = (n_0(n_1), \ldots, n_0(n_{\ell}), \ldots, n_0(n_L)) \). Without loss of generality we can confine the discussion to the case where \( K \leq L \). We complete the proof, by evaluating the trace in Eq. (58) as \( \text{tr}(U_T^{qK}(\otimes^L_{i=1} Q_i)) = \text{tr}((\otimes^L_{i=1} Q_i)U_T^{qK}) = \sum_{p \in \{0,1\}^L} \langle n_1, \ldots, n_{\ell}, \ldots, n_L | (\otimes^L_{i=1} Q_i)n_0(n_1), \ldots, n_0(n_{\ell}), \ldots, n_0(n_L) \rangle = \sum_{p \in \{0,1\}^L} \prod_{i=1}^L \langle n_{\ell}(Q_i)n_0(n_{\ell}) \rangle \) which is equal to the form \( \sum_{p \in \{0,1\}^L} \langle n_1, \ldots, n_{\ell}, \ldots, n_L | (\otimes^L_{i=1} Q_i)n_0(n_1), \ldots, n_0(n_{\ell}), \ldots, n_0(n_L) \rangle = \sum_{p \in \{0,1\}^L} \prod_{i=1}^L \langle n_{\ell}(Q_i)n_0(n_{\ell}) \rangle \) and which can be further simplified as \( \sum_{p \in \{0,1\}^L} \prod_{i=1}^L \langle n_{\ell}(Q_i)n_0(q_{i\ell}) \rangle \mod L \). We finally get \( \text{tr}(U_T^{qK}(\otimes^L_{i=1} Q_i)) = \prod_{p=1}^{L} \text{tr}[U^{q_{i\ell}}_{T}(q_{i\ell})] \). \( \square \)

E.2 Details of the Proof of Proposition 26

The Lie algebras \( t_W \) with \( W \in \{M, M+1\} \) are generated by the elements \( i \sum_{q=0}^{L-1} U_T^{q2} \times [((\otimes^L_{p=1} Q_p) \otimes \mathbf{1}_{\mathbb{Z}^2}) U_T^{q2} \). Here, we consider all combinations of \( Q_p \in \{1, 2, X, Y, Z\} \) apart from the case when \( Q_1 = \mathbf{1}_2 \). We introduce the notation

\[
F(a, W) := \text{tr} \left( U_T^{aqM} \left( i \sum_{q'=0}^{L-1} U_T^{q2} \left( \bigotimes_{p=1}^W Q_p \right) \otimes \mathbf{1}_{\mathbb{Z}^2}^{\otimes L-W} \right) U_T^{q2} \right),
\]

where \( a \in \{1, -1\} \) and \( W \in \{M, M+1\} \). Using Proposition 57, we compute the formulas \( F(1, M) = iL \prod_{p=1}^{M} \text{tr}[Q_p] = 0, F(1, M+1) = iL \text{tr}[Q_1 Q_{M+1}] \prod_{p=2}^{M} \text{tr}[Q_p], F(-1, M+1) = iL \text{tr}[Q_{M+1} Q_1] \prod_{p=2}^{M} \text{tr}[Q_p] \). It follows that the respective statements in the proposition hold for the generators of \( t_M \) and \( t_{M+1} \). Now we prove this consequence also for any element in \( t_M \) (or \( t_{M+1} \)). First, let us note that the elements generated must be contained in \( [t_M, t_M] \) (or \( [t_{M+1}, t_{M+1}] \)). Second, since all elements in \( t_{M+1} \) (and hence in \( t_M \)) commute with \( U_T^{qM} \), we have that \( \text{tr}(U_T^{qM} i h) = 0 \) holds for any element \( i h \in [t_{M+1}, t_{M+1}] \), as \( \text{tr}[(i h_{M+1}^1 i h_{M+1}^2) U_T^{qM}] = \text{tr}(i h_{M+1}^1 i h_{M+1}^2 U_T^{qM}) - \text{tr}(i h_{M+1}^2 i h_{M+1}^2 U_T^{qM}) = 0 \). Thus Proposition 26 follows.

Appendix F: Proof of Theorem 33 for \( d \) even

Let us introduce the notation \( N_2 \), which corresponds to the linear space spanned by the nearest-neighbor (and on-site) operators. Note that \( N_2 \) forms only a linear space and is in general not equal to the Lie algebra \( t_2 \) generated by its elements. We first prove a fermionic generalization of Lemma 26.

Lemma 58 Consider a fermionic system for which the number \( d \geq 6 \) of modes is even. For any \( i h \in N_2 \) the condition \( \text{tr}(i h \ell^{-2}) = 0 \) holds if \( d \) mod 4 = 2, while \( \text{tr}(i h \ell^{-4}) = 0 \) holds if \( d \) mod 4 = 0.
Proof By definition, any element \( i \hbar \in \mathcal{N}_2 \) can be written as \( i \hbar = \sum_{n=0}^{d-1} U^n i \hbar_{12} U^{-n} \), where \( i \hbar_{12} \) is a traceless skew-Hermitian operator acting only on the first two modes of the fermionic system. Therefore, \( i \hbar_{12} \) is a linear combination of the elements \( \imath n_1 m_2 n_3 m_4 \) and \( m_a m_b \) where \( a, b \in \{1, 2, 3, 4\} \) and \( a \neq b \). We obtain that \( \text{tr}(i \hbar \ell^{–b}) = \text{tr}[\sum_{n=0}^{d-1} (U^n i \hbar_{12} U^{-n}) \times U^{–b}] = \sum_{n=0}^{d-1} \text{tr}(U^n i \hbar_{12} U^{–b}) = d \text{tr}(i \hbar_{12} U^{–b}) \). If \( d \mod 4 = 2 \), we write out explicitly \( \text{tr}(i \hbar \ell^{–b})/d \) for \( b = 2 \) by applying Eq. (34):

\[
\text{tr}(i \hbar \ell^{–2})/d = \text{tr}(i \hbar_{12} U^{–2}) = \sum_{n \in \{0,1\}^d} \langle n_1, \ldots, n_d | i \hbar_{12} \ell^{–2} | n_1, \ldots, n_d \rangle \\
= \sum_{n \in \{0,1\}^d} \kappa(n) \langle n_1, \ldots, n_d | i \hbar_{12} | n_3, \ldots, n_d, n_1, n_2 \rangle, \quad \text{where}
\]

\[
\kappa(n) := (-1)^{n_1+n_2} |n_3+n_4+\cdots+n_d|.
\] (59)

In the sum given above, the basis vectors are orthogonal and thus most of the terms are zero. The only terms with non-zero contributions can occur in the cases of \( n_1 = n_{2\ell–1} \) and \( n_2 = n_{2\ell} \) with \( \ell \in \{1, \ldots, d/2\} \). In particular, we have \( \kappa(n_1, n_2, n_3, \ldots, n_{2\ell} n_{2\ell–1}) = 1 \) as \( d/2 \) is an odd number if \( d \mod 4 = 2 \). Hence we obtain that

\[
\text{tr}(i \hbar \ell^{–2})/d = \text{tr}(i \hbar_{12} U^{–2}) = \sum_{n_1, n_2 \in \{0,1\}} \langle n_1, n_2, n_1, n_2, \ldots | i \hbar_{12} | n_1, n_2, n_1, n_2, \ldots \rangle \\
= \sum_{n_1, n_2 \in \{0,1\}} \langle n_1, n_2 | i \hbar_{12} | n_1, n_2 \rangle = \text{tr}(i \hbar_{12}) = 0.
\]

If \( d \mod 4 = 0 \), we can explicitly write out the trace:

\[
\text{tr}(i \hbar \ell^{–4})/d = \text{tr}(i \hbar_{12} U^{–4}) = \sum_{n \in \{0,1\}^d} \langle n_1, \ldots, n_d | i \hbar_{12} \ell^{–4} | n_1, \ldots, n_d \rangle \\
= \sum_{n \in \{0,1\}^d} \lambda(n) \langle n_1, \ldots, n_d | i \hbar_{12} | n_5, \ldots, n_d, n_1, \ldots, n_4 \rangle, \quad \text{where}
\]

\[
\lambda(n) := (-1)^{n_1+n_2+n_3+n_4} |n_5+n_6+\cdots+n_d|.
\] (60)

The basis vectors in the sum are again orthogonal, and most of the terms are zero. The only terms that can give non-zero contributions are for the cases of \( n_1 = n_{4\ell–3} \), \( n_2 = n_{4\ell–2} \), \( n_3 = n_{4\ell–1} \), and \( n_4 = n_{4\ell} \) with \( \ell \in \{1, \ldots, d/4\} \). It follows in these cases that

\[
\lambda(n) = (-1)^{(n_1+n_2+n_3+n_4)(d/4–1)} = \begin{cases} 1 & \text{if } d \mod 4 = 8, \\ (-1)^{n_1+n_2+n_3+n_4} & \text{if } d \mod 4 = 0. \end{cases} \] (61)

The notation \( \chi := n_1, n_2, n_3, n_4, n_1, n_2, n_3, n_4, \ldots, n_4 \) is used, and we obtain

\[
\text{tr}(i \hbar \ell^{–4})/d = \text{tr}(i \hbar_{12} U^{–4}) = \sum_{n_1, \ldots, n_4 \in \{0,1\}} \lambda(n) \langle \chi | i \hbar_{12} | \chi \rangle \\
= \sum_{n_1, \ldots, n_4 \in \{0,1\}} \lambda(n) \langle n_1, \ldots, n_4 | i \hbar_{12} | n_1, \ldots, n_4 \rangle.
\] (62)
Apply Eq. (61) and obtain that Eq. (62) is zero if \( d \mod 8 = 4 \). We can also prove that Eq. (62) is zero for \( d \mod 8 = 0 \) as Eq. (62) simplifies to 
\[
\sum_{n1,n2 \in \{0,1\}} (-1)^{n1+n2} \langle n1_n2 | ih_{12} | n1_n2 \rangle \times \sum_{n1,n4 \in \{0,1\}} (-1)^{n1+n4} = 0. 
\]

**Lemma 59** Consider a fermionic system for which the number \( d \geq 6 \) of modes is even. The properties \( \text{tr}(ihU^{-2}) \neq 0 \) and \( \text{tr}(ihU^{-4}) \neq 0 \) hold for the operator \( ih_5 \) of Theorem 33.

**Proof** We proceed similarly as in the proof of Lemma 58. The operator \( ih_5 \) can be written as 
\[
\sum_{n=0}^{d-1} U^n ih_5 U^{-n}, \text{ where } ih_5 := (f_1 f_2 f_3 f_4 f_5 f_6 f_7 f_8 - 1/32). \text{ Due to this particular structure of } ih_5, \text{ we can simplify the trace } \text{tr}(ihU^{-b}) = \text{tr}[(\sum_{n=0}^{d-1} U^n ih_5 U^{-n})U^{-b}] = \sum_{n=0}^{d-1} \text{tr}(U^n ih_5 U^{-n}U^{-b}) = d \text{tr}(ihU^{-b}). \]

Let us explicitly write out the trace for \( b = 2 \) by applying Eq. (34):
\[
\text{tr}(ihU^{-2})/d = \text{tr}(ihU^{-2}) = \sum_{n \in \{0,1\}^d} \langle n_1,\ldots,n_d | ih_5 U^{-2} | n_1,\ldots,n_d \rangle \\
= \sum_{n \in \{0,1\}^d} \kappa(n) \langle n_1,\ldots,n_d | ih_5 | n_3,\ldots,n_d,n_1,n_2 \rangle \\
= \sum_{n \in \{0,1\}^d} \theta(n) \langle n_1,\ldots,n_d | n_3,\ldots,n_d,n_1,n_2 \rangle,
\]

where \( \theta(n) := (\delta_{n_1,1} \delta_{n_2,1} \delta_{n_3,1} \delta_{n_4,1} - 1/32) \kappa(n) \) and \( \kappa(n) \) was defined in Eq. (59). Most of the terms in the sum are zero as the basis vectors are orthogonal. The only terms with non-zero contributions occur for \( n_{2\ell-1} = n_1 \) and \( n_{2\ell} = n_2 \) with \( \ell \in \{1,\ldots,d/2\} \). If \( d \mod 4 = 2 \), it follows that \( \theta(n) = 31/32 \) for \( n_1 = n_2 = 1 \), and \( \theta(n) = -1/32 \) otherwise. If \( d \mod 4 = 0 \), we have \( \theta(n) = 31/32 \) for \( n_1 = n_2 = 1 \), and \( \theta(n) = 1/32 \) for \( n_1 + n_2 = 1 \), and \( \theta(n) = -1/32 \) for \( n_1 = n_2 = 0 \). We obtain
\[
\text{tr}(ihU^{-2})/d = \text{tr}(ihU^{-2}) = \sum_{n_1,n_2 \in \{0,1\}} \theta(n_1,n_2,n_1,n_2) \langle n_1,n_2,n_1,n_2,... | n_1,n_2,n_1,n_2,... \rangle \\
= \begin{cases} 7/8 & \text{if } d \mod 4 = 2, \\ 1 & \text{if } d \mod 4 = 0. \end{cases}
\]

Let us now consider the trace with \( U^{-4} \):
\[
\text{tr}(ihU^{-4})/d = \text{tr}(ihU^{-4}) = \sum_{n \in \{0,1\}^d} \langle n_1,\ldots,n_d | ih_5 U^{-4} | n_1,\ldots,n_d \rangle \\
= \sum_{n \in \{0,1\}^d} \lambda(n) \langle n_1,\ldots,n_d | ih_5 | n_5,\ldots,n_d,n_1,\ldots,n_4 \rangle \\
= \sum_{n \in \{0,1\}^d} \mu(n) \langle n_1,\ldots,n_d | n_5,\ldots,n_d,n_1,\ldots,n_4 \rangle,
\]

where \( \mu(n) := (\delta_{n_2,1} \delta_{n_3,1} \delta_{n_4,1} \delta_{n_5,1} \delta_{n_6,1} - 1/32) \lambda(n) \) and \( \lambda(n) \) was defined in Eq. (60). Again, most of the terms in the sum are zero as the basis vectors are orthogonal. Provided that
$d \mod 4 = 2$, the only terms with non-zero contributions can occur in the case of $n_{2\ell - 1} = n_1$ and $n_{2\ell} = n_2$ where $\ell \in \{1, \ldots, d/2\}$. In this case $\mu(n) = 31/32$ for $n_1 = n_2 = 1$, and $\mu(n) = -1/32$ otherwise. It follows that $\text{tr}(i\hbar_{\ell} \mathcal{U}^{-4})/d = 7/8$. If $d \mod 4 = 0$, terms with non-zero contributions can occur for $n_{4\ell - 3} = n_3$, $n_{4\ell - 2} = n_2$, $n_{4\ell - 1} = n_3$, and $n_{4\ell} = n_4$ with $\ell \in \{1, \ldots, d/4\}$. For these cases we obtain from Eq. (61) that

$$
\mu(n) = \left(\delta_{n_1,1}\delta_{n_2,1}\delta_{n_3,1}\delta_{n_4,1} - \frac{1}{32}\right) \times \begin{cases} 
1 & \text{if } d \mod 8 = 4, \\
(-1)^{n_1+n_2+n_3+n_4} & \text{if } d \mod 8 = 0.
\end{cases}
$$

Using $\chi = n_1, n_2, n_3, n_4, n_1, n_2, n_3, n_4, \ldots, n_4$ we can simplify the trace to

$$
\text{tr}(i\hbar_{\ell} \mathcal{U}^{-4})/d = \text{tr}(i\hbar_{\ell} \mathcal{U}^{-4}) = \sum_{n_1, \ldots, n_4 \in \{0,1\}} \mu(n) \langle \chi | \chi \rangle
$$

$$
= \begin{cases} 
1/2 & \text{if } d \mod 8 = 4, \\
1 & \text{if } d \mod 8 = 0.
\end{cases}
$$

Now we can prove Theorem 33 for even $d$ as given in the following proposition:

**Proposition 60** Consider a fermionic system for which the number $d \geq 6$ of modes is even. The fourth-neighbor element $i\hbar_{k} \in \mathcal{t}_{4}$ of Theorem 33 is not contained in the system algebra $\mathcal{t}_{4}$ of nearest-neighbor interactions.

**Proof** We introduce the operator

$$
\mathcal{C}_d = \begin{cases} 
\mathcal{U}^{-2} & \text{if } d \mod 4 = 2, \\
\mathcal{U}^{-4} & \text{if } d \mod 4 = 0.
\end{cases}
$$

It follows from Lemma 58 that the equality $\text{tr}(i\hbar \mathcal{C}_d) = 0$ holds for any $i\hbar \in \mathcal{N}_2$. Since $\mathcal{C}_d$ commutes with all elements of $\mathcal{t}_{4}$ and $\mathcal{t}_{2} = \text{span}(\mathcal{N}_2, \{\mathcal{t}_{4}, \mathcal{t}_{2}\})$, we have $\text{tr}(\mathcal{C}_d i\hbar_{\ell_1} i\hbar_{\ell_2}) = \text{tr}(\mathcal{C}_d i\hbar_{\ell_1} i\hbar_{\ell_2}) - \text{tr}(\mathcal{C}_d i\hbar_{\ell_1} i\hbar_{\ell_2}) = \text{tr}(\mathcal{C}_d i\hbar_{\ell_1} i\hbar_{\ell_2}) - \text{tr}(\mathcal{C}_d i\hbar_{\ell_1} i\hbar_{\ell_2}) = 0$. This means that $\text{tr}(\mathcal{C}_d i\hbar_{k}) = 0$ for all $i\hbar_{k} \in \mathcal{t}_{4}$. But we know from Lemma 59 that $\text{tr}(i\hbar \mathcal{C}_d) \neq 0$ which shows that $i\hbar_{k} \notin \mathcal{t}_{4}$.

**Appendix G: Proof of Theorem 33 for $d$ odd**

The proof of Theorem 33 for odd number of modes uses an expansion of the translation unitary $\mathcal{U}$ by the Fourier-transformed Majorana operators, which are

$$
\tilde{m}_{2k} := i(\tilde{f}_{k} - \tilde{f}_{k}^\dagger) \quad \text{and} \quad \tilde{m}_{2k+1} := \tilde{f}_{k} + \tilde{f}_{k}^\dagger.
$$

(63)

Note that the operators $\tilde{f}_{k}$ were defined in Eq. (38). The self-adjoint operators $\tilde{m}_{k}$ satisfy again the Majorana anticommutation relations $[\tilde{m}_{x}, \tilde{m}_{y}] = 2\delta_{x,y} 1$. Moreover, the trace of any $\tilde{m}_{k}$-monomial is zero, since it is a linear combination of Majorana monomials. We relate these operators to the translation unitary:
Lemma 61  The translation unitary $\mathcal{U}$ can be written as

$$\mathcal{U} = (-i)^{d-1} \exp \left[-i \sum_{k=0}^{d-1} \frac{2\pi k}{d} \left(\tilde{f}_k - \frac{1}{2} \mathbb{1}\right)\right]$$

(64)

$$\mathcal{U} = (-i)^{d-1} \exp \left[-\sum_{k=0}^{d-1} \frac{\pi k}{d} \tilde{m}_{2k+1} \tilde{m}_{2k}\right]$$

(65)

$$\mathcal{U} = (-i)^{d-1} \prod_{k=0}^{d-1} \left[\cos \left(\frac{\pi k}{d}\right) \mathbb{1} - \sin \left(\frac{\pi k}{d}\right) \tilde{m}_{2k+1} \tilde{m}_{2k}\right]$$

(66)

using the Fourier-transformed operators $\tilde{f}_k$ and $\tilde{\phi}^i_k$ as well as $\tilde{m}_{2k}$ and $\tilde{m}_{2k+1}$.

Proof  Let us denote the right hand side of Eq. (64) by $\mathcal{V}$. We apply $\tilde{m}_{2k+1} \tilde{m}_{2k} = i(2\tilde{\phi}^i_k \tilde{f}_k - \mathbb{1})$ and obtain that $\mathcal{V} = (-i)^{d-1} \exp(-\sum_{k=0}^{d-1} \pi k \tilde{m}_{2k+1} \tilde{m}_{2k}/d)$. Since the formula $[\tilde{m}_{2k+1}, \tilde{m}_{2k}, \tilde{m}_{2k+1} \tilde{m}_{2k}] = 0$ holds for all $k \neq k'$, we can split the exponential into the product $\mathcal{V} = (-i)^{d-1} \prod_{k=0}^{d-1} \exp(-\pi k \tilde{m}_{2k+1} \tilde{m}_{2k}/d)$. We employ $(\tilde{m}_{2k+1} \tilde{m}_{2k})^2 = -\mathbb{1}$ and obtain the formula

$$\exp(-\pi k \tilde{m}_{2k+1} \tilde{m}_{2k}) = \sum_{n=0}^{\infty} \frac{(-1)^n (\pi k)^{2n}}{(2n)!} \mathbb{1}$$

$$\sum_{n=0}^{\infty} \frac{(-1)^n (\pi k)^{2n+1}}{(2n+1)!} \tilde{m}_{2k+1} \tilde{m}_{2k} = \cos \left(\frac{\pi k}{d}\right) \mathbb{1} - \sin \left(\frac{\pi k}{d}\right) \tilde{m}_{2k+1} \tilde{m}_{2k}.$$ 

Thus, $\mathcal{V}$ is equal to the right hand side of Eq. (66). Similarly, the adjoint of $\mathcal{V}$ can be written as

$$\mathcal{V}^d = i^{d-1} \prod_{k=0}^{d-1} \left[\cos \left(\frac{\pi k}{d}\right) \mathbb{1} + \sin \left(\frac{\pi k}{d}\right) \tilde{m}_{2k+1} \tilde{m}_{2k}\right].$$

The commutation relations of Eq. (39) imply the formula $\tilde{m}_{2k+1} \tilde{m}_{2k} = -\tilde{f}_k \tilde{m}_{2k+1} \tilde{m}_{2k} = \tilde{\phi}_k^{i*}$.

It follows that

$$\mathcal{V}^d \mathcal{V}^d = \left[\cos \left(\frac{\pi k}{d}\right) \mathbb{1} - \sin \left(\frac{\pi k}{d}\right) \tilde{m}_{2k+1} \tilde{m}_{2k}\right] \mathcal{V}^d \left[\cos \left(\frac{\pi k}{d}\right) \mathbb{1} + \sin \left(\frac{\pi k}{d}\right) \tilde{m}_{2k+1} \tilde{m}_{2k}\right]$$

$$= e^{-2\pi ik/d} \tilde{f}_k,$$

which implies that

$$\mathcal{V}^d \mathcal{V}^d = \mathcal{V} \left[\frac{1}{\sqrt{d}} \sum_{k=0}^{d} \tilde{f}_k e^{-2\pi i nk/d}\right] \mathcal{V}^d = \frac{1}{\sqrt{d}} \sum_{k=0}^{d} \tilde{f}_k e^{-2\pi i(n+1)k/d} = f_{n+1}^{i*}.$$ 

(67)

Applying the formulas $\tilde{f}_k |0\rangle = 0$ and $[\tilde{f}_k^{i*}, \tilde{f}_k^{i*} f_k^{i*} f_k^{i*}] = 0$, we conclude that $\exp[-i \sum_{k=0}^{d-1} 2\pi k \tilde{\phi}_k^{i*} f_k/d] |0\rangle = |0\rangle$. This allows us to investigate how $\mathcal{V}$ acts on the Fock vacuum $|0\rangle$:

$$\mathcal{V} |0\rangle = (-i)^{d-1} \exp \left[-i \sum_{k=0}^{d-1} \frac{2\pi k}{d} \left(\tilde{f}_k^{i*} f_k^{i*} - \frac{1}{2} \mathbb{1}\right)\right] |0\rangle$$

$$= (-i)^{d-1} e^{-\sum_{k=0}^{d-1} \frac{\pi k}{d}} \exp \left[-i \sum_{k=0}^{d-1} \frac{2\pi k}{d} \left(\tilde{f}_k^{i*} f_k\right)\right] |0\rangle$$

$$= (-i)^{d-1} e^{-\frac{\pi}{2} (d-1)} |0\rangle = |0\rangle.$$ 

(68)
It follows from Eqs. (67) and (68) that \( V \) satisfies Eq. (34) if we substitute \( V \) for \( U \). As Eq. (34) defines \( U \) uniquely, \( U = V \) must hold.

In the next step, we provide a polynomial of \( U \) which multiplied by any nearest-neighbor Hamiltonian gives an operator with zero trace (if the system is composed of an odd number of modes). One key observation is that the action of the twisted reflection operator on the translation unitary is

\[
RU\mathcal{R}^\dagger = U^{-1},
\]

which follows directly from the definition of \( \mathcal{R} \), see Eq. (46). Using this equation and Lemma 61, one can prove the following statement:

**Lemma 62** Consider a fermionic system for which the number \( d \geq 5 \) of modes is odd and introduce the operator

\[
C_d' = (-1)^{d/4} (U^2 - U^{-2}) - (-1)^d (U^4 - U^{-4}).
\]

The equality \( \text{tr}(ihC_d') = 0 \) holds for any \( ih \in \mathbb{T}^t \).

**Proof** We will first prove that \( \text{tr}(vC_d') = 0 \) holds for all \( v \in \mathcal{N}_d \), where \( \mathcal{N}_d \) denotes the linear space spanned by the nearest-neighbor interactions (as in Appendix F). The equation \( \mathcal{R}C_d'\mathcal{R}^\dagger = -C_d' \) follows from Eq. (69). On the other hand, Eq. (46) implies that \( \mathcal{R}ih\mathcal{R}^\dagger = ih \) holds for any \( ih \in \{ih_0, ih_{ih}, ih_{hp}, ih_{cp}, ih_{int}\} \), hence \( \text{tr}(ihC_d') = \text{tr}(\mathcal{R}ih\mathcal{R}^{-1}C_d'\mathcal{R}^{-1}) = -\text{tr}(ihC_d') = 0 \).

In order to calculate \( \text{tr}(ih_chC_d') \), we first note that using Eq. (47a) the operator \( ih_ch \) can be written as

\[
ih_ch = -\sum_{k=0}^{d-1} \sin \left( \frac{2\pi k}{d} \right) \tilde{m}_{2k+1}\tilde{m}_{2k}.
\]

Next, let us expand \( U^\dagger \) using Lemma 61 as

\[
U^\dagger = \prod_{k=0}^{d-1} \left[ \cos \left( \frac{2\pi k}{d} \right) \mathbbm{1} - \sin \left( \frac{2\pi k}{d} \right) \tilde{m}_{2k+1}\tilde{m}_{2k} \right]
\]

\[
= \lambda_1 \mathbbm{1} - \lambda_1 \sum_{k=0}^{d-1} \tan \left( \frac{2\pi k}{d} \right) \tilde{m}_{2k+1}\tilde{m}_{2k} + M_1,
\]

where \( M_1 \) is a linear combination of Majorana monomials of degree greater than two and \( \lambda_1 := \prod_{k=0}^{d-1} \cos \left( \frac{2\pi k}{d} \right) \). Similarly, let us expand \( U^4 \):

\[
U^4 = \prod_{k=0}^{d-1} \left[ \cos \left( \frac{4\pi k}{d} \right) \mathbbm{1} - \sin \left( \frac{4\pi k}{d} \right) \tilde{m}_{2k+1}\tilde{m}_{2k} \right]
\]

\[
= \lambda_1 \mathbbm{1} - \lambda_1 \sum_{k=0}^{d-1} \tan \left( \frac{4\pi k}{d} \right) \tilde{m}_{2k+1}\tilde{m}_{2k} + M_2,
\]
where $M_2$ is a linear combination of Majorana monomials of degree greater than two. We employed that $\prod_{k=0}^{d-1} \cos(\frac{2\pi k}{d}) = \prod_{k=0}^{d-1} \cos(\frac{2\pi k}{d})$ holds for odd $d$.

We note that all monomials of Fourier-transformed Majorana operators have zero trace and determine the traces $\text{tr}(U^2i\hbar_{\text{ch}})$ and $\text{tr}(U^4i\hbar_{\text{ch}})$ by calculating the coefficient of $1$ in $U^2i\hbar_{\text{ch}}$ and $U^4i\hbar_{\text{ch}}$:

$$\text{tr}(U^2i\hbar_{\text{ch}}) = 2d^2\lambda_1 \sum_{k=0}^{d-1} \tan\left(\frac{2\pi k}{d}\right) \sin\left(\frac{2\pi k}{d}\right) = (-1)^d 2d^2 \lambda_1,$$

$$\text{tr}(U^4i\hbar_{\text{ch}}) = 2d^2\lambda_1 \sum_{k=0}^{d-1} \tan\left(\frac{4\pi k}{d}\right) \sin\left(\frac{2\pi k}{d}\right) = (-1)^{|d/4|} 2d^2 \lambda_1.$$

Note that $\text{tr}(i\hbar_{\text{ch}}U^{-t}) = \text{tr}(Ri\hbar_{\text{ch}}R^\dagger RU^{-t} R^\dagger) = -\text{tr}(i\hbar_{\text{ch}}U^t)$, which allows us to conclude $\text{tr}(i\hbar_{\text{ch}}C \lambda_1 C') = 2(-1)^{|d/4|} \text{tr}(i\hbar_{\text{ch}}U^2) - 2(-1)^d \text{tr}(i\hbar_{\text{ch}}U^4)$. This implies that $\text{tr}(C \lambda_1 C') = 0$, and thus $\text{tr}(C \lambda_1 ) = 0$ holds for all $\nu \in \mathbb{N}_2$. As $C$ commutes with all elements of $\mathcal{V}_2$, it also follows that $\text{tr}(i\hbar_{\text{ch}}U^t) = 0$ for any $i\hbar_{\text{ch}}U^t$.

After these preparations we can prove Theorem 33 for odd $d$ as summarized in the following proposition:

**Proposition 63** Consider a fermionic system with $d \geq 5$ odd modes and the Hamiltonian $h_o$ of Theorem 33. The generator $i\hbar_{\text{ch}} \in \mathcal{V}_2$ is not contained in the system algebra $\mathcal{V}_2$ of nearest-neighbor interactions.

**Proof** Using Eq. (47a), $i\hbar_{\text{ch}}$ can be written as

$$i\hbar_{\text{ch}} = -\sum_{k=0}^{d-1} \sin\left(\frac{6\pi k}{d}\right) \tilde{m}_{2k+1} \tilde{m}_{2k}. \quad (73)$$

Observe that $\text{tr}(i\hbar_{\text{ch}}U^{-t}) = \text{tr}(Ri\hbar_{\text{ch}}R^\dagger RU^{-t} R^\dagger) = -\text{tr}(i\hbar_{\text{ch}}U^t)$ and conclude that the formula $\text{tr}(i\hbar_{\text{ch}}C \lambda_1 C') = 2(-1)^{|d/4|} \text{tr}(i\hbar_{\text{ch}}U^2) - 2(-1)^d \text{tr}(i\hbar_{\text{ch}}U^4)$ holds. Now, the expansion of $U$ given by Eq. (72) allows us to calculate the trace of $i\hbar_{\text{ch}}C \lambda_1 C'$ as $2^{d^2}(-1)^{|d/4|} \lambda_1 \sum_{k=0}^{d-1} \tan\left(\frac{2\pi k}{d}\right) \sin\left(\frac{6\pi k}{d}\right) = 2^{d^2}(-1)^{|d/4|} \lambda_1 (-1)^{d^2} d = 2^{d^2}(-1)^{|d/4|} (-1)^{d^2} d \lambda_1 \neq 0$. On the other hand, we know from Lemma 62 that the equality $\text{tr}(C \lambda_1 i\hbar_{\text{ch}}) = 0$ holds for any $i\hbar_{\text{ch}} \in \mathcal{V}_2$. Therefore, $i\hbar_{\text{ch}} \notin \mathcal{V}_2$. \hfill \square
