Abstract: We investigated the effect of magnetic nanoparticles of Fe₃O₄ (Fe₃O₄-MNPs) on the mice immune system. Imprinting control region (ICR) mice were assigned randomly into four groups and treated with normal saline or low, medium, or high doses of Fe₃O₄-MNPs, respectively. After intravenous administration of Fe₃O₄-MNPs for 72 hours, the peripheral T cells and the induction of primary immune responses in mice were investigated by flow cytometry and determined using enzyme-linked immunosorbent assay, respectively. The results showed that the ratio of spleen to body weight was not different between the experimental groups and control group (P > 0.05). The lymphocyte transformation rates in the suspension of spleen were higher in low-dose group than those in the control group (P < 0.05), while the proliferation of splenocytes was low in the medium and high groups when compared to the control group (P < 0.05). In peripheral blood, both the proportions of subset CD4⁺ and CD8⁻ T lymphocytes in the low-dose group were higher than those in the control group, whereas there was no difference in the number of CD4⁺ T cells between the medium- and low-dose groups. Interestingly, the Fe₃O₄-MNPs enhanced the production of interleukin-2 (IL-2), interferon-γ, and IL-10 but did not affect the production of IL-4 in peripheral blood. It is concluded that Fe₃O₄-MNPs could influence immune functions of normal ICR mice in a dose-dependent manner.

Keywords: magnetic nanoparticle of Fe₃O₄, immune function, splenocyte proliferation, cytokine

Nanotechnology offers an efficient alternative for cancer diagnostics and tumor target treatment due to the unique properties of nanostructures, such as large surface-to-volume ratio, porous structure, embedded effect, and size effect, which have been recognized as offering potential promising applications in biomedical engineering. Much effort has been extended to the development of novel nanocomposites and biomaterials for DNA detection,¹ intracellular labeling,² drug carrier,³ cancer targeting,⁴ imaging,⁵ and so on. Therefore, magnetic nanoparticles of Fe₃O₄ (Fe₃O₄-MNPs) as a kind of biocompatible nanomaterial which is feasible to characterize and easily functionalize, may offer an exciting development toward developing an effective drug delivery system while biocompatible superparamagnetic particles like magnetite could be utilized in tissue-specific release of therapeutic agents and magnetic field assisted radionuclide therapy.⁶–⁹

As a novel material, though we have already proved that Fe₃O₄-MNPs have no cytotoxicity, the exact function of Fe₃O₄-MNPs on immune function has not yet been adequately clarified. In the present paper, we investigated the effects of Fe₃O₄-MNPs on the immune system in imprinting control region (ICR) mice to elucidate the interactions between Fe₃O₄-MNPs and immune system and to provide theoretic evidence for the clinical applications.
Materials and methods

Experimental agents

Experimental agents were sourced from the following locations: RPMI1640 (Gibco Chemical Co., Carlsbad, CA, USA); Anti-CD3 (PE-Cy5), Anti-CD4, Anti-CD8 (Pharmingen, San Diego, CA); Calf serum (Gibco Chemical Co); Enzyme-linked immunosorbent assay kit (Gibco, CA, USA); Con A (Sigma Chemical Co., St Louis, MO, USA).

Preparation of Fe$_3$O$_4$-MNPs

Based on our previous studies, the synthesis of Fe$_3$O$_4$-MNPs was prepared by the electrochemical deposition under oxidizing conditions. Before being applied in the present experiment, the magnetite nanoparticles were well-distributed in RPMI-1640 medium freshly added with 10% heated-inactivated fetal bovine serum (FBS) using ultrasound treatment in order to obtain Fe$_3$O$_4$-MNPs colloidal suspension.

Animals and animal care

Female and male ICR mice, which were age-matched (eight weeks of age) and weight-matched (18–22 g), were purchased from Shanghai National Center for Laboratory Animals. Animals were kept with a 12-hour light/dark cycle and received water and food ad libitum a semi-barrier system. The experiments were performed in adherence to the guidelines for the Care and Use of Laboratory Animals of the National Institute of Health.

Experimental groups and preparation for blood samples

Mice were randomly assigned to one of four groups (n = 10 per group). The doses of 5.14 mg/kg (low dose group), 20.7 mg/kg (medium dose group), and 51.4 mg/kg (high dose group) Fe$_3$O$_4$-MNPs, were dissolved in normal saline and intravenously (iv) injected into mice once. Meanwhile the wells receiving complete RPMI-1640 were regarded as control. Cells were cultured for 68 hours at 37°C in a 5% humidified CO$_2$ atmosphere, following which 10 µL MTT (0.5 mg/mL) were added to each well at 37°C in the dark for at least 4 hours, the formazan crystals were dissolved in 150 µL dimethyl sulfoxide (Sigma Aldrich) and the reduction of MTT was quantified by absorbance at a wavelength of 570 nm using a microplate reader (Model-550; Bio-Rad Laboratories, Hercules, CA, USA). The results were expressed as a mean differential optical density (OD$_{\text{mitogen}}$−OD$_{\text{control}}$).

The proportions of lymphocyte subset

Phenotypic analyses of blood lymphocytes were performed using FCM. Briefly, the cells were incubated with PE or FITC-conjugated monoclonal antibodies [Anti-CD3 (PE-Cy5), Anti-CD4 (FITC), or Anti-CD8 (PE)] for 10 minutes, washed three times, and then resuspended in FACS permeabilizing solution before determination. At least 10,000 cells were analyzed for each MoAb staining using a FACSscan flow cytometer (Becton Dickinson, Franklin Lakes, NJ, USA). Results were expressed as mean fluorescence intensity for a given molecule per cell.

Assessment of cytokines

The levels of interleukin-2 (IL-2), interleukin-4 (IL-4), interleukin-10 (IL-10), and interferon-γ (INF-γ) in serum were measured in duplicate using enzyme-linked immunosorbent assay kit according to the manufacturer’s instruction. Briefly, 50 µL samples or standard control were added to 50 µL assay diluents for each well, incubated at room temperature for 2 hours; after thorough washing, 100 µL conjugate was added to each well for incubation of 2 hours. Then 100 µL substrate solution was added to each well and incubated for 30 minutes. Finally, a 100 µL stop solution was added to each well and the optical density was measured using ELISA reader (Bio-Rad Laboratories, Hercules, CA, USA) with dual wavelength of 450 nm.

Statistical analysis

Data were analyzed using the Statistical Package for Social Science (version 13.0; SPSS Inc., Chicago, IL, USA). The
significant difference between groups was analyzed using one-way ANOVA; *P* values <0.05 were considered statistically significant.

**Results**

**The characteristic of Fe₃O₄-MNPs**

A colloidal suspension of Fe₃O₄-MNPs was achieved by using ultrasound treatment and the magnetization and the size of Fe₃O₄-MNPs were found to be 25.6 × 10⁻³ emu/mg and 20 nm, respectively (Figure 1).

**The changes of spleen weight in Fe₃O₄-MNPs-treated ICR mice**

Mice treated with Fe₃O₄-MNPs appeared healthy and their body weight gain patterns were similar to controls (data not included). The spleens of Fe₃O₄-MNPs-treated mice showed same appearance as the controls. Both the spleen weight and the ratio of spleen weight to body weight showed no significant difference between the experimental groups and the controls (Table 1). It suggested that Fe₃O₄-MNPs did not cause splenomegaly, which was due to the deposition of damaged erythrocytes or to recruitment and/or proliferation of splenic cells.

**Splenocyte proliferation**

A significant increase of splenocyte proliferative capacity was noticed after administration of Fe₃O₄-MNPs in low dose (*P* < 0.05; low dose versus control). Both administration of medium-dose and high-dose Fe₃O₄-MNPs affect splenocyte proliferation and reduced the splenocyte proliferative capacity compared with the control group (*P* < 0.05; control versus medium-dose/high-dose Fe₃O₄-MNPs) (Table 2).

**The proportions of lymphocyte subsets in peripheral blood**

There were no differences between the low-dose group and the medium-dose group in the proportions of CD4⁺ T-cell subset in peripheral blood of ICR mice, and both had more CD4⁺ T lymphocytes than the control group. But the high-dose group showed no difference compared with control (*P* > 0.05) (Figures 2 and 3). Furthermore the proportions of CD8⁺ T lymphocytes subset were slightly lower after the commencement of high dose. Though both low- and medium-dose groups indicated that they have more CD8⁺ T lymphocytes than those of control group, and the low-dose group showed significantly more when compared to the medium-dose group (*P* < 0.05) (Figures 4 and 5).

**Cytokine release**

To detect whether Fe₃O₄-MNPs can alter cytokine production patterns in peripheral blood, enzyme-linked immunosorbent assay was conducted. Fe₃O₄-MNPs altered the production of IL-2, INF-γ, and IL-10. Interestingly, low dose of Fe₃O₄-MNPs significantly increased the levels of IFN-γ, IL-2, IL-10 and IL-4 (*P* < 0.05) when compared to medium or high doses of Fe₃O₄-MNPs (*P* < 0.05), and there were no significant differences between medium and high doses of Fe₃O₄-MNPs (*P* > 0.05), suggesting that low dose of Fe₃O₄-MNPs significantly increased the ability of splenocytes to release cytokines. But no significant changes of IL-4 were observed between the experiment groups and the control group (Figure 6).

**Discussion**

Close attention has been paid to current nanoparticle techniques. It is well known that nanoparticles could present a versatile nanoscale surface for biomolecular recognition because of the numerous potential benefits in merging biomacromolecules and nanoparticles. Meanwhile, much effort has been explored to the development of new nanocomposites and their application in many research fields such as DNA detection, intracellular labeling, drug carrier, and so on.

The magnetic nanoparticle of Fe₃O₄ we tested has good biocompatibility and no cytotoxicity. Our group have proved that Fe₃O₄-MNPs could increase the intracellular effective concentration of chemotherapeutic drugs *in vitro* to reverse MDR. The focus of this study was to investigate whether Fe₃O₄-MNPs have effects on mice immune system, especially the T cell functions after given different dose.
The total body weights of mice were not changed significantly, and the spleen/body weight ratio was unchanged. Actually, quantification of body weight and organ weight forms an integral part of any toxicological study providing an initial assessment of overall animal health status, as well as potential pathology. Descriptions of the tier approach to immunotoxicity evaluation should incorporate measurements of body weight, weights of spleen, thymus, kidney, and liver, as well as organ/body weight ratios in an initial screen.15

Proliferation of lymphocytes following exposure to mitogenic stimuli is an important methodology for the assessment of cell-mediated immunity. This assay has enjoyed frequent use in immunotoxicology studies for its ease of performance and relative reproducibility.16 Therefore, we have investigated the effects of Fe\(_3\)O\(_4\)-MNsPs on lymphoproliferation in spleen following exposure to Con-A. The results showed that the proliferation of lymphocytes was significantly increased when mice were injected with 5.14 mg/kg Fe\(_3\)O\(_4\)-MNsPs compared with the controls. However, the other two groups did not act in a similar way.

To detect the levels of proportion of CD4\(^+\) or CD8\(^+\) T cells, which are markers for T cell lymphocytes. Fe\(_3\)O\(_4\)-MNsPs influenced the function of helper T cells or suppressor T cells, when the less the Fe\(_3\)O\(_4\)-MNsPs were given, the more of an increase in T cell numbers was seen, suggesting that low concentration of Fe\(_3\)O\(_4\)-MNsPs can regulate T cell functions in ICR mice.

The Th1 cytokines promote cellular immunity by activating macrophages, cytotoxic CD8\(^+\) T lymphocytes, and so on, while the Th2 cytokines enhance humoral immunity, including activation and class switching of antibody producing B cells.17 Th1 cells are defined by their ability to secrete the inflammatory cytokines IL-2 and INF-\(\gamma\) and are involved in cellular immunity, some autoimmune disease, and in chronic inflammatory disorders. The Th2-biased cells preferentially produce IL-4, IL-5, IL-10, and IL-13 and participate in humoral response and antibody production.18 In the present study, low dose of Fe\(_3\)O\(_4\)-MNsPs was found to strongly affect the production of Th1 cytokine, and also affect some Th2 cytokine release, suggesting that Fe\(_3\)O\(_4\)-MNsPs might be involved in inflammations associated with infections.

**Conclusion**

In conclusion, our results indicate Fe\(_3\)O\(_4\)-MNsPs can influence immune functions of mice in a dose-dependent manner. Further study indicated that a high dose of Fe\(_3\)O\(_4\)-MNsPs has no significant influence on the immune systems of the mice. These data could be useful for improving biomedical applications of Fe\(_3\)O\(_4\)-MNsPs, but these immunological effects of Fe\(_3\)O\(_4\)-MNsPs should be further conducted both in vivo and in vitro.
