Original Research Article

ABSTRACT

Background: Alcohol consumption is one of the public health problems in India which acts as major attributable risk factor for majority of morbidity and mortality among adults. The objectives of the study were to find out the prevalence of alcohol consumption and its associated factors in rural area by using a WHO tool, AUDIT (Alcohol Use Disorder Identification Test) and to identify extent and pattern of alcohol consumption.

Methods: This study was cross-sectional study. Three hundred sixty four male patients ≥15 years of age, attending OPD in a primary health care setting were interviewed by using a structured questionnaire and AUDIT.

Results: The overall prevalence of ever consumed alcohol was found to be 49.7%; of which 38.2% were current drinkers and 11.5% were former drinkers while rest 50.3% were lifetime abstainers. Educational status, occupation, tobacco use and positive family history were significantly associated with alcohol consumption; while type and size of family, socioeconomic status were found insignificant association. About 53.9% preferred country-made liquor while 23.8% Indian Made Foreign Liquor (IMFL). Enjoyment (45.3%), relaxation or stress buster or social cause (29.5%), peer pressure (25.2%) being the reasons for alcohol consumption. In 33% of consumers, daily drinking and in 36% consumers, 1-5 times per week frequency for alcohol drinking was seen respectively. Three fourth of them purchased alcohol from local shops. Out of 364 subjects 75% belongs to AUDIT score of low risk, 11.2% with alcohol use in excess of low risk, 3.6% with harmful and hazardous drinking and 10.2% with dependent drinking.

Conclusions: In our study, alcoholism is found to be more common among illiterates, non-formers, among tobacco users and those having positive family history. Socio economic status and age is not the bar for alcohol consumption.

INTRODUCTION

Alcohol consumption is a major public health problem in developed as well as developing countries including India. In 2012, globally harmful use of alcohol caused approximately 3.3 million deaths which is 5.9% of all deaths. Five percent of the global burden of disease and injury was attributable to alcohol consumption. As per the most recent WHO data, globally individuals above 15 years of age drink on an average 6.2 liters of pure alcohol per year which is equal to 13.5 grams of pure alcohol per day. World’s 38.3% population is reported to consume alcohol regularly.1

There are more than 200 health conditions like alcohol dependence, cardiovascular diseases, liver cirrhosis, cancer of mouth, pharynx, colon etc. and injuries are related to alcohol. Also the new data has been concluded.

on causal relationships between the harmful use of alcohol and clinical outcomes of infectious disease such as Tuberculosis, HIV /AIDS and pneumonia.1-3

As per global status report of WHO the average Indian consumes 4.3 liters of alcohol per year while the average rural Indian consumes 11.4 liters of alcohol per year. About 30% Indian population consumes alcohol on regular basis.1 There are marked variations in pattern of alcohol consumption in different parts of India. Recently in India, due to impact of western culture and urbanization seem to have changed the trend from low level to higher levels of alcohol consumption.4

According to NFHS-III survey alcohol consumption ranges from 12.5% in Jammu & Kashmir to 61.1% in Arunachal Pradesh. As per NFHS-III, overall prevalence of alcohol consumption was found to be 31.9% among men and 2.2% in women in India and it was found to be 30.8% in men and 2.8% in women respectively in Madhya Pradesh.5

This study is aimed to find out the exact prevalence and pattern of alcohol consumption in a rural area of Indore district.

METHODS

Setting

This was a cross-sectional study carried out among outdoor male patients ≥15 yrs of age during October-December 2015 in primary health care setting i.e. Rural Health Training Centre which is field practice area for a Tertiary Care Level Teaching Institute, Indore. On an average 30-35 patients are visiting this centre daily for medical care. From these OPD patients, total 364 males who gave verbal consent were included in the study. In pilot study, prevalence of alcohol consumption among females was found negligible, so that they were excluded from study.

Study tool

After obtaining verbal consent, respondents were interviewed by using a structured pre-tested questionnaire. Informations on socio-demographic details, pattern of alcohol consumption were collected.

AUDIT (Alcohol Use Disorder Identification Test), a self rated 10 item questionnaire, prepared by WHO was used to assess harmful and hazardous use of alcohol among study participants. AUDIT was developed to screen for excessive drinking and in particular to help practitioners identify people who would benefit from reducing or ceasing drinking. It has been validated in six countries including India.6-9

It was translated in local language i.e. Hindi and pre-tested for the study. It is again translated back to English to ensure its reliability and validity. Patients are further classified as per AUDIT score. Zone I refers to low risk of drinking or abstinence (AUDIT score=0-7), Zone II, consists of alcohol use in excess of low risk guidelines (AUDIT score =8-15), Zone III, refers to high risk of drinking (AUDIT score 16-19) indicative of harmful and hazardous drinking and Zone IV refers to alcohol dependence (AUDIT score ≥20).10-12

Definitions used1

Lifetime abstainers—people who have never consumed alcohol.

Current drinker—who had an alcoholic drink in last 12 months.

Former drinker—people who have previously consumed alcohol but who have not done so in the previous 12 months.

Measures of alcohol consumption

A standard drink is used to measure the alcohol intake. It always contains the same amount of pure alcohol regardless of the container size or the type of alcoholic beverage, but may not correspond to the typical serving size. It varies from country to country. In India, a standard drink corresponds to 10 ml of absolute alcohol. Depending on different concentration of alcohol in different liquor available in India one standard drink corresponds to different quantity for each type of beverage e.g. 300 ml of beer,100 ml of wine,30 ml of distilled spirit, 40 ml of arrack and 30 ml of IMFL.11

WHO guideline criteria for risk of consumption of alcohol for men on a single drinking day is low risk as 1 gm-40 gm of absolute alcohol, medium risk as 41-60 gm & high risk as >60 gm.14 So in our study, other than AUDIT scoring, depending on quantity & quality of beverage consumed, alcoholics were also categorized in three category i.e. low, medium and high risk as per WHO guideline.

Data collection and analysis

After obtaining verbal consent from patients a pre-tested structured questionnaire and AUDIT was administered to subjects to screen for Alcohol Use Disorder. Data thus collected was entered in excel sheet and then analyzed by using SPSS version 20.0. Univariate analysis was done to evaluate association between various factors and alcohol consumption. Probability value of <0.05 was considered statistically significant with their odds ratio and 95% confidence intervals. According to AUDIT scoring percentages for four levels of risk are calculated. All alcohol users were motivated for follow up at rural health
centre which is under department of community medicine of tertiary care level hospital and research centre, Indore. Dependent drinkers were further followed up at tertiary care hospital for detail management.

RESULTS

Table 1 shows sociodemographic characteristics of study participants.

| Characteristic variables | Proportion of total (N=364) | Percentage (%) |
|--------------------------|-----------------------------|----------------|
| **Age (years)**          |                             |                |
| 15-24                    | 27                          | 7.4            |
| 25-64                    | 305                         | 83.8           |
| ≥65                      | 32                          | 8.8            |
| **Education**            |                             |                |
| Illiterate               | 92                          | 25.3           |
| Literate                 | 272                         | 74.7           |
| **Marital status**       |                             |                |
| Unmarried                | 15                          | 4.1            |
| Married                  | 345                         | 94.8           |
| Divorced/Separated/ Widower | 04                      | 1.1            |
| **Type of family**       |                             |                |
| Single                   | 15                          | 4.1            |
| Nuclear                  | 81                          | 22.3           |
| Joint                    | 242                         | 66.5           |
| Extended                 | 26                          | 7.1            |
| **Family size**          |                             |                |
| <5                       | 75                          | 20.6           |
| >5                       | 289                         | 79.4           |
| **Occupation**           |                             |                |
| Farmer                   | 245                         | 67.3           |
| Laborer                  | 52                          | 14.3           |
| Service                  | 16                          | 4.4            |

| **Socio-economic status** |                             |                |
| Class I (Rs. ≥5638)      | 15                          | 4.1            |
| Class II (Rs. 2819-5638) | 37                          | 10.2           |
| Class III (Rs. 1691-2818)| 51                          | 14             |
| Class IV (Rs. 846-1690)  | 112                         | 30.8           |
| Class V (Rs. <846)       | 149                         | 40.9           |
| **Tobacco use**          |                             |                |
| Yes                      | 98                          | 27             |
| No                       | 266                         | 73             |
| **Family history of alcohol** |                         |                |
| Yes                      | 38                          | 10.4           |
| No                       | 326                         | 89.6           |

Table 2 shows univariate analysis of socio-demographic factors with alcohol consumption.

Overall 139 (38.2%) of adults had consumed alcohol in past 12 months. Among the users, 39.7% of current drinkers were from the age between 25-64 years; we even observed that majority youths 37% were also involved in alcohol consumption. In this study, more percentage of alcohol consumers was found among illiterate males (48%) as compare to literates (35%). The proportion of alcohol users were higher (100%) among divorced/ separated or widower followed by married and then unmarried once. The difference was found to be statistically insignificant.

The proportion of alcohol consumers was higher among laborers 59.3% than farmers as well as service class. Alcohol consumption did not show any significant association with family size and type of family. Although in our study, socioeconomic status has not shown any significant association with alcohol use; but it was seen that proportion of alcohol consumers was increasing as income is decreasing. Associated tobacco use was found in 97 (69.8%) current alcohol user. All those who were having positive family history of alcohol consumption i.e. 38 (27.3%) have shown significant association with alcohol use.

On univariate analysis of socio-demographic characters determining alcohol consumption, it was found that education (p<0.028), occupation (p<0.0009), associated tobacco use (p<0.0001) and positive family history for alcohol intake (p<0.0003) were significantly associated with alcohol consumption. Proportion of alcohol consumption was higher among males who were illiterate (OR=1.707, CI=1.05-2.76), laborers (OR=0.353, CI=0.191-0.652), tobacco users (OR=5.17, CI=70.19-3812.88) and having positive family history for alcohol intake (OR=171.06, CI=10.40-2812.09) (Table 2).

Pattern of alcohol consumption

Table 3 reveals the pattern of alcohol consumption in detail. Out of 364 respondents, 49.7% i.e. half of the respondents had ever consumed alcohol in their lifetime. The overall prevalence of current drinkers was found to be 139 (38.2%).

Males ≥15 year who gave consent for the study, i.e. 364 participants were included in the study. Most of the participants 83.8% were from age group 25-64 years, three fourth (75%) of them were literate, while 25% were never attended school. Almost 95% respondents were married. As study was conducted in rural area, most of them 67.3% were farmers by occupation and 66.5% were from joint family. Pertaining to their socioeconomic class 72% were from lower socioeconomic and lower middle class as per Modified B.G. Prasad Classification (Table 1).15-17
Table 2: Univariate analysis showing association between socio-demographic factors and alcohol consumption.

| Variable                  | Alcohol users (current drinker) (N=139) (%) | Alcohol non users (lifetime abstainers +former drinkers) (N=225)(%) | Unadjusted OR | 95% CI          | P value |
|---------------------------|--------------------------------------------|---------------------------------------------------------------|---------------|-----------------|---------|
| **Age (year)**            |                                            |                                                               |               |                 |         |
| 15-24                     | 10 (37)                                    | 17 (63)                                                       | 1             |                 | >0.78   |
| 25-64                     | 121 (39.7)                                 | 184 (60.3)                                                    | 0.894         | 0.396-2.019     |         |
| ≥65                       | 08 (25)                                    | 24 (75)                                                       | 1.764         | 0.576-5.398     |         |
| **Literacy**              |                                            |                                                               |               |                 |         |

Among users, most of them 29% have started consuming alcohol between 16-20 year of age, while 15.8% started consuming alcohol below 15 yr of age. The reasons for alcohol consumption were, enjoyment in 45% of users, 29.5% to escape from pain or social company, while 25.2% were consuming due to peer pressure. About three-fourth of the alcohol consumers were consuming alcohol for long term i.e. >5 years and alcohol was available to them in nearby shops of liquor within village itself. Majority of the users i.e.54% were using country-made liquor (indigenous) followed by 23.8% were consuming IMFL (Indian Made Foreign Liquor) and remaining 22.3% were consuming any kind of liquor available. When inquired about frequency of drinking, 36% were consuming alcohol 1-5 times a week while one-third of them, 33% were drinking alcohol daily. On the basis of quantity consumed 72.6%, 12.9% and 14.5% were at low, medium and high risk respectively based on WHO guideline for risk of consumption of alcohol. Almost half (48%) users were used to consume alcohol at their home and at evening time while 26% at the sight of liquor shop. Three fourth of them purchased alcohol from local shops. Majority of consumers i.e. 42% were spending <400 Rs., while 11.5% were able to spend >3000-6000 Rs. monthly on alcohol. Nearly three-fourth of consumers were drinking alcohol after diluting it with
water while 16% were drinking without dilution. Regarding willingness of leaving the habit, 67.6% wish to quit while 55% tried to quit in their lifetime (Table 3).

**Table 3: Distribution of respondents as per pattern of alcohol consumption.**

| Ever consumed (N=364) | Percentage (%) | Pattern of alcohol consumption (N=139) |
|-----------------------|----------------|---------------------------------------|
| Yes                   | 181 (49.7)     | Low Risk                              |
| No                    | 183 (50.3)     | Medium Risk                           |
| Status of drinker (N=181) |                | High Risk                             |

**AUDIT scoring**

Figure 1 shows distribution of respondents as per AUDIT score. Overall prevalence of current drinkers was found to be i.e. 139 (38.2%). Out of 364, 273 respondents (75%) were with AUDIT score 0-7 (zone I) which includes complete abstainers and low risk drinkers. Forty one (11.2%) respondents were in excess alcohol use with AUDIT score 8-15 (zone II), while 13 (3.6%) respondents were harmful and hazardous alcohol users with AUDIT score 16-19 (zone III) and rest 37 (10.2%) respondents were having dependence of alcohol with AUDIT score ≥20 (zone IV) respectively. The mean AUDIT score was 5.5 with SD ±8.66 (Figure 1).
DISCUSSION

In this study details of prevalence, pattern of drinking was studied by using WHO developed tool-AUDIT among male patients visiting Rural health care centre of tertiary care level institute, Indore. Total 364 male patients of the age ≥15 yr, attended OPD over the period of three months were involved in the study. As we had recorded under-representation of female respondents consuming alcohol in pilot study so we excluded them from our study. Majority of the participants were from 25-54 years of age group. Twenty five percent populations were illiterate, 67% participants were farmers by occupation and majority i.e. 95% were married.

Prevalence of alcohol consumption

The overall prevalence of ever consumption of alcohol was found to be 49.7% while prevalence of current drinkers was 38.2%. Lifetime abstainers were 50.2% (183). The findings are at par with the study done by Pati et al in primary health care setting in district of Odisha.18 Sujiv et al in primary care setting in rural Puducherry reported lifetime use of alcohol and current users was 58.6% and 39.8% respectively while Bhardwaj et al reported it 37.7%.19,20 Chawala et al reported prevalence of ever alcohol consumption and current alcohol consumption 25.7% and 36.9% respectively in rural block of Haryana.21 Contradictory findings were found in study done in Tamil Nadu by Ganesh et al which stated prevalence of current alcohol use was 9.4%, 29.8% by Saxena et al and 30.8% in study by Bodhare et al respectively.22-24

Correlates of alcohol consumption

As for as the association of socio-demographic determinants were concerned, 39.7% current drinkers were belonged to the age between 25-64 yr with least being above 55 year of age. These results are in conformity with Gururaj et al and Sathya et al.2,25 But in our study, change in trend has been observed that 37% youth were involved in alcohol consumption. In our study educational status was found to be statistically associated with alcohol use. Nearly half of the users, 48% were illiterate. These results is in line with Deswal et al, Gupta et al.26,27

In our study, all the divorced or widower (100%) were consuming alcohol followed by married and then unmarried once. This might be due to stress in relationships or worries which let person indulge in such habit. The results were found insignificant which is consistent with Deswal et al, Singh et al, Negi et al.26,28,29

In present study association of type of family, family size and Socio-economic status with current alcohol intake was not found significant. Although it was seen alcohol intake was higher in nuclear family, class-V, lower middle income group as per Modified BG Prasad but found to be statistically insignificantly associated.

It was observed that alcohol consumption was highest among laborers 59.3%, followed by service class (43.8%). These findings were found in line with the study done by Sumit et al.26 This is due to stress at workplace, peer pressure etc. Meena et al also found maximum alcohol use in laborer while Ramanan et al reported maximum use was among farmers.30,31

Based on our findings, association of tobacco use, family history of alcohol use was found highly significant (p<0.0003) with the current alcohol intake. It was found that 69.8% of alcohol users were also using tobacco, while Ramanan et al found it 45%.31 These findings are in congruent with study by Abdoul et al, and contradictory with the study by Mohan et al.32,33 Associated tobacco use along with the alcohol is said to have synergistic action. Tobacco use was found to be significantly associated.

Positive family history was seen in 27.3% alcohol users while these findings are similar to study done by Meena et al which stated positive family history in 23.2% cases.30 Highly significant association for positive family history was found. This is common practice in family, if parents are consuming alcohol children are obviously would have been affected by their behavior.

Pattern of alcohol consumption

In our study following pattern of drinking were observed. In present study, among 139 current drinkers, 29.5% were initiated alcohol drinking between the age of 16 to 20 years while 16% started consuming alcohol even before the 15 year which is legally prohibited age. Which signals the failure of law system, this finding is in congruent with Meena et al while Sumit et al reported corresponding it as 24 year.30,26 Basu et al reported as 18 years, while contradictory with deswal et al.34,35

When inquired about reason for alcohol use, 45% explained it for enjoyment and 29.5% were consuming for escaping from pain, work stress as well for social company and 25.2% were due to peer pressure. These findings were similar to study by Ramanan et al in which 44.4% used alcohol for fun while inconsistent findings were reported by Sreeraj et al and Meena et al i.e. 26.6% users cited to be sociable as reason for drinking, 23% to forget worries.31,35,30

About duration of alcohol consumption, three –fourth (74.8%) of drinkers were long term users i.e. consuming alcohol >5 years and 25% were recent users i.e. consuming alcohol < 5 yrs.

On the basis of quantity consumed 72.6% were at low risk, 12.9% were at medium risk while 14.5% were at high risk as per WHO guideline for risk of consumption of alcohol.14
More than half of alcohol users (53.9%) were using country-made liquor due to cost factor as well as their easy availability in the vicinity of village, followed by 24% of them were consuming IMFL (Indian Made Foreign Liquor) and 22.3% were consuming any kind of liquor available showing their dependency. Sathy estimated 33.2% hazardous drinking, while Anamitra et al reported high prevalence of 73% men with AUDIT score of ≥8. In study by Sathy et al at Andman Nicobar Islands, overall prevalence of alcohol consumption was 35% among males. One-fourth of the total users (23%) were alcohol dependents while almost 18.0% of male drinkers reported heavy drinking on typical drinking occasions.

CONCLUSION

Present study concludes that prevalence of alcohol is still high in the rural population. Alcoholism is more common among illiterates, non-farmers, among tobacco users & among those having positive family history. Socio economic status and age is not the bar for consumption. Changing trend of alcohol consumption is seen among the youths. Easy and low cost liquor availability within the vicinity also contributes. So there is need to implement more strict laws and policy makers must revise the strategies to reduce the prevalence. AUDIT was found to be very useful tool for screening of alcoholic patients at primary health care setting. So timely referral can be done for high risk alcoholic patients.

De-addiction programme, stress relievers in the form of meditation, yoga etc should also be made available to rural area.

LIMITATION OF THE STUDY

Sample was restricted to rural population only & sample size was very small. Recall bias was also there which was unavoidable. So more studies are needed in this field to cover rural and urban population.
