Abstract

In [To-Ve2] we began the study of higher sheaf theory (i.e. stacks theory) on higher categories endowed with a suitable notion of topology: precisely, we defined the notions of S-site and of model site, and the associated categories of stacks on them. This led us to a notion of model topos. In this paper we treat the analogous theory starting from (1-)Segal categories in place of S-categories and model categories.

We introduce notions of Segal topologies, Segal sites and stacks over them, giving rise to a definition of Segal topos. We compare the notions of Segal topos and of model topos, showing that the two theories are equivalent in some sense. However, the existence of a nice Segal category of morphisms between Segal categories allows us to improve the treatment of topoi in this context. In particular we construct the 2-Segal category of Segal topoi and geometric morphisms, and we provide a Giraud-like statement characterizing Segal topoi among Segal categories.

As example of applications, we show how to reconstruct a topological space from the Segal topos of locally constant stacks on it, thus extending the main theorem of [To] to the case of un-based spaces. We also give some hints of how to define homotopy types of Segal sites: this approach gives a new point of view and some improvements on the étale homotopy theory of schemes, and more generally on the theory of homotopy types of Grothendieck sites as defined by Artin and Mazur.

Key words: Stacks, Segal categories, Topoi.

1 Introduction

In [To-Ve2] we have developed a homotopy version of sheaf theory, in which not only sheaves of sets are replaced by certain simplicial presheaves (called stacks), but in which, more crucially, the base Grothendieck sites are replaced either by $S$-sites, i.e. simplicially enriched categories endowed with a suitable notion of topology, or by model sites, i.e. model categories endowed with a suitable notion of topology. These constructions have led us naturally to the concept of model topos, originally due to C. Rezk ([Re]), for which one can prove some generalizations of the basic results in topos theory, as for example the correspondence between topologies and certain localizations of categories of presheaves (see [To-Ve2, Theorem 3.8.3]). However, it seems very uneasy to further develop the theory of model topoi purely in terms of model categories, and one reason for this is the missing theory of internal Hom-objects, or equivalently the non-existence of reasonable model categories of Quillen functors between two model categories. For example, it seems very difficult to construct an analog for model topoi of the 2-category of topoi and geometric morphisms between them. The main purpose of this work is to solve this problem by introducing similar constructions in the context of Segal categories of $[I[S]] [P]$.

**Segal categories, Segal sites and stacks.** Segal categories are weak form of $S$-categories, and behave very much the same way. In fact the theory of Segal categories and of $S$-categories are equivalent in some sense (see §4.1), and it is not a bad idea to think of Segal categories as $S$-categories, at least as a first approximation. Thanks to the fundational work of C. Simpson, A. Hirschowitz and R. Pellissier (see e.g. [I[S] [P] [S]]), many (if not all) standard categorical notions are available for Segal categories, as for example categories of functors, adjunctions, limits and colimits, Yoneda lemma ... (see §3.1, 3.2, 4.1, 4.2). These constructions will allow us to follow the main line of topos theory in the new context of Segal categories.

We define a **Segal topology** on a Segal category $T$ to be a Grothendieck topology on its homotopy category $Ho(T)$ (see Definition 3.3.1). A Segal category endowed with a topology will be called a **Segal site**. For a Segal site $(T, \tau)$, one defines a Segal category of pre-stacks $\hat{T}$, as well as a sub-Segal category of stacks $T_{\sim, \tau}$ (see Definition 3.3.2 (3)).

**Segal topos and Segal category of stacks.** A **Segal topos** is defined to be a Segal category equivalent to some exact localization of a Segal category of pre-stacks $\hat{T}$ (see Definition 3.3.3). If $(T, \tau)$ is a Segal site, the sub-Segal category $T_{\sim, \tau}$ is a left exact localization of $\hat{T}$, and therefore is a Segal topos. Our first result, Theorem 3.3.8 states that a large class of Segal topoi (the ones being $t$-complete) are obtained this way. In other words, the map $\tau \mapsto T_{\sim, \tau}$ gives a one-to-one correspondence between topologies on $T$ and left exact localizations of $\hat{T}$ which are furthermore $t$-complete. The latter result is a generalization to the case of Segal topoi of the well known fact that topologies on a category are in bijection with left exact localizations of its category of presheaves. It also justifies our definition of a topology on a Segal category. We also provide a Giraud’s style statement characterizing Segal topoi among Segal categories (Conjecture 5.1.1).

**Geometric morphisms and the 2-Segal category of Segal topoi.** A crucial property of Segal categories is the existence of a reasonable Segal category of morphisms between two Segal categories. Using this construction, as well as the notion of adjunction and limits, we define for two Segal topos $A$ and $B$ a Segal category of geometric morphisms $\mathbf{RHom}_{geom}(A, B)$ (see Definition 3.4.1). These Segal categories of geometric morphisms assemble together into a 2-Segal category $\mathbf{SeT}$, of Segal topoi, which is our Segal analog of the 2-category of topos and geometric morphisms.
Segal topoi and model topoi. Let \((T, \tau)\) be an \(S\)-site (i.e. a Segal site where \(T\) is furthermore an \(S\)-category). On one hand there is the model category of stacks \(\text{Sp}_{\tau}(T)\), constructed in [Vo2], and on the other there is the Segal topos \(\Gamma_{\tau}\) of stacks over \((T, \tau)\) defined in Definition 5.3.2. Using the strictification theorem proved in [H-S], we show that there exists a natural equivalence of Segal categories (see Corollary 4.3.1)

\[
L(\text{Sp}_{\tau}(T)) \simeq \Gamma_{\tau},
\]

where \(LM\) is the simplicial localization of a model category \(M\) as defined in [D-K]. This shows that the construction \(M \mapsto LM\) gives a way to pass from model topoi to Segal topoi. Therefore, if \(M\) and \(N\) are two model topoi, one can consider \(\mathbb{R}\text{Hom}^{\text{geom}}(LM, LN)\), the Segal category of geometric morphisms from \(LM\) to \(LN\). This construction gives a solution to our original problem of defining a “category” of geometric morphisms between two model topoi.

An application: Galois interpretation of homotopy theory. As an example of application of our notion of Segal categories of geometric morphisms we provide a Galois interpretation of homotopy theory, extending the well known relations between fundamental groupoids and categories of locally constant sheaves on a space. For a \(CW\) complex \(X\), one consider the Segal category \(\text{Loc}(X)\) of locally constant stacks on \(X\), which is easily seen to be a Segal topos. For two \(CW\) complexes \(X\) and \(Y\) we prove that \(\mathbb{R}\text{Hom}^{\text{geom}}(\text{Loc}(X), \text{Loc}(Y))\) is in fact a Segal groupoid whose geometric realization is equivalent to \(\mathbb{R}\text{Hom}(X, Y)\) (see Theorem 5.2.1). In particular, taking \(X = *\) we get that \(Y\) is weakly equivalent to the geometric realization of the Segal groupoid \(\mathbb{R}\text{Hom}^{\text{geom}}(\text{Top}, \text{Loc}(Y))\) (here \(\text{Top} := \text{SSet}\) is the Segal category of simplicial sets). This last statement generalizes to the whole homotopy type the fact that the fundamental groupoid of a space is equivalent to the groupoid of fiber functors on its category of locally constant sheaves (see [SGA1, Exp. V]).

Homotopy types of Segal topoi. Based on our Galois interpretation of homotopy theory we define for any Segal topos \(T\) a morphism of Segal categories \(H_T : \text{Top} \rightarrow \text{Top}\), which has to be thought as some kind of homotopy type of \(T\); we call \(H_T\) the homotopy shape of \(T\) (see Definition 5.3.2). The morphism \(H_T\) is in fact pro-corepresentable by a pro-homotopy type \(X\). This pro-homotopy type (which is a pro-object in \(\text{Top}\) rather than a pro-object in \(\text{Ho}(\text{Top})\)) is called the homotopy type of the Segal topos \(T\). When \(T\) is the Segal topos of stacks over a Grothendieck site, this approach gives a new point of view on homotopy types of sites as defined by Artin and Mazur ([A-M]). This also allows us to define the étale pro-homotopy type of the sphere spectrum which seems to us an interesting example to consider (see 5.3.4).

Related works. In [Si] C. Simpson investigates Segal pre-topoi and the question of the existence of a theory of Segal topos is at least implicit in the text, if not clearly stated. In some sense this work, and more precisely our conjecture 5.1.1 gives a possible answer to his question.

As we have already mentioned, in his unpublished manuscript [Re] C. Rezk has introduced a notion of homotopy topos, which is a model category version of our definition of Segal topos. More recently, J. Lurie has investigated a notion of \(\infty\)-topos, equivalent to our notion of Segal topos, and for which he proved a Giraud’s theorem (therefore our conjecture 5.1.1 seems to be a theorem now). He has also related the notion of \(\infty\)-topos with a different notion of stacks (see [Lu]).

Let us also mention that A. Joyal (see [Jo]) has developed a theory of quasi-categories, which is expected to be equivalent to the theory of \(S\)-categories and of Segal categories, and for which he has defined a notion of quasi-topoi very similar to our notion of Segal topos. The two approaches are expected to be equivalent.

The work of D-C. Cisinski ([Cis]) seems to be closely related to a notion of hypertopology we discuss in Remark 5.3.3.

In his letter to L. Breen (see [Gr]), A. Grothendieck proposes some Galois interpretation of homotopy types of sites. We like to consider our Theorem 5.2.1 as a topological version of this (see also the Remark after Corollary 3.2 in [Jo]).
Acknowledgments. We wish to thank the MSRI in Berkeley for invitation to the Program “Stacks, Intersection Theory and Non Abelian Hodge Theory” (January-May 2002). In particular we wish to acknowledge many fruitful discussions with the participants to the above program. We especially thank A. Joyal, M. Kontsevich, J. Lurie, and C. Rezk for useful exchanges. We are particularly indebted to C. Simpson for suggestions, discussions on our project and for all his deep work on higher categories and higher stacks.

Notations and conventions. We will use the word \textit{universe} in the sense of [SGA4-I, Exp. I, Appendice]. We will fix three universes $U \in V \in W$, and assume that $N \in U$. The category of sets (resp. simplicial sets, resp. ...) belonging to a universe $U$ will be denoted by $\text{Set}_U$ (resp. $\text{SSet}_U$, resp. ...). The objects of $\text{Set}_U$ (resp. $\text{SSet}_U$, resp. ...) will be called $U$-sets (resp. $U$-simplicial sets, resp. ...). We will use the expression $U$-\textit{small set} (resp. $U$-\textit{small simplicial set}, resp. ... ) to mean a set isomorphic to a set in $U$ (resp. a simplicial set isomorphic to a simplicial set in $U$, resp. ...).

Our references for model categories are [Ho] and [Hi]. By definition, our model categories will always be \textit{closed} model categories, will have all \textit{small} limits and colimits and the functorial factorization property.

The word \textit{equivalence} will always mean \textit{weak equivalence} and will refer to a model category structure.

The homotopy category of a model category $M$ is $W^{-1}M$ (see [Hi, Def. 1.2.1]), where $W$ is the subcategory of equivalences in $M$, and it will be denoted as $\text{Ho}(M)$. We will say that two objects in a model category $M$ are equivalent if they are isomorphic in $\text{Ho}(M)$. We say that two model categories are \textit{Quillen equivalent} if they can be connected by a finite string of Quillen adjunctions each one being a Quillen equivalence.

For the notions of $U$-cofibrantly generated, $U$-combinatorial and $U$-cellular model category, we refer to [Ho, Hi, Du] or to Appendix B of [To-Ve2], where the basic definitions and crucial properties are recalled in a way that is suitable for our needs.

For a category $C$ in a universe $U$, we will denote by $\text{Pr}(C)$ the category of presheaves of $U$-sets on $C$, $\text{Pr}(C) := C^{\text{Set}_U^\text{op}}$.

2 Segal categories

As carefully explained in Leinster’s survey [Le], there already exist several definitions of higher categories, and most (if not all) of them might be used to develop a theory of \textit{higher sites} and \textit{higher topoi}. Because of its degree of advancement and its great flexibility, we have chosen to work with the notion of (1-)\textit{Segal categories}, which might be assimilated to $\infty$-categories where all $i$-morphisms are invertible as soon as $i > 1$.

Segal categories were first introduced by W. Dwyer, D. Kan and J. Smith in [D-K2], under the name of \textit{special bi-simplicial sets}. With the name of $\Delta$-categories, they were studied in more details by R. Schwänzl and R. Vogt in [Sc-Vo], and used in order to deal with homotopy coherence of diagrams. More recently, the homotopy theory of Segal categories was studied by C. Simpson and A. Hirschowitz in [H-S], and then reconsidered in great detail by R. Pellissier in [P]. They proved in particular the existence of a \textit{closed model structure}. Using the existence of this model structure they have showed that many of the usual categorical constructions (categories of functors, limits, colimits, adjunctions, stacks ...) have reasonable extensions to Segal categories. In this Section we review briefly the main definitions in the theory of Segal categories.

Recall from [P, H-S] that a Segal pre-category (in $U$) is a functor

$$A : \Delta^o \longrightarrow \text{SSet}_U$$

such that $A_0$ is a discrete (or constant) simplicial set. The category of Segal pre-categories in $U$ will be denoted by $\text{PrSeCat}_U$ (or $\text{PrSeCat}$ is the ambient universe $U$ is clear).

For any integer $n \geq 0$, one can consider the $(n + 1)$-morphisms $[0] \rightarrow [n]$ in $\Delta$, and the associated morphism of simplicial sets

$$A_n \rightarrow A_0^{n+1}.$$
As the simplicial set $A_0$ is discrete, the existence of the above morphism implies the existence of a natural isomorphism in $\text{SSet}$

$$A_n \simeq \coprod_{(a_0, \ldots, a_n) \in A_0^{n+1}} A(a_0, \ldots, a_n),$$

where $A(a_0, \ldots, a_n)$ is the fiber of $A_n \to A_0^{n+1}$ at the point $(a_0, \ldots, a_n)$.

For a Segal pre-category $A$, one should think of $A_0$ as the *set of objects* of $A$, and the simplicial set $A(a_0, \ldots, a_n)$ should be understood as the *space of composable morphisms* $a_0 \to a_1 \to \cdots \to a_n$. In particular, $A(a,b)$ is the space of morphisms from $a$ to $b$. Note for example that the first degeneracy morphism $A_0 \to A_1$ gives natural 0-simplices in $A(a,a)$ that play the role of identities.

Let us fix a set $O$ in $\mathbb{U}$, and consider the subcategory $\text{PrSeCat}(O)$ of Segal pre-categories $A$ with $A_0 = O$ and morphisms inducing the identity on $O$. Objects in $\text{PrSeCat}(O)$ will be called *Segal pre-categories over the set* $O$. Note that, obviously, any Segal pre-category $A$ can be considered as an object in $\text{PrSeCat}(A_0)$. A morphism $f : A \to B$ in $\text{PrSeCat}(O)$ will be called an *iso-equivalence* (resp. an *iso-fibration*) if for any $(a_0, \ldots, a_n) \in O^{n+1}$, the induced morphism

$$f_{(a_0, \ldots, a_n)} : A(a_0, \ldots, a_n) \to B(a_0, \ldots, a_n)$$

is an equivalence (resp., a fibration) of simplicial sets. There exists a simplicial closed model structure on the category $\text{PrSeCat}(O)$ where the equivalences (resp., the fibrations) are the iso-equivalences (resp., the iso-fibrations). Indeed, the category $\text{PrSeCat}(O)$ can be identified with a certain category of pointed simplicial presheaves on a certain $\mathbb{U}$-small category, in such a way that iso-equivalences and iso-fibrations correspond to objectwise equivalences and objectwise fibrations. The category $\text{PrSeCat}(O)$ with this model structure will be called the *objectwise model category of Segal pre-categories over $O$*. For this model structure, $\text{PrSeCat}(O)$ is furthermore a $\mathbb{U}$-combinatorial and $\mathbb{U}$-cellular model category in the sense of [To-Ve2, Appendix] or [HJ III Dn].

For any integer $n \geq 2$ and $0 \leq i < n$, there exists a morphism $h_i : [1] \to [n]$ in $\Delta$, sending 0 to $i$ and 1 to $i + 1$. For any $n \geq 2$ and any $A \in \text{PrSeCat}$, the morphisms $h_i$ induces a morphism of simplicial sets

$$A_n \to A_1^n,$$

called *Segal morphism*. This morphism breaks into several morphisms of simplicial sets

$$A(a_0, \ldots, a_n) \to A(a_0, a_1) \times A(a_1, a_2) \times \cdots \times A(a_{n-1}, a_n),$$

for any $(a_0, \ldots, a_n) \in A_0^{n+1}$.

For any integer $n \geq 1$ and any $(a_0, \ldots, a_n) \in A_0^{n+1}$, the functor

$$\text{PrSeCat}(O) \to \text{SSet}$$

$$A \mapsto A(a_0, \ldots, a_n)$$

is co-representable by an object $h_{(a_0, \ldots, a_n)} \in \text{PrSeCat}(O)$. The natural morphisms mentioned above, give rise to morphisms in $\text{PrSeCat}(O)$

$$h(a_0, \ldots, a_n) : h_{(a_0, a_1)} \prod h_{(a_1, a_2)} \prod \cdots \prod h_{(a_{n-1}, a_n)} \to h_{(a_0, \ldots, a_n)}.$$

The set of all morphisms $h(a_0, \ldots, a_n)$, for all $n \geq 2$, and all $(a_0, \ldots, a_n) \in O^{n+1}$, belongs to $\mathbb{U}$. As the objectwise model category $\text{PrSeCat}(O)$ is a $\mathbb{U}$-cellular and a $\mathbb{U}$-combinatorial model category, the following definition makes sense.

**Definition 2.0.1** Let $O$ be a $\mathbb{U}$-set. The model category of Segal pre-categories over $O$ in $\mathbb{U}$ is the left Bousfield localization of the objectwise model category $\text{PrSeCat}(O)$ with respect to the morphisms $h(a_0, \ldots, a_n)$, for all $n \geq 2$, and all $(a_0, \ldots, a_n) \in O^{n+1}$. This model category will simply be denoted by $\text{PrSeCat}(O)$. 
The equivalences in the model category structure $\text{PrSeCat}(O)$ of Definition 2.0.1 will simply be called equivalences. The homotopy category $\text{Ho}(\text{PrSeCat}(O))$ will always refer to the model structure $\text{PrSeCat}(O)$ of the above definition. while the homotopy category of the objectwise model structure will be denoted by $\text{Ho}^\text{iso}(\text{PrSeCat}(O))$.

It is clear that an object $A \in \text{PrSeCat}(O)$ is fibrant if and only if it satisfies the following two conditions

1. For any $n \geq 1$ and any $(a_0, \ldots, a_n) \in O^{n+1}$, the simplicial set $A_{(a_0, \ldots, a_n)}$ is fibrant.

2. For any $n \geq 2$ and any $(a_0, \ldots, a_n) \in O^{n+1}$, the natural morphism

$$A_{(a_0, \ldots, a_n)} \to A_{(a_0, a_1)} \times A_{(a_1, a_2)} \times \ldots \times A_{(a_{n-1}, a_n)}$$

is an equivalence of simplicial sets.

The general theory of left Bousfield localization (see [Hi]) tells us that $\text{Ho}(\text{PrSeCat}(O))$ is naturally equivalent to the full subcategory of $\text{Ho}^\text{iso}(\text{PrSeCat}(O))$ consisting of objects satisfying condition (2) above. Furthermore, the natural inclusion $\text{Ho}(\text{PrSeCat}(O)) \to \text{Ho}^\text{iso}(\text{PrSeCat}(O))$ possesses a left adjoint

$$\text{SeCat} : \text{Ho}^\text{iso}(\text{PrSeCat}(O)) \to \text{Ho}(\text{PrSeCat}(O))$$

which is the left derived functor of the identity functor on $\text{PrSeCat}(O)$.

**Definition 2.0.2**

1. A Segal pre-category $A$ is a Segal category if for any $n \geq 2$ and any $(a_0, \ldots, a_n) \in A_0^{n+1}$, the natural morphism

$$A_{(a_0, \ldots, a_n)} \to A_{(a_0, a_1)} \times A_{(a_1, a_2)} \times \ldots \times A_{(a_{n-1}, a_n)}$$

is an equivalence of simplicial sets.

2. The Segal category associated to a Segal pre-category $A$ over $A_0$, is $\text{SeCat}(A) \in \text{Ho}(\text{PrSeCat}(A_0)) \subset \text{Ho}^\text{iso}(\text{PrSeCat}(A_0))$.

Any $U$-small category $C$ might be considered as a Segal category, with the same set of objects $C_0$ and such that

$$C_{(a_0, \ldots, a_n)} := \text{Hom}_C(a_0, a_1) \times \text{Hom}_C(a_1, a_2) \times \ldots \text{Hom}_C(a_{n-1}, a_n)$$

for any $(a_0, \ldots, a_n) \in C_0^{n+1}$. In other words, the simplicial object $C : \Delta^o \to \text{SSet}$ is simply the nerve of the category $C$, which obviously satisfied condition (1) of definition 2.0.2 above. This allows us to view the category of $U$-small categories as a full subcategory of $\text{PrSeCat}$.

If $T$ is an $S$-category (in $U$), i.e. a category enriched over simplicial sets, we can consider it as a Segal pre-category $T : \Delta^o \to \text{SSet}$ by defining

$$T_0 := \text{Ob}(T) \quad T_n := \coprod_{(a_0, \ldots, a_n) \in T_0^{n+1}} \text{Hom}_T(a_0, a_1) \times \ldots \times \text{Hom}_T(a_{n-1}, a_n),$$

the simplicial and degeneracies morphism being induced by the compositions and identities in $T$. As a Segal pre-category, $T$ has the special property that the natural morphisms

$$T_{(a_0, \ldots, a_n)} \to T_{(a_0, a_1)} \times \ldots \times T_{(a_{n-1}, a_n)}$$

are all isomorphisms of simplicial sets. In particular, $T$ is always a Segal category. This allows us to view the category $S - \text{Cat}$ of $S$-categories as the full subcategory of $\text{PrSeCat}$ consisting of objects $A$ such that all morphisms

$$A_{(a_0, \ldots, a_n)} \to A_{(a_0, a_1)} \times \ldots \times A_{(a_{n-1}, a_n)}$$

are isomorphisms of simplicial sets.
More generally, a Segal category $A$ might be seen as a \textit{weak category in SSet}. Indeed, for any two objects $(a, b) \in A_0^2$, the simplicial set $A_{(a,b)}$ can be considered as the space of morphisms from $a$ to $b$. The composition of morphisms is given by a diagram

$$
\begin{array}{ccc}
A_{(a,b,c)} & \longrightarrow & A_{(a,c)} \\
\sim & \downarrow & \\
A_{(a,b)} \times A_{(b,c)} & & 
\end{array}
$$

where the horizontal morphism is induced by the morphism $[1] \to [2]$ in $\Delta$ which sends 0 to 0 and 1 to 2. The vertical morphism being an equivalence of simplicial sets, this diagram gives a \textit{weak composition morphism}, i.e. a morphism $A_{(a,b)} \times A_{(b,c)} \to A_{(a,c)}$, which is well defined only up to equivalence. From this point of view, the higher simplicial identities of $A$ should be seen as providing the associativity and higher coherency laws for this composition.

If $A$ is a Segal category, one can define the \textit{homotopy category} $\text{Ho}(A)$, whose set of objects is $A_0$ and whose set of morphisms from $a$ to $b$ is $\pi_0(A_{(a,b)})$. The composition of morphisms in $\text{Ho}(A)$ is given by the following diagram

$$
\begin{array}{ccc}
\pi_0(A_{(a,b,c)}) & \longrightarrow & \pi_0(A_{(a,c)}) \\
\sim & \downarrow & \\
\pi_0(A_{(a,b)}) \times \pi_0(A_{(b,c)}) & & 
\end{array}
$$

where the horizontal morphism is induced by the morphism $[1] \to [2]$ in $\Delta$ which sends 0 to 0 and 1 to 2.

Any Segal pre-category $A$ can be considered as an object in $\text{PrSeCat}(A_0)$, where $A_0$ is the set of objects of $A$. Applying the functor $\text{SeCat}$, one finds a natural morphism in $\text{Ho}^{\text{iso}}(\text{PrSeCat}(A_0))$

$$
A \to \text{SeCat}(A).
$$

This morphism has to be thought of as a (Segal) \textit{categorification of $A$}. This way, one can define the homotopy category of the Segal pre-category $A$ to be $\text{Ho}(\text{SeCat}(A))$. In the case $A$ is already a Segal category, the natural morphism $A \to \text{SeCat}(A)$ is an iso-equivalence, and therefore induces an isomorphism $\text{Ho}(A) \simeq \text{Ho}(\text{SeCat}(A))$. This shows that the homotopy category functor $A \mapsto \text{Ho}(A)$ is well defined.

An object in a Segal category $A$ is an element in $A_0$. Most of the time they will be considered up to equivalences, or in other words as isomorphism classes of objects in $\text{Ho}(A)$. In the same way, a morphism $a \to b$ in $A$ is a 0-simplex in $A_{(a,b)}$, mots often considered as a morphism in $\text{Ho}(A)$ (i.e. up to homotopy).

A morphism in a Segal category $A$ (i.e. an element of $A_{a,b}$ for some $(a,b) \in A_0^2$) is called an \textit{equivalence} if its image in $\text{Ho}(A)$ is an isomorphism. There exists a sub-Segal category $A^{\text{int}}$ of $A$, consisting of all objects and equivalences between them. The Segal category $A^{\text{int}}$ is a Segal groupoid (i.e. all its morphisms are equivalences) and is actually the maximal sub-Segal groupoid of $A$ (see [H-S §2]).

Let $f : A \to B$ be a morphism in $\text{PrSeCat}$. This morphism induces a morphism of sets $f : A_0 \to B_0$, as well as a morphism in $\text{PrSeCat}(A_0)$

$$
A \to f^*(B),
$$

where $f^*(B)$ is defined by the formula

$$
f^*(B)_{(a_0,\ldots,a_n)} := B_{(f(a_0),\ldots,f(a_n))} \quad (a_0,\ldots,a_n) \in A_0^{n+1}.
$$

Composing with the morphism $B \to \text{SeCat}(B)$, one gets a morphism

$$
A \to f^*(\text{SeCat}(B))
$$

which is well defined in $\text{Ho}^{\text{iso}}(\text{PrSeCat}(A_0))$. The Segal pre-category $f^*(\text{SeCat}(B))$ is clearly a Segal category, and therefore there exists a unique factorization in $\text{Ho}^{\text{iso}}(\text{PrSeCat}(A_0))$

$$
\begin{array}{ccc}
A & \longrightarrow & f^*(\text{SeCat}(B)) \\
\downarrow & & \\
\text{SeCat}(A). & & 
\end{array}
$$
In particular, there are natural morphisms in \( \text{Ho}(\text{SSet}) \)

\[
\text{SeCat}(A)_{(a,b)} \to \text{SeCat}(B)_{(f(a),f(b))}
\]

for any \((a,b) \in A_0^2\). The induced morphism on the connected components, together with the map \(A_0 \to B_0\), give rise to a well defined functor

\[
\text{Ho}(f) : \text{Ho}(\text{SeCat}(A)) \to \text{Ho}(\text{SeCat}(B)).
\]

**Definition 2.0.3** Let \( f : A \to B \) be a morphism of Segal pre-categories.

- The morphism \( f \) is fully faithful if for any \((a,b) \in A_0^2\), the induced morphism
  \[
  \text{SeCat}(A)_{(a,b)} \to \text{SeCat}(B)_{(f(a),f(b))}
  \]
  is an isomorphism in \( \text{Ho}(\text{SSet}) \).

- The morphism \( f \) is essentially surjective if the induced functor
  \[
  \text{Ho}(\text{SeCat}(A)) \to \text{Ho}(\text{SeCat}(B))
  \]
  is essentially surjective.

- The morphism \( f \) is an equivalence if it is fully faithful and essentially surjective.

It is important to notice that when \( f : A \to B \) is a morphism between Segal categories, then \( A \) and \( B \) are iso-equivalent to \( \text{SeCat}(A) \) and \( \text{SeCat}(B) \), and therefore the previous definition simplifies.

**Theorem 2.0.4** ([P Thm. 6.4.4]) There exists a closed model structure on the category \( \text{PrSeCat} \), of Segal pre-categories (in the universe \( U \)), where the equivalences are those of Definition 2.0.3 and the cofibrations are the monomorphisms. This model category is furthermore simplicial, \( U \)-cellular and \( U \)-combinatorial.

For any \( A \) and \( B \) in \( \text{PrSeCat} \), the natural morphism in \( \text{Ho}^{\text{iso}}(\text{PrSeCat}) \)

\[
\text{SeCat}(A \times B) \to \text{SeCat}(A) \times \text{SeCat}(B)
\]

is an isomorphism. This is the product formula of [P Thm. 5.5.20]. From this, one deduces formally the following very important corollary.

**Corollary 2.0.5** ([P Thm. 5.5.20, Thm. 6.4.4]) The model category \( \text{PrSeCat} \) is internal (i.e. is a symmetric monoidal model category with the direct product as the monoidal product).

As explained in [Ho Thm. 4.3.2], the previous corollary implies that the homotopy category \( \text{Ho}(\text{PrSeCat}) \) is cartesian closed; the corresponding internal \( \text{Hom} \)-objects will be denoted by \( \underline{\text{Hom}}(A,B) \in \text{Ho}(\text{PrSeCat}) \), for \( A \) and \( B \) in \( \text{Ho}(\text{PrSeCat}) \). Recall that \( \underline{\text{Hom}}(A,B) \) is naturally isomorphic to \( \text{Hom}(A,RB) \), where \( \text{Hom} \) denotes the internal \( \text{Hom} \)-object in the category \( \text{PrSeCat} \) and \( RB \) is a fibrant model of \( B \) in \( \text{PrSeCat} \). For any \( A \), \( B \) and \( C \) in \( \text{Ho}(\text{PrSeCat}) \), one has the derived adjunction formula

\[
\underline{\text{Hom}}(A,\underline{\text{Hom}}(B,C)) \simeq \underline{\text{Hom}}(A \times B,C).
\]

The existence of these derived internal \( \text{Hom} \)-objects is of fundamental importance as it allows one to develop the theory of Segal categories in a very similar fashion as usual category theory. A first example is the following definition. For any category \( C \) together with a subcategory \( S \), we denote by \( L(C,S) \) the Dwyer-Kan simplicial localization of \( C \) with respect to \( S \) (see [D-K1]); \( L(C,S) \) is an \( S \)-category hence a Segal category. When \( C \) is a model category we will always take \( S \) to be the subcategory of weak equivalences and we will simply write \( LC \) for \( L(C,S) \).

**Definition 2.0.6**

1. The Segal category of \( U \)-small simplicial sets is defined to be \( \text{Top} := L(\text{SSet}_U) \).

2. Let \( T \) be a \( U \)-small Segal category. The Segal category of pre-stacks over \( T \) is defined to be

\[
\hat{T} := \underline{\text{Hom}}(\text{Top}^\text{op},\text{Top}).
\]

Note that, as usual, if \( T \) is a \( U \)-small Segal category, then \( \hat{T} \) is a \( V \)-small Segal category for \( U \in V \).
3 Segal topoi

The existence of internal Hom’s mentioned above, and more generally of the model structure on \( \PrSeCat \), allows one to extend to Segal categories most of the basic constructions in category theory (for some of these constructions, see [H-S, Si]). In this paragraph we will first recall some of the basic extensions and then use them to describe a notion of Segal topos, analogous to the usual notion of topos in the context of Segal categories. We will state the results without proofs.

3.1 Adjunctions

Let us start by the definition of adjunction between Segal categories, as introduced in [H-S, §8]. Let \( f : A \to B \) be a morphism between fibrant Segal categories. We will say that \( f \) has a left adjoint, if there exists a morphism \( g : B \to A \) and an element \( u \in \text{Hom}(A, A)_{gf, Id} \) (i.e. a natural transformation \( gf \Rightarrow Id \)) such that for any \( a \in A_0 \) and \( b \in B_0 \), the natural morphism (well defined in \( \text{Ho(SSet)} \))

\[
B_{(f(a), b)} \xrightarrow{g_*} A_{(gf(a), g(b))} \xrightarrow{u_*} A_{(a, g(b))}
\]

is an isomorphism in \( \text{Ho(SSet)} \).

One can check that if \( f \) has a left adjoint, then the pair \((g, u)\) is unique up to equivalence. More generally one can show that the Segal category of left adjoints to \( f \) (i.e. of all pairs \((g, u)\) as above) is contractible. This justifies the terminology \( g \) is the left adjoint of \( f \), and \( u \) is its unit, for any such pair \((g, u)\).

Definition 3.1.1 A morphism \( f : A \to B \) in \( \text{Ho(PrSeCat)} \) has a left adjoint if for any \( A' \) and \( B' \) fibrant models of \( A \) and \( B \), one of its representative \( f : A' \to B' \) in \( \PrSeCat \) has a left adjoint in the sense defined above.

In a dual way one defines the notion of right adjoints.

3.2 Limits

Let \( I \) and \( A \) be two Segal categories. The natural projection \( I \times A \to A \) yields by adjunction a well defined morphism in \( \text{Ho(PrSeCat)} \)

\[
c : A \to \mathbb{R}\text{Hom}(I, A).
\]

The morphism \( c \) is the constant diagram functor, and sends an object \( a \in A_0 \) to the constant morphism \( I \to \{a\} \subset A \).

Definition 3.2.1 1. A Segal category \( A \) has limits (resp. colimits) along a category \( I \) if the natural morphism \( c : A \to \mathbb{R}\text{Hom}(I, A) \) has a right (resp. left) adjoint. The right adjoint (resp. left adjoint) is then denoted by

\[
\text{Lim}_I : \mathbb{R}\text{Hom}(I, A) \to A \quad (\text{resp. Colim}_I \mathbb{R}\text{Hom}(I, A) \to A).
\]

2. Let \( U \subset \mathbb{V} \) be two universes, and \( A \) a Segal category in \( \mathbb{V} \), \( A \in \text{Ho(PrSeCat}_U) \). The Segal category \( A \) has \( U \)-limits (resp. \( U \)-colimits), if it has limits (resp. colimits) along any \( U \)-small category \( I \).

3. A Segal category \( A \) has finite limits if it has limits along the categories \( (2 \leftarrow 0 \leftarrow 1) \) and \( \emptyset \). A Segal category has finite colimits if its opposite Segal category \( A^{op} \) has finite limits.

When concerned with limits and colimits in Segal categories we will use the same notations as usual. For example, coproducts will be denoted by \( \coprod \), fibered products by \( x \times_y z \), ....

Remark 3.2.2 One can show that any Segal category \( A \) with finite limits in the sense above has also limits along all categories \( I \) whose nerve is a finite simplicial set. This justifies the terminology of having finite limits.
The following proposition is a formal consequence of the definitions and the adjunction formula for internal Hom’s.

**Proposition 3.2.3** For a $\mathbb{U}$-small Segal category $T$, the Segal category $\hat{T}$ has $\mathbb{U}$-limits and $\mathbb{U}$-colimits.

Let $f : A \to B$ be a morphism of Segal categories, and $I$ any category such that $A$ and $B$ have limits along $I$. The universal property of adjunction implies that for any $x_* \in \mathbb{R}Hom(I, A)$, there exists a well defined and natural morphism in $\text{Ho}(B)$

$$f(\text{Lim}_I x_i) \to \text{Lim}_I f(x_i).$$

We will say that $f$ preserves limits along $I$ if for any $x_* \in \mathbb{R}Hom(A, B)$, the induced morphism $f(\text{Lim}_I x_i) \to \text{Lim}_I f(x_i)$ is an isomorphism in $\text{Ho}(B)$. One shows, for example, that a morphism having a left adjoint always preserves limits.

**Definition 3.2.4** Let $A$ and $B$ be two Segal categories with finite limits.

1. A morphism $f : A \to B$ in $\text{Ho}(\text{PrSeCat})$ is left exact if it preserves limits along $2 \to 0 \to 1$ and $\emptyset$.
2. The Segal category $A$ is a left exact localization of $B$ if there exists a morphism $i : A \to B$ in $\text{Ho}(\text{PrSeCat})$, which is fully faithful and possesses a left adjoint which is left exact.

In a dual way one defines the notion of colimits preserving morphism, right exact morphism and right exact localization.

### 3.3 Topologies and Segal topoi

**Definition 3.3.1** A Segal topology on a Segal category $T$ is a Grothendieck topology on the homotopy category $\text{Ho}(T)$. A Segal category together with a Segal topology is called a Segal site.

The functor $\pi_0$, sending a simplicial set to its set of connected components, induces a morphism of Segal categories $\pi_0 : \text{Top} \to \text{Set}$. By composition, one gets for any $\mathbb{U}$-small Segal category $T$, a morphism

$$\pi^p_0 : \hat{T} \to \mathbb{R}Hom(T, \text{Set}) \simeq \mathbb{R}Hom(\text{Ho}(T), \text{Set}) \simeq \text{Pr}(\text{Ho}(T)),$$

where $\text{Pr}(\text{Ho}(T))$ is the category of presheaves of sets on the (usual) category $\text{Ho}(T)$.

In the same way, for any simplicial set $K$, the exponential functor $(-)^K : \text{SSet} \to \text{SSet}$, restricted to the full subcategory of fibrant objects, induces a morphism of Segal categories

$$(-)^{\mathbb{R}K} : \text{Top} \to \text{Top}.$$ 

By composition, this induces a morphism of Segal categories of pre-stacks

$$(-)^{\mathbb{R}K} : \hat{T} \to \hat{T}.$$

**Definition 3.3.2** Let $(T, \tau)$ be a $\mathbb{U}$-small Segal site.

1. A morphism $f : F \to G$ in $\hat{T}$ is a $\tau$-local equivalence if for any integer $n \geq 0$, the induced morphism of presheaves of sets on $\text{Ho}(T)$

$$\pi^p_0 (F^{\mathbb{R}_0 \Delta^n}) \to \pi^p_0 (F^{\mathbb{R}_0 \Delta^n} \times_{G^{\mathbb{R}_0 \Delta^n}} G^{\mathbb{R}_0 \Delta^n})$$

induces an epimorphism of sheaves on the site $(\text{Ho}(T), \tau)$.
2. An object \( F \in (\hat{T})_0 \) is called a stack for the topology \( \tau \), if for any \( \tau \)-local equivalence \( f : G \to H \) in \( \hat{T} \), the induced morphism

\[ f^* : \text{Hom}_{\text{Ho}(\hat{T})}(H, F) \to \text{Hom}_{\text{Ho}(\hat{T})}(G, F) \]

is bijective.

3. The Segal category of stacks on the Segal site \( (T, \tau) \) is the full sub-Segal category \( T_{\sim, \tau} \) of \( \hat{T} \), consisting of stacks.

As mentioned in the Introduction of \cite{To-Ve2}, one possible definition of a usual Grothendieck topos is as a full subcategory of a category of presheaves such that the inclusion functor possesses a left adjoint which is left exact. The following definition is an analog of this for Segal categories.

**Definition 3.3.3** A \( \mathbb{U} \)-Segal topos is a Segal category which is a left exact localization of \( \hat{T} \), for a \( \mathbb{U} \)-small Segal category \( T \).

**Remark 3.3.4**

- When \( T \) is a \( \mathbb{U} \)-small Segal category, \( \hat{T} \) is only \( \mathbb{V} \)-small for \( \mathbb{U} \in \mathbb{V} \). Therefore, a \( \mathbb{U} \)-Segal topos does not belong to \( \mathbb{U} \) but only to \( \mathbb{V} \).
- By definition of left exact localizations in \cite{To-Ve2} a \( \mathbb{U} \)-Segal category \( A \) is a Segal topos if and only if there exists a \( \mathbb{U} \)-small Segal category \( T \) and a morphism \( i : A \to \hat{T} \), which is fully faithful and has a left exact left adjoint. The morphism \( i \) and the Segal category \( T \) are however not part of the data.

As a direct consequences of the definition one has the following result.

**Proposition 3.3.5** A \( \mathbb{U} \)-Segal topos has \( \mathbb{U} \)-limits and \( \mathbb{U} \)-colimits.

In a similar way as in \cite{To-Ve2} Def. 3.8.2], we define the notion of truncated objects in a Segal category \( A \). An object \( a \in A \) is \( n \)-truncated, if for any \( x \in A \) the simplicial set \( A(x, a) \) is \( n \)-truncated. An object will be simply called truncated if it is \( n \)-truncated for some \( n \).

**Definition 3.3.6** A Segal category \( A \) is \( t \)-complete if truncated objects detect isomorphisms in \( \text{Ho}(A) \) (i.e. a morphism \( u : x \to y \) is an isomorphism in \( \text{Ho}(A) \) if and only if \( u^* : [y, a]_{\text{Ho}(A)} \to [x, a]_{\text{Ho}(A)} \) is bijective for any truncated object \( a \in \text{Ho}(A) \)).

The fundamental example of a \( t \)-complete Segal category is the following.

**Proposition 3.3.7** 1. Let \( (T, \tau) \) be \( \mathbb{U} \)-small Segal site. The natural inclusion functor \( T_{\sim, \tau} \to \hat{T} \) has a left exact left adjoint.

2. The Segal category \( T_{\sim, \tau} \) of stacks on \( (T, \tau) \) is a \( t \)-complete \( \mathbb{U} \)-Segal topos.

**Proof:** It is a consequence of the corresponding fact in the context of model categories (see \cite{To-Ve2} Proposition 3.4.10 (2)) and the comparison theorem \cite{4.3.1}.

We are now ready to state the analog of Theorem 3.8.3 of \cite{To-Ve2} for Segal categories. We fix a \( \mathbb{U} \)-small Segal category \( T \). Any topology \( \tau \) on \( T \) gives a full subcategory of stacks \( T_{\sim, \tau} \), which by the previous proposition, is a \( t \)-complete left exact localization of \( \hat{T} \). The proof of the following theorem can be established, with some work, using the same statement for \( S \)-categories (proved in \cite{To-Ve2} Theorem 3.8.3), and the comparison result of Corollary \cite{4.3.1}.

**Theorem 3.3.8** With the above notations, the rule \( \tau \mapsto T_{\sim, \tau} \) establishes a bijection between Segal topologies on \( T \) and (equivalence classes) of \( t \)-complete left exact localizations of \( \hat{T} \).
Remark 3.3.9 The hypothesis of $t$-completeness in Theorem 3.3.8 might appear unnatural, and it would be interesting to understand whether there exists a kind of “topologies” on $T$ which are in bijection with arbitrary left exact localizations of $\hat{T}$. As explained in [To-Ve2] Remark 3.8.7 (3), one way to proceed would be to introduce a hyper-topology on a Segal category, a notion suggested to us by some remarks of V. Hinich, A. Joyal and C. Simpson. A hyper-topology on a (Segal) category would consist in specifying directly the hypercovers (and not only the coverings, like in the case of a topology). The data of these hypercovers should satisfy appropriate conditions ensuring that the “corresponding” left Bousfield localization is indeed exact. Then, it seems reasonable that Theorem 3.3.8 can be generalized to a bijective correspondence between hyper-topologies on $T$ and arbitrary left exact Bousfield localizations of $\hat{T}$.

Theorem 3.3.8 suggests also a way to think of higher topologies on $n$-Segal categories (and of higher topoi) for $n \geq 1$ as appropriate left exact localizations. We address the reader to [To-Ve2, Remark 3.8.7 (4)] for a brief discussion on this point.

3.4 Geometric morphisms

The main advantage of Segal categories with respect to $S$-categories is the existence of a reasonable theory of internal Hom’s (see Corollary 2.0.5). For the purpose of topos theory, this will allow us to define the notion of geometric morphisms between Segal topoi, and more generally of the Segal category of geometric morphisms between two Segal topoi.

Definition 3.4.1 Let $A$ and $B$ be two $U$-Segal topoi.

1. A morphism $f : B \to A$ in $\text{Ho}(\text{PrSeCat})$ is called geometric if it is left exact and has a right adjoint.
2. The full sub-Segal category of $\mathbb{R}\text{Hom}(B, A)$ consisting of geometric morphisms will be denoted by $\mathbb{R}\text{Hom}_{\text{geom}}(A, B)$.

Remark 3.4.2 1. As one uses the internal Hom’s for Segal categories in order to define the 2-Segal category of Segal categories (see [H-S, §2]), one can use the notion of geometric morphisms between Segal topoi to define the 2-Segal category of Segal topoi. More precisely, one defines the 2-Segal category of $U$-Segal topoi $\text{SeT}_U$ as follows. Its objects are the fibrant Segal categories in $\mathbb{V}$ which are $U$-Segal topoi. For $A$ and $B$ two $U$-Segal topoi, the 1-Segal category of morphisms is $\text{Hom}_{\text{geom}}(A, B)$, the full sub-Segal category of $\text{Hom}(B, A)$ consisting of geometric morphisms. Note that $\text{SeT}_U$ is an element of $W$, for a universe $W$ such that $U \in \mathbb{V} \in W$.

2. In part (1) of Definition 3.4.1, the right adjoint is not part of the data of a geometric morphism. Strictly speaking, this might differ from the original definition of geometric morphisms, but the uniqueness of adjoints implies that the two notions are in fact equivalent (i.e. give rise to equivalent 2-categories of topoi).

3. There is also a notion of essential geometric morphism of topoi as described for example, in [M-M, p. 360]. In the same way one can define the refined notion of essential geometric morphisms of Segal topoi. They form a full sub-Segal category of the Segal category of geometric morphisms.

The standard example of a geometric morphism of Segal topoi is given by continuous morphisms of Segal sites. Let $(T, \tau)$ and $(T', \tau')$ be two $U$-small Segal sites, and $f : T \to T'$ be a morphism in $\text{Ho}(\text{PrSeCat})$. The morphism $f$ induces a morphism in $\text{Ho}(\text{PrSeCat})$ between the corresponding Segal categories of pre-stacks

$$f^* : \hat{T'} \to \hat{T}.$$ 

We say that the morphism $f$ is continuous if it preserves the full sub-Segal category of stacks. In this case, it induces a well defined morphism in $\text{Ho}(\text{PrSeCat})$

$$f^* : (T')^\sim_{\tau'} \to T^\sim_{\tau}.$$ 

One can show that this morphism is left exact and possesses a left and a right adjoint, $f_!$ and $f_*$. In particular, $f^*$ defines a geometric morphism $T^\sim_{\tau} \to (T')^\sim_{\tau'}$. 
4 Comparison between model topoi and Segal topoi

4.1 S-categories vs. Segal categories

As we already observed, any $S$-category (i.e. simplicially enriched category) is in a natural way a Segal category. Furthermore, it is clear that a morphism $T \to T'$ between $S$-categories is an equivalence if and only if it is an equivalence in the model category $\text{PrSeCat}$. Therefore, the inclusion functor $j : S-Cat \to \text{PrSeCat}$ induces a well defined functor on the level of homotopy categories

$$j : \text{Ho}(S-Cat) \to \text{Ho}(\text{PrSeCat}).$$

This functor is known to be an equivalence of categories (see [Si, p. 7]). Since we know that $\text{Ho}(\text{PrSeCat})$ is cartesian closed, then so is $\text{Ho}(S-Cat)$.

Let $C$ be a $\mathbb{U}$-small category, $S \subset C$ a subcategory (that we may suppose to contain all the isomorphisms) and $L(C, S)$ its simplicial localization, considered as a Segal category and therefore as an object in $\text{Ho}(\text{PrSeCat})$. It comes equipped with a natural localization morphism $L : C \to L(C, S)$ in $\text{Ho}(\text{PrSeCat})$ defined by the diagram

$$
\begin{array}{ccc}
L(C, \text{iso}) & \longrightarrow & L(C, S) \\
\sim & \downarrow & \\
C & & 
\end{array}
$$

where the horizontal map is induced by the identity functor on $C$ and the vertical equivalence in $\text{PrSeCat}$ is adjoint to the (usual) equivalence of categories $\pi_0 L(C, \text{iso}) \simeq C$.

The following proposition says that $C \to L(C, S)$ is the universal construction in $\text{Ho}(\text{PrSeCat})$ which formally inverts the morphisms in $S$.

Proposition 4.1.1 ([H-S, Prop. 8.6, Prop. 8.7]) For any $A \in \text{Ho}(\text{PrSeCat})$, the natural morphism

$$L^* : \mathbb{R}\text{Hom}(L(C, S), A) \to \mathbb{R}\text{Hom}(C, A)$$

is fully faithful. Its essential image consists of those morphisms $C \to A$ mapping elements of $S$ to equivalences in $A$.

Proposition 4.1.1 has the following important corollary.

Corollary 4.1.2 Let $(C, S)$ (resp. $(D, T)$) be a $\mathbb{U}$-small category with a subcategory $S \subset C$ (resp. $T \subset D$). Then, the natural morphism in $\text{Ho}(\text{PrSeCat})$

$$L(C \times D, S \times T) \to L(C, S) \times L(D, T)$$

is an isomorphism.

4.2 The strictification theorem

Let $T$ be a $\mathbb{U}$-small $S$-category, and $M$ be a simplicial model category which will be assumed to be $\mathbb{U}$-cofibrantly generated. The category of simplicial functors from $T$ to $M$ is denoted by $M^T$, and is endowed with its projective objectwise model structure: equivalences and fibrations are defined objectwise. We consider the evaluation functor

$$M^T \times T \to M,$$

as a morphism in $\text{PrSeCat}$. This functor clearly sends objectwise equivalences in $M^T \times T$ to equivalences in $M$, and therefore induces a well defined morphism in $\text{Ho}(\text{PrSeCat})$ between the corresponding simplicial localizations along equivalences

$$L(M^T \times T) \simeq L(M^T) \times T \to LM,$$
which yields, by adjunction, a morphism
\[ L(M^T) \longrightarrow \mathbb{R}\text{Hom}(T, LM). \]

The strictification theorem is the following statement. It says that the Segal category of functors from \( T \) to \( LM \) can be computed using the model category \( M^T \) of \( T \)-diagrams in \( M \).

**Theorem 4.2.1** (Strictification theorem) Under the previous hypotheses and notations, the natural morphism
\[ L(M^T) \longrightarrow \mathbb{R}\text{Hom}(T, LM) \]
is an isomorphism.

**Sketch of proof:** The theorem is proved in [16-S, Theorem 18.6] when \( T \) is a Reedy category. In the general case, one can find a Reedy category \( C \) and a subcategory \( S \subset C \) together with an equivalence \( L(C, S) \simeq T \). The theorem now follows from the case of a Reedy category, Proposition 4.1.1 and its analog for model categories (see [10-Ve2, Theorem 2.3.5] for references). \( \Box \)

This theorem is the central result needed to compare the construction of the category of stacks on an \( S \)-site ([16-Ve2, §3]) to the theory of stacks over Segal sites presented here. Note that Theorem 4.2.1 implies that
\[ \hat{T} \simeq L(\text{SSet}^T) = L(\text{SSet}^{T^{op}}) = L(\text{Pr}(T, \text{SSet})). \]

The strictification theorem 4.2.1 has one fundamental consequence which is the *Yoneda lemma for Segal categories* proved in [S1]. Let \( A \) be a Segal category (say in \( U \)); we know that we can find an \( S \)-category \( A' \) and an equivalence \( A' \simeq A \). For the \( S \)-category \( A' \) one has a natural simplicially enriched Yoneda morphism \((A')^{op} \times A' \longrightarrow \text{SSet}_U\). By adjunction this gives a well defined morphism of \( S \)-categories \( A' \longrightarrow \text{SSet}_U^{(A')^{op}} \).

Composing this with the morphism of Theorem 4.2.1 we get a morphism of Segal categories
\[ h : A \simeq A' \longrightarrow \hat{A}' \simeq \hat{A}, \]
well defined in the homotopy category of Segal categories. Now, Theorem 4.2.1 results of [D-K3] and again the simplicially enriched Yoneda lemma together imply that the morphism \( h \) is fully faithful. This is the Yoneda lemma for the Segal category \( A \) of [S1]. More generally, the same kind of argument proves the following proposition.

**Proposition 4.2.2** (Yoneda lemma) Let \( A \) be a Segal category, and \( a \in A \) an object. Let \( F \in \hat{A} \) be a morphism from \( A^{op} \) to \( \text{Top} \). There exists a natural equivalence of simplicial sets
\[ F(a) \simeq \hat{A}_{(h_a, F)}. \]

We finish this subsection with the following definition of representable and corepresentable functors.

**Definition 4.2.3** Let \( A \) be a Segal category and \( F \in \mathbb{R}\text{Hom}(A^{op}, \text{Top}) \) be an object. \( F \) is called representable if it is equivalent to \( h_a \) for some \( a \in A \).

Dually, an object \( F \in \mathbb{R}\text{Hom}(A, \text{Top}) \) is called corepresentable if it is representable when considered as a functor from \((A^{op})^{op} \) to \( \text{Top} \) (i.e. equivalent to \( h_a \) for some \( a \in A^{op} \)).

### 4.3 Comparison

Recall from [16-Ve2, §3.8] that a (\( t \)-complete) *model topos* is a model category Quillen equivalent to the model category \( \text{SPr}_r(T) \) of stacks over some \( S \)-site \((T, \tau)\). The results of the previous subsection imply that the notions of model topos and of Segal topos are related via the functor \( L \), which sends a model category to its simplicial localization (along equivalences). More precisely, if one starts with a \( U \)-small \( S \)-site \((T, \tau)\), then one has the model categories of pre-stacks \( \text{SPr}(T) \) and of stacks \( \text{SPr}_r(T) \) on \( T \), as defined in [16-Ve2, §3]. One the other hand, the \( S \)-site \((T, \tau)\) might be considered in a trivial way as a \( U \)-small Segal site, and one can consider the associated Segal categories of pre-stacks \( \hat{T} \) and of stacks \( T \sim \tau \). Theorem 4.2.1 implies the following comparison result.
Corollary 4.3.1  
1. If $M$ is a $\mathbb{U}$-model topos then $LM$ is a $\mathbb{U}$-Segal topos.

2. Let $(T, \tau)$ be a $\mathbb{U}$-small $S$-site. There exists natural isomorphisms in $\text{Ho}(\text{PrSeCat})$

$$L(\text{SPr}(T)) \simeq \hat{T} \quad L(\text{SPr}_\tau(T)) \simeq T^{\sim, \tau}.$$ 

Therefore the theory of model topoi, investigated in [To-Ve 2], embeds in the present theory of Segal topoi where it actually finds a richer environment, mainly because when viewed as Segal topoi (via the simplicial localization $L$), two model topoi do have a Segal category of geometric morphisms between them (as explained in Definition 3.4.1) while it is not clear what a model category of geometric morphisms between model topos should be.

Let us also mention that all results and constructions of [To-Ve 2] provide through corollary 4.3.1 analogs results and constructions in the context of Segal topoi. This way, we obtain the existence of internal Hom’s, a theory of truncated objects and truncation functors . . . .

Finally, corollary 4.3.1 together with theorem 3.3.8 implies the following important fact.

Corollary 4.3.2  
A $t$-complete $\mathbb{U}$-Segal topos is a presentable Segal category in the sense of Lurie ([Lur, Prop. 1.4.1]).

Proof: Indeed, $T$ is equivalent to some $L\text{SPr}_\tau(T)$. As $\text{SPr}_\tau(T)$ is a cofibrantly generated model category, $T$ is a presentable Segal category (see [Si] for details). \qed

Remark 4.3.3  
Corollary 4.3.2 states that any $t$-complete Segal topos is a presentable Segal category. The question whether any Segal topos is a presentable Segal category is open.

5 Further examples and applications

In this last section we give some further materials and some examples of applications of the theory of Segal topos.

5.1 Giraud’s theorem

In order to state the conjectural Giraud’s theorem for Segal topos, we need some preliminaries notations and definitions.

- A simplicial set is called $essentially \mathbb{U}$-small if it is equivalent to a $\mathbb{U}$-small simplicial set.
- A coproduct $\coprod_{i \in I} x_i$ in a Segal category $A$ with initial object $\emptyset$ is called disjoint if for any $i \neq j$ the square

$$
\begin{array}{ccc}
\emptyset & \longrightarrow & x_i \\
\downarrow & & \downarrow \\
x_j & \longrightarrow & \coprod_{i \in I} x_i
\end{array}
$$

is cartesian in $A$.

- Let $X_* : \Delta^{op} \longrightarrow A$ be a simplicial object in a Segal category $A$. We say that $X_*$ is a groupoid object if it satisfies the following two conditions.

- Let $X_* : \Delta^{op} \longrightarrow A$ be a simplicial object in a Segal category $A$. We say that $X_*$ is a groupoid object if it satisfies the following two conditions.
1. The Segal morphisms (defined as in §2)

\[ X_n \rightarrow X_1 \times_{X_0} X_1 \times_{X_0} \cdots \times_{X_0} X_1 \]

are equivalences (this condition includes the fact that the fibered product of the left hand side exists in \( A \)).

2. The morphism

\[ d_2 \times d_1 : X_2 \rightarrow X_1 \times_{d_0, X_0, d_1} X_1 \]

is an equivalence.

- Finally, let \( A \) be a \( V \)-small Segal category whose simplicial sets of morphisms are essentially \( U \)-small. A \( U \)-small set of strong generators for \( A \) is a \( U \)-small set \( E \) of objects in \( A \) (considered as a full sub-Segal category of \( A \)), such that the natural morphism

\[ A \rightarrow \hat{A} \rightarrow \hat{E} \]

is fully faithful (the first morphism is the Yoneda embedding \( h \) of Proposition 4.2.2 and the second one is the restriction morphism from \( A \) to \( E \)).

The analog of Giraud’s theorem for Segal categories is the following.

**Conjecture 5.1.1** (Giraud’s theorem for Segal topoi) *Let \( A \) be a \( V \)-small Segal category. Then \( A \) is a \( U \)-Segal topos if and only if it satisfies the following conditions.*

1. The simplicial sets of morphisms in \( A \) are essentially \( U \)-small.
2. The Segal category \( A \) has all \( U \)-small colimits, and coproducts in \( A \) are disjoint.
3. For all groupoid objects \( X_* \) in \( A \), the natural morphism

\[ X_* \rightarrow N(X_0 \rightarrow |X_*|) \]

is an equivalence of simplicial objects in \( A \) (here \( |X_*| \) is the colimit of the simplicial diagram \( X_* \) and \( N(X_0 \rightarrow |X_*|) \) is the nerve of the natural morphism \( X_0 \rightarrow |X_*| \)).
4. Colimits in \( A \) are stable by pullbacks. In other words, for any \( U \)-small category \( I \), any \( I \)-diagram \( x_* \) in \( A \), and any morphisms

\[ \text{Colim}_{i \in I} x_i \rightarrow z \rightarrow y \], the natural morphism

\[ \text{Colim}_{i \in I} (x_i \times_z y) \rightarrow (\text{Colim}_{i \in I} x_i) \times_z y \]

is an equivalence.
5. The Segal category \( A \) has a \( U \)-small set of strong generators.

Conjecture 5.1.1 can be directly compared with Theorem 1 of the appendix of [M-M]. It can also be compared with the version of Giraud’s theorem in the context of model topoi stated by C. Rezk (unpublished). A proof of the conjecture 5.1.1 have been recently given by J. Lurie in [Lu] (at least for presentable Segal categories).

Finally, one can easily prove the following proposition, which together with the previous conjecture would give a Giraud’s theorem of \( t \)-complete Segal topoi, and therefore, by Theorem 3.3.8 a characterization of Segal categories of the form \( T^{\sim \tau} \).

For this, let us recall that a morphism \( f : F \rightarrow G \) in a Segal topos \( A \) is an *epimorphism* if the natural morphism

\[ |N(F \rightarrow G)| \rightarrow G, \]
from the geometric realization of the nerve of $f$ down to $G$, is an equivalence in $A$. We will then say that an augmented simplicial object $X_* \to Y$ in a Segal topos $A$ is a hyper-cover if for any $n \geq 0$ the induced morphism
\[
X_*^{\Delta^n} \to X_*^{\partial \Delta^n} \times_{Y^{\partial \Delta^n}} Y^{\Delta^n}
\]
is an epimorphism.

**Proposition 5.1.2** A Segal topos $A$ is $t$-complete if and only if for all hyper-cover $X_* \to Y$ the induced morphism
\[
|X_*| \to Y
\]
is an equivalence.

### 5.2 A Galois interpretation of homotopy theory

In this number, we will give an application of the notion of geometric morphisms between Segal topoi to the Galois interpretation of homotopy theory of [10].

Let $X$ be a CW complex in $U$, and $SPr(X)$ be the category of $U$-simplicial presheaves on $X$ (i.e. presheaves of $U$-small simplicial sets on the site of open subsets of $X$). The category $SPr(X)$ is endowed with its local projective model structure of [11]. We consider the full subcategory $PrLoc(X)$ of $SPr(X)$, consisting of locally $h$-constant objects in the sense of [10]. They are the simplicial presheaves $F$ which are, locally on $X$, equivalent (for the local model structure) to a constant simplicial presheaf. We define $Loc(X) := LPrLoc(X)$, the simplicial localization of $PrLoc(X)$ along the local equivalences, and we view it as a $V$-small Segal category.

The following theorem is the higher analog of the Galois interpretation of the theory of fundamental groupoids explored by Grothendieck in [SGA1]. It is also an extension of the main theorem of [10] to the case of unbased spaces.

**Theorem 5.2.1**

1. The Segal category $Loc(X)$ is a $t$-complete $U$-Segal topos.

2. Let $X$ and $Y$ be two $U$-small CW-complexes. The Segal category $\mathbb{R}Hom_{geom}(Loc(X), Loc(Y))$ is a Segal groupoid (i.e. its homotopy category is a groupoid, or equivalently all its morphisms are equivalences).

3. Let $X$ and $Y$ be two $U$-small CW-complexes. There exists a natural isomorphism in $Ho(SSet)$
\[
\mathbb{R}Hom(X, Y) \simeq |\mathbb{R}Hom_{geom}(Loc(X), Loc(Y))|,
\]
where $|\mathbb{R}Hom_{geom}(Loc(X), Loc(Y))|$ is the geometric realization (see [15], §2) of the Segal category $\mathbb{R}Hom_{geom}(Loc(X), Loc(Y))$.

4. The functor
\[
Loc : \quad Ho(\text{Top}) \to Ho(\text{SeT}_U) \subset Ho(\text{PrSeCat})
X \quad \mapsto \quad Loc(X)
\]
is fully faithful.

**Sketch of proof:** The theorem is mainly a consequence of results in [10].

1. This follows from [10] Theorem 2.13, 2.22 and the strictification theorem [12] which shows that $Loc(X)$ is equivalent to $\tilde{BG}$, where $G$ is the simplicial group of loops on $X$ (we assume here that $X$ is connected for the sake of simplicity), and $BG$ is the Segal category with a unique object and $G$ as the endomorphism simplicial monoid.

2. As above, let us write $Loc(X) \simeq \tilde{BG} \simeq \mathbb{R}Hom(BG^{op}, Top)$. By adjunction one has
\[
\mathbb{R}Hom_{geom}(Loc(X), Loc(Y)) \simeq \mathbb{R}Hom(BG, \mathbb{R}Hom_{geom}(Top, Loc(Y))).
\]
As \( \text{Loc}(\ast) \cong \text{Top} \), this shows that one can assume \( X = \ast \). One can also clearly assume that \( Y \) is connected. Therefore, it is enough to show that all objects in \( \mathbb{R} \text{Hom}^{\text{geom}}(\text{Top}, \text{Loc}(Y)) \) are equivalent (compare with \([\text{SGA1}, \text{Corollary 5.7}]) \).

Let \( y \in Y \) be a base point and \( \omega_y : \text{Loc}(Y) \rightarrow \text{Top} \) the fiber-at-\( x \) morphism. We will prove that any \( \omega \in \mathbb{R} \text{Hom}^{\text{geom}}(\text{Top}, \text{Loc}(Y)) \) is equivalent to \( \omega_y \). Indeed, by \([\text{To}, \text{Theorem 2.22}]\) we know that \( \omega_y \) is co-represented by some \( E \in \text{Loc}(Y) \), corresponding to the action of the loop group of \( Y \) on itself. Since \( E \neq \emptyset \), the exactness assumption on \( \omega \) implies that \( \omega(E) \neq \emptyset \). The Yoneda lemma \([\text{To}, \text{Lemma 1.22}]\) implies that \( \omega(E) \cong \mathbb{R} \text{Hom}^{\text{geom}}(\text{Top}, \text{Loc}(Y))(\omega_y, \omega) \), and therefore one sees that there exists a morphism \( u : \omega_y \rightarrow \omega \). We need to show that \( u \) is an equivalence, or equivalently that for any \( F \in \text{Loc}(Y) \), the induced morphism \( u_F : F_y \rightarrow \omega(F) \) is an equivalence of simplicial sets. Considering this morphism on the level of \( \pi_0 \), and using \([\text{SGA1}, \text{Corollary 6.3}]\), one sees that for any \( F \in \text{Loc}(Y) \) the induced morphism \( \pi_0(u_F) : \pi_0(F_y) \rightarrow \pi_0(\omega(F)) \) is bijective. Moreover, applying this to \( F^\mathbb{R}K \), for \( K \) a finite simplicial set, and using exactness of \( \omega \) we see that \( F_y \rightarrow \omega(F) \) is in fact an equivalence.

(3) As above, one can suppose that \( X = \ast \) and that \( Y \) is connected. Let us write \( Y \cong BG \), where \( G \) is a simplicial group. Using \([\text{To}, \text{Theorem 2.13.,2.22}]\), we need to show that the natural morphism

\[
BG \rightarrow \mathbb{R} \text{Hom}^{\text{geom}}(\text{Top}, \widehat{BG})
\]

is an equivalence of Segal categories. The fact that this morphism is fully faithful is \([\text{To}, \text{Corollary 3.2}]\). On the other hand, point (2) above shows that all objects in \( \mathbb{R} \text{Hom}^{\text{geom}}(\text{Top}, \widehat{BG}) \) are equivalent, i.e. that the above morphism is also essentially surjective.

(4) The functor

\[
\text{Loc} : \text{Ho}(\text{Top}) \rightarrow \text{Ho}(\text{SeT}_U)
\]

has a right adjoint, sending a Segal topos \( A \) to the geometric realization of the Segal groupoid \( \mathbb{R} \text{Hom}^{\text{geom}}(\text{Top}, A)^{\text{int}} \) (the interior of the Segal category \( \mathbb{R} \text{Hom}^{\text{geom}}(\text{Top}, A) \), see \([\text{LSS}, \text{§2}]\). It is the maximal sub-Segal groupoid of \( \mathbb{R} \text{Hom}^{\text{geom}}(\text{Top}, A) \). The fact that the adjunction morphism \( X \rightarrow |\mathbb{R} \text{Hom}^{\text{geom}}(\text{Top}, \text{Loc}(X))| \) is an isomorphism for any \( X \) in \( \text{Ho}(\text{Top}) \) is the content of point (3).

\[ \square \]

\( \ast \)From Theorem \([\text{To}, \text{Theorem 5.2.1}]\), one deduces the following reconstruction result. Note that the Segal category \( \text{Top} = \text{LSSet}_U \) of simplicial sets is equivalent to \( \text{Loc}(\ast) \), \( \ast \) denoting the one-point space.

**Corollary 5.2.2** The Segal topos \( \text{Loc}(X) \) determines \( X \). More precisely, there exists a natural isomorphism in \( \text{Ho}(\text{SSet}) \)

\[
X \cong |\mathbb{R} \text{Hom}^{\text{geom}}(\text{Top}, \text{Loc}(X))|.
\]

In particular, if \( X \) and \( Y \) are two \( \mathbb{U} \)-small CW-complexes such that the Segal categories \( \text{Loc}(X) \) and \( \text{Loc}(Y) \) are equivalent, then \( X \) and \( Y \) are homotopy equivalent.

### 5.3 Homotopy types of Segal sites

The reconstruction of a homotopy type from the Segal category of locally constant stacks on it explained in the last subsection suggests that one could try to extend homotopy theory to Segal sites, in the same way as the theory of fundamental group is extended to the more general setting of \([\text{SGA1}, \text{Exp. V}]\). For nice enough Grothendieck sites, a pro-homotopy type has been constructed in \([\text{A-M}]\). However, the approach of \([\text{A-M}]\) is very different from the galoisian point of view originally adopted in \([\text{SGA1}, \text{Exp. V}]\), and no relations have still been made explicit between certain stacks on the site and certain stacks on its associated homotopy type, as, for example, locally constant sheaves corresponds to continuous representations of the fundamental group. Moreover, the construction of \([\text{A-M}]\) only gives a pro-object in the homotopy category of spaces, whereas various works on étale homotopy theory and pro-finite completions suggest that one should actually expect an object in the homotopy category of pro-spaces instead.

In this last part we propose a very general approach to define homotopy types of Segal sites, which follows the original galoisian point of view of \([\text{SGA1}]\) and \([\text{To}]\). Not all the details of the construction will
be presented here.

Let $T$ be a $U$-Segal topos. We assume that $T$ is presentable Segal category in the sense of \[Lu\] (e.g. $T$ is a $t$-complete Segal topos, see Corollary 4.3.2).

We wish to define an associated morphism of Segal categories $H_T : \text{Top} \to \text{Top}$.

For a $U$-small simplicial set $Y$, we consider $\text{Loc}(Y)$, the Segal category of locally constant stacks on its geometric realization (by \[To\] Theorem 2.13) $\text{Loc}(Y)$ is also equivalent to the comma Segal category $\text{Top}/Y$ of objects over $Y$ and the Segal category of geometric morphisms $\mathbb{R}\text{Hom}_{\text{geom}}^\text{geom}(T, \text{Loc}(Y))$.

On the other hand we can look at the unique geometric morphism $p : T \to \text{Top}$, with inverse image $p^* : \text{Top} \to T$, and define the cohomology of $T$ with coefficients in a $U$-small simplicial set $Y$ as

$$\mathbb{H}(T,Y) := T(\ast, p^*(Y)).$$

Note that, as the simplicial sets of morphisms in $T$ are essentially $U$-small, so is $\mathbb{H}(T,Y)$. We have the following comparison result.

**Lemma 5.3.1** The Segal category $\mathbb{R}\text{Hom}_{\text{geom}}^\text{geom}(T, \text{Loc}(Y))$ is a Segal groupoid whose geometric realization is naturally equivalent to the cohomology space of $T$ with coefficients in $Y$:

$$|\mathbb{R}\text{Hom}_{\text{geom}}^\text{geom}(T, \text{Loc}(Y))| \simeq \mathbb{H}(T,Y).$$

**Proof:** Let us first describe the natural morphism

$$\phi_{T,Y} : |\mathbb{R}\text{Hom}_{\text{geom}}^\text{geom}(T, \text{Loc}(Y))| \to \mathbb{H}(T,Y).$$

First of all, by \[To\] Theorem 2.13, one has a natural equivalence between $\text{Loc}(Y)(\ast, Y)$ and $\text{Map}(Y,Y)$, where $Y$ is the constant stack on $Y$ with fiber $Y$. Therefore, the identity provides a natural element $c_Y \in \text{Loc}(Y)(\ast, Y)$. Now, if $f^* : \text{Loc}(Y) \to T$ is the inverse image of a geometric morphism $f \in \mathbb{R}\text{Hom}_{\text{geom}}^\text{geom}(T, \text{Loc}(Y))$, the image of $c_Y$ by $f^*$ gives an element in $T(\ast, f^*(Y)) \simeq \mathbb{H}(T,Y)$. This defines the morphism $\phi_{T,Y}$.

To prove that $\mathbb{R}\text{Hom}_{\text{geom}}^\text{geom}(T, \text{Loc}(Y))$ is a Segal groupoid and that $\phi_{T,Y}$ is an equivalence, one writes $T$ as a left localization of $\hat{B}$, for some Segal category $B$. Then, $\mathbb{R}\text{Hom}_{\text{geom}}^\text{geom}(T, \text{Loc}(Y))$ is a left exact localization of $\mathbb{R}\text{Hom}_{\text{geom}}^\text{geom}(\hat{B}, \text{Loc}(Y))$, and using the functoriality of $\phi_{T,Y}$ in $T$ one is reduced to the case where $T$ is of the form $\hat{B}$ where the lemma follows easily from the adjunction formula

$$\mathbb{R}\text{Hom}_{\text{geom}}(\hat{B}, \text{Loc}(Y)) \simeq \mathbb{R}\text{Hom}(\text{op}, \mathbb{R}\text{Hom}_{\text{geom}}(\text{Top}, \text{Loc}(Y))),$$

and theorem 5.2.1. \hfill \Box.

We define $H_T(Y)$ as the geometric realization of the Segal groupoid $\mathbb{R}\text{Hom}_{\text{geom}}^\text{geom}(T, \text{Loc}(Y))$:

$$H_T(Y) := |\mathbb{R}\text{Hom}_{\text{geom}}^\text{geom}(T, \text{Loc}(Y))| \in \text{Top}. $$

This defines a morphism $H_T : \text{Top} \to \text{Top}$, which is abstractly considered as “some” homotopy type associated to the Segal topos $T$. By the previous lemma, one also has a natural equivalence $H_T(Y) \simeq \mathbb{H}(T,Y)$, for any $U$-small simplicial set $Y$.

**Definition 5.3.2** The homotopy shape of the Segal topos $T$ is defined to be the object $H_T \in \mathbb{R}\text{Hom}(\text{Top}, \text{Top})$ defined above.

A fundamental consequence of Theorem 5.2.1 is that if $T$ is the Segal topos of stacks over the Grothendieck site of a CW complex $X$, then $H_T$ is corepresented by the homotopy type of $X$. In general we do not expect $H_T$ to be corepresentable, but one can prove that $H_T$ is pro-corepresentable in the context of Segal categories. This last fact is more or less equivalent to the fact that the morphism $H_T$ is left exact, which follows from Lemma 5.3.1. Let us be more precise.
A Segal category $K$ is called finite, if for any filtered system of Segal categories \( \{B_i\}_{i \in I} \), the natural morphism
\[
\text{Colim}_{i \in I} \mathbb{R}\text{Hom}(K, B_i) \to \mathbb{R}\text{Hom}(K, \text{Colim}_{i \in I} B_i)
\]
is an equivalence. A Segal category $A$ is left filtered if for any finite Segal category $K$ and any $K$-diagram \( x \in \mathbb{R}\text{Hom}(K, A) \), there exists an object $a \in A$ and a morphism $a \to x$ in $\mathbb{R}\text{Hom}(K, A)$ (here, $a$ also denotes the constant $K$-diagram in $A$ with value $a$).

**Proposition 5.3.3** Let $T$ be a $U$-Segal topos which is a presentable Segal category (e.g. a $t$-complete Segal topos). There exists a left filtered $U$-small Segal category $A$ and an $A$-diagram $\chi(T) \in \mathbb{R}\text{Hom}(A, \text{Top})$ such that for any $Y \in \text{Top}$ there is a natural equivalence
\[
H_T(Y) \simeq \text{Colim}_{a \in A^o} \text{Hom}(\chi(T)_a, Y).
\]

In the other words, the two endomorphisms of $\text{Top}$
\[
Y \mapsto H_T(Y) \quad \text{and} \quad Y \mapsto \text{Colim}_{a \in A^o} \text{Hom}(\chi(T)_a, Y)
\]
are equivalent as objects in $\mathbb{R}\text{Hom}(\text{Top}, \text{Top})$.

**Sketch of proof:** Let us recall that we have assumed $T$ to be a presentable Segal category. Therefore, there exists a regular cardinal $\alpha \in U$ such that, for any simplicial set $Y$, $H_T(Y) \simeq \text{Colim}_{Y} H_T(Y_i)$, where $Y_i$ runs through the sub-simplicial sets of $Y$ whose cardinality is less than $\alpha$ (chose $\alpha$ so that $*$ is a $\alpha$-small object in $T$ and observe that $H_T(Y) \simeq T_{[\ast, Y]}$).

We now consider $H_T$, restricted to the full sub-category $\text{Top}_{\leq \alpha}$ of $\text{Top}$ consisting of simplicial sets of cardinality less than $\alpha$. We define $A$ to be the Segal category of objects of the morphism $H_T : \text{Top}_{\leq \alpha} \to \text{Top}$. In other words, $A$ is the Segal category of pairs $\langle Y, x \rangle$, where $Y \in \text{Top}_{\leq \alpha}$ and $x \in H_T(Y)$ (the Segal category $A$ is also denoted by $\int H_T$ in [LES]). As $H_T$ is left exact and by the choice of the cardinal $\alpha$, one sees that $A$ satisfies the conditions of the proposition. \( \square \)

The diagram $\chi(T)$ of proposition 5.3.3 is called the **pro-homotopy type of the Segal topos $T$**. It is not a pro-simplicial in the usual sense, as the indices live in a filtered Segal category $A$ rather than in an actual filtered category. However, this seems to be of so much importance, as pro-objects in the Segal setting behave very much the same way as usual pro-objects. Also, as argued in [Lu], it seems that the two notions are more or less equivalent, and that the Segal category $A$ of proposition 5.3.3 can in fact be chosen to be a usual filtered category.

In any case, when $A$ is a filtered Segal category then its homotopy category $\text{Ho}(A)$ is a filtered category in the usual sense. Therefore, the $A$-diagram $\chi(T)$ of proposition 5.3.3 induces a $\text{Ho}(A)$-diagram in $\text{Ho}(\text{Top})$, i.e. a pro-object in the homotopy category of spaces. When $T$ is the Segal topos of stacks over a locally connected Grothendieck site, we suspect that this induced pro-object is equivalent to the one constructed by Artin and Mazur in [A-M]. The pro-homotopy type $\chi(T)$ of the Segal topos $T$ is therefore a refinement and a generalization of Artin-Mazur’s construction.

An interesting example of application of homotopy types of Segal topoi would be the study of the **étale homotopy type of the sphere spectrum**, defined by using the Segal site $(\text{Spec} S, \text{ét})$ defined in [16-Ve2, §5]. We can, for example, ask the following more precise question.

**Question 5.3.4** Let $T := \text{Spec} S^\wedge, \text{ét}$ be the small étale Segal topos of the sphere spectrum defined in [16-Ve2, §5], and $S^\wedge, \text{ét} := \chi(T)$ be its pro-homotopy type as defined above. Describe $S^\wedge, \text{ét}$, and in particular compare it with the étale homotopy type of $\text{Spec} \mathbb{Z}$.

One could also ask, for each rational prime $p$, a similar question for the $p$-localized sphere spectrum $S_p$; in this case it seems natural to ask whether the corresponding pro-corepresentative space is determined by the Morava $K$-theories $K(n)$ or $E$-theories $E(n)$, $n \geq 0$, in analogy with the standard chromatic picture.
