THE RIEMANN PROBLEM FOR THE SHALLOW WATER EQUATIONS WITH DISCONTINUOUS TOPOGRAPHY

PHILIPPE G. LEFLOCH AND MAI DUC THANH

ABSTRACT. We construct the solution of the Riemann problem for the shallow water equations with discontinuous topography. The system under consideration is non-strictly hyperbolic and does not admit a fully conservative form, and we establish the existence of two-parameter wave sets, rather than wave curves. The selection of admissible waves is particularly challenging. Our construction is fully explicit, and leads to formulas that can be implemented numerically for the approximation of the general initial-value problem.

1. Introduction

1.1. Shallow water equations. We consider the one-dimensional shallow water equations

\[
\begin{align*}
\partial_t h + \partial_x (hu) &= 0, \\
\partial_t (hu) + \partial_x (h(u^2 + g \frac{h}{2})) &= -gh \partial_x a, \\
\partial_t a &= 0,
\end{align*}
\]  

(1.1)

where \(h\) denotes the height of the water from the bottom to the surface, \(u\) the velocity of the fluid, \(g\) the gravity constant, and \(a\) the height of the river bottom from a given level. Following LeFloch [18] we supplement the first two balance laws for the fluid with the equation \(\partial_t a = 0\) corresponding to a fixed geometry. Adding the equation \(\partial_t a = 0\) allows us to view the shallow water equations (the first two equations in (1.1)), which form a strictly hyperbolic system of balance laws in nonconservative form, as a non-strictly hyperbolic system of balance laws with a linearly degenerate characteristic field.

We are mainly interested in the case that \(a\) is piecewise constant

\[
a(x) = \begin{cases} 
    a_L, & x < 0, \\
    a_R, & x > 0,
\end{cases}
\]

where \(a_L, a_R\) are two distinct constants. The Riemann problem associated with (1.1) is the initial-value problem corresponding to the initial conditions of

\[
(h, u, a)(x, 0) = \begin{cases} 
    (h_L, u_L, a_L), & x < 0, \\
    (h_R, u_R, a_R), & x > 0.
\end{cases}
\]

(1.2)

Since \(a\) is discontinuous, the system (1.1) cannot be written in a fully conservative form, and the standard notion of weak solutions for hyperbolic systems of conservation laws does not apply. However, the equations still make sense within the
framework introduced in Dal Maso, LeFloch, and Murat [7]. (For a recent review see [19] [20].)

1.2. **DLM generalized Rankine-Hugoniot relations.** Consider an elementary discontinuity propagating with the speed $\lambda$ and satisfying the equations (1.1). Observe that the Rankine-Hugoniot relation associated with the third equation in (1.1) simply reads

$$-\lambda[a] = 0, \quad (1.3)$$

where $[a] := a_+ - a_-$ denotes the jump of the bottom level function $a$, and $a_{\pm}$ denotes its left- and right-hand traces. Then, we have the following possibilities:

(i) either the component $a$ remains constant across the propagating discontinuity,

(ii) or $a$ changes its levels across the discontinuity and the discontinuity is stationary, i.e., the speed $\lambda$ vanishes.

This observation motivates us to define the admissible elementary waves of the system (1.1). First of all, assume that the bottom level $a$ remains constant across a discontinuity; then, $a$ should be constant in a neighborhood of the discontinuity. Eliminating $a$ from (1.1), we obtain the following system of two conservation laws

$$\partial_t h + \partial_x (hu) = 0,$$

$$\partial_t (hu) + \partial_x (h(u^2 + gh)) = 0,$$  \quad (1.4)

Thus, the left- and right-hand states are related by the Rankine Hugoniot relations corresponding to (1.4)

$$-\lambda[h] + [hu] = 0,$$

$$-\lambda[hu] + [h(u^2 + gh)] = 0,$$  \quad (1.5)

where $[h] := h_+ - h_+$, etc.

Second, suppose that the component $a$ is discontinuous so that the speed vanishes. Then, the solution is independent of the time variable, and it is natural to search for a solution obtained as the limit of a sequence of time-independent smooth solutions of (1.1). (See below.)

Suppose that $(x, t) \mapsto (h, u, a)$ is a smooth solution of (1.1). Then, the system (1.1) can be written in the following form, as a system of conservation laws for the (now conservative) variables $(h, u, a)$:

$$\partial_t h + \partial_x (hu) = 0,$$

$$\partial_t u + \partial_x (\frac{u^2}{2} + g(h + a)) = 0,$$

$$\partial_t a = 0.$$  \quad (1.6)

Hence, time-independent solutions of (1.1) satisfy

$$(hu)' = 0,$$

$$(\frac{u^2}{2} + g(h + a))' = 0,$$  \quad (1.7)
where the dash denotes the differentiation with respect to $x$. Trajectories initiating
from a given state $(h_0, u_0, a_0)$ are given by

$$
hu = h_0 u_0,
$$

$$
\frac{u^2}{2} + g(h + a) = \frac{u_0^2}{2} + g(h_0 + a_0).
$$

(1.8)

It follows from (1.8) that the trajectories of (1.7) can be expressed in the form

$$
u = u(h),
$$

$$
a = a(h).
$$

Now, letting $h \to h_\pm$ and setting $u_\pm = u(h_\pm), a_\pm = a(h_\pm)$, we see that the states $(h_\pm, u_\pm, a_\pm)$ satisfy the Rankine-Hugoniot relations associated with (1.6), but with zero shock speed:

$$
[h u] = 0,
$$

$$
[\frac{u^2}{2} + g(h + a)] = 0,
$$

(1.9)

The above discussion leads us to define the elementary waves of interest, as follows.

**Definition 1.1.** The admissible waves for the system (1.1) are the following ones:

(a) the rarefaction waves, which are smooth solutions of (1.1) with constant
component $a$ depending only on the self-similarity variable $x/t$;

(b) the shock waves which satisfy (1.5) and Lax shock inequalities and have
constant component $a$;

(c) and the stationary waves which have zero speed and satisfy (1.9).

As will be checked later, the system (1.1) is not strictly hyperbolic, as was already observed in the previous work [21]. Recall that therein we studied the Riemann problem in a nozzle with variable cross-section and constructed all of the Riemann solutions. The present model is analogous, and our main purpose in the present paper is to demonstrate that the technique in [21] extends to the shallow water model and to construct the solution of the Riemann problem. The lack of strict hyperbolicity and the nonconservative form of the equation make the problem particularly challenging. Some aspects of this problem are also covered by Alcrudo and Benkhaldoun [1]. For works on various related models including scalar conservation laws we refer to [22, 15, 14, 13, 12, 9, 8, 2].

1.3. **Results and perspectives.** As we will show, waves in the same characteristic field may be repeated in a single Riemann solution. This happens when waves cross the boundary of the strictly hyperbolic regions and the order of characteristic speeds changes. We will also show below that the Riemann problem may not always have a solution. The Riemann problem may admit exactly one, or two, or up to three distinct solutions for different ranges of left-hand and right-hand states. Thus, uniqueness does not hold for the Riemann problem, as was already observed for the nozzle flow system.

Each possible construction leads to a solution that depends continuously on the left-hand and right-hand states. This is a direct consequence of the smoothness of the elementary wave curves; by the implicit function theorem, the intermediate waves depend continuously on their left- or right-hand states as well as on the Riemann data. These results agree with [21] which covered fluids in a nozzle with variable cross section.
In the present model, the curve of stationary wave is strictly convex. To find stationary waves, one needs to determine the roots of a nonlinear equation (see the function $\varphi$ in (3.1)) which is convex and, therefore, can be easily computed numerically. The Riemann solver derived in the present paper should be useful in combination with numerical methods for shallow water systems developed in [3, 4, 11, 10, 16, 6] for which we refer to the lecture notes by Bouchut [5].

2. **Background**

2.1. **Shallow water equations as a non-strictly hyperbolic system.** We now discuss the system (1.1) in the nonconservative variables $U = (h, u, a)$. From (1.6) it follows that, for smooth solutions, (1.1) is equivalent to

\[
\begin{align*}
\partial_t h + u \partial_x h + h \partial_x u &= 0, \\
\partial_t u + g \partial_x h + u \partial_x u + g \partial_x a &= 0, \\
\partial_t a &= 0,
\end{align*}
\]

(2.1)

which can be written in the nonconservative form

\[
\partial_t U + A(U) \partial_x U = 0,
\]

(2.2)

where the Jacobian matrix $A(U)$ is given by

\[
A(U) = \begin{pmatrix} u & u & 0 \\ g & u & g \\ 0 & 0 & 0 \end{pmatrix}.
\]

The eigenvalues of $A$ are

\[
\lambda_1(U) := u - \sqrt{gh}, \quad \lambda_2(U) := u + \sqrt{gh}, \quad \lambda_3(U) := 0,
\]

(2.3)

and corresponding eigenvectors can be chosen as

\[
\begin{align*}
r_1(U) := (h, -\sqrt{gh}, 0)^t, \\
r_2(U) := (h, \sqrt{gh}, 0)^t, \\
r_3(U) := (gh, -gu, u^2 - gh)^t.
\end{align*}
\]

(2.4)

We see that the first and the third characteristic fields may coincide:

\[
(\lambda_1(U), r_1(U)) = (\lambda_3(U), r_3(U))
\]

on a hypersurface in the variables $(h, u, a)$, which can be identified as

\[
C_+ := \{(h, u, a) \mid u = \sqrt{gh}\}.
\]

(2.5)

Similarly, the second and the third characteristic fields may coincide:

\[
(\lambda_2(U), r_2(U)) = (\lambda_3(U), r_3(U))
\]

on a hypersurface in the variables $(h, u, a)$, which can be identified as

\[
C_- := \{(h, u, a) \mid u = -\sqrt{gh}\}.
\]

(2.6)

The third eigenvalue $(\lambda_3, r_3)$ is linearly degenerate, and we have

\[
-\nabla \lambda_1(U) \cdot r_1(U) = \nabla \lambda_2(U) \cdot r_2(U) = \frac{3}{2} \sqrt{gh} \neq 0, \quad h > 0.
\]

Note also that the first and the second characteristic fields $(\lambda_1, r_1)$, $(\lambda_2, r_2)$ are genuinely nonlinear in the open half-space $\{(h, u, a) \mid h > 0\}$.

It is convenient to set

\[
C = C_+ \cup C_- = \{(h, u, a) \mid u^2 - gh = 0\},
\]
In conclusion we have established (cf. Figure 1):

**Lemma 2.1.** On the hypersurface $C_+$ in the variables $(h, u, a)$ the first and the third characteristic speeds coincide and, on the hypersurface $C_-$, the second and the third characteristic speeds coincide. Hence, the system (1.1) is non-strictly hyperbolic.

The hypersurface $C$ divides the phase domain into three disjoint regions, denoted by $A_1$, $A_2$ and $A_3$, in which the system is strictly hyperbolic. More precisely, we define

\begin{align*}
A_1 & := \{(h, u, a) \in \mathbb{R}_+ \times \mathbb{R}_+ \times \mathbb{R}_+ \mid \lambda_2(U) > \lambda_1(U) > \lambda_3(U)\}, \\
A_2 & := \{(h, u, a) \in \mathbb{R}_+ \times \mathbb{R}_+ \times \mathbb{R}_+ \mid \lambda_2(U) > \lambda_3(U) > \lambda_1(U)\}, \\
A_2^+ & := \{(h, u, a) \in A_2 \mid u > 0\}, \\
A_2^- & := \{(h, u, a) \in A_2 \mid u < 0\}, \\
A_3 & := \{(h, u, a) \in \mathbb{R}_+ \times \mathbb{R}_+ \times \mathbb{R}_+ \mid \lambda_3(U) > \lambda_2(U) > \lambda_1(U)\}.
\end{align*}

The strict hyperbolicity domain is not connected, which makes the Riemann problem delicate to solve.

### 2.2. Wave curves

We begin by investigating some properties of the curves of admissible waves.

First, consider shock curves from a given left-hand state $U_0 = (h_0, u_0, a_0)$ consisting of all right-hand states $U = (h, u, a)$ that can be connected to $U_0$ by a shock wave. Thus, it follows from (1.6) that $U$ and $U_0$ are related by the Rankine-Hugoniot relations

\begin{align*}
-\lambda [h] + [hu] &= 0, \\
-\lambda [hu] + [h(a^2 + g_2)] &= 0, \quad (2.8)
\end{align*}
where \([h] = h - h_0\), etc, and \(\bar{\lambda} = \bar{\lambda}(U_0, U)\) is the shock speed.

Fix the state \(U_0\). A straightforward calculation from the Rankine-Hugoniot relations (2.8) shows that the restriction to the \((h, u)\) plane of the Hugoniot set consists of two curves given by

\[
u = u_0 \pm \sqrt{\frac{g}{2}} (h - h_0) \sqrt{\left(\frac{1}{h} + \frac{1}{h_0}\right)}.
\]

(2.9)

Moreover, along these two curves it holds

\[
\frac{du}{dh} = \pm \sqrt{\frac{g}{2}} \left(\sqrt{\frac{1}{h} + \frac{1}{h_0}} - (h - h_0) \frac{1}{2h^2 \sqrt{\frac{1}{h} + \frac{1}{h_0}}}ight)
\]

\[
\rightarrow \pm \sqrt{\frac{g}{h_0}} \text{ as } h \rightarrow h_0.
\]

Since the \(i\)-th-Hugoniot curve is tangent to \(r_i(U_0)\) at \(U_0\), we conclude that the first Hugoniot curve associated with the first characteristic field is

\[
\mathcal{H}_1(U_0) : \quad u := u_1(h, U_0) = u_0 - \sqrt{\frac{g}{2}} (h - h_0) \sqrt{\left(\frac{1}{h} + \frac{1}{h_0}\right)}, \quad h \geq 0,
\]

(2.10)

while one associated with the second characteristic field is

\[
\mathcal{H}_2(U_0) : \quad u := u_2(h, U_0) = u_0 + \sqrt{\frac{g}{2}} (h - h_0) \sqrt{\left(\frac{1}{h} + \frac{1}{h_0}\right)}, \quad h \geq 0.
\]

(2.11)

Along the Hugoniot curves \(\mathcal{H}_1, \mathcal{H}_2\), the corresponding shock speeds are given by

\[
\bar{\lambda}_{1,2}(U_0, U) = \frac{hu_{1,2} - h_0 u_0}{h - h_0}
\]

\[
= u_0 \mp \sqrt{\frac{g}{2}} \left(\frac{h + h_0^2}{h_0}\right), \quad h \geq 0,
\]

(2.12)

As is customary, the shock speed \(\bar{\lambda}_i(U_0, U)\) is required to satisfy Lax shock inequalities [17]:

\[
\lambda_i(U) < \bar{\lambda}_i(U_0, U) < \lambda_i(U_0), \quad i = 1, 2.
\]

(2.13)

Thus, the 1-shock curve \(S_1(U_0)\) initiating from the left-hand state \(U_0\) and consisting of all right-hand states \(U\) that can be connected to \(U_0\) by a Lax shock associated with the first characteristic field is

\[
S_1(U_0) : \quad u = u_1(h, U_0) = u_0 - \sqrt{\frac{g}{2}} (h - h_0) \sqrt{\left(\frac{1}{h} + \frac{1}{h_0}\right)}, \quad h > h_0.
\]

(2.14)

Similarly, the 2-shock curve \(S_2(U_0)\) issuing from a left-hand state \(U_0\) consisting of all right-hand states \(U\) that can be connected to \(U_0\) by a Lax shock associated with the second characteristic field is

\[
S_2(U_0) : \quad u = u_1(h, U_0) = u_0 + \sqrt{\frac{g}{2}} (h - h_0) \sqrt{\left(\frac{1}{h} + \frac{1}{h_0}\right)}, \quad h < h_0.
\]

(2.15)

We summarize these results in the following proposition.
Lemma 2.2 (Shock wave curves). Given a left-hand state $U_0$, the 1-shock curve $S_1(U_0)$ consisting of all right-hand states $U$ that can be connected to $U_0$ by a Lax shock is

$$S_1(U_0): \quad u = u_1(h, U_0) = u_0 - \sqrt{\frac{g}{2}} (h - h_0) \sqrt{\left(\frac{1}{h} + \frac{1}{h_0}\right)}, \quad h > h_0.$$ 

The 2-shock curve $S_2(U_0)$ consisting of all right-hand states $U$ that can be connected to $U_0$ by a Lax shock is

$$S_2(U_0): \quad u = u_1(h, U_0) = u_0 + \sqrt{\frac{g}{2}} (h - h_0) \sqrt{\left(\frac{1}{h} + \frac{1}{h_0}\right)}, \quad h < h_0.$$

In view of the Lax shock inequalities (2.13), we also conclude that the backward 1-shock curve $S_{B1}(U_0)$ issuing from a right-hand state $U_0$ and consisting of all left-hand states $U$ that can be connected to $U_0$ by a Lax shock associated with the first characteristic field is

$$S_{B1}(U_0): \quad u = u_1(h, U_0) = u_0 - \sqrt{\frac{g}{2}} (h - h_0) \sqrt{\left(\frac{1}{h} + \frac{1}{h_0}\right)}, \quad h < h_0,$$

Similarly, the backward 2-shock curve $S_{B2}(U_0)$ issuing from a right-hand state $U_0$ and consisting of all left-hand states $U$ that can be connected to $U_0$ by a Lax shock associated with the second characteristic field is

$$S_{B2}(U_0): \quad u = u_1(h, U_0) = u_0 + \sqrt{\frac{g}{2}} (h - h_0) \sqrt{\left(\frac{1}{h} + \frac{1}{h_0}\right)}, \quad h > h_0.$$ 

Next, we discuss the properties of rarefaction waves, i.e., smooth self-similar solutions to the system (1.1) associated with one of the two genuinely nonlinear characteristic fields. These waves satisfy the ordinary differential equation:

$$\frac{dU}{d\xi} = \frac{r_i(U)}{\nabla \lambda_i \cdot r_i(U)}, \quad \xi = x/t, \quad i = 1, 2.$$

For waves in the first family, we have

$$\frac{dh(\xi)}{d\xi} = -2h(\xi) \sqrt{\frac{g}{h(\xi)}} = -\frac{2}{3} \frac{1}{\sqrt{g}},$$

$$\frac{du(\xi)}{d\xi} = -2\sqrt{gb(\xi)} = \frac{2}{3},$$

$$\frac{da(\xi)}{d\xi} = 0.$$

It follows that

$$\frac{du}{dh} = -\sqrt{\frac{g}{h}},$$

therefore, the integral curve passing through a given point $U_0 = (h_0, u_0, a_0)$ is given by

$$u = u_0 - 2\sqrt{g}(\sqrt{h} - \sqrt{h_0}).$$

Moreover, the characteristic speed should increase through a rarefaction fan, i.e.,

$$\lambda_1(U) \geq \lambda_1(U_0),$$

which implies

$$h \geq h_0.$$
Thus, we define a rarefaction curve \( R_1(U_0) \) issuing from a given left-hand state \( U_0 \) and consisting of all the right-hand states \( U \) that can be connected to \( U_0 \) by a rarefaction wave associated with the first characteristic field as

\[
R_1(U_0) : \quad u = v_1(h, U_0) := u_0 - 2\sqrt{g}(\sqrt{h} - \sqrt{h_0}), \quad h \leq h_0. \tag{2.20}
\]

A 1-rarefaction wave is determined by

\[
u = u_0 + \frac{2}{3}\left(\frac{x}{t} - \frac{x_0}{t_0}\right) \tag{2.21}\]

while \( h \) is determined by the equation (2.20) and the component \( a \) remains constant.

Similarly, we define the rarefaction curve \( R_2(U_0) \) issuing from a given left-hand state \( U_0 \) and consisting of all the right-hand states \( U \) that can be connected to \( U_0 \) by a rarefaction wave associated with the second characteristic field as

\[
R_2(U_0) : \quad u = v_2(h, U_0) := u_0 + 2\sqrt{g}(\sqrt{h} - \sqrt{h_0}), \quad h \geq h_0. \tag{2.22}
\]

The \( u \)-component of the 2-rarefaction wave is determined by \( \text{(2.21)} \) and the \( h \)-component is given by \( \text{(2.22)} \).

We can summarize the above results in:

**Lemma 2.3** (Rarefaction wave curves). Given a left-hand state \( U_0 \), the 1-rarefaction curve \( R_1(U_0) \) consisting of all right-hand states \( U \) that can be connected to \( U_0 \) by a rarefaction wave associated with the first characteristic field is

\[
R_1(U_0) : \quad u = v_1(h, U_0) := u_0 - 2\sqrt{g}(\sqrt{h} - \sqrt{h_0}), \quad h \leq h_0. \tag{2.20}
\]

The 2-rarefaction curve \( R_2(U_0) \) consisting of all right-hand states \( U \) that can be connected to \( U_0 \) by a rarefaction wave associated with the second characteristic field is

\[
R_2(U_0) : \quad u = v_2(h, U_0) := u_0 + 2\sqrt{g}(\sqrt{h} - \sqrt{h_0}), \quad h \geq h_0. \tag{2.22}
\]

We will also need backward curves which we define here for completeness. Given a right-hand state \( U_0 \), the 1-rarefaction curve \( R^B_1(U_0) \) consisting of all left-hand states \( U \) that can be connected to \( U_0 \) by a rarefaction wave associated with the first characteristic field is

\[
R^B_1(U_0) : \quad u = v_1(h, U_0) := u_0 - 2\sqrt{g}(\sqrt{h} - \sqrt{h_0}), \quad h \geq h_0. \tag{2.23}
\]

The 2-rarefaction curve \( R^B_2(U_0) \) consisting of all left-hand states \( U \) that can be connected to \( U_0 \) by a rarefaction wave associated with the second characteristic field is

\[
R^B_2(U_0) : \quad u = v_2(h, U_0) := u_0 + 2\sqrt{g}(\sqrt{h} - \sqrt{h_0}), \quad h \leq h_0. \tag{2.24}
\]

In turn, we are in a position to define the wave curves, as follows

\[
W_1(U_0) = S_1(U_0) \cup R_1(U_0), \quad W^B_1(U_0) = S^B_1(U_0) \cup R^B_1(U_0),
\]

\[
W_2(U_0) = S_2(U_0) \cup R_2(U_0), \quad W^B_2(U_0) = S^B_2(U_0) \cup R^B_2(U_0). \tag{2.25}
\]

Some properties of the wave curves are now checked.
Lemma 2.4 (Monotonicity properties). The wave curve $W_1(U_0)$ can be parameterized in the form $h \mapsto u = u(h), h > 0$, where the function $u$ is strictly convex and strictly decreasing in $h$. The wave curve $W_2(U_0)$ can be parameterized in the form $h \mapsto u = u(h), h > 0$, where the function $u$ is strictly concave and strictly decreasing in $h$.

Proof. We only give the proof for the 1-wave curve $W_1(U_0)$, the proof for $W_2(U_0)$ being similar. For the shock part $S_1(U_0)$, we have

$$\frac{du}{dh} = -\sqrt{\frac{g}{2h} + \frac{h}{h_0} + h} < 0.$$ 

For the rarefaction part $R_1(U_0)$, we have

$$\frac{du}{dh} = -\sqrt{\frac{g}{h}} < 0.$$ 

This establishes the desired monotonicity property of $W_1(U_0)$.

The convexity of $W_1(U)$ follows from the fact that $du/dh$ is increasing. Indeed, along the shock part $S_1(U_0)$ it holds

$$\frac{d^2u}{dh^2} = \sqrt{\frac{g}{2h^2} \left( \frac{1}{2h^2} + \frac{h}{h_0} \right) \sqrt{\frac{1}{h} + \frac{1}{h_0}} + \frac{1}{2h^2} \sqrt{\frac{1}{h} + \frac{1}{h_0}} + \frac{h}{2h^2} - \frac{h}{2h^2} + \frac{h}{h_0} + \frac{h}{h_0}} > 0$$

and, along the rarefaction part $R_1(U_0)$,

$$\frac{d^2u}{dh^2} = \frac{\sqrt{g}}{2h^{3/2}} > 0,$$

which completes the proof. □

Next, we consider the 3-curve from a state $U_0$, which consists of all states $U$ that can be connected to $U_0$ by a stationary wave. As seen in (1.9), $U$ and $U_0$ are related by the Rankine-Hugoniot relations

$$[hu] = 0$$
$$\left[ \frac{u^2}{2} + g(h + a) \right] = 0.$$ 

This leads to a natural definition of a curve parameterized in $h$:

$$W_3(U_0) : \left\{ \begin{array}{l}
u = u(h) = \frac{h_0 u_0}{h}, \\
a = a(h) = a_0 + \frac{u^2 - u_0^2}{2g} + h - h_0. \end{array} \right. \quad (2.27)$$

3. Admissibility conditions for stationary waves

3.1. Two possible stationary jumps. In view of the discussion in the previous section, the states across a stationary wave are constraint by the Rankine-Hugoniot relations (2.26). From a given left-hand state we have to determine the right-hand state, which has three components, determined by the two equations (2.26). Moreover, since the component $a$ changes only through stationary waves (which
propagate with zero speed) for given bottom levels \( a_{\pm} \) we should solve for \( u \) and \( h \) in terms of \( a \). Thus, we rewrite (2.26) in the form
\[
    u = \frac{h_0 u_0}{h},
\]

\[
    a_0 - a + \frac{u^2 - u_0^2}{2g} h - h_0 = 0.
\]

Substituting for \( u \) and re-arranging the terms, we obtain
\[
    u = \frac{h_0 u_0}{h},
\]

\[
    a_0 - a + \frac{u_0^2}{2g} (\frac{h_0^2}{h^2} - 1) h - h_0 = 0.
\]

This leads us to search for roots of the function
\[
    \varphi(h) := a_0 - a + \frac{u_0^2}{2g} (\frac{h_0^2}{h^2} - 1) h - h_0.
\]

Let us set
\[
    h_{\min}(U_0) := \left( \frac{u_0^2 h_0^2}{g} \right)^{1/3},
\]

\[
    a_{\min}(U_0) := a_0 + \frac{u_0^2}{2g} (\frac{h_0^2}{h_{\min}^2} - 1) h_{\min} - h_0.
\]

Some useful properties of the function \( \varphi \) in (3.1) are now derived.

**Lemma 3.1.** Suppose that \( U_0 = (h_0, u_0, a_0) \) and \( a \) are given with \( u_0 \neq 0 \). The function \( \varphi : (0, +\infty) \to \mathbb{R} \) is smooth and convex and, for some \( h_{\min} \), it is decreasing in the interval \((0, h_{\min})\) and is increasing in the interval \((h_{\min}, +\infty)\), with
\[
    \lim_{h \to 0} \varphi(h) = \lim_{h \to +\infty} \varphi(h) = +\infty.
\]

Furthermore, if \( a \geq a_{\min}(U_0) \) then the function \( \varphi \) has two roots \( h_{\pm}(U_0) \) with \( h_{-}(U_0) \leq h_{\min}(U_0) \leq h_{+}(U_0) \). These inequalities are strict whenever \( a > a_{\min}(U_0) \).

**Proof.** The smoothness of the function \( \varphi \) and the limiting conditions are obvious. Moreover, we have
\[
    \frac{d\varphi(h)}{dh} = -\frac{u_0^2 h_0^2}{gh^3} + 1
\]

(for \( u_0 \neq 0 \)) which is positive if and only if
\[
    h > \left( \frac{u_0^2 h_0^2}{g} \right)^{1/3} = h_{\min}(U_0).
\]

This establishes the monotonicity property of \( \varphi \). Furthermore, we have
\[
    \frac{d^2\varphi(h)}{dh^2} = \frac{3u_0^2 h_0^2}{gh^4} \geq 0,
\]

which shows the convexity of \( \varphi \). If \( a > a_{\min}(U_0) \), then \( \varphi(h_{\min}(U_0)) < 0 \). The other conclusions follow immediately. \( \square \)

It is straightforward to check:
Proposition 3.3. Fix a left-hand state \( h \). The roots \( a \) satisfy the following inequalities:
\[
\begin{align*}
& h_{\min}(U_0) > h_0, \quad U_0 \in A_1 \cup A_3, \\
& h_{\min}(U_0) < h_0, \quad U_0 \in A_2, \\
& h_{\min}(U_0) = h_0, \quad U_0 \in C,
\end{align*}
\]

The roots \( h^* \) and \( h_* \) satisfy the following inequalities:
\[
\begin{align*}
& \text{(i)} \quad \text{If } a > a_0, \text{ then } h_*(U_0) < h_0 < h^*(U_0). \\
& \text{(ii)} \quad \text{If } a < a_0, \text{ then } h_0 < h_*(U_0) \quad U_0 \in A_1 \cup A_3, \\
& \quad \quad \quad h_0 > h^*(U_0) \quad U_0 \in A_2.
\end{align*}
\]

The function \( a_{\min}(U_0) \) satisfy the following inequalities:
\[
\begin{align*}
& a_{\min}(U_0) < a_0, \quad (h_0, u_0) \in A_1 \cup A_2 \cup A_3, \\
& a_{\min}(U_0) = a_0, \quad (h_0, u_0) \in C_\pm.
\end{align*}
\]

The states that can be connected by stationary waves are characterized as follows.

Proposition 3.4. For \( u_0 \neq 0 \), the state \((h_1(U_0), u_1(U_0))\) belongs to \(A_1\) if \( u_0 < 0 \), and belongs to \(A_3\) if \( u_0 > 0 \), while the state \((h_2(U_0), u_2(U_0))\) always belongs to \(A_2\). Moreover, we have
\[
(h_{\min}(U_0), u = h_0 u_0 / h_{\min}(U_0)) \in \begin{cases} C^+, & u_0 > 0, \\ C^-, & u_0 < 0. \end{cases}
\]

It is interesting to observe that the shock speed in the genuinely nonlinear characteristic fields will change sign along the shock curves. Therefore, it exchanges its order with the linearly degenerate field, as stated in the following theorem.

Proposition 3.5. (a) If \( U_0 \in A_1 \), then there exists \( \bar{U}_0 \in S_1(U_0) \cap A_2^+ \) corresponding to \( h = \bar{h} > h_0 \) such that
\[
\begin{align*}
& \bar{\lambda}_1(U_0, \bar{U}_0) = 0, \\
& \bar{\lambda}_1(U_0, U) > 0, \quad U \in S_1(U_0), h \in (\bar{h}_0, \bar{h}_0), \\
& \bar{\lambda}_1(U_0, U) < 0, \quad U \in S_1(U_0), h \in (\bar{h}_0, +\infty).
\end{align*}
\]
If \( U_0 \in A_2 \cup A_3 \), then
\[
\bar{\lambda}_1(U_0, U) < 0, \quad U \in S_1(U_0). \tag{3.10}
\]

(b) If \( U_0 \in A_3 \), then there exists \( U_0 \in S_2^B(U_0) \cap A_2^- \) corresponding to \( h = h > h_0 \) such that
\[
\bar{\lambda}_2(U_0, U) = \lambda_2(U_0, \bar{U}_0) = 0, \quad U \in S_1(U_0).
\]
\[
\bar{\lambda}_2(U_0, U) > 0, \quad U \in S_2^B(U_0), \quad h \in (h_0, \bar{h}_0),
\]
\[
\bar{\lambda}_2(U_0, U) < 0, \quad U \in S_2^B(U_0), \quad h \in (\bar{h}_0, +\infty).
\tag{3.11}
\]

If \( U_0 \in A_1 \cup A_2 \), then
\[
\bar{\lambda}_2(U_0, U) > 0, \quad U \in S_2^B(U_0). \tag{3.12}
\]

3.2. Two-parameter wave sets. From Proposition 3.4 and the arguments in the previous section, we can now construct wave composites. It turns out that two-parameter wave sets can be constructed. For definiteness, we now illustrate this feature on a particular case. Suppose that \( U_0 = (h_0, u_0, a_0) \in A_2^+ \). We can use a stationary wave from \( U_0 \) to a state \( U_m = (h_m, u_m, a_m) \in A_2^+ \) using \( h^* \), followed by another stationary wave from \( U_m \) to \( U \in A_1 \) using the corresponding value \( h_* \), then we continue with 1-waves, and as in \( A_1 \) the characteristic speed is positive. As \( a_m \) can vary, the set of such states \( U \) forms a two-parameter set of composite waves containing first and third waves. Such wave sets were constructed even for strictly hyperbolic systems by Hayes and LeFloch \[12\].

To make the Riemann problem well-posed, it is necessary to impose an additional admissibility criterion.

3.3. The monotonicity criterion. Since the Riemann problem for (1.1) may in principle admit up to a one-parameter family of solutions, we now require that the Riemann solutions of interest satisfy a monotonicity condition in the component \( a \).

(MC) (Monotonicity Criterion) Along any stationary curve \( W(U_0) \), the bottom level \( a \) is a monotone function in \( h \). The total variation of the bottom level component of any Riemann solution must not exceed (and, therefore, is equal to) \(|a_L - a_R|\), where \( a_L, a_R \) are left-hand and right-hand cross-section levels.

A similar selection criterion was used by Isaacson and Temple \[14, 15\] and by LeFloch and Thanh \[21\], and by Goatin and LeFloch \[8\]. Under the transformation (if necessary)
\[
x \rightarrow -x, \quad u \rightarrow -u,
\]
a right-hand state \( U = (h, u, a) \) transforms into a left-hand state of the form \( U' = (h, -u, a) \). Therefore, it is not restrictive to assume that
\[
a_L < a_R. \tag{3.13}
\]

Lemma 3.6. The Monotonicity Criterion implies that stationary shocks do not cross the boundary of strict hyperbolicity. In other words, we have:

(i) If \( U_0 \in A_1 \cup A_3 \), then only the stationary shock based on the value \( h^*(U_0) \) is admissible.

(ii) If \( U_0 \in A_2 \), then only the stationary shock using \( h^*(U_0) \) is admissible.
Proof. Recall that the Rankine-Hugoniot relations associated with the linearly degenerate field (2.27) implies that the component $a$ can be expressed as a function of $h$:

$$ a = a(h) = a_0 + \frac{u^2 - u_0^2}{2g} + h - h_0, $$

where

$$ u = u(h) = \frac{h_0 u_0}{h}. $$

Thus, differentiating $a$ with respect to $h$, we find

$$ a'(h) = \frac{uu'}{g} + 1 = -u \frac{h_0 u_0}{gh^2} + 1 = -\frac{u^2}{gh} + 1 $$

which is positive (resp. negative) if and only if

$$ u^2 - gh < 0 \quad (\text{resp. } u^2 - gh > 0) $$

or $(h, u, a) \in A_2$ (resp. $\in A_1$ or $\in A_3$). Thus, in order that $a'$ keeps the same sign, the point $(h, u, a)$ must remain on the same side as $(h_0, u_0, a_0)$ with respect to $C_\pm$. The conclusions in (i) and (ii) follow. \qed

It follows from Lemma 3.6 that for a given $U_0 = (h_0, u_0, a_0) \in A_i$, $i = 1, 2, 3$, and a level $a$, we can define a unique point $U = (h, u, a)$ so that the two points $U_0, U$ can be connected by a stationary wave satisfying the (MC) criterion. We have a mapping

$$ SW(\cdot, a) : [0, \infty) \times \mathbb{R} \times \mathbb{R}_+ \to [0, \infty) \times \mathbb{R} \times \mathbb{R}_+ $$

such that $U_0$ and $U$ can be connected by a stationary wave satisfying the (MC) condition. Observe that this mapping is single-valued except on the hypersurface $\mathcal{C}$, where it has two-values.

Let us use the following notation: $W_i(U_0, U)$ will stand for the $i$th wave from a left-hand state $U_0$ to the right-hand state $U$, $i = 1, 2, 3$. To represent the fact that the wave $W_i(U_1, U_2)$ is followed by the wave $W_j(U_2, U_3)$, we use the notation:

$$ W_i(U_1, U_2) \oplus W_j(U_2, U_3). \quad (3.15) $$

4. The Riemann Problem

In this section we construct the solutions of the Riemann problem, by combining Lax shocks, rarefaction waves, and stationary waves satisfying the admissibility condition (MC).

Recall that for general strictly hyperbolic systems of conservation laws, the solution to the Riemann problem exist when the initial jump is sufficiently small only. That is to say that the right-hand states $U_R$ should lie in a small neighborhood of the left-hand state $U_L$. However, for the system (1.1), we can cover large data and essentially cover a full domain of existence for any given left-hand state. More precisely, we determine the precise range of right-hand states in which the Riemann solution exists.
4.1. Solutions containing only one wave of each characteristic family. We begin by constructing solutions containing only one wave corresponding to each characteristic field which is identified as each family of waves. This structure of solutions is standard in the theory of strictly hyperbolic system of conservation laws. In the next subsection we will consider solutions that contain up to two waves in the same family. The following theorem deals with the case where the left-hand state \( U_L \) is in \( A_1 \).

**Theorem 4.1.** Let \( U_L \in A_1 \) and set \( U_1 := \text{SW}(U_L, a_R), \{U_2\} = \mathcal{W}_1(U_1) \cap \mathcal{W}_2(U_R) \). Then, the Riemann problem \((1.1)-(1.2)\) admits an admissible solution with the following structure

\[
W_3(U_L, U_1) \oplus W_1(U_1, U_2) \oplus W_2(U_2, U_R),
\]

provided \( h_2 \leq h_1 \). (Figure 2).

**Proof.** Observe that the set of composite waves \( \text{SW}(W_1(U_L), a_R) \) consists of three monotone decreasing curves, and each lies entirely in each region \( A_i, i = 1, 2, 3 \). The monotone increasing backward curve \( \mathcal{W}_2(U_R) \) therefore may cut the three composite curves at a unique point, two point, or else does not meet the wave composite set. The Riemann problem therefore may admit a unique solution, two solutions, or has no solution.

The state \( U_L \) belongs to \( A_1 \) and in this region, the \( \lambda_3 \) is the smallest of the three characteristic speeds. A stationary wave from \( U_L = (h_L, u_L, a_L) \) to \( U_1 = (h_1, u_1, a_R) \) exists, since \( a_L \leq a_R \). Moreover, by Lemma 3.6, we have \( U_1 \in A_1 \).

If \( h_2 \leq h_1 \), then the stationary wave is followed by a 1-rarefaction wave with positive speed, and then can be continued by a 2-wave \( W_2(U_2, U_R) \). If \( h_2 > h_1 \), then the 1-wave in (3.15) is a shock wave. Since \( h_2 \leq h_1 \) and \( U_1 \in A_1 \), the shock speed \( \lambda_2(U_1, U_2) \geq 0 \), and thus it can follow a stationary wave (with zero speed).
Moreover, it is derived from (2.12) that
\[ \tilde{\lambda}_1(U_1, U_2) = u_1 - \sqrt{\frac{g}{2}} \left( \frac{h_2^2}{h_1^2} \right) \]
\[ = \frac{h_2^2 u_1 - h_1 u_1}{h_2 - h_1} \]
\[ = u_2 - \sqrt{\frac{g}{2}} \left( \frac{h_1^2}{h_2^2} \right) \]

thus
\[ \tilde{\lambda}_1(U_1, U_2) \leq u_2 + \sqrt{\frac{g}{2}} \left( h - \frac{h_R^2}{h_R} \right) = \tilde{\lambda}_2(U_2, U_R). \] (4.2)

This means the 1-shock \( S_1(U_1, U_2) \) can always follow the 2-shock \( S_2(U_2, U_R) \). Similar for rarefaction waves. Therefore, the solution structure (3.15) holds. \( \square \)

The following theorem deals with the case where the left-hand state \( U_L \) is in \( A_1 \cup A_2 \).

**Theorem 4.2.** Let \( U_L \in A_1 \cup A_2 \). Then there exists a region of values \( U_R \) such that \( SW(W_1(U_L), a_R) \cap W_2^R(U_R) \neq \emptyset \). In this case this intersection may contain either only one or both points \( U_1 \in A_2 \) and \( U_2 \in A_3 \). The Riemann problem (1.1)-(1.2) therefore has a solution with the structure
\[ W_1(U_L, U_3) \oplus W_3(U_3, U_1) \oplus W_2(U_1, U_R), \] (4.3)
where \( U_3 \in W_1(U_L) \) is the point such that \( U_1 = SW(U_3, a_R) \), and also
\[ W_1(U_L, U_4) \oplus W_3(U_4, U_2) \oplus W_2(U_2, U_R), \] (4.4)
where \( U_4 \in W_1(U_L) \) is the point such that \( U_2 = SW(U_4, a_R) \), if \( h_2 \geq \bar{h}_R \) whenever \( U_R \in A_2 \). (Figure 3)

**Proof.** The solution may begin with a 1-wave, either 1-shock with a negative shock speed to a state \( U_3 \), or a 1-rarefaction wave with \( \lambda_1(U_3) \leq 0 \), followed by a stationary wave \( W_3(U_3, U_1) \) from \( U_3 \) to \( U_1 \), then followed by a 2-wave \( W_2(U_1, U_R) \) from \( U_1 \) to \( U_R \). It is similar in the case of \( U_2 \). However, in order that the stationary wave \( W_3(U_4, U_2) \), for some \( U_4 \in W_1(U_L) \) and \( U_4 \in A_3 \) obviously, to be followed by a 2-wave \( W_2(U_2, U_R) \), it is required that the wave is a shock with non-negative shock speed \( \lambda_2(U_2, U_R) \). This is equivalent to \( h_2 \geq \bar{h}_R \). \( \square \)

**Theorem 4.3.** Let \( U_L \in A_3 \) and \( U_R \in A_1 \cup A_2 \), and set \( U_1 = SW(W_1^R(U_R), a_L) \cap W_1(U_L) \) and \( U_2 = SW(U_1, a_R) \in W_2^R(U_R) \).

(i) If \( U_1 \in A_3^+ \cup C_+ \cup \{ u = 0 \} \), the Riemann problem (1.1)-(1.2) has a solution with the following structure
\[ W_1(U_L, U_1) \oplus W_3(U_1, U_2) \oplus W_2(U_2, U_R). \] (4.5)

(ii) If \( U_1 \in A_3^+ \cup C_- \), provided \( h_R \geq \bar{h}_2 \), the Riemann solution (4.5) also exists.

(iii) If \( U_1 \in A_1 \cup A_3 \), the construction (4.5) does not make sense. (Figure 4).
Proof. If $U_1 \in A_2 \cup C$, the non-positive speed wave $W_1(U_L, U_1)$ can be followed by a stationary wave $W_3(U_1, U_2)$.

When $U_2 \in A_2^-$, if $U_1 \in A_2^+ \cup C_+ \cup \{u = 0\}$, then this stationary wave can always be followed by a 2-wave $W_2(U_2, U_R)$, since the wave speed of the 2-wave is positive. This establishes (i).

If $U_1 \in A_2^- \cup C_-$, the wave speed of the 2-wave $W_2(U_2, U_R)$ is non-negative if and only if $h_R \geq \bar{h}_2$. This proves (ii).
If $U_1 \in A_1$, the 1-wave has positive speed. So it can not be followed by a stationary wave. If $U_1 \in A_3$, then $U_2 \in A_3$ by the (MC) criterion. So the 2-wave $W_2(U_3, U_R)$ has negative speed. So it can not be proceeded by a stationary wave. This proves (iii).

The above theorem enables $U_R$ to vary in each region $A_1, A_2$, and $A_3$. The next theorem enables $U_L$ to vary in all the three regions.

**Theorem 4.4.** Let $U_R \in A_3$. Set $U_1 = SW(U_R, a_L)$, $U_2 = W_2^B(U_1) \cap W_1(U_L)$. A Riemann solution exists and has the following structure

$$W_1(U_L, U_2) \oplus W_2(U_2, U_1) \oplus W_3(U_1, U_R),$$

provided $h_2 \leq \bar{h}_1$. (Figure 3).

**Proof.** The stationary wave $W_3(U_1, U_R)$ turns out to have the greatest wave speed. In order for this wave to be proceeded by the 2-wave $W_2(U_1, U_2)$, the wave speed of this 2-wave has to be non-positive. This is equivalent to the condition $h_2 \leq \bar{h}_1$, according to Proposition (3.5). Similar to (4.4), we have

$$\lambda_1(U_L, U_2) \leq \lambda_2(U_2, U_1),$$

so that the 1-wave $W_1(U_L, U_2)$ can follow the 2-wave $W_2(U_2, U_1)$. □

4.2. **Solutions containing more than one wave of each characteristic family.** It is remarkable feature of the shallow water system that we can also construct solutions with four elementary waves, using three available characteristic fields. This illustrates one of the difficulties in coping with the Riemann problem when the system under consideration is not strictly hyperbolic.
Theorem 4.5. Let $U_L \in A_2 \cup A_3$ and set $U_+ = W_1(U_L) \cap C_{-}, \{U_1\} = SW(U_+, a_R) \cap A_1, \{U_2\} = W_1(U_1) \cap W_2^b(U_R)$. The Riemann problem (1.1)-(1.2) has a solution with the following structure

$$R_1(U_L, U_+) \oplus W_3(U_+, U_1) \oplus W_1(U_1, U_2) \oplus W_2(U_2, U_R),$$

provided $h_2 \leq \tilde{h}_1$. (Figure 6).

Theorem 4.6. For any $U_L$, set $\{U_1\} = SW(C_{-}, a_R) \cap W_2^b(U_R) \cap A_2, \{U_2\} = W_1(U_2) \cap W_1(U_L)$. Then the Riemann problem (1.1)-(1.2) has a solution with the following structure

$$W_1(U_L, U_3) \oplus R_2(U_3, U_2) \oplus W_3(U_2, U_1) \oplus W_2(U_1, U_R),$$

provided $h_R \geq \bar{h}_1$ and $h_3 \leq h_2$. (Figure 7).

Thus, we see that the Riemann problem (1.1)-(1.2) has a solution consisting of a 1-, a 3-, and two 2-waves.

It is interesting to note that there are solutions satisfying the (MC) criterion which contain three waves with the same speed (zero). This is the case when a stationary wave jumps from the level $a = a_L$ to an intermediate level $a_m$ between $a_L$ and $a_R$, followed by an "intermediate" $k$-shock with zero speed at the level $a_m$, $k = 1, 3$, and then followed by another stationary wave jumping from the level $a_m$ to $a_R$. Thus, there are only two possibilities:

(i) $U_L$ belongs to $A_1$ and a 1-shock with zero speed is used.

(ii) $U_R$ belongs to $A_3$ and a 2-shock with zero speed is used.

We just describe the first case (i), as the second case is similar. Recall from Proposition 3.5 that for any $U \in A_1$, there exists a unique point denoted by $\tilde{U} \in W_1(U) \cap A_2$ such that $\check{\lambda}_1(U, \tilde{U}) = 0$. 

}\end{quote}
Theorem 4.7. \( U_L \in A_1 \) and set
\[
SW(U_L, [a_L, a_R]) := \bigcup_{a \in [a_L, a_R]} SW(U_L, a),
\]
\[
\overline{SW}(U_L, [a_L, a_R]) := \{ \bar{U} \mid U \in SW(U_L, [a_L, a_R]) \}.
\]
Whenever
\[
\overline{SW}(U_L, [a_L, a_R]) \cap W^B_2(U_R) \neq \emptyset
\]
there exist \( a_m \in [a_L, a_R] \), \( U_1 = SW(U_L, a_m) \), and
\[
U_2 \in \overline{SW}(U_L, [a_L, a_R]) \cap W^B_2(U_R)
\]
that defines a solution with the structure
\[
W_3(U_L, U_1) \oplus S_1(U_1, \bar{U}_1) \oplus W_3(\bar{U}_1, U_2) \oplus W_2(U_2, U_R).
\]
