Toward a New Model of the Central Engine of GRB*

Plamen P. Fiziev†, Denitsa R. Staicova‡

Abstract

We present new developments of the simple model of the central engine of GRB, proposed recently. The model is based on minimal assumptions: some rotating compact relativistic object at the center and stable perturbations of its rotating gravitational field, described by Teukolsky Master Equation. We show that using nonstandard polynomial solutions to the angular Teukolsky equation we can describe the formation of collimated jets of various forms. Appearance of imaginary part of the superradiance-like frequency is established for the first time for pure vacuum black hole jet solutions of Teukolsky equation.

1 Introduction

Gamma-ray bursts (GRB) are among the most powerful astrophysical objects in the Universe. They are considered as highly collimated ($\theta_{\text{jet}} \sim 2^\circ - 5^\circ$) explosions on cosmic distances emitting huge amounts of energy in very short periods of time ($\sim$ seconds) [1, 2, 3, 4]. Despite the increasing amount of observational data, the theory of GRB is still far from being clear. One of the major problems is the lack of understanding of the nature of the so called central engine – its physical nature and the process involved in the emission of huge amounts of energy ($\sim 10^{51} - 10^{54}$ erg).

Unexpected feature discovered by the mission SWIFT is the existence of flares – a surprising evidence of late time activity of the central engine [3, 4, 5]. There are clear indications that in some cases the flares are produced by energy injection by the central engine. Although number of theories and models have been suggested to explain the light curves of GRB, the process however remains a mystery that cannot be solved without a good model of the central engine.

The current focus of GRB physics is on the propagation of the emitted matter that can explain the observed light curves. The most used is the fireball model (for details see [1]). That model, however, cannot explain the observed flares. Another basic model is the cannonball model of long GRBs [6].

The central engine – the physical object producing the GRB – before SWIFT epoch usually was considered to be a Kerr [7] black hole (BH) – a hypothetical result of the death of a massive star for the long GRB ($T_{90} > 2s$) (see [3], [8]) or as part of a binary merger of compact objects (BH-BH, NS-BH, or NS-NS; where NS=neutron star) for short GRB ($T_{90} < 2s$). The first hypotheses seems to be hardly compatible with the observed flares, produced via energy injection by the central engine. The second hypotheses was recently refuted by the existing detectors of gravitational waves [9]. The latest analysis shows that the short and long GRB may have a similar central engine (except for its duration) [10].

It was believed that one of the possible models for such engine could be a Kerr black hole (KBH) in super-radiant mode [11, 12] – the wave analogue of the Penrose process. The late-time evolution of a perturbation of a Kerr metrics is governed by the quasi-normal modes (QNM) – oscillation with complex frequencies that are determined only by the BH parameters (mass, charge and angular momentum).

---

*This article is based on the talk given on 18.09.2007 at the Fourth Aegean Summer School, 17-22 September 2007, Lesvos, Greece
†E-mail: fiziev@phys.uni-sofia.bg
‡E-mail: denijane@gmail.com
Those frequencies are obtained solving the Teukolsky Master Equations with certain boundary conditions. According to the standard theory, superradiance occurs in the process of scattering of exterior waves on KBH for real frequencies $\omega < \omega_{\text{critical}} = am/2Mr_+$ ($m > 0$ – integer, $r_+ > 0$ being the event horizon radii) [12].

Another process which was currently related with the GRB central engine is the Blandford-Znajek process [14] based on electromagnetic extraction of energy from KBH. Sometimes it is considered as an electromagnetic analog to Penrous process. The realization of this idea has its own achievements and problems (see in [14]).

However, the Penrose process seems to be not efficient enough to explain the huge amount of promptly radiated energy in relativistic jets ($\sim 10^{41} - 10^{44}$ erg) [15], as shown long time ago by Wald (see in [12]).

In a series of talks [16], we have presented a mathematical description of relativistic jets that can help to penetrate into the mysterious physics behind the central engine. A simple model, based on novel solutions of the angular Teukolsky equation, however, not regular, but singular ones [16, 17, 19] was proposed. They seem to describe in natural way the most important feature of the relativistic jets – their collimation. In this paper, we would like to announce the recent results of our numerical simulations. The main new result is the appearance of a complex critical frequency, which play the role of the well known superradiance ones. Its imaginary part is of the same order of amplitude as the real part and yields an exponential abatement of the superradiance-like emission in jets, created by KBH.

2 A Toy Model of Central Engine

Our simplified model was already presented in [16, 17]. Thus, we will omit the details and give only a summary of the basic ideas behind it. In brief, the jets observed in GRBs require a rotating object – KBH or a compact massive matter object, to produce them. In the jet’s problem we can use the Kerr metric to describe the gravitational field of that object at least in a very good approximation [17], since the visible jets are formed at distances about 20-100 event-horizon-radii [15]. At such distances one practically is not able to distinguish the exterior field of KBH from the exterior field of rotating objects of complete different kinds (see for example [17] and the references therein).

As a result, the only working way to get information about the real nature of the central engine is to study jet’s spectra. The different objects yield different frequencies of perturbations of space-time geometry, because of the different boundary conditions on their surface (See the articles by Fiziev in [13] and [17]). Thus, measuring the real jet’s frequencies one can get indisputable evidences about the actual nature of the central engine.

In the present article we are probing only the KBH model for generation of jets. The results for other possible models will be discussed elsewhere. Due to the well known "no hair" theorems, the non-charged KBH solutions of Einstein equations, which potentially may be of astrophysical interest, depend on extremely small number of parameters – the mass and the angular momentum. The unique boundary conditions on the event horizon yield unique robust spectra, defined only by the mass and the angular momentum of the KBH. These spectra differ essentially from the spectra of relativistic jets, generated by central engine of any other nature. Thus the KBH-based model of relativistic jets seems to be easily recognizable from observational point of view, at least up to the disguise effects by the KBH environment.

Using the Teukolsky Master Equation (TME) we acquire the linearized perturbation of the Kerr metric (see [11]). From there, we follow the procedure established by Teukolsky for separation of the variables in the TME using the substitution: $\Phi = e^{(\omega t + \mu \phi)} S(\theta) R(r)$ where $m = 0, \pm 1, \ldots$ and $\omega = \omega_R + i\omega_I$ is a complex frequency (with $\omega_I > 0$).

The exact solution of radial equation for the radial function $R(r)$:

$$\Delta \frac{d^2}{dr^2} R(r) + 2 (s + 1)(r - M) \frac{d}{dr} R(r) + \left( \frac{K^2 - 2is(r - M)K}{\Delta} - 4i\omega R - \lambda \right) R(r) = 0$$

(1)

can be expressed in terms of confluent Heun functions [16, 17, 18, 19]).
The most important for GRB physics seem to be electromagnetic waves with \( s = -1 \). In this case two independent exact solutions in outer domain are:

\[
R_1 (r) = C_1 e^{-i\omega r} \left( r - r_- \right)^{i\frac{\omega (a^2 + r_+^2) + am}{r_+ - r_-}} \left( r - r_+ \right)^{i\frac{\omega (a^2 + r_-^2) + am}{r_+ - r_-} + 1} \, \text{HeunC} \left( \alpha, \beta, \gamma, \delta, \eta, -\frac{r - r_+}{r_+ - r_-} \right)
\]

and

\[
R_2 (r) = C_2 e^{-i\omega r} \left( r - r_+ \right)^{i\frac{\omega (a^2 + r_+^2) + am}{r_+ - r_-}} \left( r - r_- \right)^{i\frac{\omega (a^2 + r_-^2) + am}{r_+ - r_-} + 1} \, \text{HeunC} \left( \alpha, -\beta, \gamma, \delta, \eta, -\frac{r - r_-}{r_+ - r_-} \right),
\]

where: \( \alpha = 2i(\gamma_+ - r_r) \omega, \beta = -2i(\omega (a^2 + r_r^2) + am) \), \( \gamma = -2i(\omega (a^2 + r_r^2) + am) + 1 \), \( \delta = -2i(\gamma_+ - r_r) \omega(1 - i (r_r - r_r) \omega) \), \( \eta = \frac{1}{2} r_r^4 + (4i\omega - 8a^2 r_r) r_r^3 + (1 - 4a\omega m - 2a^2 a^2 - 2A) (r_r^2 - r_r^2) + (4i\omega r_r - 8i\omega r_r + 4A - 4a^2 a^2 + 2) r_r - 4a^2 (m + \omega a)^2 \)

For the angular function \( S(\theta) \), as an exact solution the angular equation:

\[
\left[ (1 - u^2) S'_{lm,u} \right]_u + \left[ (a\omega u)^2 + 2a\omega su + s + s A_{lm} - \frac{(m + su)^2}{1 - u^2} \right] S_{lm} = 0
\]

we use polynomial solutions in terms of Heun polynomials \([16, 17, 18, 19]\). In equation \( 4 \) we are using the variable \( u = \cos \theta \). Putting \( \Omega = \omega a \) we have explicit expressions:

\[
S^{(-1)}_{s,s,m}(\theta) = e^{\pm i \Omega \cos \theta} \left( \cos \frac{\theta}{2} \right)^{\frac{|s-m|}{2}} \left( \sin \frac{\theta}{2} \right)^{-\frac{|s+m|}{2}} \times \text{HeunC} \left( \pm 4\Omega, |s-m|, |s+m|, -4\Omega s, \frac{m^2 - s^2}{2} + 2\Omega s - \Omega^2 - A - s, \cos^2 \frac{\theta}{2} \right)
\]

and

\[
S^{(1)}_{s,s,m}(\theta) = e^{\pm i \cos \theta} \left( \cos \frac{\theta}{2} \right)^{\frac{|s-m|}{2}} \left( \sin \frac{\theta}{2} \right)^{-\frac{|s+m|}{2}} \times \text{HeunC} \left( \pm 4\Omega, |s+m|, |s-m|, -4\Omega s, \frac{m^2 - s^2}{2} - 2\Omega s - \Omega^2 - A - s, \sin^2 \frac{\theta}{2} \right).
\]

The polynomial solutions of TME describe one way waves and are most suitable for modeling of the relativistic jets \([17]\). Posing the polynomial condition on the angular solutions, we obtain for the one way electromagnetic waves on Kerr background the explicit formula

\[
A_{s=-1,m}(\omega) = -\Omega^2 - 2\Omega m \pm 2\sqrt{\Omega^2 + \Omega m}. \tag{7}
\]

This simple form of the separation constant \( A \) for polynomial solutions is the most significant mathematical advantage of our model of jets, generated by electromagnetic perturbations of Kerr metric.

The KBH boundary condition for the radial equation ca be obtained using the following assumptions:

1. On the horizon we allow only incoming in the horizon waves. Then we obtain the different solution working in each interval of frequencies: a) for \( m = 0 \), only \( R_2 \); b) for \( m > 0 \) \( R_1 \), if \( \omega_R \in (-\omega_{cr}, 0) \) and \( R_2 \) on the outside; for \( m < 0 \) \( R_1 \) when \( \omega_R \in (0, \omega_{cr}) \) and \( R_2 \) outside.

2. On infinity we allow only outgoing waves. In general, the function \( \mathcal{R} \) is a linear combination of an ingoing \( (R_r) \) and an outgoing \( (R_-) \) wave: \( \mathcal{R} = C_- R_- + C_+ R_+ \) with some constants \( C_- \) and \( C_+ \). In order to have only outgoing waves, we need to have \( C_- = 0 \). This equation defines the spectral condition for the frequency \( \omega \). The main mathematical problem is that the explicit form of the constant \( C_- \) is not known. Therefore to solve the spectral problem we use the around way, proposed by Fiziev in \([13]\):
The straightforward check shows that for solutions (2), (3) we have \( \lim_{r \to \infty} \frac{R}{\bar{R}} = 0 \) in the special direction \( \arg(r) = 3\pi/2 - \arg(\omega) \) in complex plane \( \mathbb{C}_r \). Taking \( \lim_{r \to \infty} \frac{R}{\bar{R}} \) in this direction, we obviously obtain the spectral condition for \( \omega \) in the form

\[
C_{\omega} = \lim_{r \to \infty} \frac{R}{\bar{R}} = 0.
\]

3 Numerical Results

The numerical evaluations with confluent Heun functions are generally too complicated for a number of reasons. At present the only software package able to deal with them is Maple. Unfortunately, the existing versions of Maple package require too much time for numerical evaluation, even on modern fast computers with large amount of memory. Additional problem is that the procedure calculating those functions is not working well in the whole complex plane and special attention must be paid to the regions where the procedure becomes unstable.

3.1 Visual Resemblance of the Solutions and Real Jets

We already reported that plotting the solutions of the angular equations with relation (7), we obtain figures that resemble jets (see [16, 18]). Illustrations of the jet features of the model can be seen from the animations of such oscillating solutions on our site [20].

An interesting comparison with Nature can be obtained looking at the picture of the discovered by NASA’s Spitzer Space Telescope “tornado-like” object Herbig-Haro 49/50, created from the shock waves of powerful protostellar jet hitting the circum-stellar medium. "More observations should help us to unravel its mysterious nature" [21]. Without any doubts in this case the jet is not related with BH. This one, as well as many other real observations prove the presence of BH to be not necessary for generation of jets. The collimated jets of GRB are another example of a possible application of our simple model. There the main problem still remains the physical nature of the central engine, too. Clearly, if possible, a common model of jets of different scales is most desirable.

Figure 1: Some of the shapes of jets that our model can represent. Compare it with the picture of Herbig-Haro 49/50 (see [21])

3.2 Complex Super-Radiance-like Jet Modes

The study of the solutions of radial Teukolsky equation (1) is much more complicated from computational point of view. Even after fixing the relation (7) between \( A \) and \( \omega \), solving the KBH boundary condition (8) for radial equation is not a straight-forward process, because of the analytical and numerical problems connected with the evaluation of the confluent Heun function. Our method consisted in plotting and examining the spectral condition in the complex plane \( \mathbb{C}_{\omega} \) to find points that resemble roots of the transcendental equation (8). Then we tested those points with more precise root-finding algorithms.
Thus we found for the case $s = -1, 2M = 1, a/M = 0.99, |m| = 1$ two roots:

$$\omega_{1,2} = \pm 0.8676087 + i 0.1236275.$$ 

For the case $m = 0$ we obtained another pair of roots

$$\omega_{1,2} = \pm 0.006394 + i 0.1354325801.$$ 

To confirm those roots, we plotted the studied function in small regions around the zeroes and obtained the expected conus-like form of the modulus of the function in the complex domain and the complete rotation of its phases in angle $2\pi$ around its simple zeroes.

Interesting in these roots is that the absolute value of their real part is precisely the known critical frequency $\omega_{cr} = am/2Mr_+, m > 0$ that is connected with the superradiance phenomena (for a recent review see the last reference in [13]). To the best of our knowledge this is the first time that an imaginary part of this quantity is discovered solving BH boundary conditions in pure vacuum (i.e. without any mirrors, etc). In the case of jet’s solution we have a critical phenomenon around the complex value of the frequency. It’s explicit manifestation is the change of the role of solutions (2) and (3) outside the even horizon of KBH when $|\omega_R|$ crosses the critical value $am/2Mr_+$. The complexity of the critical frequency shows an essential difference between our jets-from-KBH solutions and standard QNM, obtained using regular solutions of the angular equation (4) [11]. It is also important that the real and the imaginary parts of the critical frequency are with the same magnitude.

The lack of zeros with $\omega_I < 0$ in our numerical studies can be both due to the stability of the model, or to numerical problems in that area. The study of the zeroes is a field of intensive research by the team and more conclusive results will be presented somewhere else.

4 Conclusion

Our simple toy model of central engine seems to be able to produce some of the basic features observed in GRB. The Teukolsky Master Equation with the correct boundary conditions is fundamental enough to account for all types of GRB. The polynomial angular solutions of TME show a jet-like structure. In the radial equation, the essential assumptions we used is that the imaginary part of the frequency with BH boundary conditions (only entering waves on the horizon and only going to infinity waves) should be positive. This provides stability of the solutions in direction of time-future infinity and indicates an explosion in direction of time-past infinity. The roots we found numerically agree with our assumption. Interesting new result is the complex critical frequency $\omega^{jet} = \omega_R + i\omega_I (\omega_I \sim \omega_R)$ of ”superradiance” that appeared, showing that jet’s to-be-superradiance modes decrease exponentially in time in the direction of the future and blow up in direction of the past.
