AN EXAMPLE OF AN ALMOST GREEDY UNIFORMLY BOUNDED ORTHONORMAL BASIS FOR $L_p([0,1])$

MORTEN NIELSEN

ABSTRACT. We construct a uniformly bounded orthonormal almost greedy basis for $L_p([0,1]), 1 < p < \infty$. The example shows that it is not possible to extend Orlicz’s theorem, stating that there are no uniformly bounded orthonormal unconditional bases for $L_p([0,1]), p \neq 2$, to the class of almost greedy bases.

1. INTRODUCTION

Let $\mathcal{B} = \{e_n\}_{n \in \mathbb{N}}$ be a bounded Schauder basis for a Banach space $X$, i.e., a basis for which $0 < \inf_n \|e_n\|_X \leq \sup_n \|e_n\|_X < \infty$. An approximation algorithm associated with $\mathcal{B}$ is a sequence $\{A_n\}_{n=1}^\infty$ of (possibly nonlinear) maps $A_n : X \to X$ such that for $x \in X$, $A_n(x)$ is a linear combination of at most $n$ elements from $\mathcal{B}$. We say that the algorithm is convergent if $\lim_{n \to \infty} \|x - A_n(x)\|_X = 0$ for every $x \in X$. For a Schauder basis there is a natural convergent approximation algorithm. Suppose the dual system to $\mathcal{B}$ is given by $\{e^*_k\}_{k \in \mathbb{N}}$. Then the linear approximation algorithm is given by the partial sums $S_n(x) = \sum_{k=1}^n e^*_k(x)e_k$.

Another quite natural approximation algorithm is the greedy approximation algorithm where the partial sums are obtained by thresholding the expansion coefficients. The algorithm is defined as follows. For each element $x \in X$ we define the greedy ordering of the coefficients as the map $\rho : \mathbb{N} \to \mathbb{N}$ with $\rho(\mathbb{N}) \supseteq \{j : e^*_j(x) \neq 0\}$ such that for $j < k$ we have either $|e^*_\rho(k)(x)| < |e^*_\rho(j)(x)|$ or $|e^*_\rho(k)(x)| = |e^*_\rho(j)(x)|$ and $\rho(k) > \rho(j)$. Then the greedy $m$-term approximant to $x$ is given by $\mathcal{G}_m(x) = \sum_{j=1}^m e^*_\rho(j)(x)e_{\rho(j)}$. The question is whether the greedy algorithm is convergent. This is clearly the case for an unconditional basis where the expansion $x = \sum_{k=1}^\infty e^*_k(x)e_k$ converges regardless of the summation order. However, Temlyakov and Konyagin [4] showed that the greedy algorithm may also converge for certain conditional bases. This leads to the definition of a quasi-greedy basis.

Definition 1.1 [4]. A bounded Schauder basis for a Banach space $X$ is called quasi-greedy if there exists a constant $C$ such that for $x \in X$, $\|\mathcal{G}_m(x)\|_X \leq C\|x\|_X$ for $m \geq 1$.

Wojtaszczyk proved the following result which gives a more intuitive interpretation of quasi-greedy bases.

Theorem 1.2 [9]. A bounded Schauder basis for a Banach space $X$ is quasi-greedy if and only if $\lim_{m \to \infty} \|x - \mathcal{G}_m(x)\|_X = 0$ for every element $x \in X$.

Key words and phrases. Bounded orthonormal systems, Schauder basis, quasi-greedy basis, almost greedy basis, decreasing rearrangements.
In this note we study quasi-greedy bases for $L_p := L_p([0,1]), 1 < p < \infty$, with a particular structure. We are interested in uniformly bounded bases $B = \{e_n\}_{n \in \mathbb{N}}$ such that $B$ is an orthonormal basis for $L_2$. It is a well-known result by Orlicz that such a basis can be unconditional only for $p = 2$, so it is never trivially quasi-greedy except for $p = 2$.

It was proved by Temlyakov [8] that the trigonometric system in $L_p, 1 \leq p \leq \infty, p \neq 2$, fails to be quasi-greedy. Independently, and using a completely different approach, Córdoba and Fernández [1] proved the same result in the range $1 \leq p < 2$. One can also verify that the Walsh system fails to be quasi-greedy in $L_p, p \neq 2$. This leads to a natural question: are there any uniformly bounded orthonormal quasi-greedy bases for $L_p$?

A negative answer to this question would give a nice improvement of Orlicz’s theorem to the class of quasi-greedy bases. However, such an improved result is not possible. Below we construct a uniformly bounded orthonormal almost greedy basis for $L_p, 1 < p < \infty$.

**Definition 1.3.** A bounded Schauder basis $\{e_n\}_n$ for a Banach space $X$ is almost greedy if there is a constant $C$ such that for $x \in X$,

$$\|x - G_n(x)\|_X \leq C \inf \left\{ \|x - \sum_{j \in A} e_j^*(x)e_j\| : |A| = n, \alpha_j \in \mathbb{C}, j \in A, n \in \mathbb{N} \right\}.$$
construction to define quasi-greedy for $X \oplus \ell_2$, with $X$ a quasi-Banach space with a Besselian basis.

Let us introduce some notation. The Rademacher functions are given by $r_k(t) = \text{sign}(\sin(2^k \pi t))$ for $k \geq 1$. Khintchine’s inequality will be essential for the estimates below. The inequality states that for $1 \leq p < \infty$ there exist $A_p, B_p$ such that for any finite sequence $\{a_k\}_{k \geq 1}$,

\begin{equation}
A_p \left( \sum_k |a_k|^2 \right)^{1/2} \leq \left( \int_0^1 \left| \sum_k a_k r_k(t) \right|^p dt \right)^{1/p} \leq B_p \left( \sum_k |a_k|^2 \right)^{1/2}.
\end{equation}

Khintchine’s inequality shows that the Rademacher functions form a democratic system in $L_p$. However, the Rademacher system is far from complete so it cannot be used directly to obtain an almost greedy basis in $L_p$. In our example we use the fact that the Rademacher functions form subsystems of a complete system, namely the Walsh system. The Walsh system $\mathcal{W} = \{W_n\}_{n=0}^\infty$ is defined as follows. For $n = \sum_{j=1}^k \varepsilon_j 2^{j-1}$, the binary expansion of $n \in \mathbb{N}$, we let

\begin{equation}
W_n(t) = \prod_{j=1}^k r_{\varepsilon_j}^j(t).
\end{equation}

The Walsh system forms a uniformly bounded orthonormal basis for $L_2$ and a Schauder basis for $L_p$, $1 < p < \infty$, see [3]. The idea is to reorder the Walsh system such that we obtain large dyadic blocks of Rademacher functions with the remaining Walsh functions placed in between the Rademacher blocks. Let us consider the details.

For $k = 1, 2, \ldots$, we define the $2^k \times 2^k$ Olevskiï matrix $A^k = (a^{(k)}_{ij})_{i,j=1}^{2^k}$ by the following formulas

$$a^{(k)}_{i1} = 2^{-k/2} \quad \text{for} \quad i = 1, 2, \ldots, 2^k,$$

and for $j = 2^s + \nu$, with $1 \leq \nu \leq 2^s$ and $s = 1, 2, \ldots, k - 1$, we let

$$a^{(k)}_{ij} = \begin{cases} 
2^{(s-k)/2} & \text{for} \quad (\nu - 1)2^{k-s} < i \leq (2\nu - 1)2^{k-s-1} \\
-2^{(s-k)/2} & \text{for} \quad (2\nu - 1)2^{k-s-1} < i \leq \nu 2^{k-s} \\
0 & \text{otherwise}.
\end{cases}$$

One can check (see [3] Chapter IV) that $A^k$ are orthogonal matrices and there exists a finite constant $C$ such that for all $i, k$ we have

\begin{equation}
\sum_{j=1}^{2^k} |a^{(k)}_{ij}| \leq C.
\end{equation}

Put $N_k = 2^{10k}$ and define $F_k$ such that $F_0 = 0$, $F_1 = N_1 - 1$ and $F_k - F_{k-1} = N_k - 1$, $k = 1, 2, \ldots$. We consider the Walsh system $\mathcal{W} = \{W_n\}_{n=0}^\infty$ on $[0, 1]$. We split $\mathcal{W}$ into two subsystems. The first subsystem $\mathcal{W}_1 = \{r_k\}_{k=1}^\infty$ is the Rademacher functions with their natural ordering. The second subsystem $\mathcal{W}_2 = \{\phi_k\}_{k=1}^\infty$ is the collection of Walsh functions not in $\mathcal{W}_1$ with the ordering from $\mathcal{W}$. We now impose the ordering

$$\phi_1, r_1, r_2, \ldots, r_{F_1}, \phi_2, r_{F_1+1}, \ldots, r_{F_2}, \phi_3, r_{F_2+1}, \ldots, r_{F_3}, \phi_4, \ldots$$
The block $B_k := \{\phi_k, r_{F_k-1+1}, \ldots, r_{F_k}\}$ has length $N_k$, and we apply $A^{10^k}$ to $B_k$ to obtain a new orthonormal system $\{\psi^{(k)}_i\}_{i=1}^{N_k}$ given by

$$\psi^{(k)}_i = \frac{\phi_k}{\sqrt{N_k}} + \sum_{j=2}^{N_k} a_{ij}^{(10^k)} r_{F_k-1+j-1}.$$  

(4)

The system ordered $\psi^{(1)}_1, \psi^{(1)}_2, \psi^{(2)}_1, \psi^{(2)}_2, \ldots$ will be denoted $B = \{\psi_k\}_{k=1}^\infty$. It is easy to verify that $B$ is an orthonormal basis for $\ell_2$ since each matrix $A^{10^k}$ is orthogonal. The system is uniformly bounded which follows by (3) and the fact that $W$ is uniformly bounded. The system $B$ is our candidate for an almost greedy basis for $L_p$, $1 < p < \infty$.

We split the proof of Theorem [4] into three parts. First we prove that $B$ is democratic in $L_p$. Then we prove that the system forms a Schauder basis for $L_p$, and the final step is to prove that the system forms a quasi-greedy basis for $L_p$.

**Lemma 2.1.** The system $B = \{\psi_k\}_{k=1}^\infty$ is democratic in $L_p$, $1 < p < \infty$, with

$$\left\| \sum_{k \in A} \psi_k \right\|_p \approx |A|^{1/2}.$$

**Proof.** Fix $2 < p < \infty$. Let $S = \sum_{k \in A} \psi_k$ with $|A| = N$. We write

$$S = \sum_{k=1}^\infty \sum_{j \in \Lambda_k} \psi_j^{(k)} = \sum_{k=1}^\infty \frac{|\Lambda_k|}{\sqrt{N_k}} \phi_k + \sum_{k=1}^\infty \sum_{i \in \Lambda_k, j = 2} a_{ij}^{(10^k)} r_{F_k-1+j-1} := S_1 + S_2,$

with $\sum_k |\Lambda_k| = |A|$, and $|\Lambda_k| \leq N_k$. Notice that the coefficients of $\sum_{j \in \Lambda_k} \psi_j^{(k)}$ relative to the block $B_k$ has $l_2$-norm $|\Lambda_k|^{1/2}$ since $A^{10^k}$ is orthogonal. Hence, by Khintchine’s inequality,

$$\|S_2\|_p = \left\| \sum_{k=1}^\infty \sum_{j = 2}^{N_k} \left( \sum_{i \in \Lambda_k} a_{ij}^{(10^k)} \right) r_{F_k-1+j-1} \right\|_p \leq B_p \left( \sum_k |\Lambda_k| \right)^{1/2} = B_p N^{1/2}.$$

We now estimate $S_1$. Write

$$S_1 = \sum_{k=1}^\infty \frac{|\Lambda_k|}{\sqrt{N_k}} \phi_k = \sum_{k \in A} \frac{|\Lambda_k|}{\sqrt{N_k}} \phi_k + \sum_{k \in B} \frac{|\Lambda_k|}{\sqrt{N_k}} \phi_k := S^1_1 + S^2_1,$$

where $A = \{k : |\Lambda_k| \leq (N_k)^{3/4}\}$ and $B = \{k : |\Lambda_k| > (N_k)^{3/4}\}$. Using the Cauchy-Schwartz inequality,

$$\|S^1_1\|_p \leq \sum_{k \in A} \frac{|\Lambda_k|}{\sqrt{N_k}} \leq \left( \sum_{k \in A} |\Lambda_k| \right)^{1/2} \left( \sum_{k \in A} \frac{|\Lambda_k|}{N_k} \right)^{1/2} \leq N^{1/2} \left( \sum_{k \in \mathbb{N}} N_k^{-1/4} \right)^{1/2} = CN^{1/2}.$$

We turn to $S^2_1$. If $B$ is empty, we are done. Otherwise, $B$ is a finite set and we can define $L = \max B$. We have

$$\sum_{k \in B, k < L} \frac{|\Lambda_k|}{\sqrt{N_k}} \leq \sum_{k \in B, k < L} \sqrt{N_k} \leq \sum_{j=1}^{10^{L-1}} j^{1/2} \leq 2 \cdot 2^{(10^{L-1})/2} \leq 2 \cdot 2^{(10^L)/4} \leq 2 \frac{|\Lambda_L|}{\sqrt{N_L}}.$$
Hence,
\[
\|S_2^2\|_p \leq \sum_{k \in B} \frac{|\Lambda_k|}{N_k} \leq 3 \frac{|\Lambda_L|}{\sqrt{N_L}} \leq 3 \sqrt{|\Lambda|} = 3N^{1/2},
\]
where we used that $|\Lambda_L| \leq N_L$. We conclude that $\|S\|_p \leq C' N^{1/2}$, with $C'$ independent of $\Lambda$. Since $N^{1/2} = \|S\|_2 \leq \|S\|_p$ we deduce that $B$ is democratic in $L_p$, $2 \leq p < \infty$. For $1 < q < 2$ we have $\|S\|_q \leq \|S\|_2 = N^{1/2}$. By Hölder’s inequality,
\[
N = \|S\|_2^2 \leq \|S\|_q \|S\|_p \leq C_p N^{1/2} \|S\|_q,
\]
for $1/q + 1/p = 1$. Again, we conclude that $\|S\|_q \approx N^{1/2}$, so $B$ is democratic in $L_q$, $1 < q < 2$. \(\square\)

Next we prove that $B$ is a basis for $L_p$.

**Lemma 2.2.** The system $B = \{\psi_k\}_{k=1}^\infty$ is a Schauder basis for $L_p$, $1 < p < \infty$.

**Proof.** Notice that $\text{span}(B) = \text{span}(W)$ by construction, so $\text{span}(B)$ is dense in $L_p$, $1 < p < \infty$, since $W$ is a Schauder basis for $L_p$. Fix $2 < p < \infty$ and let $f \in L_p$. Let
\[
S_n(f) = \sum_{k=1}^n \langle f, \psi_k \rangle \psi_k \quad \text{and} \quad S_{L-1}(f) = \sum_{k=1}^{L-1} \sum_{j=1}^{N_k} \langle f, \psi^{(k)}_j \rangle \psi^{(k)}_j + \sum_{k=1}^m \langle f, \psi^{(L)}_k \rangle \psi^{(L)}_k := T_1 + T_2.
\]

Let us estimate $T_1$. If $L = 1$ then $T_1 = 0$, so we may assume $L > 1$. The construction of $B$ shows that $T_1$ is the orthogonal projection of $f$ onto
\[
\text{span}\left( \bigcup_{k=1}^{L-1} \bigcup_{j=1}^{N_k} \{ \psi^{(k)}_j \} \right) = \text{span}\left\{ \{W_0, W_1, \ldots, W_{L-2}\} \cup \{r_{\ell_0}, r_{\ell_0+1}, \ldots, r_{F_{L-1}}\} \right\},
\]
with $\ell_0 = \lfloor \log_2(L) \rfloor$. It follows that we can rewrite $T_1$ as
\[
T_1 = \sum_{k=0}^{L-2} \langle f, W_k \rangle W_k + P_R(f),
\]
where $P_R(f)$ is the orthogonal projection of $f$ onto $\text{span}\{r_{\ell_0}, r_{\ell_0+1}, \ldots, r_{F_{L-1}}\}$. Thus, using Khintchine’s inequality,
\[
\|T_1\|_p \leq C_p \|f\|_p + B_p \|f\|_p,
\]
where $C_p$ is the basis constant for the Walsh system in $L_p$. Next we rewrite $T_2$ in the system $\{\phi_L, r_{F_{L-1}+1}, \ldots, r_{F_L}\}$,
\[
T_2 = \sum_{k=1}^m \langle f, \psi^{(L)}_k \rangle \phi_L \frac{1}{\sqrt{N_L}} + \sum_{j=2}^{N_L} \left( \sum_{k=1}^m \langle f, \psi^{(L)}_k \rangle a_j^{(10^j)} \right) r_{F_{L-1}+j-1}.
\]
By Khintchine’s inequality, and the fact that $A^{10^k}$ is orthogonal,
\[
\left\| \sum_{j=2}^{N_L} \left( \sum_{k=1}^{m} \langle f, \psi_k^{(L)} \rangle a_{ij}^{(10^k)} \right) r_{F_{L-1}+j-1} \right\|_p \leq B_p \| \{ \langle f, \psi_k^{(L)} \rangle \} \|_{\ell_2} < \infty.
\]
Also,
\[
\left\| \sum_{k=1}^{m} \langle f, \psi_k^{(L)} \rangle \frac{\phi_L}{\sqrt{N_L}} \right\|_p \leq \sum_{k=1}^{m} |\langle f, \psi_k^{(L)} \rangle| \frac{1}{\sqrt{N_L}} \leq \| \{ \langle f, \psi_k^{(L)} \rangle \} \|_{\ell_2} \sqrt{\frac{m}{N_L}} \leq \| \{ \langle f, \psi_k^{(L)} \rangle \} \|_{\ell_2},
\]
so $\| T_2 \|_p < \infty$. The estimates of $T_1$ and $T_2$ are independent of $n$, and we obtain that $\sup_n \| S_n(f) \|_p < \infty$. Using the Banach-Steinhaus theorem we deduce that $\{ S_n \} \subset$ is a uniformly bounded family of linear operators on $L_p$. We conclude that $\mathcal{B}$ is a Schauder basis for $L_p$, $2 < p < \infty$, and the result for $1 < p < 2$ follows by a duality argument. \( \square \)

We can now complete the proof of Theorem 1.4. Lemma 2.3 below together with Lemmas 2.1 and 2.2 immediately give Theorem 1.4.

**Lemma 2.3.** The system $\mathcal{B} = \{ \psi_k \}_{k=1}^{\infty}$ is a quasi-greedy basis for $L_p$, $1 < p < \infty$.

**Proof.** First we consider $2 < p < \infty$. Let $f \in L_p \subset L_2$. Then we have the $L_p$-norm convergent expansion
\[
f = \sum_{i=1}^{\infty} \langle f, \psi_i \rangle \psi_i,
\]
with $\| \{ \langle f, \psi_i \rangle \} \|_{\ell_2} \leq \| f \|_2 \leq \| f \|_p$. It suffices to prove that $\mathcal{G}_m(f)$ is convergent in $L_p$ since $\mathcal{G}_m(f) \to f$ in $L_2$. We write (formally)
\[
f = \sum_{k=1}^{N_k} \sum_{j=1}^{N_k} \langle f, \psi_j^{(k)} \rangle \psi_k^{(k)}
= \sum_{k=1}^{N_k} \sum_{j=1}^{N_k} \langle f, \psi_j^{(k)} \rangle \frac{\phi_k}{\sqrt{N_k}} + \sum_{k=1}^{N_k} \sum_{i=1}^{N_k} \langle f, \psi_i^{(k)} \rangle \sum_{j=2}^{m} a_{ij}^{(10^k)} r_{F_{k-1}+j-1}
= S^1 + S^2.
\]
Consider a sequence $\{ \varepsilon_i^k \} \subset \{0, 1\}$. By Khintchine’s inequality, and the fact that each $A^{10^k}$ is orthogonal,
\[
\left\| \sum_{k=1}^{N_k} \sum_{j=2}^{N_k} \left( \sum_{i=1}^{N_k} \varepsilon_i^k \langle f, \psi_i^{(k)} \rangle a_{ij}^{(10^k)} \right) r_{F_{k-1}+j-1} \right\|_p \leq B_p \left( \sum_{k=1}^{N_k} \sum_{i=1}^{N_k} \varepsilon_i^k |\langle f, \psi_i^{(k)} \rangle|^2 \right)^{1/2}.
\]
It follows that $S^2$ is convergent and actually converges unconditionally in $L_p$. From this and the convergence of the series (5), we conclude that the partial sums for the series $S^1$,
\[
S^1_n = \sum_{k=1}^{L-1} \sum_{j=1}^{N_k} \langle f, \psi_j^{(k)} \rangle \frac{\phi_k}{\sqrt{N_k}} + \sum_{j=2}^{m} \langle f, \psi_j^{(L)} \rangle \frac{\phi_L}{\sqrt{N_L}}
\]
converge in $L_p$. 

The series defining \( S^2 \) converges unconditionally, so it suffices to prove that the series defining \( S^1 \) converges in \( L_p \) when the coefficients \( \{ \langle f, \psi_i \rangle \} \) are arranged in decreasing order. We define the sets

\[
\Lambda_k = \left\{ j : \frac{1}{N_k} < |\langle f, \psi_j^{(k)} \rangle| < \frac{1}{N^{1/10}_k} \right\}
\]

(6)

\[
\Lambda'_k = \left\{ j : |\langle f, \psi_j^{(k)} \rangle| \leq \frac{1}{N_k} \right\}
\]

\[
\Lambda''_k = \left\{ j : |\langle f, \psi_j^{(k)} \rangle| \geq \frac{1}{N^{1/10}_k} \right\}
\]

Then (formally)

\[
S^1 = \sum_{k=1}^{\infty} \sum_{j \in \Lambda_k} \langle f, \psi_j^{(k)} \rangle \frac{\phi_k}{\sqrt{N_k}} + \sum_{k=1}^{\infty} \sum_{j \in \Lambda'_k} \langle f, \psi_j^{(k)} \rangle \frac{\phi_k}{\sqrt{N_k}} + \sum_{k=1}^{\infty} \sum_{j \in \Lambda''_k} \langle f, \psi_j^{(k)} \rangle \frac{\phi_k}{\sqrt{N_k}} = T + T' + T''.
\]

Notice that \( \sum_{j \in \Lambda_k} |\langle f, \psi_j^{(k)} \rangle| \frac{\phi_k}{\sqrt{N_k}} \leq 1/\sqrt{N_k} \), so the series defining \( T' \) converges absolutely in \( L_p \). For \( T'' \) we notice that \( |\Lambda'_k| \leq \frac{\|f\|_2^2}{N^{1/5}_k} \), so

\[
\sum_{j \in \Lambda'_k} \left| \langle f, \psi_j^{(k)} \rangle \right| \frac{\phi_k}{\sqrt{N_k}} \leq \sum_{j \in \Lambda'_k} \frac{|\langle f, \psi_j^{(k)} \rangle|}{\sqrt{N_k}} \leq \frac{\|f\|_p \|f\|_2^2}{N^{3/10}_k},
\]

and the series defining \( T'' \) converges absolutely in \( L_p \).

The series defining \( S^1 \), \( T' \) and \( T'' \) converge in \( L_p \), so we may conclude that the series defining \( T \) converges in \( L_p \). From (6), we get

\[
|\langle f, \psi_i^{(k)} \rangle| > \frac{1}{N_k} \geq \frac{1}{N^{1/10}_{k+1}} \geq |\langle f, \psi_j^{(k+1)} \rangle|, \quad i \in \Lambda_k, j \in \Lambda_{k+1}; k = 1, 2, \ldots
\]

so when we arrange \( T \) by decreasing order, the rearrangement can only take place inside the blocks. The estimate

\[
\sum_{j \in \Lambda_k} \left| \langle f, \psi_j^{(k)} \rangle \right| \frac{\phi_k}{\sqrt{N_k}} \leq \left( \sum_{j \in \Lambda_k} |\langle f, \psi_j^{(k)} \rangle|^2 \right)^{1/2} \frac{|\Lambda_k|^{1/2}}{\sqrt{N_k}}, \quad k \geq 1,
\]

shows that rearrangements inside blocks are well-behaved, and

\[
\sum_{j \in \Lambda_k} \left| \langle f, \psi_j^{(k)} \rangle \right| \frac{\phi_k}{\sqrt{N_k}} \rightarrow 0 \quad \text{as} \quad k \rightarrow \infty.
\]

We conclude that \( G_m(f) \) is convergent in \( L_p \) and consequently \( B \) is a quasi-greedy basis in \( L_p, 2 \leq p < \infty \). Fix \( 1 < q < 2 \) and let \( p \) be given by \( 1/q + 1/p = 1 \). By Lemma [2.1], for any finite subset \( A \subset \mathbb{N} \),

\[
\left\| \sum_{k \in A} \psi_k \right\|_q \left\| \sum_{k \in A} \psi_k \right\|_p \leq C|A|,
\]

so \( B \) is a so-called bi-democratic system in \( L_p \). It follows from [2] Theorem 5.4; (1) \( \Rightarrow \) (2)] that \( B \) is a quasi-greedy basis for \( L_q \). This completes the proof. \( \square \)
Remark 2.4. To get a uniformly bounded quasi-greedy basis consisting of smooth functions, we can use the same construction based on the trigonometric system with any lacunary subsequence playing the role of the Rademacher system.

Acknowledgment. The author would like to thank Boris Kashin and Rémi Gribonval for discussions on uniformly bounded quasi-greedy systems that provided inspiration for our example.
