Abstract: In this work, the effects of silver (Ag) nanoparticles on the melting behavior, isothermal crystallization kinetics, and morphology of polyoxymethylene (POM) were studied. It was found that the melting peak temperature ($T_m$) and the crystallization temperature ($T_C$) of POM/Ag nanocomposites shifted to higher temperature with the content of Ag nanoparticles increased. In addition, the isothermal crystallization kinetics of POM/Ag nanocomposites were determined by Avrami and Lauritzen-Hoffman models. The results of crystallization half-time ($t_{0.5}$), reciprocal of crystallization half-time ($\tau_{0.5}$), Avrami exponent ($n$), and Avrami rate constant ($k$) showed that low loading of Ag nanoparticles ($\leq 1$ wt%) accelerated the crystallization rate of POM. However, when the content of Ag nanoparticles reached 2 wt%, they aggregated together and restrained crystallization of POM. Meanwhile, the results of nucleation parameter ($K_g$) and surface free energy of folding ($\delta_e$) revealed that Ag nanoparticles reduced the energy need to create a new crystal surface, leading to faster crystallization. Moreover, the crystallization activation energies ($\Delta E$) were determined using the Arrhenius model, which suggested that Ag nanoparticles induced the heterogeneous nucleation by lowering the $\Delta E$. Furthermore, polarized light microscopy results indicated Ag nanoparticles generated a great amount of nucleation sites and led to the formation of smaller spherulites.

Keywords: POM; Ag nanoparticles; POM/Ag nanocomposites; isothermal crystallization kinetics; heterogeneous nucleation; nucleation sites

1. Introduction

Polyoxymethylene (POM), also referred to as polyacetal or polyformaldehyde, is a semi-crystalline thermoplastic polymer [1,2]. It is well known that POM can be prepared in two main forms as copolymers and homopolymers. POM homopolymers have good fatigue strength and high durability but are not easy to process. In contrast, POM copolymers have good chemical durability and thermal stability, and are easy to process [3]. POM is one of the most widely used engineering thermoplastics in many areas of application such as agriculture, automobiles, the mechanical industry, and electromechanical equipment [4–6], which is due to its high tensile strength and rigidity, excellent wear and friction, and solvent resistance [7–9]. On one hand, the physical properties of POM are governed by the crystallization [10]. On the other
hand, the crystallization behavior of POM depends on its supramolecular structure [11,12]. However, POM has a linear molecular chains as (-CH\(_2\)-O-\(_n\) structure which leads to high crystallinity, which limits its application [13–15]. Therefore, many studies have reported on the effect of additives on the crystallization performance of POM [16]. For instance, Durmus et al. [17] investigated the effects of methyl-polyhedral oligomeric silsesquioxanes (methyl-POSS) on the isothermal crystallization behavior of POM. It was found that the addition of 2 wt% of methyl-POSS increased the reciprocal of crystallization half-time (\(\tau_{0.5}\)) of POM (0.133 min\(^{-1}\)) approximately six fold, which demonstrated that methyl-POSS accelerated the crystallization rate of POM. The effects of poly(ethylene oxide) (PEO) on the crystallization and orientation of POM were studied by Tan et al. [18]. They pointed out that the melting point (161.3 J/g) and the crystallinity (50.7%) of POM were reduced by the addition of PEO. In addition, they also declared that PEO significantly decreased the spherulite size of POM. One interesting study on the crystallinity and crystal morphology of POM nanocomposite containing octakis((3-glycidoxypropyl) dimethylsiloxy) octasilsesquioxane (GPOSS) was performed by Czarnecka-Komorowska et al. [19]. It was shown that GPOSS reduced the spherulite size (48 μm) of POM, and increased the crystallization growth rate and the crystallinity degree (72%) of POM due to the heterogeneous nucleation of GPOSS. Jiao et al. [20] studied the effect of tributyl(octyl)phosphonium bis(trifloromethane-sulfonyl) imide (TBOP-TFSI) on the crystallization behaviors of POM. It was found that small amounts (0.5 wt%) of TBOP-TFSI could facilitate the nucleation of POM. Furthermore, they also declared that TBOP-TFSI decreased hemi-crystalline time (\(t_{0.5} = 2.4\) min) and increased crystallinity (51.3%) of POM.

The synthesis and properties of Ag nanoparticles have attracted widespread attention owing to their unique volume effects, surface effects, and quantum size [21,22], as well as their high conductivity [23,24], excellent catalytic activities [25,26], and broad antiviral and antibacterial properties [27,28]. Meanwhile, nanocomposites containing Ag nanoparticles have widely been applied in a variety of areas [29] such as flexible supercapacitor electrodes [30], solar energy harvesting [31], catalytic degradation of organic dyes [32], wound healing [33], and so on. Rangraz et al. [34] anchored Ag nanoparticles on the selenium-doped graphitic carbon nitride (Se-g-C\(_3\)N\(_4\)) to fabricate the Se-g-C\(_3\)N\(_4\)/Ag nanocomposites and investigated its catalytic activities. They demonstrated that the Se-g-C\(_3\)N\(_4\)/Ag nanocomposites could be a novel, robust, recoverable and effective catalyst for the hydrogenation of nitroarene compounds. In addition, Shi et al. [35] investigated the effects of Ag loading and crystallization temperature on the crystallization behavior of polypropylene (PP). They found that the PP/Ag nanocomposites had higher crystallization rate (\(t_{0.5} = 18.1\) s) and lower Avrami exponent (2.30 ≤ n ≤ 2.84) than that for PP (\(t_{0.5} = 20.2\) s, 2.53 ≤ n ≤ 2.94), which indicated that the Ag nanoparticles increased amount of nucleation sites and crystallization rate of PP owing to the heterogeneous nucleation. Furthermore, Makvandi et al. [36] synthesized thermosensitive and injectable hydrogels containing corn silk extract-nanosilver (CSE-Ag), and demonstrated that as-synthesized CSE-Ag nanocomposites could promote high bone differentiation of mesenchymal stem cells (MSCs) and act a potential scaffold for bone tissue regeneration. Therefore, the combination of Ag nanoparticles and POM to prepare POM/Ag nanocomposites is one of the meaningful studies.

In our previous work, we successfully synthesized Ag nanoparticles with a monolayer of surfactants composed of oleic acid and n-propylamine, and the average size of Ag nanoparticles was approximately 10 nm, with a narrow size distribution. Meanwhile, the Ag nanoparticles gave rise to a better compatibility with POM and could be well dispersed in the POM matrix [37].

In this work, a simple melting processing method was used to prepare POM/Ag nanocomposites, as shown in Figure 1. To illustrate the dispersion and compatibility of Ag nanoparticles in POM, the micromorphology of POM/Ag nanocomposites were observed by transmission electron microscopy (TEM). In addition, differential scanning calorimetry (DSC) and polarized light microscopy (PLM) were employed to further study the effects of Ag nanoparticles content on the melting behavior, isothermal crystallization kinetics and morphology of POM.
2. Experimental

2.1. Materials

Polyoxymethylene (POM) was obtained by Yunnan, Yuntianhua Co., Ltd., Shanghai, China. The melt flow index of POM is 2.5 g/10 min at 230 °C with a standard weight of 2.16 kg, and the density of POM is 1.40 g/cm³. Silver nitrate (99.8%), oleic acid (99%), anhydrous ethanol (99.7%), n-propylamine (98%), and ascorbic acid (99.7%) were purchased from Sinopharm Chemical Reagent Co., Ltd., Shanghai, China.

2.2. Synthesis of Ag Nanoparticles

The silver nitrate was reduced by ascorbic acid to prepare Ag nanoparticles, under the stability of oleic acid and n-propylamine. Therefore, the as-synthesized Ag nanoparticles were coated with a monolayer of surfactants consisting of oleic acid and the n-propylamine. In addition, the detailed preparation process and characterization of the Ag nanoparticles can be found in a previously published paper [37].

2.3. Preparation of POM/Ag Nanocomposites

POM/Ag nanocomposites were prepared by melting processing method in a torque rheometer. The mixing process has continued for 10 min at 190 °C, and the roller speed was 60 rpm. In addition, POM and Ag nanoparticles were both dried in vacuum oven overnight at 80 °C prior to melt processing to get rid of moisture. Furthermore, the compositions of POM/Ag nanocomposites were listed in Table 1.

Table 1. The compositions of POM/Ag nanocomposites.

| Samples | POM (wt%) | Ag Nanoparticles (wt%) |
|---------|-----------|------------------------|
| POM     | 100       | 0                      |
| POM-1   | 99.9      | 0.1                    |
| POM-2   | 99.5      | 0.5                    |
| POM-3   | 99.0      | 1.0                    |
| POM-4   | 98.0      | 2.0                    |

2.4. Transmission Electron Microscopy (TEM)

The dispersion of Ag nanoparticles in POM was investigated using TEM (Tecnai G2 F30, FEI, Hillsboro, OR, USA). All TEM samples preparation process: POM/Ag nanocomposites were cut by ultrathin slicer (Artos 3D, Shanghai, China) and placed onto an amorphous carbon-coated copper grid. The size of the Ag nanoparticles was analyzed using Image J software.

2.5. Differential Scanning Calorimetry (DSC)

The DSC measurements of POM/Ag nanocomposites were performed on a DSC 204F1 (Netzsch, Selb, Germany) to determine the crystallization and melting runs of POM/Ag nanocomposites. The complete procedure mainly included melting-crystallization runs and isothermal crystallization runs, as follows:
(a) In melting-crystallization runs, POM/Ag nanocomposites weighing about 6–8 mg were heated from 30 °C to 200 °C in an aluminum crucible with a heating rate of 10 °C/min and maintained at 200 °C for 5 min to erase the thermal history, then cooled from 200 °C to 30 °C with a cooling rate of 10 °C/min. After completion of the melt-crystallization process, samples were kept at 30 °C for 5 min. Then the samples were heated again from 30 °C to 200 °C with the heating rate of 10 °C/min. The second melting and the first cooling curves were recorded.

(b) In isothermal crystallization runs, we referred to the isothermal crystallization experiment performed by Durmus et al. [17]. Before the isothermal crystallization experiment, we observed the isothermal crystallization time of POM/Ag nanocomposites at the T_{cry} (130 °C, 135 °C, 140 °C and 145 °C) by polarized light microscopy (PLM) with a hot stage. It was found that the isothermal crystallization time of POM/Ag nanocomposites at the T_{cry} was less than 30 min. POM/Ag nanocomposites weighing about 6–8 mg were heated from 30 °C to 200 °C in an aluminum crucible with a heating rate of 10 °C/min and maintained at 200 °C for 5 min to erase the thermal history, then cooled from 200 °C to the isothermal crystallization temperature (T_{cry}) (130 °C, 135 °C, 140 °C and 145 °C) with a cooling rate of 100 °C/min and maintained at T_{cry} for 30 min. The first cooling curve was recorded.

Furthermore, the degree of crystallinity (X_C) was calculated by the Equation (1):

\[
X_C(\%) = \frac{\Delta H_m}{(1 - \alpha)\Delta H_{om}} \times 100
\]

where \(\Delta H_m\) is the enthalpy of second melting endotherms of POM/Ag nanocomposites, \(\Delta H_{om}\) is the enthalpy of melting of 100% crystalline form of polymer, and \(\alpha\) is the weight fraction of Ag nanoparticles. The \(\Delta H_{om}\) value of POM is 326 J/g [38].

2.6. Polarized Light Microscopy (PLM)

The isothermal crystallization morphologies of POM/Ag nanocomposites were observed using PLM (Axio Imager A2, Zeiss, Shanghai, China) equipped with a digital camera (Axiocam Mr 5, Zeiss, Shanghai, China). All POM/Ag nanocomposites were firstly melted at 200 °C and maintained for 5 min to eliminate the thermal history. Subsequently, the temperature of the sample was rapidly reduced to 140 °C with cooling rate of 100 °C/min and maintained at 140 °C for 30 min. The photographs of POM/Ag nanocomposites were then taken.

3. Results and Discussion

3.1. Morphology of POM/Ag Nanocomposites

The TEM images of POM/Ag nanocomposites are given in Figure 2. It was found that Ag nanoparticles easily aggregated together in POM. In addition, when the content of Ag nanoparticles was low (≤1 wt%), it was difficult to observe larger-size clusters of Ag nanoparticles, and most of the clusters of Ag nanoparticles were smaller than 200 nm. At the same time, the clusters of Ag nanoparticles separated from each other. However, when the content of Ag nanoparticles increased to 2 wt%, it easily formed the larger-size clusters of Ag nanoparticles (≥200 nm). This result proved that when the content of Ag nanoparticles was low (≤1 wt%), the monolayer surfactants on the surface of Ag nanoparticles had a strong effect and passivated the surface of Ag nanoparticles, which effectively inhibited the large-scale agglomeration of Ag nanoparticles. However, when the content of Ag nanoparticles reached 2 wt%, they would be easily aggregated together due to monolayer surfactants of Ag nanoparticles with weak effect, which resulted in poor dispersion of Ag nanoparticles in POM. This result was consistent with the analysis result of SEM images of POM/Ag nanocomposites in the previous paper [37].

3.2. Melting and Crystallization Behavior of POM/Ag Nanocomposites

The melting and crystallization behavior of POM/Ag nanocomposites at the heating/cooling rate of 10 °C/min are shown in Figure 3a,b, respectively, and the DSC parameters are given in Table 2. As seen in Figure 3a, the melting behavior and range of POM/Ag nanocomposites were similar. It was clear that the endothermic peaks appearing between 160 °C and 175 °C could be assigned to the melting process of POM crystals. On one hand, as shown in Figure 3a, it was found that the melting peak temperature (Tm) of POM/Ag nanocomposites shifted to higher temperature with content of Ag nanoparticles increased, which indicated that Ag nanoparticles significantly affected the melt behavior of POM to some extent [37]. On the other hand, it was found the enthalpy of second melting endotherms (ΔHm) and the degree of crystallinity (XC) of POM/Ag nanocomposites first increased, then decreased as the content of Ag nanoparticles increased (Figure 3b,c). This could be attributed to the fact that the efficient heterogeneous nucleation of Ag nanoparticles could accelerate the crystallization rate of POM, which increased the degree of crystallinity of POM to a higher level, when the amount of Ag nanoparticles of POM/Ag nanocomposites was low (≤1 wt%) [37]. However, when the amount of Ag nanoparticles increased to 2 wt%, the Ag nanoparticles easily aggregated together to form a lot of large clusters in the POM matrix, which could affect the heterogeneous nucleation of Ag nanoparticles and restrained crystallization of POM to some degree [37].

Table 2. Differential scanning calorimetry (DSC) parameters of POM/Ag nanocomposites at the heating/cooling rate of 10 °C/min.

| Samples | Tm (°C) | Tc (°C) | ΔHm (J/g) | XC (%) |
|---------|---------|---------|-----------|--------|
| POM     | 166.24 ± 0.24 | 139.64 ± 0.14 | 152.94 ± 3.2 | 46.91 ± 0.9 |
| POM-1   | 166.83 ± 0.31 | 141.83 ± 0.12 | 157.89 ± 1.9 | 48.43 ± 0.5 |
| POM-2   | 167.91 ± 0.37 | 142.81 ± 0.21 | 164.08 ± 2.4 | 50.33 ± 0.7 |
| POM-3   | 169.23 ± 0.35 | 142.83 ± 0.32 | 166.64 ± 2.8 | 51.12 ± 0.8 |
| POM-4   | 169.81 ± 0.11 | 141.71 ± 0.29 | 163.71 ± 2.1 | 50.21 ± 0.6 |
3.3. Isothermal Crystallization Kinetics of POM/Ag Nanocomposites

Figure 4 shows the complete isothermal crystallization process of POM/Ag nanocomposites, and the times for isothermal crystallization of POM/Ag nanocomposites are given in Table 3. It was found that the crystallization exotherms of POM/Ag nanocomposites became flatter and the time for isothermal crystallization process increased with the increasing of crystallization temperature (Figure 4). In addition, as shown in Figure 4a and Table 3, it was clear that the time for isothermal crystallization of POM was about 7.74 ± 0.2 min at 145 °C. However, the POM/Ag nanocomposites crystallized for approximately 5–6 min at 145 °C (Figure 4b–e). Simultaneously, the time for isothermal crystallization of POM/Ag nanocomposites at other crystallization temperatures (130 °C, 135 °C, 140 °C) were also illustrated that the Ag nanoparticles accelerated the isothermal crystallization rate of the POM. What’s more, as the content of Ag nanoparticles increased, the time for isothermal crystallization of POM/Ag nanocomposites first decreased, then increased. Meanwhile, the time for isothermal crystallization of POM-3 was shortest. For instance, it only took about 2.53 min for POM-3 to fully crystallize at 130 °C, whereas the time for the isothermal crystallization process of other POM/Ag nanocomposites were more than 2.53 min at 130 °C. Therefore, this result also demonstrated that when the content of Ag nanoparticles was less than 1 wt%, the Ag nanoparticles enhanced the isothermal crystallization rate of POM due to the efficient heterogeneous nucleation. However, when the content of Ag nanoparticles increased to 2 wt%, the Ag nanoparticles easily aggregated together, which had a certain inhibitory effect on crystallization process of POM. The effect of Ag nanoparticles on isothermal crystallization of POM/Ag nanocomposites was in good accordance with that of Ag nanoparticles on non-isothermal crystallization of POM/Ag nanocomposites [37].

| POM-4   | 2.78 ± 0.2                    | 3.78 ± 0.2                    | 4.89 ± 0.2                    | 6.21 ± 0.2                    |
3.3.1. Avrami Model Analysis of POM/Ag Nanocomposites

The Avrami model [40] is used to describe the isothermal crystallization rates of POM/Ag nanocomposites, as shown in Equation (2):

\[ X_t = 1 - \exp(-kt^n) \]  

where \( X_t \) is the relative degree of crystallinity as a function of time, \( n \) is the Avrami exponent, which is also a constant depends on the nucleation mechanism and crystal growth, and \( t \) is the time for isothermal crystallization process. The \( k \) is the Avrami rate constant, which associate with nucleation and growth rate of crystal.

In addition, the \( X_t \) can be calculated by the Equation (3):

\[ X(t) = \frac{\int_0^t \frac{dH(t)}{dt} dt}{\int_0^\infty \frac{dH(t)}{dt} dt} = \frac{\Delta H_t}{\Delta H_\infty} \]  

where \( H(t) \) is the crystallization enthalpy during the infinitesimal time interval (\( dt \)), \( dH/dt \) is the heat flow rate, \( \Delta H_t \) is the heat enthalpy. \( \Delta H_\infty \) is the total heat enthalpy in the crystallization process. The plots of \( X_t \) versus \( t \) for POM/Ag nanocomposites were shown in Figure 5a–e. It was found that all curves had the characteristic sigmoidal shape with time increased. In the first one, the first non-linear part of the curves was considered to be the induction and nucleation step in entire crystallization process of POM/Ag nanocomposites. For the next one, the linear part of the curves was seen as primary crystallization step in entire crystallization process. Finally, the second non-linear part of the curves was considered as crystallization termination step owing to the spherulites of POM/Ag nanocomposites impingement in the late stage of entire crystallization process. In addition, the curves of POM/Ag nanocomposites shifted to the right when the crystallization temperature increased. This result suggested that the rate of nucleation decreased with the increase of temperature, which resulted in the decrease of crystallization rate of POM/Ag nanocomposites. Furthermore, it was found that the time for isothermal crystallization of POM/Ag nanocomposites first decreased, then increased, as the content of Ag nanoparticles increased. It also implied that the isothermal crystallization rate of POM were accelerated by the small amount of Ag nanoparticles (\( \leq 1 \text{ wt\%} \)) due to the efficient heterogeneous nucleation. However, when the content of Ag nanoparticles increased to 2 wt\%, they easily aggregated, which affected the crystallization process of POM.

Figure 5. Relative degree of crystallinity \( (X_t) \) as a function of time \( (t) \) for POM/Ag nanocomposites: (a) POM, (b) POM-1, (c) POM-2, (d) POM-3 and (e) POM-4.
Meanwhile, the crystallization half-time ($t_{0.5}$) of POM/Ag nanocomposites can be directly obtained from Figure 5 and are given in Table 4. It was clearly shown that the $t_{0.5}$ values of POM/Ag nanocomposites decreased with the $T_{cry}$ increased. In addition, comparing the $t_{0.5}$ values of POM/Ag nanocomposites at the same crystallization temperature ($T_{cry} = 145 \, ^\circ\text{C}$), it was found that the crystallization rate of POM/Ag nanocomposites kept to the following order: POM-3 ($\approx 2.464 \, \text{min}$) > POM-2 ($\approx 2.513 \, \text{min}$) > POM-4 ($\approx 2.574 \, \text{min}$) > POM-1 ($\approx 2.766 \, \text{min}$) > POM ($\approx 3.426 \, \text{min}$). This result proved that smaller amounts ($\leq 1 \, \text{wt\%}$) of Ag nanoparticles acted as heterogeneous nucleating agents of POM and accelerated the isothermal crystallization rate of POM. However, when the amount of Ag nanoparticles increased to 2 wt\%, Ag nanoparticles aggregated together and restrained crystallization of POM. Meanwhile, the reciprocal of crystallization half-time ($t_{cry}$) was employed to quantitatively compare the isothermal crystallization rates of POM/Ag nanocomposites. The plots of $t_{0.5}$ versus $T_{cry}$ of POM/Ag nanocomposites are shown in Figure 6, and the $t_{0.5}$ values are given in Table 4. It was shown that the $t_{0.5}$ values of POM/Ag nanocomposites first increased, then decreased when the content of Ag nanoparticles increased. This result proved that when the content of Ag nanoparticles was less than 1 wt\%, Ag nanoparticles enhanced the crystallization rate of POM owing to the heterogeneous nucleation effect. However, when the content of Ag nanoparticles increased to 2 wt\%, a certain inhibitory action appeared in the crystallization process of POM, which was due to the aggregation of the Ag nanoparticles.

Table 4. Parameters of Avrami analysis for POM/Ag nanocomposites.

| Samples  | $T_{cry}$ (°C) | $t_{0.5}$ (min)       | n   | $t_{0.5}$ (min$^{-1}$) | $k \times 10^{-3}$ (min$^{-n}$) $^a$ | $k \times 10^{-3}$ (min$^{-n}$) $^b$ |

$^a$ $k$ determined from Equation (4); $^b$ $k$ determined from Equation (5).

In addition, Equation (2) can be taken in the double-logarithmic form to obtain Equation (4):

$$\ln[-\ln(1 - X_t)] = \ln(k) + n \ln(t)$$  \hspace{1cm} (4)

The plots of $\ln(-\ln(1 - X_t))$ versus $\ln(t)$ are shown in Figure 7. Moreover, the plots of $n$ and $k$ versus $T_{cry}$ are shown in Figure 8a,b, respectively. In addition, the $n$ and $k$ values are given in Table 4.
It can be seen in Figure 8a that the $n$ values of POM were less than that of POM/Ag nanocomposites, which demonstrated that Ag nanoparticles increased the amount of effective nucleation sites owing to the nucleation effect of Ag nanoparticles. Meanwhile, it was clear from Figure 8b that the $k$ values of POM/Ag nanocomposites decreased when the $T_{cry}$ increased from 130 °C to 145 °C, which suggested that the crystallization rate of POM/Ag nanocomposites decreased with increasing temperature. In addition, it was shown that the $k$ values first decreased, then increased when the content of Ag nanoparticles increased. This result demonstrated that when the content of Ag nanoparticles was less than 1 wt%, the Ag nanoparticles enhanced the crystallization rate of POM. However, when the content of Ag nanoparticles reached 2 wt%, they restrained the crystallization process of POM, which was due to the interaction between Ag nanoparticles and POM chains.

![Figure 7](image-url)  
Figure 7. Plots of $\ln(-\ln(1-X_i))$ as a function of $\ln(t)$ for POM/Ag nanocomposites: (a) POM, (b) POM-1, (c) POM-2, (d) POM-3 and (e) POM-4.

![Figure 8](image-url)  
Figure 8. (a) Avrami exponent ($n$), (b) experimental Avrami rate constant ($k$), and (c) theoretical Avrami rate constant ($k$) of POM/Ag nanocomposites.
The theoretical $k$ was estimated by the well-fitting logarithmic representation of Equation (5):

$$t_{0.5} = \left( \frac{\ln 2}{k} \right)^{1/n}$$  \hspace{1cm} (5)

The plots of theoretical $k$ versus $T_{cry}$ are shown in Figure 8c, and theoretical $k$ values list in Table 4. It was seen that the theoretical $k$ values first decreased, then increased when the content of Ag nanoparticles increased, which was in good accordance with the result of the experimental $k$ values.

3.3.2. Lauritzen-Hoffman Model Analysis of POM/Ag Nanocomposites

The Lauritzen-Hoffman model, also referred to Lauritzen-Hoffman secondary nucleation theory, was used to determine the spherulitic growth rate ($G$) during the isothermal crystallization process of POM/Ag nanocomposites. The Lauritzen-Hoffman model defined three different crystallization regimes based on the relationships between the rate of secondary nucleation ($i$) and the lateral growth rate of spherulite ($g$). In regime I, this is $i << g$. In addition, $i$ is on the order of $g$ in regime II. However, this is $i >> g$ in regime III [17]. In addition, it can be used to calculate $G$ of POM/Ag nanocomposites by using the isothermal crystallization data, as shown in Equation (6) [41]:

$$G = G_0 \exp \left[ \frac{-U^*}{R(T_C - T_\infty)} \right] \exp \left[ \frac{-K_g}{T_C \Delta Tf} \right]$$  \hspace{1cm} (6)

where $G_0$ is a pre-exponential factor; $T_C$ is the crystallization temperature and $R$ is the ideal gas constant. $U^*$ is the activation energy necessary for the macromolecules to diffuse to the crystal phase in the melting state, which was obtained by Equation (7). $f$ is a corrective factor, which is $f = 2T_C/(T_C - T_0 m)$. $T_\infty$ is a hypothetical temperature below which the molecular chain ceases motion, which is commonly defined as $(T_g - 30)$ K. $\Delta T = T_0 m - T_C$ is the supercooling temperature. $K_g$ is the nucleation parameter, which relate to the fold and lateral surface energies. Equation (6) can be linearized as the Equation (8) by performing the logarithmic transformation.

$$U^* = \frac{C_1 T_C}{C_2 + T_C - T_g}$$  \hspace{1cm} (7)

$$\ln G + \frac{U^*}{R(T_C - T_\infty)} = \ln G_0 - \frac{K_g}{T_C \Delta Tf}$$  \hspace{1cm} (8)

where $C_1 = 4120 \text{ cal mol}^{-1}$, $C_2 = 51.6 \text{ K}$. $K_g$ and $G_0$ can be acquired from the slope and intercept of the Equation (8), respectively. In addition, the $G(\tau_{0.5})$ values are also used in Equation (8). The Lauritzen-Hoffman model plots of POM/Ag nanocomposites are given in Figure 9, and $K_g$ values list in Table 5.

![Figure 9. Lauritzen-Hoffman model plots of POM/Ag nanocomposites.](image-url)
As shown in Figure 9, it was clear that the slopes trend of POM/Ag nanocomposites was the same, which indicated that it did not appear regime transition in the isothermal crystallization process of POM/Ag nanocomposites when the isothermal crystallization temperature increased. What’s more, two processes of crystal growth of the polymer were described in detail by the Lauritzen-Hoffman secondary nucleation theory [42]. First of all, the first stem deposited on the growing crystal surface (secondary nucleation). Secondly, subsequent stems attached to the chain of the crystal surface (surface spreading process). It was clear that the spherulites’ growth process of POM/Ag nanocomposites depended on the rate of secondary nucleation and the rate of surface spreading process. Therefore, the Ag nanoparticles of POM/Ag nanocomposites could act as the nucleating center of POM and create the crystal interfaces, which reduced the spherulite nucleus size of POM and accelerated the crystallization process of POM. In addition, it was found that $K_g$ values of POM/Ag nanocomposites were smaller than that of POM, which proved that the addition of Ag nanoparticles reduced the energy need to create a new crystal surface, which accelerated the crystallization rate of POM. Simultaneously, it was shown that the $K_g$ values of POM/Ag nanocomposites first decreased, then increased when the content of Ag nanoparticles increased, and the $K_g$ value of POM-3 was smallest. This result demonstrated that when the content of Ag nanoparticles were less than 1 wt%, the Ag nanoparticles reduced the nucleation energy of POM and enhanced the crystallization rate of POM owing to the heterogeneous nucleation effect. However, when the content of Ag nanoparticles increased to 2 wt%, they easily aggregated together and decreased the amount of nucleating centers and new crystal surfaces, which had a certain inhibitory action on the crystallization process of POM.

In the isothermal crystallization process of POM/Ag nanocomposites, $K_g$, an isothermal crystallization kinetic parameter, is related to the energy need for the formation of nuclei owing to the heterogeneous nucleation of Ag nanoparticles. In addition, $K_g$ can be calculated by Equation (9):

$$K_g = \frac{n b_0 \delta \Delta H_f T_m^0}{\Delta H_f k_B}$$  \hspace{1cm} (9)

where $b_0$ is the thickness of the stem added on the substrate, $n$ is the variable constant of the crystallization process, $\delta$ is the lateral surface free energy, $\delta_e$ is the surface free energy of folding, $k_B$ is the Boltzman constant, $\Delta H_f$ is the melting enthalpy per unit volume of crystals. $n$ value is equal to 4 at high temperature and low temperature, and $n$ value is equal to 2 at intermediate temperatures [17]. In addition, the lateral surface free energy ($\delta$) is calculated by Equation (10) [42]:

$$\delta = 0.11 \Delta H_f \sqrt{a_0 b_0}$$  \hspace{1cm} (10)

where $a_0$ and $b_0$ are both the unit cell parameters of POM, and $a_0 b_0$ corresponds to the chain cross-section in the POM crystal. Therefore, $\delta_e$ can be calculated by using the determined $K_g$ values and the crystal parameters ($n = 4, b = 0.447 \text{ nm}, k_B = 1.38 \times 10^{-23} /K, \Delta H_f = 3.55 \times 10^8 \text{ J/m}^3$ and $\delta = 14.7 \times 10^6 \text{ J/m}^2$) [43], which are listed in Table 5. It is well known that when $\delta_e$ values are larger, the energy need for the chain folding onto the nucleus surface is higher. In addition, it was found that the $\delta_e$ values of the POM/Ag nanocomposites decreased in the order of POM (1.02 J/m$^2$) > POM-4 (0.93 J/m$^2$) > POM-1 (0.92 J/m$^2$) > POM-2 (0.88 J/m$^2$) > POM-3 (0.87 J/m$^2$). This result proved that the addition of Ag nanoparticles reduced the surface free energy of folding ($\delta_e$) and accelerated the crystallization rate of POM.

### Table 5. Lauritzen-Hoffman model parameters of POM/Ag nanocomposites.

| Samples     | POM | POM-1 | POM-2 | POM-3 | POM-4 |
|-------------|-----|-------|-------|-------|-------|
| $K_g$ (×10^5 K$^2$) | 2.48 ± 0.02 | 2.23 ± 0.03 | 2.15 ± 0.05 | 2.11 ± 0.06 | 2.27 ± 0.04 |
| $\delta_e$ (J/m$^2$)  | 1.02 ± 0.03 | 0.92 ± 0.03 | 0.88 ± 0.01 | 0.87 ± 0.02 | 0.93 ± 0.01 |
| $N$ (m$^3$) | (5.63 ± 0.2) × 10^{10} | (1.29 ± 0.3) × 10^{11} | (5.71 ± 0.1) × 10^{11} | (2.16 ± 0.3) × 10^{12} | (9.15 ± 0.2) × 10^{11} |
Furthermore, the addition of Ag nanoparticles reduced the surface free energy of folding (δc), which could increase the amount of effective crystal nuclei (N). Therefore, the N values of POM/Ag nanocomposites can be calculated using Equation (11), as follows:

\[ k = \frac{4}{3} \pi NG_0 \]  

(11)

The N values of POM/Ag nanocomposites are given in Table 5. It was obvious that the addition of Ag nanoparticles increased the number of effective crystal nuclei of POM. This result demonstrated that Ag nanoparticles reduced the surface free energy of folding (δc) owing to the heterogeneous nucleation, which increased number of effective crystal nuclei and enhanced the crystallization rate of POM.

3.3.3. Isothermal Crystallization Activation Energy Analysis of POM/Ag Nanocomposites

The isothermal crystallization activation energy (ΔE) of POM/Ag nanocomposites can be determined by using the crystallization rate constant (k) of Avrami parameter [44]. Therefore, the ΔE values can be calculated by the Arrhenius equation, as follows:

\[ k^{1/n} = k_0 \exp(-\Delta E/RT_C) \]  

(12)

where R is the ideal gas constant, k0 is a pre-exponential factor and T_C is the crystallization temperature. Equation (12) is taken in the linearized form to obtain Equation (13).

\[ \frac{1}{n \ln k} = \ln k_0 - \frac{\Delta E}{RT_C} \]  

(13)

The fitted lines of 1/nlnk versus 1/T_C for POM/Ag nanocomposites are shown in Figure 10, and the r values and ΔE values are given in Table 6. It was found that the ΔE values of POM/Ag nanocomposites were less than that of POM (≈65.14 ± 0.12 kJ/mol). This result indicated that the isothermal crystallization activation energy was reduced by Ag nanoparticles due to the heterogeneous nucleation [45]. It is well known that the magnitude of activation energy (|ΔE|) related to energy need for the motion of polymer chains during the transformation from the melt into the crystalline state, and higher |ΔE| values, mean that this transformation needs to release more energy [46]. It was shown that the |ΔE| values of POM/Ag nanocomposites (POM-1 ≈ 70.81 kJ/mol, POM-2 ≈ 74.14 kJ/mol, POM-3 ≈ 74.21 kJ/mol, POM-4 ≈ 74.39 kJ/mol) were larger than that of POM (≈65.14 kJ/mol). This result demonstrated that when the amount of Ag nanoparticles increased, they easily aggregated and inhibited the movement of macromolecular chains of POM, which restrained the isothermal crystallization process of the POM.

![Figure 10. Plots of 1/nlnk versus 1/T_C for the POM/Ag nanocomposites.](image-url)
which was used to investigate the effect of Ag nanoparticles on the isothermal crystallization behavior of POM. As seen in Figure 11a, in POM there were a few nuclei and spherulites with dimensions of the order of approximately 100 μm, and the interface between the spherulites was clearly visible. In addition, Figure 11b–d shown that POM/Ag nanocomposites exhibited a drastic reduction in the size of spherulites as compared to POM. Meanwhile, the amount of spherulites increased with no clear distinction between the interfaces of adjacent spherulites owing to heterogeneous nucleation of Ag nanoparticles. These results also implied Ag nanoparticles generated a large number of nuclei and effective nucleation sites. Furthermore, the nucleation density could affect the crystallization process of polymer [47]. Therefore, the large amount of crystal nuclei led to the formation of smaller spherulites in the limited space of POM. However, when the content of Ag nanoparticles increased to 2 wt%, the Ag nanoparticles easily aggregated and reduced heterogeneous nucleation of Ag nanoparticles, which reduced amount of effective nucleation sites. Furthermore, as seen in Figure 11e, it was clear that the spherulite size of POM became larger and the interface between the spherulites became more visible due to agglomeration of Ag nanoparticles.

**Table 6.** Isothermal crystallization activation energy of POM/Ag nanocomposites.

| Samples | POM | POM-1 | POM-2 | POM-3 | POM-4 |
|---------|-----|-------|-------|-------|-------|
| Activation energy ΔE (kJ/mol) | −65.14 ± 0.12 | −70.81 ± 0.20 | −74.14 ± 0.19 | −74.21 ± 0.17 | −74.39 ± 0.14 |
| r       | 0.997 | 0.996 | 0.998 | 0.998 | 0.997 |

3.4. **Morphology of POM/Ag Nanocomposites**

The isothermal crystallization behavior results of POM/Ag nanocomposites are further supported by the PLM study. Figure 11 compares the spherulite morphology of POM/Ag nanocomposites, which was used to investigate the effect of the Ag nanoparticles on the isothermal crystallization behavior of POM. On the other hand, Figure 11a–d shown that POM/Ag nanocomposites exhibited a drastic reduction in the size of spherulites as compared to POM. Meanwhile, the amount of spherulites increased with no clear distinction between the interfaces of adjacent spherulites owing to heterogeneous nucleation of Ag nanoparticles. These results also implied Ag nanoparticles generated a large number of nuclei and effective nucleation sites. Furthermore, the nucleation density could affect the crystallization process of polymer [47]. Therefore, the large amount of crystal nuclei led to the formation of smaller spherulites in the limited space of POM. However, when the content of Ag nanoparticles increased to 2 wt%, the Ag nanoparticles easily aggregated and reduced heterogeneous nucleation of Ag nanoparticles, which reduced amount of effective nucleation sites. Furthermore, as seen in Figure 11e, it was clear that the spherulite size of POM became larger and the interface between the spherulites became more visible due to agglomeration of Ag nanoparticles.

4. **Conclusions**

In this work, we prepared POM/Ag nanocomposites using a simple melting compounding route. The dispersion and size of Ag nanoparticles in POM was investigated using transmission electron microscopy (TEM). It indicated that when the content of Ag nanoparticles was low (≤1 wt%), the clusters of Ag nanoparticles were smaller than 200 nm and were separated from each other owing to the monolayer surfactants on the surface of Ag nanoparticles. However, when the content of Ag nanoparticles reached 2 wt%, they easily aggregated to form the larger-size clusters of Ag nanoparticles (≥200 nm), which resulted
in poor dispersion of Ag nanoparticles in POM. In addition, the isothermal crystallization process and melting behavior of POM/Ag nanocomposites were investigated by differential scanning calorimetry (DSC). It was found that as the content of Ag nanoparticles increased, the degree of crystallinity ($X_C$) of POM/Ag nanocomposites first increased, then decreased, and the $X_C$ of POM/Ag nanocomposites with 1 wt% Ag nanoparticles was largest. Furthermore, the isothermal crystallization kinetics of POM/Ag nanocomposites were studied by the Avrami model. On one hand, it was found that the $t_0$ values of POM/Ag nanocomposites ($T_m = 145 \, ^\circ C$) kept to the following order: POM-3 ($\approx 2.464 \, \text{min}$) $>$ POM-2 ($\approx 2.513 \, \text{min}$) $>$ POM-4 ($\approx 2.574 \, \text{min}$) $>$ POM-1 ($\approx 2.766 \, \text{min}$) $>$ POM ($\approx 3.426 \, \text{min}$). On the other hand, the $n$ values of POM were less than that of POM/Ag nanocomposites. Meanwhile, Lauritzen-Hoffman secondary nucleation theory described the crystal growth of POM as two processes. It was found that the nucleation parameter ($K_0$) of POM/Ag nanocomposites were smaller than that of POM ($\approx 2.48 \times 10^5 \, \text{K}^2$). Similarly, the surface free energy of folding ($\delta_0$) values decreased in the order of POM ($\approx 1.02 \, \text{J/m}^2$) $>$ POM-4 ($\approx 0.93 \, \text{J/m}^2$) $>$ POM-1 ($\approx 0.92 \, \text{J/m}^2$) $>$ POM-2 ($\approx 0.88 \, \text{J/m}^2$) $>$ POM-3 ($\approx 0.87 \, \text{J/m}^2$). These results proved that addition of Ag nanoparticles accelerated the crystallization rate of POM. Furthermore, it was clearly seen that the $\Delta E$ values of POM/Ag nanocomposites (POM-1 $\approx −70.81 \, \text{kJ/mol}$, POM-2 $\approx −74.14 \, \text{kJ/mol}$, POM-3 $\approx −74.21 \, \text{kJ/mol}$, POM-4 $\approx −74.39 \, \text{kJ/mol}$) were less than that of POM ($\approx −65.14 \, \text{kJ/mol}$). However, the $|\Delta E|$ values of POM/Ag nanocomposites were larger than that of POM. It revealed that when the amount of Ag nanoparticles was low ($\leq 1 \, \text{wt\%}$), they reduced the isothermal crystallization activation energy and accelerated the crystallization rate of POM. However, when the content of Ag nanoparticles increased to 2 wt%, they aggregated together and inhibited the movement of the POM molecular chain, which reduced the effect of heterogeneous nucleation of Ag nanoparticles. In short, this study demonstrated that Ag nanoparticles could effectively be used to control the isothermal crystallization and melting behavior of POM by balancing the competition between POM molecular chain restriction and heterogeneous nucleation activity.
